Abstract—One of the most serious concerns for green globalization is water pollution. Being a riverine country, Bangladesh is focused to improve its water quality with its increasing population. Water quality monitoring in daily basis has always been a costly initiative in terms of time, human resources for large number of water bodies scattered throughout the country; the task become more daunting for ensuring sustainability after cleaning or improving water quality once. The consistency of drinking water must be monitored in real time in order to ensure its safety. Quality of water also needs to be addressed for irrigation and fish farming. In this paper, a multi-sensor buoy especially for canal water of Dhaka city has been designed for condition monitoring and predictive maintenance purpose and developed accordingly to facilitate the measurement of water quality in a regular interval; monitoring the water quality changes trends; reporting the data to the authority; and finally relating the trends to develop a model for the future. The design and implementation for this real-time water quality monitoring using the Internet of Things (IoT) is of a low-cost framework. The prototype has been deployed and validated with its operations towards the purpose. The system which consists of multiple sensors, is used to measure the water's physical and chemical parameters including the Temperature, pH, turbidity, and the TDS (total dissolved solids) of the water. The core controller will process and calculate values received from the sensors. Arduino is used as a central controller. Finally, the sensors data are sent to respective parties via short messages (SMS) and also viewed on internet using WI-FI system. The developed mechanism can also be implicated for similar water quality monitoring network including lakes and rivers.

Keywords—Internet of Things (IoT), pH sensor, Turbidity sensor, Temperature sensor, TDS sensor, Arduino, WI-FI module.

I. INTRODUCTION

In twenty-first century, there have been many developments but the trade-off with pollution, global warming, climate change and other issues. Clean drinking water is currently a huge issue due to the increased world's pollution. Water quality monitoring in real time is becoming more difficult as a result of global warming, limited water

supplies, and an increasing population, among other factors. Therefore, better methodologies for monitoring water quality parameters in real time are needed [1]. Potential of Hydrogen (pH) is one of the parameters of water quality which needs to be monitored regularly. It indicates whether the water is acidic or alkaline. The range of pH scale is 0 to 14. Pure water should have pH of 7 whereas a pH of less than 7 is acidic, more than 7 is alkaline. A pH value between 6.5 and 8.5 pH is acceptable for pure drinking. Turbidity is a measure dirtiness of water. Using turbidity sensor, we can measure the dirt present in the water. The chances of diarrhea disease increases with the drinking water having higher turbidity. The World Health Organization (WHO) establishes that the turbidity of drinking water should not be more than 5 NTU, and should ideally be below 1 NTU. The temperature sensor detects how much hot or cold the water is. Temperature will vary from time to time. Such as, it will be a higher temperature at day time whereas it will be a much lower temperature at night. A TDS meter is a small device which senses the Total Dissolved Solids in water. Dissolved ionized solids, such as salts and minerals, increase the conductivity of a solution. So, TDS meter measures the conductivity of the solution and estimates the TDS from that reading. Traditional water quality monitoring methods entail the manual collection of water samples from various locations.

Bangladesh Segment of the population, economic, and technological developments throughout the world have increased our capacity to consciously and inadvertently affect the environment in which we live in and that sustains us. Humans have emerged as the primary cause of environmental change. Our actions have an effect on the global environment, especially the climate. This, in turn, affects the volume and geographical and seasonal distributions of precipitation falling on watersheds, as well as the timing of runoff. We are changing the amount of our water sources on which we need to exist, both physically and economically, as a result of changes in landscapes, increased food and energy production,

and the influx of people into metropolitan areas. We rely on water not only for survival, but also for economic well-being. Water is used in the production of everything we make. There are no replacements, and while it is renewable, there is a limited supply. We have interrupted and over allocated river flow regimes, sometimes to the point of drying them out, as well as the lakes downstream. We have depleted groundwater aquifers, contaminated many, if not the majority, of our water bodies, including estuaries, coastal zones, and even seas, and destroyed ecosystems. We did this primarily to meet short-term economic aims, which may also not have included long-term ecological or even economic viability of the region or basin, as well as our own health. Water is becoming a more important policy problem on a global scale. The third World Water Development Report of the United Nations warns [1], the existing inequitable, unsustainable usage of water may have highly negative implications in an unprecedented way. Poor water management jeopardizes both economic progress and security. As a result, worries about a worldwide energy crisis have now been joined by worries about an impending global water catastrophe. The energy-water nexus, which includes the impacts of water usage on energy consumption as well as the consequences of energy production on water use, is garnering more attention. [2]. By 2050, the globe will have to feed and supply energy for an extra 2–2.5 billion people, in addition to meeting a billion people's existing unmet power demands. To fulfill the nutritional demands of this growing population, we must take into account the quantity of water used in the production of various items, particularly energy and food. Water managers have significant challenges in terms of energy and food security. Interactions and feedback loops connect energy production, water, food security, and climate change. Growing, transporting, processing, and trading food goods, for example, consume a lot of water and energy. The Comprehensive Assessment of Water Management in Agriculture provides a comprehensive examination [3]. This work demonstrates that in a business-as-usual scenario, water consumption in agriculture would almost double. The fast growth of the urban population is driving the construction of infrastructure and services like as road networks, water supply, sanitation, sewage, and drainage, as well as the city's expansion into floodplains and low-lying areas [2]. These urbanizations have a significant negative impact on water quality, particularly in humid tropical areas. [3].

However, in Dhaka, the relief-controlled structures of the region were successfully drained to the floodplain and low-lying area by streams and canals (local word 'KHALS') (JICA 1991) and eventually to the downstream via big rivers. The city's canals used to be the linking channels for the rivers that encircled the larger Dhaka area. [4]. Although there were many canals in the past, but the Institute of Water Modelling (IWM) has identified there exists 50 canals in the city at present; of which many has retained only the name due to the land fillings, waste disposal. Only 26 of them deemed recoverable by the authority [5].

Canal water needs to be monitored from time to time in order to keep the water clean since it's become very dirty over times as shown in Fig.1. There are many canals in our city which are under Dhaka City Corporation and all these canals are connected to rivers. We can be benefited from canal water in many scenarios. For instance, this water further can be used in irrigation, aqua culture, and also as drinking water. If not used in above cases, eventually this water goes back to river. Hence, in order to keep river water safe, it is of utmost importance to monitor water quality of canal water which further is connected to river. Monitoring water quality is extremely important and needs a system by which it can be monitored. For this purpose, a system has been made called a buoy with which four sensors will be connected which are pH sensor, temperature sensor, TDS sensor, and turbidity sensor. These sensors will sense the pH level, temperature, TDS value, and turbidity. A handsome number of data needs to be collected. We will take the collective measure. Then with the help of GSM module, via SMS, web, or apps, we will deliver the data collected to the authority/party. GSM module is being used because it is a remote data collection procedure.

This is done mainly so that river water does not get polluted. If the canal water is used for drinking water, it needs to be clean and TDS should be less than 50. If it is used for irrigation and aqua culture, and if it is not clean then it will have a huge impact on agriculture and the overall food cycle will be interrupted. Crops and fishes will die and living things will be affected badly. pH value should be 5.0 to 7.0 for irrigation and 6.5 to 9.0 for aqua culture. After monitoring, if the quality of water is bad then we can let Dhaka WASA or the Director of Environment to know about it and they will look into it. There can be many reasons of pollution of canal water such as garbage disposal, industrial waste, urban runoff, etc.

The purpose of this paper is dual. One is to present a complete assessment of recent work in the field of smart water quality monitoring in terms of application, communication technology utilized, sensor types used, and so on. The second goal is to propose a low-cost, less sophisticated smart water quality monitoring system that employs a controller with an integrated Wi-Fi module to monitor parameters such as pH, turbidity, and conductivity. The device also features an alarm feature that notifies the user when water quality metrics are out of range. The monitoring system analyzes data collected in real time and recommends appropriate corrective actions.

Fig. 1. A typical canal water condition of of Dhaka city

The necessity of user engagement in water quality management, as well as awareness of other aspects such as cleanliness, hygienic practices, storage, and disposal, are critical concerns in preserving water resource quality. Inadequate water quality promotes disease, kills people, and stifles socio-economic progress. Waterborne illnesses take the lives of around 5 million people globally [10-11, 13-16].

The organization of the paper is as follows, Section II presents the description of the proposed system, details of hardware and software requirements are provided in Section III. Section IV describes the hardware prototype. The obtained results are discussed in Section V and finally Section VI provides the conclusion.

II. PROPOSED SYSTEM

Figure 2 depicts the proposed system's block diagram, which monitors conductivity, turbidity, water level, and pH as critical parameters. The fundamental component of the IoT-enabled water quality monitoring system is a controller. The majority of IoT-based solutions employ a microcontroller with external Wi-Fi. Such design is not cost efficient, they are inefficient in terms of power, and result in complicated circuitry. The TI CC3200 in this work is a single chip microcontroller with an integrated Wi-Fi module and an ARM Cortex M4 core that can be linked to the closest Wi-Fi hot spot for internet access.

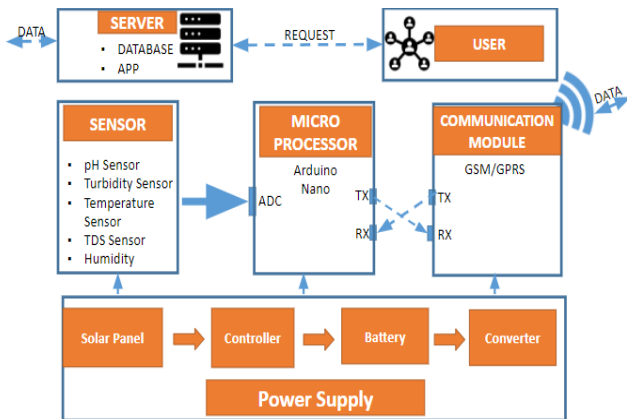

Fig. 2. Block diagram of the proposed system

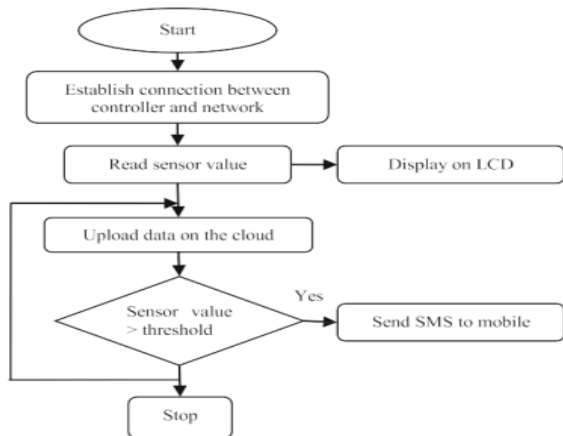

Fig. 3. Flow chart of the proposed system

As the suggested system is designed to monitor residential water quality, sensors are directly connected to the controller. Sensor characteristics such as conductance, clarity, water level, and pH are monitored by immersing the sensor in various water solutions. The measured parameters may be seen on an LCD display. The controller sends sensor data to the cloud. The threshold is determined in the system computing on WHO criteria. If the quantity exceeds the threshold, a message is delivered from the cloud to the user's mobile device. A mobile application was created that allows users to access the information acquired by each sensor in the cloud. This may be utilized by both water quality monitoring agencies and users.

III. SYSTEM DESIGN

A. Hardware components used in the project

- Arduino Nano
- pH sensor
- Turbidity sensor
- TDS Sensor
- Waterproof Digital temperature sensor: DS18B20
- Humidity Sensor Module: DHT22
- GSM module: Sim808

B. Software components used in the project

- Software: Arduino IDE and SMS marketing
- Web server: Ubidots and Cloud

TABLE I. SPECIFICATIONS OF THE HARDWARE COMPONENTS

Component Name	Specifications
DHT22	Measuring Range(0 to 14.00 pH), sensitivity (0.002 pH) Stability(0.02 pH/24 hrs), Temperature range(-5 to 95C degree Celsius) Pressure range(0 to 100 psi)
DS18B20	Usable temperature range: -55 to 125°C (-67°F to +257°F) Unique 64 bit ID burned into chip ±0.5° C Accuracy from -10° C to +85° C Usable with 3.0V to 5.5V power/data
GSM module	Quad-band 850 /900/1800/1900MHZ GPRS mobile station class B Supply voltage range 3.4V ~ 4.4V Supports 3.0V to 5.0V logic level
Arduino Nano	Operating voltage: 5 volts Input voltage: 6 to 20 volts DC per I/O pin: 40 m, DC for 3.3 V pin: 50 mA
pH sensor	Measuring Range(0 to 14.00 pH), sensitivity (0.002 pH). Stability(0.02 pH/24 hrs), Temperature range(-5 to 95C degree Celsius) Pressure range(0 to 100 psi)
Turbidity sensor	Operating Current: 40mA (MAX) Insulation Resistance: 100M (Min) Analog output: 0-4.5V Operating Temperature: 5°C~90 °C Storage Temperature: -10°C~90°C
TDS Sensor	Input Voltage: 3.3 ~ 5.5V Output Voltage: 0 ~ 2.3V Working Current: 3 ~ 6mA

IV. HARDWARE PROTOTYPE

A. Prototype testing

A water monitoring buoy system regularly measures a number of water factors, monitoring water quality. The system comprises of a few components, counting a data logger, buoy stage, solar control, temperature string, mooring equipment, & sensors. Rather than calling it system, we can call it a water quality monitoring buoy 'station'.

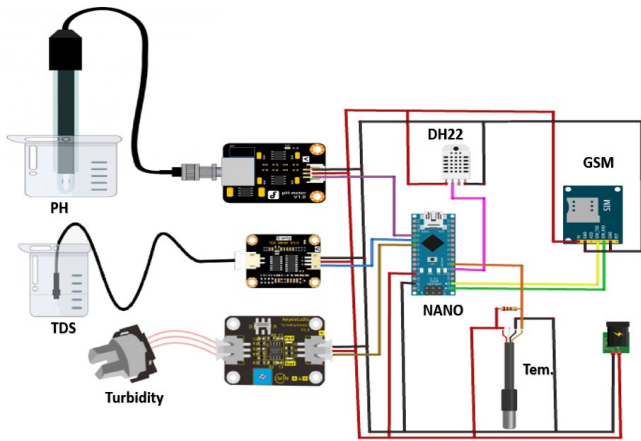

Fig. 4. Schematic of the proposed system

Fig. 5. Prototype testing in the lab

Fig. 6. Data hitting to the server during laboratory testing

Fig. 7. Prototype installation in the canal

Before installing in the canal, the prototype was built according to the circuit diagram shown in Fig.4 and tested in the laboratory after proper calibration as shown in Fig.5. Figure 6 depicts a graphical depiction of parameters observed and saved in the cloud over time. Experiments were then carried out by immersing the sensors in various water solutions collected on the campus grounds. the parameter values recorded for three distinct samples.

B. Installation

For installation, at first the required materials need to be lowered into the water. After placing the materials on the canal floor, the swimmers who will be installing the buoy come down to assemble some additional materials such as to install concrete block with chain and assembled with the rope of the buoy. In some cases, some markers can be placed and tied with the rope attached to the concrete. This is done to avoid any missing trail of buoy in case there is a change in the location of the anchor in canal floor or due to current. After all the materials are ready, the buoy is attached which has been tied with rope on water surface. Finally, the buoy is installed in local canal in the Bashundhara area of Dhaka city as shown in Fig.7.

Sensors are located at the bottom of the block buoy. Water quality metrics may be monitored using a variety of sensors. These sensors are submerged in the water to be examined, which can be either stored or flowing water. Sensors translate physical parameters into quantifiable electrical quantities, which are sent onto controllers through an optional wireless communication device. The controller's primary role is to read data from sensors, potentially process it, and communicate it to the application through appropriate communication technologies. The communication technology and parameters to be monitored are determined by the application's requirements. Data management tools, data analysis, and an alarm system based on monitored parameters are all part of the application.

C. Data Collection

There are three main ways in which data can be collected. Data can be collected via SMS, Apps, or Web. In this

research, both SMS and Web is used. The data sent by the controller is saved in the "Ubidots" cloud. "Ubidots" offers a framework for developers to collect data and transform it into valuable information. The capabilities it includes are real-time dashboard for analyzing data or controlling devices, as well as the ability to share data via public connections. Data saved in the cloud may be utilized for in-depth analysis. When the monitored parameter surpasses the threshold limit, the cloud is configured to send an SMS alert.

The system is linked to the IoT platform cloud by performing the following steps:

1. Use a mobile phone or a personal computer to connect to the access point by entering the SSID and password.
2. Wi-Fi is then used to link the controller to the access point.
3. Log in to the cloud platform and generate a token.
4. In the program, enter the token id.
5. Controller data is put into the cloud.
6. On the cloud platform, data may be examined.

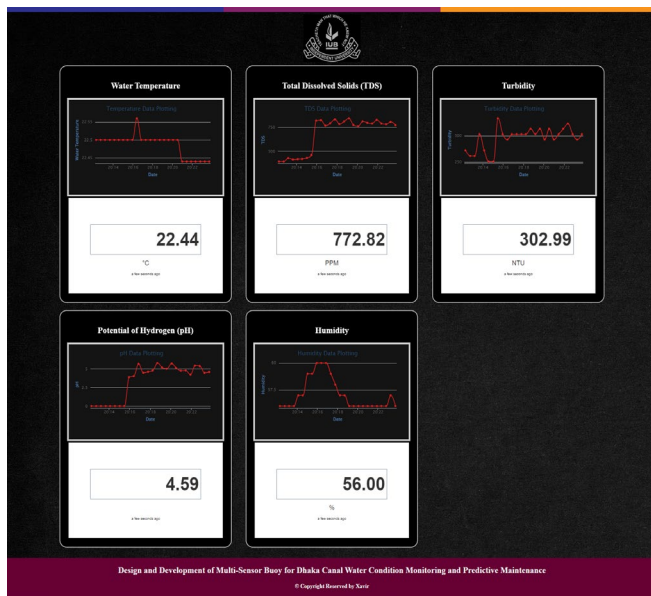

Fig. 8. Data collected through website

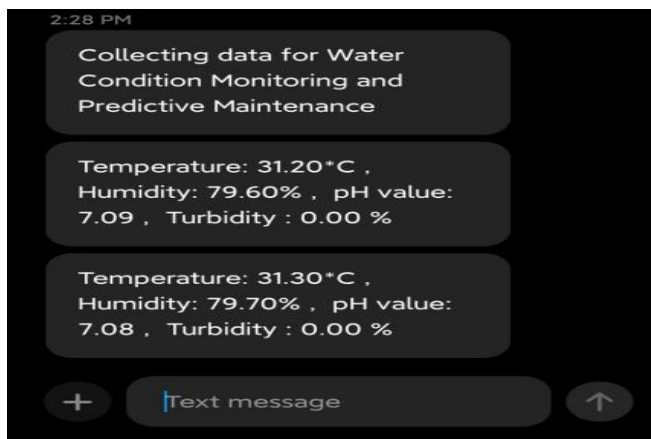

Fig. 9. Data sent via SMS

The buoy measures five parameters: conductivity, pH, turbidity, temperature, and water level. At first, all of the sensors' data have been calibrated and then they have been compared between raw data that we have got through message and actual data. After comparing all data, the accurate result or data has been found out. The configuration is linked to the Ubidots platform. The sensing data from developed prototype has been received via web as shown in Fig.8 and as text message via GSM module Sim808a as shown in Fig.9. The measured values are the compared to WHO drinking water quality requirements.

V. RESULT ANALYSIS

We have collected TDS, pH, turbidity and temperature data for 10 days and then average data has been plotted to see the difference as shown in Figs. 10, 11, 12 and 13, respectively. It has been observed that water condition changes slowly. As we can see, our very first day's average TDS data is 1500 ppm and our last days data is 1602ppm which means water is getting dirty. Within 10 days, it can be seen that the canal water shows big difference of pH which is in very bad condition. Values of turbidity is found within the standard values. However, temperature changes between 22.5°C to 24.5°C as expected since it may vary throughout the day and night.

Fig. 10. Average TDS values in ppm

Fig. 11. Average values of pH over time

Fig. 12. Average values of turbidity in NTU

Fig. 13. Average values of temperature in degree C

TABLE II. COMPARISON BETWEEN STANDARD VALUE AND COLLECTED DATA VALUE

Sensor	Measured value	Standard value
Temperature	23.47 °C	25 °C
pH	5.51	7.85
TDS	294.94 ppm	280 ppm
Turbidity	1561.75 NTU	1000 NTU

The measured data are compared with that of the standard values as listed in Table II to understand the condition of water quality of Dhaka canal. From the above data, it can be observed that the values of TDS, Turbidity, and pH all tend to increase very slowly which correlates the water pollution situation in Dhaka city, which is worsening day by day.

VI. CONCLUSION

In this paper, a low-cost, IoT-based, real-time water quality monitoring system of Dhaka city canal water has been presented. The multi-sensor buoy, which costs approximately USD 200, measured and sent the water’s electrochemical data

to the appropriate parties via sms and web successfully. Its materialness was credited to its long length activity, adaptability, and reproducibility. The system used economically accessible electrochemical sensors to screen water quality boundaries precisely and show the outcome in the web utilizing GSM technology. This multi-sensor buoy can be used to monitor the water quality covering a huge region like lakes and other different waterways which need consistent observation because of its significance both to humanity and nature.

Abstract—An impetuous popularity of electric vehicles (EVs) are of great concern in the field of automobile research. Since electric vehicles run through electric motor so it is important to have reliable DC-DC boost converter which can give stable required voltage for the motor controller. In this paper a modified cascaded DC-DC boost converter has been presented. The proposed boost converter can achieve high gain at intermediate duty cycle thereby lowering down the conduction loss, which will be ideal for EVs motor controller and other renewables energy applications. The analysis of the proposed converter is performed both in ideal and non-ideal conditions. The analysis of MOSFET's junction temperature has also been performed in order to confirm its viability for EV's motor controller and other renewable energy applications.

Keywords—DC-DC boost converter, Boost Converter, Electric vehicle, Pulse Width Modulation, Loss profile, Heat sink.

I. INTRODUCTION

The demand of Electric Vehicles (EVs) is increasing rapidly due to its efficiency and clean environmental aspects including the positive impact on climate change. In EVs the electric motor is one of the important system which gets power from low voltage battery system and in most cases the battery voltage is amplified to the required motor voltage to have smooth operations [1-2]. A high gain DC-DC boost converter is needed to full fill this requirement.

A DC-DC boost converter can be isolated and non-isolated type. In isolated boost converter high frequency transformer has been used which add extra cost and the converter will be bulky due to increased turns ratio at the secondary side. On the other hand, in the most non isolated boost converter the high gain has been achieved at high duty cycle which increases the conduction losses and decays the life cycle of the active switches those have been used in the converter [3-9].

High duty cycle conveys the active switch has to be turn on at most of the time and due to the internal resistance of the active switch an extensive amount of power will be lost which causes the thermal issues of the switch [10]. In most cases the high gain dc-dc boost converter might consist of multiple switched inductor and capacitor which get charged when the

switch conducts and discharge when the switch does not conduct. So, the high duty cycle means these passive elements get a smaller time to get discharged. As a result, these passive elements can be saturated which will be exaggerated for the converter. Therefore, high gain at intermediate duty cycle is a great concern in the field of EVs and other renewable applications.

For the switch, thermal cooling heat sink is a great option due to its robustness and cost effectiveness. The heat sink increases the area that is connected with the environment and helps the heat to flow easily from case to ambient [11-12]. Consequently, heat sink helps to maintain the temperature that is being generated in the junction of the MOSFET.

This paper presents a high gain dc-dc boost converter at intermediate duty cycle for EV's motor controller and other renewable applications. A detailed power loss calculations and active switch junction temperature analysis with three different cases are evaluated.

II. PROPOSED SYSTEM

The proposed cascaded dc-dc boost converter system has been depicted in Fig.1. The converter consists of two active switches. The switches are being controlled in complementary fashion which made the control system simple. In the first stage, the two inductors L4, L5, three diodes D9, D10 and D11 and one capacitor help to amplify the input voltage. In the second stage, two inductors L1, L2, three diodes D1, D2, D3 amplify the voltage. In the final stage, voltage again amplified via two capacitors C1, C2, and two D4, D5. Lastly, the L3, C3 filter provide the final output voltage.

Fig.1. Proposed System

III. STEADY-STATE ANALYSIS

A. Ideal Condition

For this analysis all the components are assumed to be ideal and lossless, and the inductors and capacitors are chosen in such a way that can withstand ripple. The switching frequency is fixed, and the system is being analyzed in open loop CCM conditions. The Proposed converter has two different modes.

I. Mode 1

The converter will be analyzed at $0 < t < DT$ period. This time the switch one (S1) is closed and switch two (S2) is open. The equivalent circuit is shown in Fig. 2 (a). this time the L4 and L5 are being charged since the S1 in closed. The L1 and L2 are being discharged since S2 in open consequently the C1 and C2 are being charged via D5 and D4 besides L3 and C3 are responsible to have smooth continuous output current and voltage. The important equations for these modes are

$$v_{L1} = v_{L2} = v_{in} \tag{1}$$

$$v_{L3} = v_{in} + 2v_{C1} - v_0 \tag{2}$$

$$v_{L4} = v_{L5} = v_{in} - v_0 \tag{3}$$

$$v_{L4} = \frac{v_{in}-v_{C4}-v_0}{2} \tag{4}$$

II. Mode 2

The converter will be analyzed at $DT < t < T$ period. This time the switch two (S2) is closed and switch one (S1) is open. The equivalent circuit is shown in Fig. 2 (b). This time the inductors L4 and L5 are being discharged along with input voltage. The L1 and L2 are being charged through D1 and D3. Besides the C1 and C2 are being discharged to the load. L3 and C3 are responsible for continuous operations. The important equations for these modes are

$$v_{L1} = v_{L2} = -\frac{1}{2}v_{C1} \tag{5}$$

$$v_{L3} = v_{C1} - v_0 \tag{6}$$

$$v_{L4} = v_{L5} = v_{in} \tag{7}$$

$$v_{L4} = \frac{v_{in}-v_{C4}}{2} \tag{8}$$

After manipulating all the equations, the gain for the proposed converter appeared as

$$G = \frac{4D+3D'}{D'} \tag{9}$$

Figure 3 implicate that the theoretical vs simulated gain result when all the components are assumed to be ideal and lossless. It is clear that the proposed converter can give 5.5 to 9 times gain at intermediate duty cycle however 39 times gain can be achieved through this converter.

Figure 4 shows the theoretical gain comparison between the proposed converter and the references when all the components are assumed to be ideal and lossless. The results show that the proposed converter can give high gain at low, intermediate and high duty cycle compared with the references. Reference converters can give high gain at high duty cycle instead of low and intermediate duty cycle at ideal

conditions. Which clearly says that the conduction loss will be higher for the references whereas for the proposed converter conduction loss would be lower since high gain is being achieved at low and intermediate duty cycle.

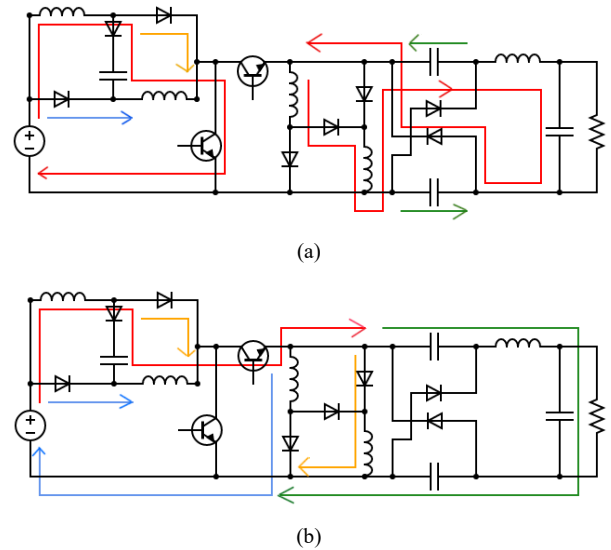

Fig.2. Working modes of the converter (a) Mode 1 and (b) Mode 2

Fig.3. Ideal Gain of the proposed converter Theoretical vs Simulated.

Fig.4. Theoretical Ideal Gain of the proposed converter vs references.

B. NON-IDEAL CONDITIONS

For this analysis all the components are assumed to be non-ideal and are related to real world with losses. The effect of the small ripple approximation is not excluded. For switch S1 and S2 MOSFET SUP60020E has been chosen. The switching frequency is fixed, and the system is being

analyzed in open loop continuous conduction mode (CCM) conditions. The Proposed converter has two different modes in non-ideal conditions.

I. Mode 1

The important equations for this mode are

$$v_{L4} = v_{in} - I_{RL4}R_{L4} - v_{D10} - I_{RD10}R_{D10} - v_o \quad (10)$$

$$v_{L5} = v_{in} - v_{D9} - I_{RD9}R_{D9} - I_{RL5}R_{L5} - v_o \quad (11)$$

$$v_{L1} = v_{in} - v_{s2} - I_{RS2}R_{S2} - I_{RL1}R_{L1} - v_{D1} - I_{RD1}R_{D1} \quad (12)$$

$$v_{L2} = v_{in} - v_{s2} - I_{RS2}R_{S2} - v_{D3} - I_{RD3}R_{D3} - I_{RL2}R_{L2} \quad (13)$$

$$v_{L3} = v_{in} - v_{s2} - I_{RS2}R_{S2} + 2v_{c1} - I_{RC1}R_{C1} - I_{RL3}R_{L3} - v_o - I_{RC2}R_{C2} \quad (14)$$

II. Mode 2

The important equations for this mode are

$$v_{L4} = v_{in} - I_{RL4}R_{L4} - v_{D10} - I_{RD10}R_{D10} - I_{S1}R_{S1} - v_{s1} \quad (15)$$

$$v_{L5} = v_{in} - v_{D9} - I_{RD9}R_{D9} - I_{RL5}R_{L5} - I_{S1}R_{S1} - v_{s1} \quad (16)$$

$$v_{L3} = -2v_{L1} - I_{RL1}R_{L1} - v_{D2} - I_{RD2}R_{D2} - I_{RL2}R_{L2} - v_{D5} - I_{RD5}R_{D5} - I_{RL3}R_{L3} - v_o - v_{D4} - I_{RD4}R_{D4} \quad (17)$$

$$v_{L1} = \frac{1}{2}(-I_{RL1}R_{L1} - v_{D2} - I_{RD2}R_{D2} - I_{RL2}R_{L2} - v_{D5} - I_{RD5}R_{D5} - I_{RC1}R_{C1} - v_{c1}) \quad (18)$$

$$v_{L1} = \frac{1}{2}(-I_{RL1}R_{L1} - v_{D2} - I_{RD2}R_{D2} - I_{RL2}R_{L2} - v_{c2} - I_{RC2}R_{C2} - v_{D4} - I_{RD4}R_{D4}) \quad (19)$$

After manipulating all the equations, the non-ideal gain is found as

$$G = \frac{1}{D} \times A \times (D + B + C) \quad (20)$$

where, $A = 1 - \frac{I_{RL4}R_{L4}}{v_{in}} - \frac{v_{D10}}{v_{in}} - \frac{I_{RD10}R_{D10}}{v_{in}} - \frac{I_{S1}R_{S1}}{v_{in}} D' - \frac{v_{s1}}{v_{in}} D'$ (21)

$$B = \left[\frac{2D}{D'} - \frac{2Dv_{s2}}{D'v_{in}} - \frac{2(I_{RS2}R_{S2})D}{D'v_{in}} - \frac{2(I_{RL1}R_{L1})D}{D'v_{in}} - \frac{2Dv_{D1}}{D'v_{in}} - \frac{2(I_{RD1}R_{D1})D}{D'v_{in}} - \frac{(I_{RL1}R_{L1})}{v_{in}} - \frac{v_{D2}}{v_{in}} - \frac{(I_{RD2}R_{D2})}{v_{in}} - \frac{(I_{RL2}R_{L2})}{v_{in}} - \frac{v_{D5}}{v_{in}} - \frac{(I_{RD5}R_{D5})}{v_{in}} - \frac{(I_{RC1}R_{C1})}{v_{in}} \right] (2D + D') \quad (22)$$

$$C = \left[-\frac{Dv_{s2}}{v_{in}} - \frac{(I_{RS2}R_{S2})D}{v_{in}} - \frac{(I_{RC1}R_{C1})D}{v_{in}} - \frac{(I_{RL3}R_{L3})D}{v_{in}} - \frac{(I_{RC2}R_{C2})D}{v_{in}} + \frac{(I_{RC1}R_{C1})D'}{v_{in}} - \frac{(I_{RD5}R_{D5})D'}{v_{in}} - \frac{(I_{RL3}R_{L3})D'}{v_{in}} - \frac{v_{D4}D'}{v_{in}} - \frac{(I_{RD4}R_{D4})D'}{v_{in}} \right] \quad (23)$$

Figure 5 implicate the non-ideal theoretical vs simulated gain result. It is clear that in non-ideal case the proposed converter can give 4 to 7 times gain in intermediate duty cycle however 13.3 times gain can be achieved through this converter. Besides due to non-ideal characteristics the gain become zero at max duty cycle.

Table I compare the gain and number of switches between the proposed converter and the references.

Fig.5. Non-Ideal Gain of the proposed converter Theoretical vs Simulated

TABLE I: IDEAL GAIN AND NUMBER OF SWITCH ANALYSIS WITH REFERENCES

Reference	Gain	Switch
3	$\frac{D^2}{(1-D)^2}$	1
4	$\frac{3D}{1-D}$	1
5	$\frac{1+3D}{1-D}$	2
6	$\frac{1+D}{1-D}$	2
7	$\frac{(3+D)D}{1-D}$	1
8	$\frac{1+3D}{1-D}$	4
Proposed converter	$G = \frac{4D + 3D'}{D'}$	2

IV. POWERLOSS CALCULATION OF MOSFET

To determine of a converter's reliability, the power loss of a switch must be in concern [10]. The power loss of MOSFET can be determined by the conduction loss and switching loss and shown in equation 22.

$$P_s = P_c + P_{sw} \quad (24)$$

The conduction loss can be calculated as

$$P_c = I_D^2 \times R_{DS(ON)} \times D \quad (25)$$

The switching loss can be calculated as

$$P_{sw} = P_{sw(ON)} + P_{sw(OFF)} \quad (26)$$

$$P_{sw(ON)} = I_D \times V_D \times t_{ON} \times \frac{1}{2} \times f_{sw} \quad (27)$$

$$P_{sw(OFF)} = I_D \times V_D \times t_{OFF} \times \frac{1}{2} \times f_{sw} \quad (28)$$

After manipulating equations 8 to 25 the power losses of MOSFETs have been analyzed and depicted in Fig.6. This graph also relates to efficiency (η) of the converter by assuming non-ideal characteristics. At low to intermediate duty cycle the power losses (P_{s1} and P_{s2}) in both S1 and S2 switches are around 3W to 9.5W. And with the increase in duty cycle the power loss also increases consequently decay the converter efficiency.

Fig.6. Non-ideal MOSFET power loss results of proposed converter (a) S1 (b) S2

V. THERMAL ANALYSIS OF MOSFET

The MOSFET thermal analysis has been performed based on the conduction method. The MOSFET junction structure and connection between the thermal conductor and heat sink has been expressed in equation 26.

$$T_j = P \times (R_{\theta ca} + R_{\theta cs} + R_{\theta jc}) + T_a \quad (29)$$

where

T_j = MOSFET junction temperature

P = MOSFET power loss

$R_{\theta ca}$ = Case to Air thermal conduction resistance
 $R_{\theta cs}$ = Case to Heat sink thermal conduction resistance
 $R_{\theta jc}$ = Junction to Case thermal conduction resistance
 T_a = Ambient temperature

Three different modes have been performed to determine the MOSFET junction temperature. Power switch without heatsink and natural cooling (T1). Power switch with heatsink and natural cooling (T2). Power switch with heatsink and forced cooling (T3). For heatsink EV-T220-51E has been assigned to perform the analysis. Besides for forced cooling 500 (ft/min) Air flow has been chosen at ambient temperature and assumed to be constant.

After manipulating equations 22 to 26 the non-ideal MOSFET thermal analysis has been performed and depicted in Fig.7(a) for switch 1 and (b) for switch 2. These graphs implicate that the with the increase in duty cycle the temperature also increase in junction of the MOSFETs. At natural cooling with no heatsink attached with MOSFET the junction temperature is 459.8°C and 397.348°C for S1 and S2 consistently. Which is exaggerated for MOSFET. With heatsink and natural cooling the MOSFET junction temperature drops to 121.25°C and 109.78°C at 0.6 duty cycle for S1 and S2 consistently. After adding fan with 500 (ft/min) air flow the temperature drops to 85.00°C and 76.38°C at 0.6 duty cycle for S1 and S2 consistently.

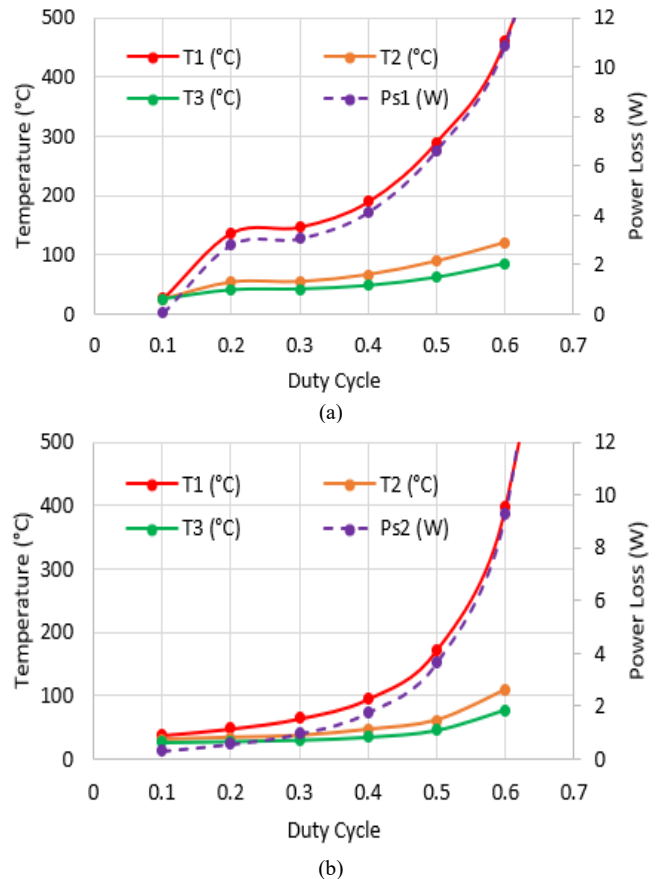

Fig.7. Non-ideal MOSFET Thermal analysis with power loss of proposed converter (a) S1 (b) S2

VI. CONCLUSION

This paper proposes a modified cascaded dc-dc boost converter for electric vehicles motor controller and other renewable applications. The power loss for MOSFET with thermal analysis are also presented. The proposed converter can achieve 4.5 to 9 times gain at 0.4 to 0.6 duty cycle. Due to high gain at intermediate duty cycle the conduction loss is minimum and with heatsink attached to MOSFET the junction temperature is at acceptable range and the temperature even more decayed should a cooling fan is added along with a heatsink.

Abstract—With the healthcare system’s ongoing digital transformation and the need for patient data sharing to become an essential step to understanding the patient’s health history, cyber security must stay at the forefront and be made a top priority. As a result, most existing data-sharing systems depend on trusted third parties. As a result, these systems lack interoperability, data fragmentation, integrity, security, and privacy. In our previous work, we designed a framework based on Blockchain to secure patient health records exchange (SPHRS) that is fully controlled by the patient in terms of revoking or granting access and creating access policies for care providers. The framework achieves security by using smart contracts for user identity authentication and verification. The distributed IPFS storage is applied to store the encrypted patient health records and ensure immutability. In addition, NuCypher software takes advantage of a proxy re-encryption protocol to store the encryption and decryption keys securely. In this study, we assess the framework’s performance by testing metrics such as blockchain transactions’ gas consumption, throughput, Average response time, and average. Bytes. Furthermore, the security of the framework is discussed. SPHRS demonstrates how we can establish a novel approach to efficiently secure patient health record sharing. However, it shows a promising result that can potentially transform the digital patient healthcare system.

Index Terms—Ethereum blockchain, throughput, Avg.Bytes, IPFS, security, transaction, proxy re-encryption, privacy, health records.

I. INTRODUCTION

The healthcare industry generates large volumes of patient health data. This information must be accessible by the care provider promptly to provide immediate care in an emergency and must be kept private and stored securely. Moreover, the lack of trust and interoperability makes it difficult to exchange records between different health systems and among providers; as a result, doctors frequently have incomplete patient records. Meanwhile, the massive amount of PHR collected daily forces the healthcare system to adopt a centralized storage mechanism that lacks transparency or relies on a third party to store and manage these health records, which can be costly. Moreover, most healthcare systems use centralized storage to hold their patient’s data or traditional paper records without backup in case of a threat that can cause data loss or damage. Even if the healthcare

systems moved to cloud storage, they would face security threats [1].

Lately, the healthcare system has been struck by different cyber-attacks such as ransomware and distributed denial of service attacks with these traditional database practices. In addition, while the health sector is under unexpected pressure from the Covid-19 pandemic, patient health records are under cyber-attacks. Cybersecurity breaches hit a record height in 2021, exposing the patient’s health records. In 2021, 45 million individuals were impacted by healthcare attacks which is about a 26.5 percent increase from the previous year and three times higher than three years ago, according to a report that inspects the breach data reported to the US department of health and services (HHS) by healthcare organizations [2]. This suggests that more and more records are breached each year. Moreover, the healthcare industry is a prime target for attackers to monetize PHR and sell them to whoever can pay more. As a result, cybercriminals are expanding their activities to exploit security vulnerabilities across the healthcare supply chain.

As we continue into 2022, healthcare organizations must guard their cybersecurity stance and third-party vendors with access to data and networks. To avoid the consequences of increasingly sophisticated attacks, our focus should be on ensuring a solid framework to enhance PHR sharing, improve interoperability, strengthen health data sharing security, and ensure that patients are put first [3]. According to HIPAA Journal [4], as evidenced in the below Figures, the healthcare industry’s data breaches have increased nearly every year since the Department of Health and Human Services Office for Civil Rights first started publishing summaries of healthcare data Breaches. Figure 1.

According to figure 1, between 2009 and 2021, about 4.5 thousand healthcare data breaches of 500 or more records have been reported to the HHS’ Office for Civil Rights. Those breaches lead to the loss, damage, and exposure of millions of healthcare records.

As illustrated in figure 2, the exposure of the personal identity information of patients in healthcare sectors is on the rise. From the figure 2, there is an elevation in the number of records that are exposed each year, with a huge increase in 2015 due to a massive healthcare

Fig. 1: Healthcare Data Breaches of 500 or more records

Fig. 2: Individuals Affected by the healthcare data Breaches

record breach where more than one hundred thousand records were exposed, stolen, or unauthorized disclosed and affected these health plans: Anthem Inc, Premera Blue Cross, and Excellus [5]. Healthcare system security is missing something critical if data breaches are on the rise almost every year, costing healthcare providers millions of dollars and impacting millions of patients. The use of blockchain technology can enhance HIPAA compliance and protect patient records. More importantly, as it relates to HIPAA, the security and confidentiality features of Blockchain improve cybersecurity and compliance with privacy laws. In other words, blockchain cybersecurity integrated into distributed storage solutions provide an innovative approach to managing HIPAA-compliant health records systems[6].

The remainder of our paper is arranged as follows: In section 2, background. In Section 3, motivation. In section 4, related work. Section 5 proposed the model and its implementation. In section 6, discussion of the proposed framework performance aspects. Finally, a conclusion is in section 7.

II. BACKGROUND

This section briefly describes some technologies related to the proposed framework.

A. Blockchain

Blockchain provides an immutable ledger of transactions for the data exchange system [7]. An unauthorized user cannot change or modify the recorded transactions on the Blockchain. This ensures system reliability and integrity. Furthermore, adding access control using Blockchain can provide system transparency and solve the problem of data breaches. Any illegal activity of an unauthorized user is detected and can prevent malicious transactions. As well as the smart contracts [8] to achieve authentication and user verification.

B. Interplanetary File System (IPFS)

It is a peer-to-peer distributed file system. It provides a content-addressed block storage model to uniquely identify files in a global file system[9]. IPFS gives a high throughput. IPFS has no access control, and files over IPFS can be directly accessed by their respective hash value, making it easier to integrate with different blockchains as an off-chain storage solution where Blockchain acts as an access control system.

C. NuCypher

NuCypher[10] software has two main components. It is a decentralized blockchain-based key management system (KMS) encryption and access control service that can be implemented on a private or Ethereum network. In our framework, it manages the encryption and decryption keys and enables data sharing between users using proxy-re-encryption over the network. NuCypher uses decentralized network to delegate encryption/decryption rights. Hence, decentralized KMS helps conditionally grant and revoke access to sensitive data to as many recipients as the patient like by just creating policies that can be either time-based or condition-based.

D. Ethereum Smart Contracts

The smart contracts are automatically executed when the rules in the contract are met. A smart contract automatically enforces predetermined rules between parties without the need for intermediaries, with a credible public ledger. It can store metadata and program some events according to some conditions. They are transaction protocols that intend to enforce the terms of the contract and can be used by the developers in creative ways in programming functionality [11].

E. Proxy re-encryption (PRE)

Proxy re-encryption is a public key cryptographic primitive where a data owner can grant the right to decrypt his data to other data requesters [12]. After a semi-trusted proxy re-encrypts the ciphertext, which is under an owner's public key, a data requestor can decrypt the new ciphertext through his secret key. Identity-based proxy re-encryption (IBPRE) is a PRE scheme in which data owners and requestors take their identities as public keys and no longer need public infrastructure (PKI).

III. MOTIVATION

Patient health records (PHR) are the foundation of any patient health record exchange system. The data must be shared among various healthcare entities so that health professionals have the information they need to make informed decisions that can impact their lives. However, accessing and sharing patient health records is facing a big challenge by compromising the patient's confidentiality and privacy without breaking confidentiality or compromising patient privacy is an ongoing challenge in today's increasingly digitized world [14].

Patient health record sharing plays a huge part in the healthcare system by enhancing interoperability. To address the issues of the existing PHR sharing and ensure data privacy and security during data sharing, the need for a secure, reliable system that enables care providers to diagnose and treat patients becomes an even greater priority.

Motivated by the need for a more reliable system that will guarantee the security and the privacy of the PHR sharing and solves the problem of the lack of interoperability, the lack of clear definition of the data ownership, and the protection of sensitive records while making the information accessible to authorized providers, we designed a framework that can ensure all the above (SPHRS).

The built system can facilitate secure, trustable management and aggregation of PHR data. In addition, the system will ensure patient privacy protection and guarantee security where patients are allowed to manage their health records efficiently among multiple providers. These features can only be achieved using blockchain technology [15], an ideal way to lay the foundation for decentralization and supporting healthcare data integration across various use cases. It also has the potential to solve existing issues in health records sharing.

It is impossible to store a large amount of data within the Blockchain. Ethereum blockchain has a cost associated with performing a transaction, known as a "gas fee," if one wants to store data, the gas price will be high and impractical. The alternative will store the data on secured off-chain decentralized IPFS storage and store the hash on the Blockchain. The main advantage is that IPFS allows patients to keep their large medical files securely, such as X-ray scans, MRI scans, and more, to solve the issue of the latency and block size limit in the Blockchain.

In our previous paper, we built a fully decentralized model in all its essence and discussed our framework's contribution in detail. In contrast, in this paper, we will focus more on testing and evaluating the performance measure of our framework. The proposed architecture makes the following contributions:

- This study presents a solution for patient health records exchange using the Ethereum blockchain for verification and authentication of the users and to prevent and deny an unauthorized provider access to the patient's sensitive information.

- The Patients own and control the access to their data which eliminates all the barriers for the patients to request copies of their health records or send them to another doctor.
- The health records are stored in a distributed tamper-proof Interplanetary File System IPFS, which is fully distributed off-chain storage and makes it possible to efficiently distribute high volumes of data. Furthermore, it provides fast PHRs retrieval capability.
- Data is encrypted and stored in IPFS and can only be decrypted with the provider's private key. Therefore, if a malicious party compromises the network, there is no way to read patient data.
- This study uses the Ethereum blockchain smart contracts Smart for identity verification and authentication of the doctor and the healthcare entities, making it difficult for an unauthorized doctor to access the data.
- This study performs the vulnerability and security analysis on the unauthorized doctor who wants to access the records and the ability of the patient to revoke the doctor's access to these PHRs at any time.

IV. RELATED WORK

Blockchain is taking the world by storm. It is implemented almost in every existing field. The blockchain potential in the healthcare sector is undeniable to increase healthcare data security, privacy, and interoperability and is seen as the new model for health data sharing. However, most existing schemes use the centralized approach for storing data. This section reviews the current systems related to blockchain-based on PHRs sharing and access management control. In [16], the authors introduced how Blockchain would facilitate the health sector. The specified data sharing is why Blockchain should be used in healthcare to deal with authorized users' access, data availability, and obtaining of health records. It also considers the data storage, either on-chain or off-chain storage. However, the challenges and barriers to using Blockchain were the huge volumes of health records, patient access control, security, and privacy.

The authors [17] designed a Medshare system based on a blockchain approach for healthcare information exchange using cloud services. The proposed method provides security of health records and access control. However, they had not considered the problem of key management and scalability. The evaluation of the performance of the proposed system was done on network latency measurements using theoretical analysis. In [18], the authors proposed a secure ABE system with multiple authorities for Blockchain in Electronic Health Records. They used an attribute-based signature scheme for numerous electronic health record management users with Blockchain. In this attribute-based, their objective is to achieve security and privacy of the system and achieve the immutability of the information ledger. However, the system lacks interoperability and privacy.

In [19], the authors proposed an implementation of MedChain based on a Hyperledger blockchain system to

manage health data. The system has three components: an access control scheme, cloud storage, and a user interface. Patient health data is encrypted and stored on the cloud while the hash of the data is stored in the Blockchain. However, the system does not consider how different healthcare entities can connect and share patient health data. In [20], the author presents a blockchain-based health record exchange system that guarantees patient privacy and integrity of his health data. The model provides a patient’s record immutability. However, the model has not considered another alternative to store the huge amount of data that the Blockchain cannot support.

In [21][22], the authors present a framework based on Blockchain to address the data scattered among different healthcare systems. The medical data is stored in a decentralized structure and uses the blockchain immutability property to provide security. In addition, the authors make use of smart contract transactions to transfer medical records. However, the system stores medical data cloud-based, which can be easily compromised, and unauthorized users can access sensitive medical data.

In [23], the authors present Medrec system, an Ethereum-based record management system for EHRs. The method leverages Blockchain to administer user authentication, the confidentiality of health records, accountability, and data exchange. MedRec provides patients with a complete history of their health records through an inalterable log easily accessed across different providers. However, MedRec only integrates with the provider’s current storage solution. Therefore, the system is not patient-centric.

All the above approaches have no restriction on privacy security and hence pose a threat to the integrity of the health records. Furthermore, relying on centralized storage to store health records which means a third-party dependency, is a major disadvantage. These proposed approaches have not considered an alternative solution to store huge data that is not supported by the Blockchain. In this study, we have resolved most of the healthcare sector’s issues by integrating technologies such as Blockchain, IPFS storage, and other emerging technologies like NuCypher to provide higher quality healthcare for the patient.

V. PROPOSED MODEL AND ITS IMPLEMENTATION

This section offers a solution that can help improve patient care, care coordination, and the nation’s overall health. SPHRS [24] uses the Ethereum blockchain that features smart contracts to safeguard security and privacy by verifying and authenticating all the involved parties who can access the PHRs. In addition, the IPFS is used to resolve the storage cost and scalability issues. Our solution removes the need for a reliable centralized authority. It gives security and privacy to the patient health records exchange. The robustness of the infrastructure with high integrity and resiliency is achieved by using NuCypher software to store safely and securely the encryption re-encryption keys. Figure 3.

The system model has the following entities:

- The data owner, who is the patient, can grant or revoke access to an unauthorized provider.
- The encryptor is the Healthcare entity and is the PHRs source that encrypts and stores records on IPFS.
- The provider retrieves records from IPFS and grants access to the patient.
- Ursulas are nodes on the NuCypher network representing the proxy re-encryption proxy. They are responsible for re-encrypting data and enforcing the access policy created by the patient.

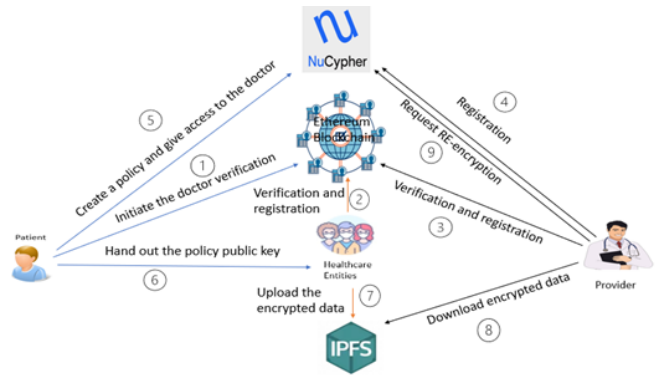

Fig. 3: : Secured Patient Health Records Sharing based on Blockchain

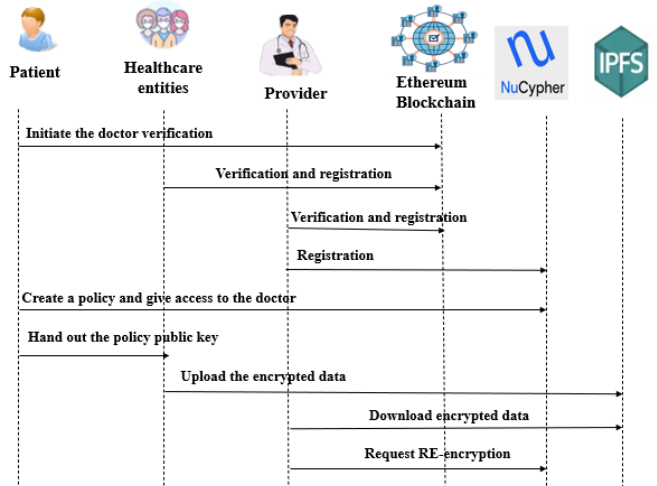

Fig. 4: Sequence Diagram for Sharing Patient Health Records

Our proposed framework consists of four parts:

A. Users Authentication and Registration

There is currently a provider and healthcare entities verification smart contract initiated by the patient and deployed on the Ethereum test network. There are two parts to this smart contract:

- Information receiving: The provider and the healthcare entities can submit their basic information, which will

be used to verify their credentials and identity : A function in the smart contract that tells us whether a provider and the healthcare entities with a specific id have been verified yet. After that, the provider must be authenticated to be able to create an account on the Blockchain.

B. Patient grants the provider access by creating a policy

For any authorized provider to permit access to the patient’s encrypted health records, the patient must create a policy and upload it to the NuCypher Network. The patient combines his private key and the provider’s public key to get the re-encryption key and send it to the proxy servers. Next, the patient collects information about the nodes or Ursulas who provide the proxy re-encryption service linked with the policy. Each Ursula gives their encrypted key, and the patient generates n re-encryption key shares (kFrag). The Ursulas remain ready to re-encrypt data. The list of Ursulas and other information are stored in a Treasure Map. Every time the patient creates a policy, this policy has an associated policy public key, which the healthcare entity can use to encrypt data on the patient’s behalf.

C. Encryption and upload of PHR to IPFS by the Healthcare Entities

The healthcare entities use the public policy key generated when the policy was first created from the patient and encrypt PHRs. Next, the Healthcare entities use a randomly generated symmetric key to encrypt the PHRs and then encrypt the symmetric key with the patient’s policy public key. Finally, the Healthcare entities upload the encrypted symmetric key and the encrypted PHR and store them at IPFS.

D. Retrieval of Patient’s Health Records by the provider

For the provider to access the patient health records, he must use the treasure map to allocate the list of Ursulas who stand ready for the re-encryption operation. Then, the provider obtains the encrypted data from the IPFS and sends a re-encryption request to the relevant Ursulas on the network. If the policy is satisfied and the provider is an authorized user, Ursula decrypts the provided re-encryption key share and re-encrypts the provider’s public key. Afterward, the provider can decrypt the capsule with the private key to obtain the symmetric key used in data encryption. Then can access the data after decrypting the records.

VI. PERFORMANCE EVALUATION

This section aims to provide the performance evaluation by conducting several tests to validate the performance of the proposed healthcare system and reduce the risks associated with this novel approach. This study assesses the transaction’s performance in terms of gas consumption, transaction throughput, average time, and sent and received byte. This section explains the evaluation of different security perspectives and user data requirements.

A. Transaction Gas fees

We evaluate the performance of the proposed framework by determining the cost of the transaction in terms of gas consumption. Every transaction on The Ethereum blockchain contains data. Therefore, we calculate the gas fee associated with different transactions of the proposed framework. In the Ethereum, ” ETH” is used to calculate the transaction fees [25], which is an Ethereum coin, and its units are Wei and gwei. The transaction fee is the product of the gas consumed and the gas price. Table 1 relates the gas consumption values to the various functions used in the smart contract. After deploying the blockchain smart contract to the Ethereum, a public Rinkeby testing network (aka testnet) was used for this, which is a network that operates as the main Ethereum network, but where Ether has no value and is free to acquire-making them ideal for testing your contracts at no cost. The transaction and the execution gas were recorded. Hence, the transaction cost is the amount of gas required to send data on Ethereum, and the execution cost is the computational fee necessary to execute the function.

TABLE I: Gas Consumption of the Ethereum Transaction

Smart Contract	Function	Transaction Fee (Ether)		
		Trial 1	Trial 2	Trial 3
Doctor Verification	setDoctor	0.000046317	0.000046329	0.000046329
	changePatient	0.000028777	0.000028777	0.000028777
Doctor Authentication	setPrimaryInfo	0.000089364	0.000040201	0.000040213
	set Doctor Info	0.000137441	0.000062734	0.000062710
Healthcare Entity Authentication	setPrimaryInfo	0.000089364	0.000040249	0.000040237
	sethealthcareEntityInfo	0.000137335	0.000062784	0.000062808

We implemented and deployed three smart contracts. Table 1 exhibit the transaction costs of the used functions. The setDoctorInfo and sethealthcareEntityInfo, their general information inside the smart contracts, make up the major share of the transaction costs. On the other hand, patient function changes have a much lower cost. As for the remaining functions, starting with setPrimaryInfo, the costs are slightly increased as they perform expensive checks using the primary information of the doctor and the healthcare entities.

B. Performance Testing

SPHRS scalability is very important for the application. To spin up a network for scalability testing, we create a network of a varied number of users(Threads). SPHRS was tested with varying numbers of users in terms of the NuCypher endpoint for the policy encryption key for the label. The results show that NuCypher, even a decentralized

PREservice, performs well for endpoint policy encryption keys. To evaluate the performance, we are using Apache JMeter, a desktop performance testing tool to analyze and test applications [26]. Using JMeter, we mimic the number of users from 10 to 5000 users using the system and performing its several features. In JMeter, the throughput signifies the number of requests made in a given period, and its unit is KB/Sec. The average represents the average response time of all the total samples. The values for received and sent represent how many kilobytes of data were received and sent, respectively. While the Avg. Byte means the average data size passed through each API call. We repeatedly called the same API with the same data size for each experiment.

Fig. 5: Throughput vs the Number of Users

Fig. 6: Received KB per second vs. the Number of Users

As findings for the above figures 5 to 9, we can conclude that as the number of users increases, the throughput, received and sent data, and the Average response time all increase. While, in threads 10, 50, 100, and 150, the Avg. Bytes are 302. The average started to increase later because some API calls started to return errors, and therefore, the response included more bytes. The errors partly came because we were experimenting on my local machine, and it is very machine intensive to have 500+ threads open at once. With the above experimentation and comparison, we conclude that SPHRS is viable. A decentralized alternative

Fig. 7: Send KB per second vs. The Number of Users

Fig. 8: Average Response Time of all the Users

to the currently present centralized option. Some outlined benefits of SPHRS will be:

- SPHRS can perform better in response to throughput
- Decentralization also makes sure no single point of failure.
- SPHRS provides data governance to the patient, thus increasing transparency, decreasing delay, and improving services.

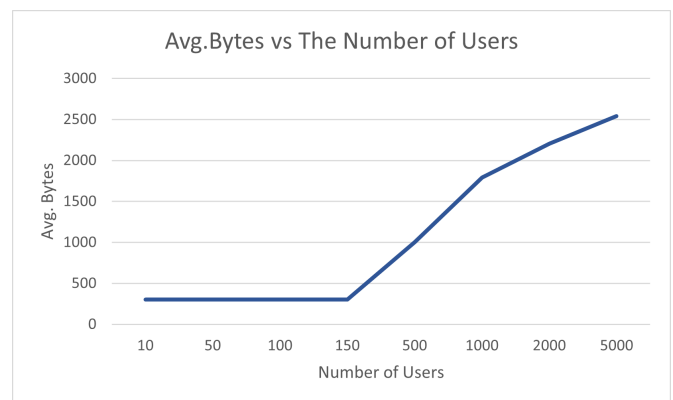

Fig. 9: Avg. Bytes vs. The Number of Users

VII. CONCLUSION

This paper tests the performance metrics of our proposed secured PHRs framework. Our Blockchain framework based on secure PHR sharing includes all the expected health records sharing system criteria. We identify the security vulnerability in the existing approaches, and we tackled these issues in our proposed framework by proposing efficient solutions through an actual prototype implementation. Furthermore, our framework surpasses the current systems because it enhances the privacy and the security of the patient health records exchange. Finally, we evaluated the performance metrics of our proposed framework. For future work, we will investigate how the framework is protected against inside and outside threats by testing the vulnerability of the framework against various types of cyber-attacks [27]. Moreover, we will extend this implementation work in terms of scalability by increasing the number of patients, providers, and the size of the health records. Finally, we will enhance the performance of the existing framework and test the performance metrics in terms of transaction dissemination latency, security, and scalability. The measurement will be evaluated using the following platforms: the GRE tunnel setup between Kyutech in Japan and CCNY in the US and Extending the CCNY- Japan tunnel experiment to the COSMOS experiment.

Abstract—In the last decade, smartphones have evolved tremendously. They became powerful computers that fit in our pockets. Today, with the huge adoption of smartphones. Smartphone security has become essential. Nowadays, a smartphone has become a complex piece of equipment that a single device incorporates users, Operating systems, manufacturers, carriers, and app developers. With such complexity, smartphones can be subject to many attack vectors. This paper explores one of them which is network-based attacks on cell phones. This paper discusses the several types of attacks then, it proposes an input fuzzing system for network-based attacks on phone. The proposed system is novel, as today for the previously mentioned attack vector, fuzzing is done using an emulator. This paper introduce a new fuzzing system for smartphones that addresses network-based attacks. This is done by setting up a network environment using SDRs. The proposed setup allows fuzz testing for Smartphones and baseband OSeS for network-based attacks coming through SMS, WAP, and calls.

Index Terms—Mobile Network, Attacks, Network-based attacks

I. INTRODUCTION

A smartphone is essentially a small computer that can fit in one's hand. The beauty of using a smartphone lies in its ability to perform different functions and allow its users to access networks such as the Internet while providing convenience. In the past two decades, there has been rapid growth in the number of mobile devices utilized, especially with the global smartphone boom. Smartphones took over the wider consumer market, and as of 2021 according to the Pew Research Center, 85% of US adults use smartphones [1]. Smartphone revolution is global. The number of smartphones has reached 6.2 Billion globally in 2021. Smartphones are used for many applications in our daily life. This includes banking, games, emails, and e-commerce. With the wide range of applications and use cases, smartphones holds very sensitive data, this includes pictures, call logs messages emails. Also, smartphone has several ways to sense its surrounding such as cameras and microphones. Therefore, smartphones became a valuable target for attackers. This created new security challenges. Attacks on smartphones have been on the rise in the last few years. According to the 2021 Mobile Security Report, 40% of all mobile devices

are vulnerable to attacks [2]. Moreover, The same report also stated that nearly every company witnessed at least one smartphone malware attack last year. 93% of the said attacks stemmed from the mobile network.

Many of attacks on phones comes to the mobile network. A mobile network allows users to access the network while on the move. It consists of base stations where each cover a limited area or "cell." When joined together these cells provide radio coverage over a wide geographic area. This enables a large number mobile devices to communicate with each other and to the internet. To connect to a mobile network, a smartphone uses a wireless protocol (e.g. GSM, 3G, LTE). Smartphones include a "side" OS known as the baseband OS. This OS implements the wireless protocol. The baseband runs on a dedicated processor that is different from the one where the smartphone OS runs. which is known as the baseband processor. A baseband processor is a chip in a smartphone, that helps convert digital data into radio frequency signals which can then be transmitted over a Radio Access Network. This processor is different from the processor than runs the smartphone OS and applications. The baseband chip incorporates encryption keys used to authenticate to the mobile network and are stored on a tamper-resistant smart card known as the SIM card along with other user identification information that allows the phone to connect to the network.

Network-based attacks on smartphones attacks either coming from network or an entity intercepting the communication (man-in-the-middle attack). Such attacks include denial of service, malware injection, and others. With many attack vectors, researchers attempt to find vulnerabilities before they are discovered and exploited by hackers. One technique to discover vulnerabilities is input fuzzing. Input fuzzing is a process in which malformed inputs are sent to the targets with the objective to trigger bad behaviors, such as crashes, infinite loops, and/or memory leaks. Input fuzzing has been a tool used by programmers and penetration testers to detect problems in the systems. In this paper, we implement a system of input fuzzing targeting Smartphones. In this system it is possible to input fuzz the network-based attack vector on

smartphones. This would include, Short messages service (SMS), wireless application protocol (WAP) Pushes, pagings, and phone calls. We show details about this implementation using Two different Software defined Radio (SDR) chipsets.

II. BACKGROUND

Mobile networks are maintained by the carrier that provides SIM cards. The smartphone maintains a baseband chip that uses authentication information on the Simcard to access the network. There are many ways to attack this setup. For one, attackers can target the Simcard, in a demonstration, it was shown that a text message from a spoofed carrier can obtain the 56-bit DES encryption key of a SIM [3]. Alternatively, an attacker could target the baseband OS [4] [5]. One attack used a carrier Over-The-Air (OTA) update mechanism to bypass the lock screen [6], or flash a Samsung Galaxy S6 baseband remotely [7]. On the other hand, Man-in-the-middle attacks targets communications between the smartphone and the cellphone towers. GSM has a short encryption key which makes it very easy to attack [8]. Another issue with GSM is its lack of authentication of the base station, Thus an attacker with a spoofed base station can capture the SIM and the phone information and intercept outgoing calls and texts [9].

Alternatively, attackers target the OS on smartphones. This would be trying to exploit weakness or poor design on Oses of smartphones. There are has been several exploits reported on attacks targeting system using SMS [10] [11]. For example, one vulnerability allows a setup message to create buffer overflow [12] Other attacks are done through WAP [13] [14]. For example on Samsung Galaxy S4 through S7 a a malformed WAP PUSH SMS causes the Android runtime to continually crash, rendering the device unusable until a factory reset is performed [15]. Also, attacks using calls [16] [17], for example, An issue was discovered on LG mobile devices with Android OS 11 software. Attackers can bypass the lockscreen protection mechanism after an incoming call has been terminated [18]. Exploits also targets iMessage the iPhone messaging App. A zero-click exploit against iMessage targets Apple's image rendering library, that would allow arbitrary code execution.

One technique to discover such attacks is input fuzzing. Fuzzing does not have to detect an exploit. But it can detect weakness that can be investigate further, which could lead to detect exploits. Fuzzing also discover how a phone would react to different input. For example, Apple operating system iOS crashed when received a special character [19]. There has been several implementation to input fuzz smartphones. Inputting fuzzing targets different aspect of the smartphone. Including the Operating system [20], Applications [21], and drivers [22]. Also, there are systems to input fuzz the baseboard OS using an emulator [23]. This paper introduce a new fuzzing system for smartphones that addresses network-based attacks. This is done by setting up a network environment using SDRs. The proposed setup allows fuzz testing for

Smartphones and baseband Oses for network-based attacks coming through SMS, WAP, and calls.

III. SYSTEM MODEL

The proposed Fuzzer for Network-based attack vector on smartphone is as shown in Fig.1 and consists of the following elements:

- 1) **Fuzzer dictionary:** This dictionary consist of the list of the inputs to be tried by the fuzzer. It is very useful to provide fuzz target with a set of characters, values, and different text format that are expected to find in the input. Adding a dictionary highly improves the efficiency of finding new weakness. In general, a fuzzer is as good as the dictionary. A well-rounded dictionary that has a list of letters, characters, and inputs in different unicodes would be a great testing tools to find weakness. Alternatively, a dictionary could include a set of network configuration messages to study their impact on the targeted phone.

Fig. 1. System overview

- 2) **Fuzzing script:** The fuzzing scripts reads the input from the fuzzer dictionary and sends that to be transmitted by the SDR. The script usually would include a loop that goes through a elements of the fuzzer dictionary. It is important that the loop has enough sleep time to incorporate the the transmission ques and the buffer size of the SDR.
- 3) **SDR:** An SDR uses software for the modulation and demodulation of radio signals and can be used to imitate the performance of a radio communication protocol (e.g., GSM, 3G, UMTS, 5G). In general, different protocols entails different types of communication format, which leads to different nature for the attack vector. Therefore, it is important to input fuzz the smartphone with the appreciate protocols and communication format with the appropriate fuzzing dictionary.
- 4) **The target:** The target is usually a Smartphone. Usually, in the proposed fuzzing system, both Baseband

OS, and Smartphone OS can be targeted with the input fuzzing.

IV. IMPLEMENTATION

The implementation of the proposed system follows the element discussed in the in the previous section and are implemented as follows:

- 1) **Fuzzer dictionary:** a text file. Each input is written on a newline. The fuzzing system is running on DragonOS, which is a linux disturbiton that is tailored for wireless applications.
- 2) **Fuzzing script:** The fuzzing scripts reads the input from the fuzzer dictionary and sends that to be transmitted by the SDR. The script is written using python.
- 3) **SDR:** Two different models of SDR ware used. The USRP b205mini [24], which was used with an open-source communication package referred to as osmocomb [25]. Osmocom includes software and tools that implements a variety of mobile communication standards, such as GSM, DECT, TETRA and others. The other type of SDR used was BladeRF 2.0 micro xA5 [26] with software package known as YateBTS [27].
- 4) **The target:** For the purpose of the implementation a Samsung galaxy S6 was used.

The implementation is shown in Fig 2.

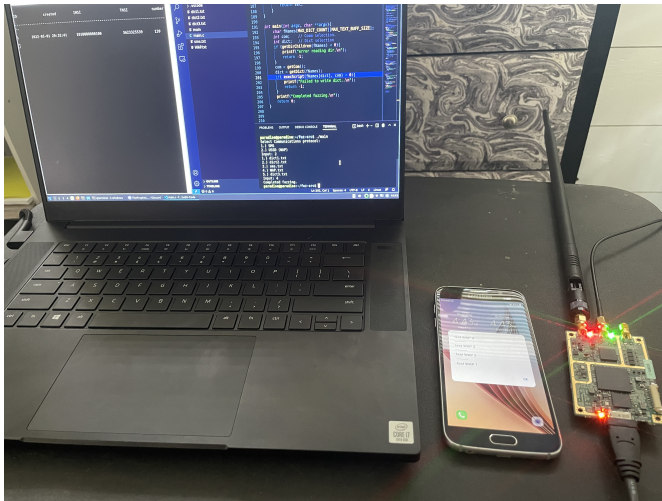

Fig. 2. Proposed fuzzing system implementation

V. CONCLUSION

In the last decade, smartphones have evolved tremendously and today became essential in our daily lives. With the Smartphones carrying many valuable information about their users, they have been a target for attackers. Smartphones can be targeting through several attack vector. This paper discussed network-based attack vector on smartphones. Such attack vector requires smartphone developers to test them

and fortify them against such attacks. One technique to test smartphones against such attacks is input fuzzing. This paper introduced a new fuzzing system for smartphones that addresses network-based attacks. This is done by setting up a network environment using SDRs. The proposed setup allows fuzz testing for Smartphones and baseband OSe for network-based attacks coming through SMS, WAP, and calls. The proposed system was implemented with two different models of SDRs. The proposed system is a powerful tool to automatically test smartphones against a vast number of inputs sent by the network.

Abstract—Human Immunodeficiency Virus (HIV) is one of the variants of the retrovirus that integrates into the human genome and affects the human immune system. HIV-1 is the common HIV that is studied. Previous studies have revealed that the HIV integration site plays a key role in the treatment of the fatal disease as it is critical in the latent viral reservoir formation process. This reservoir is the roadblock in the search of a cure to HIV. The whole life cycle of the virus depends on this site. In the clinical studies pertaining to the provirus integration sites, a wealth of data is collected from routine clinical care of HIV patients in the form of medical records to analyze HIV integration targeting to combat the immunity to antiretroviral therapy (ART). A novel futuristic review of the researches done on HIV, particularly on works done to analyse the integration sites, has been presented here. This study concludes that building upon previously collected data and progressing towards improvement by the incorporation of the latest technologies will unravel new information that can help in the betterment of the future prospectives of a breakthrough in the cure of HIV/AIDS.

Index Terms—Integration sites, HIV, ART, DNA sequence, LEDGF/p75

I. INTRODUCTION

HIV integration sites (IS) have a major play in the viral infection and the whole life cycle of the retrovirus [1] [2]. It determines the viral rebound after antiretroviral therapy (ART) is disturbed [3] [4] [5] [6]. Furthermore, the persistence of the infected cells is also determined by the HIV IS [7] [8].

Few in-depth laboratory researches have been done for the identification of HIV IS [5] and most researches have been done for finding out

other related activities after using the isolated IS in different types of cells as input i.e. to analyze the evolution of the virus after integration [9]. In fact, very less has been done for the study of the integration sites except for the integration targeting in ART [10]. The existing studies only statistically work towards integration targeting for ART that is to say they focus on the already infected cells and study the after-effects of the HIV integration pathway based on the analysis of various ‘other’ factors [4] [11]. Very few studies exist that solely study the exact sites of HIV integration and most take the ART into center stage. Clinical trials with the novel diagnostic technologies involving only experimental and biomarker epidemiology fall short in contributing to the goal of UNAIDS 95-95-95 to completely end the AIDS disease by 2030. The reason being the current rate at which new protein sequences are being generated is very fast. An improved automatic method [12] will serve the purpose in a better way. The scope of this survey was limited to HIV/AIDS medical care, clinical research and the scarcely available AI studies focused upon the analysis of genotype or phenotype factors for HIV integration site targeting. As there are very few studies involving AI, this review is devoted to addressing the following question: “What progresses have been made to predict the IS of a HIV provirus?” majorly based on the studies using statistical modeling or laboratory experiments as the mean. This addressing of the issue is eventually culminated with a discussion about ML (Machine learning) based approaches in the field.

II. IMPORTANCE OF PREDICTION OF INTEGRATION SITES OF A HIV PROVIRUS

Gary et al. [1] indicated the importance of integration sites with the computational prediction of nucleosomes using massively parallel pyrosequencing to find out the relation between major grooves in chromatin and sites of HIV integration and to show that the effects of histone modifications on the HIV integration process was partially independent of other genomic features incorporated during the integration process. The pyrosequencing and some methods that they called as the bioinformatic methods were used for the prediction of nucleosomes occupancy positions, annotation of each base pair with statistical tools for its likelihood of hosting integration for periodicity analysis of nucleosomes and also, correlation of integration sites with the ENCODE results. They did this to imply that investigating many diverse aspects of retroviral DNA integration is useful. They stressed the importance of the selection of acceptor integration target sites for both the host and the virus. Pyrosequencing is a process using the sequencing by synthesis of DNA polymerase along with light detection. The process is depicted in Fig 1. Prior to pyrosequencing, Jurkat T cells were infected with the HIV-based vector. Then the fact of DNA sequences guiding nucleosome positioning [13] was used and the placement of nucleosomes on chromosomal regions hosting integration events was mapped using the nucleosomes positioning prediction tool available at <http://genie.weizmann.ac.il/pubs/nucleosomes06/index.html>. Illustration of the nucleosome-DNA interaction model thus formed by the lab is presented in Fig 2¹.

They referred to the work by Segal et al. [14] for this. Pyrosequencing helps in clarifying the nucleosomal structure. Alignment of the integration site patterns relative to the nucleosome's symmetrical centre revealed that integration is favored at the backbone sites of phosphate at the edges of major grooves which face outwards. It was the first to study whether integration in host-cell chromosomal DNA takes place in a nucleosome-wrapped region which matches in-vivo DNA. As these are lab based methods, we outline how these are intensely based on new data and are expensive every time in comparison to learning it with ML-based techniques. The vector of viral stock was prepared by transfection with the HIV vector segment along with the packaging or helping viruses into the 293T cell line. The Viral supernatant was then harvested

for thirty-eight hours after transfection, filtered through 4.5 nanometers sized filters, treated with DNase I, concentrated and frozen. DNA from host-virus junctions was prepared using PCR. The PCR products were gel purified, dissolved in an enzyme pool, and dispatched to 454 Life Sciences for pyrosequencing. Integration sites were accepted for reporting only if the sequences beginning within the 3 bp of HIV LTR ends had greater than 98% sequence match; it was aligned for the best match to the human genome (hg17) using BLAT. BLAT interface²³ is presented in Fig 3. In addition a transcription-based profiling was performed using Affymetrix microarrays which use gene chip probe arrays which we are not concerned with while dealing with the integration sites. Analysis in the ENCODE Consortium Encyclopedia of integration site positions revealed the epigenetic associations of the integration sites. They finally inferred that nucleosome-wrapped chromosomal DNA is the in-vivo integration target, and other finding unrelated to IS (like targeting by PSIP1/LEDGF/p75 , HIV cure with LEDGINs will only affect some part of HIV-1 expression and not form a complete cure).

Debyser et al. [15] highlighted the Hurdles in the search for an HIV-1 Cure. They focused on patients undergoing combination antiretroviral therapy (cART). They mentioned the difficulty being the failure of current treatments to eradicate HIV as this infected DNA persists in long-lasting cellular reservoirs and inducing a viral rebound whenever the treatment is disturbed. In their review article, they focused on post-integration latency, where cells contain an integrated provirus that is latent as far as the generation of viral fragments is concerned. They analyzed the role of LEDGIN-mediated blocking-locking of epithelium-derived growth factor p75 (LEDGF/p75) based on previous studies. This use of LEDGIN as the antiviral to block the interaction of p75 and Integrase forms part of what is called retargeting. They pointed out that LEDGF/p75 determines HIV integration site selection more than any other protein does.

Debyser et al. in their other paper [16] mentioned that the retroviral family preferentially integrates near a unique genomic profile locality. They provided for validation of LEDGF/p75 as an antiviral target and highlighted the efforts undertaken to develop small-molecule-based inhibitors

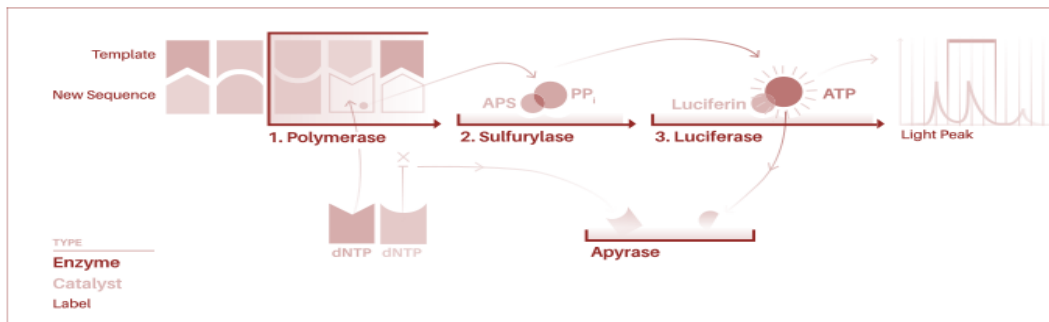

Fig. 1: The process involved in Pyrosequencing.

Fig. 2: Nucleosome-DNA interaction model predicted by the Segal Lab

of the interaction between HIV integrase (IN) and LEDGF/p75. During HIV replication it is mentioned that LEDGF/p75 has been identified as the exclusive tether of lentivirus integration with IN associated with the viral genome into the host chromatin. They were referring to some colocalization studies for this finding. Also this review paper mentioned LEDGF/p75 binds and protects IN from degradation and stimulates the catalytic activity of being in in-vivo as well as in-vitro. They mostly detailed the mechanism of targeting IN and its interaction with LEDGF/p75 (an antiviral tethering factor and cofactor target of many similar studies mentioned in the review paper) to the transcription region for HIV integration. They finally discussed some proposal for a safer MLV-derived vector for gene-therapeutic application. The HIV integration site was mentioned a few times for the emphasis of the role of LEDGF/p75 in facilitating of HIV integration.

Vansant et al. [17] confirmed the findings that the antivirals LEDGINs block the interaction between the co-factor LEDGF/p75 and the HIV-1 enzyme called integrase but they emphasized that closeness of silent proviruses to the epigenetic chromatin markers are associated with RNA expression and thus there is an association between provirus integration site and viral expression. It was a lab-

based research as to support their findings they did cell culture of SupT1 and Jurkat cells using the RPMI medium with 10% (v/v) fetal bovine serum and 0.01% (v/v) gentamicin. HEK293T cells were cultured in Eagle's medium modified with Dulbecco with five% (v/v) FBS (GIBCO) and 0.01% (v/v) gentamicin (GIBCO). For the viral Vector production Linear polyetylenimine (PEI) was used to cotransfect HEK293T cells with the packaging pHCC1. Other methods like Transduction, DNALibrary preparation, sequencing, Flow cytometry, cell sorting, qPCR(quantitative polymerase chain reaction), Bisulfite cytosine methylation analysis, RNA sequencing, Gene enrichment analysis, ChIP-sequencing and mRNA purification were incorporated along with LEDGIN CX014442 as the treatment agent for inhibiting LEDGF/p75. Chromatin immunoprecipitation (ChIP) is a precipitation method to study the interactions of proteins with the specific DNA regions. This requires the work by a specific antibody. Insertion sites were retrieved with more confidence using the transduction method of Barcoded HIV-ensembles (BHIVE). They found that the centrifugation with LEDGIN CX014442 during infection significantly changed and balanced off the chromosomal distribution as measured statistically in terms of the Chi-square test ($P < 0.0001$) and also increases the distance of integration sites to the chromatin H3K36me3. This work also mentions that HIV-1 integration is dependent on the LEDGF/p75 binding to H3K36me3 chromatin marker near the enhancer regions.

Patro et al. [6] narrowed down on the fact that the state of the persistent HIV provirus populations in the infected CD4+ T cells i.e. the structure of the proviral sequence in the latent reservoir along with its clonality has a link to the position of the integration sites. To reveal this link they used multiple-displacement amplification (MDA, see Fig 4) of cellular DNA which was already

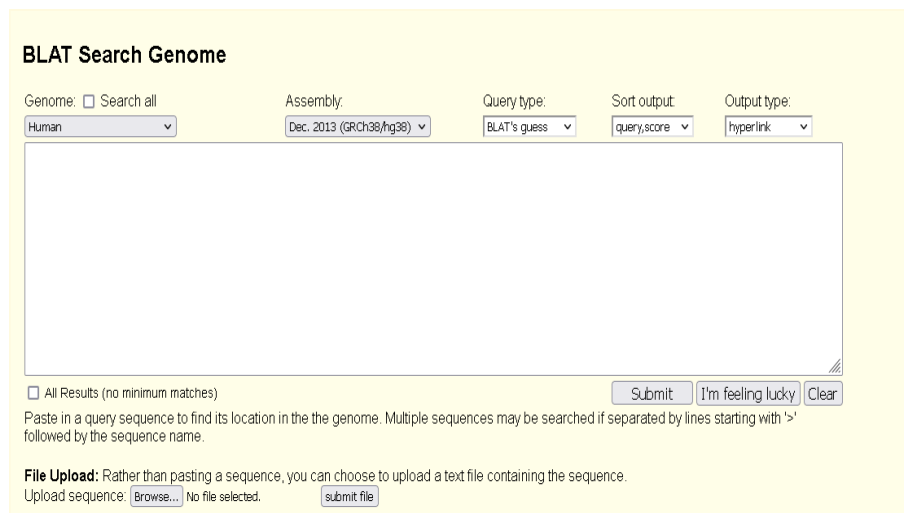

Fig. 3: Illustration of the BLAT interface.

Fig. 4: MDA in progress.

diluted to a proviral endpoint so as to obtain the whole length of the proviral sequences for what is called “viral reconstruction” and their corresponding integration sites. The MDA was combined with Single-genome sequencing (SGS) and integration site analysis (ISA) to get the information regarding the structure of the persistent or clonal HIV. This was because the standard SGS has demerit of not being able to establish clonality of the provirus. So, they were finding out the origin of clonal proviral DNA And this has an implication for the removal of latent reservoir which is the obstacle to HIV treatment. They found that identical proviral sequences can result from both cellular expansion and viral genetic bottlenecks occurring prior to ART initiation and following ART failure. They applied the above mentioned methods starting with SGS to the lymph node and peripheral blood mononuclear cells of 5 ART undergoing donors to determine whether groups of identical sub-genomic proviral sequences are the result of

viral genetic bottlenecks or cellular expansion. SGS encompasses the region encoding P6, protease and reverse transcriptase (P6–PR–RT). They found that the identical sub-genomic proviral sequences can result from both viral genetic bottlenecks and cellular expansion occurring prior to ART initiation and following ART failure. A similar work was done by Brandt et. al. [13] who used the integration sites to predict the Clones of HIV-1-Infected Cell.

From the works discussed till now that targeting of integration sites with the help of various factors like LEDGIN mediated retargeting, analysis constrained in subtelomeric and pericentromeric regions, introducing new sequencing techniques etc the focus is not as highly constrained to the discovery of integration sites as is required. Given that we have discussed diverse experimental works, now we conclude briefly outlining what the experimental works that are similar in nature are doing. Most work target and characterize integration sites characteristics using the ART-based tools validating some phenomena as per preset constraints [18] [19] [20] [21] [22]. Given that a cure has not been obtained yet with the experimental methods some strong theory based automation may help to find some knowledge into the working of the HIV-1 virus. Due to the lack of studies based on DL or even ML focusing on IS, given the importance of IS and given the targets (UNAIDS 95-95-95) for the treatment of AIDs, there is need for some automation to speed up the processes involving much of already available large quantity of resources. So there is a need to redirect towards

ML based techniques.

III. CURRENT STATUS OF RESEARCH WORK DONE WITH ML FOR 'PREDICTION' OF INTEGRATION SITES OF AN HIV PROVIRUS

There is only one work solely dedicated to predict the integration sites of the HIV provirus [2]. Other related works are discussed below. Berry et al. [23] compared in a constrained way, his methodology with a machine learning strategy [24] that splits a chromosome again and again so as to get the gaps which may host many integration sites (IS) for the HIV-based vectors. He found Clumps by scan statistics based method (an ML based clustering method). His approaches found localized clusters of integration sites and provided the way forward for the comparison of the different clusters of integration sites with incorporated ART vectors.

In the work by Shen et al. [25], analysis based on the RF regression and KNN were performed on geno-phenotype data for HIV reverse transcriptase (RT) and protease (PR). This was done in order to predict the resistance against the HIV. Even though this paper used machine learning in explicit way it did not use it for the prediction of integration sites.

In their paper, Santoni et al. [26] used a few markers and identified markers with the highest F scores by combinatorial calculation of the markers and generated a supermarker. This was based on their derivation of efficiency of the F score in ranking and recognizing genetics involved with retrovirus integration site. This was done to accomplish the development of a method for displaying and detecting associations between chromatin and integration sites of the retrovirus. But these works were based on feature engineering-based methods. And as mentioned before there is a need for the machine learning to automate the process of classification of the enormous data related to the HIV integration sites to help in further treatment to eradicate HIV.

As discussed by Halin et. al. [2], who did a research based on deep learning and attention framework solely to extract the integration sites with Convolutional Neural Networks (CNNs), random forest-based model performed poorly even with extended input incorporating surrounding genomic attributes. The same was the case with the Score20 [23] the method which is a position weight matrix-based (PWM) conventional method using a lesser context. They [2] compared it with three baselines methods viz. logistic regression fitting [27], random forest construction [28] and gradient boosting decision tree (GBDT) construction [29]

[30] to come to such a conclusion. In their paper [2], Halin et. al. used a deep learning and attention-based framework. The main components used in their architecture is a dense neural network having the convolutional network.

As we can clearly observe that there is a dearth of ML-based work for the HIV integration sites identification and the datasets generated are huge after each experiment and are increasing the load of genomic consortium database like Gene Expression Omnibus. In addition taking into account the costs incurred in such experiments, there must be some studies done in order to combine the power of Deep Learning (DL) [9] [11] into the existing results and put to use the knowledge already available.

Deep learning architectures for HIV integration site learning and prediction have robust metrics already available, which are AUC-ROC, AUC-PR and F_β score [31] [2] for analysis of the results in comparison to the self-designed statistical tests like conservative estimate [6].

IV. CONCLUSION HIGHLIGHTING THE CONTRIBUTION OF THIS WORK

Keeping in view the fact that a very less amount of work exists with Deep Learning, we hope that some DL methods for the analysis of the integration sites will be developed very soon. So, the paper highlights that no work has been done to 'predict' sites with advanced DL frameworks.

So we can also summarily say that there is a problem in the detection of the integration sites selected by the HIV for integration and it has been done solely in lab-experiments [32]. However, AI especially in bioinformatics is really very effective tool to get faster, accurate and highly insightful results while saving time and money [9] [11] consumed in the procurement and synthesis and the overall experiment. Also, DL will use the pre-existing data to take comprehensive advantage of it rather than repetitively mining out new data from scratch. This repetitive discovery of new data to some extent also redundantly spans over many studies as we have seen in which were analyzing the role of LEDGIN, which need to be organized before proceeding with the next stock of experiments. AI techniques like DL can help by automatically detecting the useful features.

V. CONTRIBUTION

It is the first and the only work solely dedicated towards identifying the HIV integration sites while emphasizing the criticality of the role played by the sites. Also, this is the only paper trying to

target DL tools throwing light towards the path of the new-age hope of using the AI to its extreme benefit which is the true use of informatics. This paper further suggest that rather than beating around the bush stressing on the factors like PSIP1/LEDGF/p75, it is better to block the integration sites.

Abstract—This paper presents the design and development of a smart garage door system, which is operated by an Arduino microcontroller via the use of a mobile application and the Blynk cloud sever. Further, this mobile application allows the smart garage door to be controlled and accessed from any remote location via the use of the Blynk cloud server which is connected to the Internet using Wi-Fi or 3G/4G network. The operations of this smart garage door also function using the Google assistant voice command. Finally, this smart garage door application has been tested and it is able to successfully perform the basic operations of a smart garage door as proposed in the initial design and development stage.

Keywords—smart home, IoT, smart garage door, Arduino, mobile application

I. INTRODUCTION

Internet of Things (IoT) has become a major computing paradigm and the latest disruptive technology after the Cloud computing. The ability of IoT to connect with other systems and applications, from low to high level has prompted and promoted an unprecedented array of applications in all fields of human activity from science, engineering, business, health, leisure and everyday life, especially for home usage. In recent years, there has been a growing interest in smart home systems. The concept of smart home system is the ability to automate most of the household appliances with the use of network technology that enables users to perform tasks before arriving at their home with minimum human intervention [1, 2].

The development of smart home provides a remote interface for home appliances via network technology (i.e., wireless transmission, the internet and android application), to provide control and monitoring via the use of mobile applications [3, 4]. Furthermore, studies have also suggested the development of smart home system, enhanced power efficiency and improves the quality of living [5, 6]. In line with the development of smart homes, the term Internet of Things (IoT) appeared and began to spread widely [7]. The concept of IoT is defined as the interconnection network system between everyday household objects (e.g., house appliances, house doors, and garage doors) [8, 9]. The use of IoT in the smart home development has also promoted: (1) better security system and (2) convenience for home users. One of the popular IoT adoption in smart home project is the smart garage door system [10-12]. The development of this system help promotes the life safety and convenience of a home resident. The concept of the smart garage door allows users to operate the door remotely via the use of networking protocols and IoT sensors [13, 14]. Furthermore, the smart garage door mitigates the door operation, as the users can access the garage from anywhere with the help of mobile application installed inside smart phone devices. This in turn helps reduce the manual operation of the garage door opening and closing. The development of the smart garage door system also helps reducing as trespassing as the opening and closing of the door is controlled by the home owners via the mobile of a mobile application [15]. Furthermore, the use of IoT sensors has also made it possible for home owners, to remotely control the garage door from anywhere via a smartphone [16]. Although, previous literature has highlighted the benefits of the smart garage door system, previous literature has also stressed the development cost of this system is high and the energy usage of this system is inefficient, thus limiting the implementation of smart garage doors in residential area.

II. LITERATURE REVIEW

A. Garage door system

The use of IoT smart garage doors is an easy process to safeguard the security of residential premises [17]. In recent years, the popularization of the IoT technology has increased the: (1) safeguards, (2) security and (3) easy use of a garage gate. Furthermore, the use of IoT technology in the garage gate has promoted several advantages [18, 19]. Among the advantages highlighted in previous literature is: (1) door can be opened and closed from any remote places [20, 21], (2) promotes security as only authorized residents can enter the premises and (3) auto mode shut down if the garage door is left open for a certain period. Despite the above mentioned, advantages of incorporating the use of IoT technology in the garage door, there are 2 main disadvantages or problems reported in the literature. The problems are: (1) networking issues and (2) security and privacy issues. In terms of the networking issues, the network can be hacked by unauthorized personnel thus gaining access to the premises [15, 22], and in terms of the privacy issue, users or home residents are uninformed about any error that may occur while the garage door is being opened or closed [23, 24]. (e.g., the door has not closed properly) [25, 26]. Based on the disadvantages highlighted above, realization of the smart garage door needs a better design and development effort [27, 28].

B. Current issues and proposed solution

Previous literature highlights that the development of the smart garage door system is to meet the resident goals of comfort living, life safety, security and efficiency. Furthermore, this system is also a part of the smart home overall system, and can be controlled with the use of Internet (via mobile application). However, there are numerous issues relating to the usage, design and development cost and implementation of the smart garage door system. Among the issues presented in the literature, the design and development cost in the implementation of the smart garage door is frequently raised [29, 30]. Previous research also highlights the evolving state of IoT development has created several problems in the areas of: (1) user home device integrations, (2) high implementation cost and (3) customization of IoT device integration between different types of users [10, 15, 31].

Thus, this research project proposes a new and lower cost prototype solution to design and develop a smart garage door. Further, this research project is to develop a smart garage door - based on Android smartphones access through the use of a simple mobile application system. The aim of this research project is to design and develop an Android mobile application as an input to open and close garage doors using the Wi-Fi or 3G or 4G. The garage door may be controlled if there is a network signal in that location. This mobile application also utilizes the Google Assistant function as an additional feature in opening or closing the garage door. This paper is organized as follows; the next section will illustrate the methodology employed in the design and development of this research project. Each phase of the methodology will be briefly explained. Following that, is the results and discussion section. In this section, the appropriate tests will be highlighted and explained. Finally, a short conclusion and future areas for this research project will be presented.

III. METHODOLOGY

The following subsections will briefly illustrate the methodology process of this research project.

1) IOT development

This research project adopts a modified version of the methodology proposed by Fahmideh and Zowghi [32]. Further, this methodology has been in favour for various IoT projects [31, 33]. Figure 1 (refer below) illustrates in brief the overall flow of the methodology adopted in this research project.

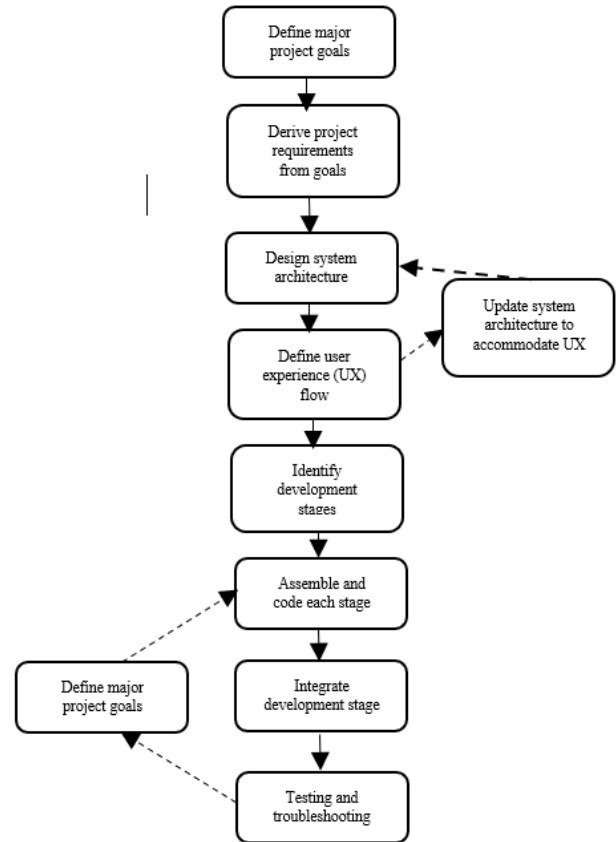

Fig. 1. IoT project development approach

This research project first begins by defining the main objectives that needs to be accomplished. Following that, the research project is broken down into specific requirements (i.e., software, hardware, and all other important tasks). The hardware and software requirement for this project is highlighted in figures 2 and 3, respectively. Next, the overall research project architecture is constructed. The IoT system architecture is comprised of various functional layers to enable IoT applications, including a sensing layer, network layer, and application layer (refer figure 3). Following that, appropriate user interfaces are created as this system is a mobile application. Each user interface is well thought out, to meet each specific requirement in the design and development of the smart garage door project. Examples of the user interface is shown in figures 4 and 5, respectively. The next stage is prototype development stage.

This stage encapsulates the overall components (i.e.: hardware, software, networking, and their integration) along with their interactions within the research project. In this stage, the chosen hardware and software will then be assembled and coded accordingly. The codes will also be linked together with the user interface designed prior to the prototype development. This smart garage door runs on the Arduino IDE, integrated with Blynk (refer figure 6).

No	Hardware	Specification
1	Laptop HP	Processor: Intel® Core™ i5-1035G1 CPU @ 1.00GHz 1.19 GHz RAM: 8.00 GB
2	Honor 50 Lite	CPU: Octa-core (4x2.0 GHz Kryo 260 Gold & 4x1.8 GHz Kryo 260 Silver) Chipset: Qualcomm SM6115 Snapdragon 662 (11 nm)
3	Things board	Esp32
4	Garage door	Servo MG 995
5	RFID Scanner	RFID RC-552
6	LED light	Green and red

Fig. 2. Hardware requirement

No	Software	Details
1	Android 11	The operating system for mobile phone
2	Microsoft Word	As documentation to report the project
3	Windows 10	The operating system for laptop
4	Arduino	Software design using C++ and Java
5	Blynk	The mobile application for the project

Fig. 3. Software requirement

Fig. 4. Smart garage door interface

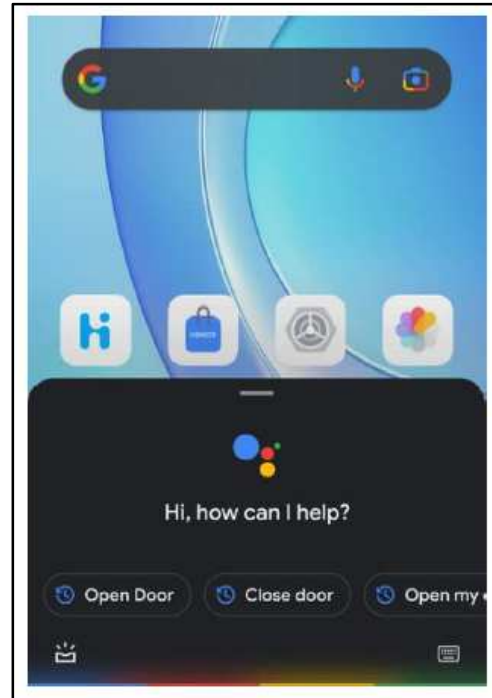

Fig. 5. Smart garage door interface (Google assistance)

2) IoT system architecture

The designing of an IoT system architecture should conform to the most needed systems requirements regarding horizontal scalability when the system is used multiple times. Furthermore, the designing of a IoT system architecture should have the following features (if possible) [34]:

1. Flexibility – solution must ensure better user experience and interface simplicity
2. Evaluation and prediction – access data will be stored and eventually used for better resource management and further improvement of balance between individual comfort and overall work efficiency
3. Energy savings – better utilization of power consumption resources

Base of the features above, this research project adopts the IoT architecture (refer figure 2) by [35] which comprises of: (1) the perception layer (2) the network layer and (3) the application layer. Each layer is then linked to a specific source code embedded inside Arduino IDE connected to the cloud server (i.e., Blynk), and the mobile application.

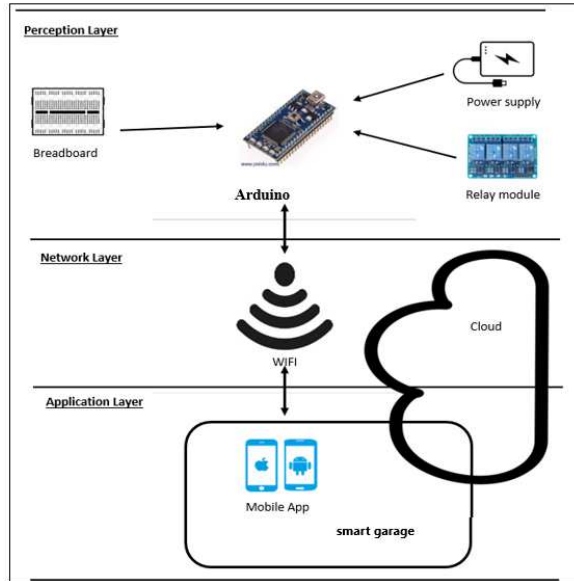

Fig. 6. IoT system architecture

3) Prototype design

The prototype design (refer figure 7) is a physical layout showing the overall functionality of the smart garage door system. There are two sections in this prototype, the: (1) hardware structure and (2) IoTs (sensors). This prototype design will show the actual flow of the mobile application, the IoT and the micro controller. This prototype is designed merely as a proof of concept in highlighting the design and development of this research project.

Fig. 7. Prototype design

IV. RESULTS AND DISCUSSION

This smart garage door was tested to demonstrate its overall feasibility and effectiveness. The smart garage door underwent three types of testing: (1) user interface, (2) user expectation and (3) overall satisfaction. Each of the test outcome is presented in the subsection below.

A. User interface

The purpose of this test is to get the testers (participants) feedback or their satisfaction level when using the smart garage mobile application - interface. The result is presented in Figure 8.

Fig. 8. User interface testing result

From Figure 8 above, it shows that the majority of respondents are satisfied with the design of the smart garage mobile application.

B. User expectation

The purpose of this test is to assess whether output presented by the smart garage mobile application is well understood by the respondents [38]. The user expectation also provides a clearer picture, as to highlight the design and development of the system. Based on the results (refer figure 9, 83% of the respondents can understand the output of the smart garage mobile application.

Fig. 9. User expectation

C. Overall satisfaction test

The overall satisfaction test presents the overall user satisfaction towards the smart garage mobile application. Based on the results (refer Figure 10) it indicates that users are very satisfied (score 5) with the research project. The results also indicate that this smart garage mobile application can help the users in overcoming their problems as highlighted in previous literature.

Fig. 10. Overall satisfaction test

V. CONCLUSION

In conclusion, the main aim of this research project is to design and develop a smart garage door via the use of a mobile application. Further, this project used the Arduino micro controller to control the system via IoT wireless connection. This research project will make accessing the garage door more convenient and faster with the help of the mobile application.

This research project contributes to homeowners by providing them with an alternative simple solution to design and development their own smart garage door system, as this research project provides homeowners with security, energy efficiently (low operating cost) and convenience. This research project also contributes to the literature as the design and development of the smart garage door mobile application system utilizes the Google Assistant feature. This feature is a particularly important feature when homeowners have limited motion access to mobile phone usage.

For future work, the security level criteria should be considered in designing the smart garage door system. The implementation of face detection, fingerprint, voice recognition should also be implemented together with the Internet of Things (IoT). The use of mobile application in this system should also be improved as the mobile application is the visible frontier of the system to end

ACKNOWLEDGMENT

{ moshfique.uddin, rohit.roy, saima.miduri, rashedur.rahman}@northsouth.edu

Abstract— The majority of people despise the chore of ironing clothes but enjoy wearing nice, crisp, wrinkle-free clothes. IronMan provides steam ironing services right to your door. IronMan is a service that supplies ironing and laundry services online. In this work, the system allows to create an innovative Internet of Things (IoT)-based Laundry Services E-commerce business model. This work will bring laundry service right to your door, in the palm of your hand. This work will include a proper Android app for accessing nearby laundry shop services from home and a related website to this android app. In this application, a machine learning model was used to create intelligent logistic management systems. Using this application, people can easily access laundry services while staying at home. Nowadays people are more inclined to market from online shops rather than going outside. The current initiative follows the same pattern for laundry service providers and consumers. In most laundry shops, they do not keep records of their customers. So there is a possibility that the clothes of the customers may mix up with one another. This system helps users to not only track their orders but also physically scan their items using image classification into their list with an image proof to avoid any mismatch and help customers claim if a mix-up happens. This application has a location tracker for riders to accept the nearest order so that the customer gets a smooth experience. It also has a website for users to create their account and check their services display and customers can order from both web and phone.

Keywords—*Android-Web, Internet of Things (IoT), Image Classification, Machine Learning.*

I. INTRODUCTION

Trying to imagine life without technology is nearly impossible. People have become so reliant on technology that it has become an inseparable part of our lives. The internet of things or IoT [1] influences people's lifestyle from how people react to how people behave from air conditioners that all people can control with smartphones, from using smartphones to get area addresses, ordering food using smartphones, etc. IoT method collects data from different uses of different software and devices and uses that data to make another software or device work better. The method IoT in recent days was implemented on other E-commerce platforms to have the best outcomes for the business. For this application, this method is used and an E-commerce platform [2] is built named Ironman which will provide laundry services from nearby accessible

shops. An application that acts as a go-between all the iron-laundry shops and people. IronMan allows you to order from anywhere at any time without having to pause everything. Scroll through the app to find your favorite shop and tap to order. This project includes a customer application, as well as a shop owner and delivery application. Alongside the project also have a website relevantly. In Bangladesh, approximately 50 million people use the internet on a daily basis.

People are increasingly inclined to use various technologies and applications. The objective of this work is to generate a smart iron-laundry application that will allow people to order from anywhere at any time. Delivery partners will arrive in less than 20 minutes to pick up your clothes. The entire washing, ironing, and folding process are completed quickly and efficiently. IronMan assignees are equipped with an app that indicates successful pickups and deliveries.

An Android application will be used to access the services. Using the shop owners' application, shop owners can create shops and add items to the database. Users can access it through the customer app; Riders will use the rider application. There is an image classification model [3] which can classify customer clothes to track the clothes' identity. There has been implemented a logistic regression machine learning model [4], for which a set of data was collected from people who were thinking about this project via a survey. This model can predict the sustainability of IronMan.

II. LITERATURE REVIEW

According to the most recent studies and research, many familiar applications and research journals are already related to this research work. However, those studies had some gaps that are hoped to be filled with the current initiative. Extensive research has been done and a few research articles are here to compare this work.

The authors in [5] describe Laundry Applications, and the primary goal of developing Laundry Applications is to create employment. The intended application is also helpful for working people, students, and people who live outside their homes and do not have time to wash their clothes. So, in essence, they are attempting to connect people (customers and

Dhobis) so that they can benefit from one another. There is a decent amount of services available in this application, so the customer can easily select the services, date of service, time of service, etc. They are creating their laundry shop and intend to help unemployed people.

They targeted people who are willing to order laundry services online. They are the administrator as well as the shop owner. Consequently, the customer does not have the option of selecting a specific shop from their list of options. They tried to be available everywhere, but they were not adaptable.

Here IronMan solved the problem with the shops. Because it is an open platform, and the primary goal is to act as a middleman between laundry shops and people. As a by-product, the app allows multiple shop owners to register their businesses. As a necessary consequence, people can select and order from any shop. IronMan also provides image classification, so people do not have to fear losing their clothes. It is a machine learning model that can detect images from the database and verify the owner of the cloth.

B. Project Background Related Application

According to our most recent observation on research journals, there are already a plethora of well-known applications are gettable on Google Play and the Apple App Store.

Here are a few examples of popular and similar applications:

- Sheba.xyz [6]
- Laundry Vai [7]

In Bangladesh, many more related applications are available. Those applications have a lot in common, but they also have some differences and limitations. For instance, in the Sheba.xyz app, one can only communicate with one store, and there is no other laundry shop. Laundry Vai and Sheba.xyz are nearly identical applications to ours, but both have some limitations. These applications only contain information about their own services, only available within Dhaka.

On the other hand, IronMan is a fantastic platform for laundry services, with information on all local laundry shops throughout Bangladesh. The earlier apps also do not allow customers to track their orders or provide convenient payment gateway services. The plan is to develop an application that would give the same benefits across the country.

C. Project Background Related Literature

The theoretical literature review of this project reviewed what other researchers had written related to our topic to compile, categorize, and evaluate it.

The authors in [8] discuss big data analytics, smart logistics management, and machine learning techniques used on an IoT platform for laundry services based on e-commerce. Data capture, storage, analysis, search, sharing, migration, visualization, tracking, updating, data privacy, and data sources are significant data analysis challenges. Data capture, storage,

analysis, search, sharing, migration, visualization, tracking, updating, data privacy, and data sources are all big data analysis challenges. Using this data to make the program better is the central concept. Intelligent logistics [9] in real-time value networks enable customers to accurately navigate the entire life cycle of the transportation process, including purchases and contracts, shipment planning, execution and tracking, yard management, appointment schedules, and financial and claims settlement - all individually, cloud-based platform. A single connection to a real-time value network can connect to the thousands of companies already signed on, including partners and carriers. This is the network's worth. Other advantages include lower annual freight costs, better customer service, streamlined transportation processes, and reduced network inventory. In the work [10], the authors implemented big data analytics, intelligent logistics management, and machine learning to make the laundry service into an innovative IoT based e-commerce platform. They used Dijkstra's algorithm to find the shortest path with the least amount of traffic and the least amount of distance. They collected the data and then analyzed it using big data analytics. An idea was taken and tried to put into action in this work. This application also used machine learning techniques to test the sustainability of this idea by using people's thoughts about it as datasets.

The second paper was "Food panda: Changing the Way Bangladeshis Eat Meals" [11]. We selected this paper to understand the marketing better and promoting strategies and how to gather traffic and audiences so that our work "IronMan" can turn into a successful project. The following paper covers the part of the relationship between early business practices and companies' medium and long-term challenges and opportunities. It can give us an insight into our future challenges in building an e-commerce app, IronMan. The paper also discusses the food order process and delivery system. So we can use those ideas on this app to have a better delivery process so that this app can be sustainable and durable.

The third paper was "Customers' Use Intentions of Using Online Laundry Service" [12]. The journal depicts the customer psychology of choosing an online laundry service. The following study aims to understand customers' intentions to use online laundry services through one-on-one interviews as the qualitative research method approach. The findings revealed that customers' preferences to use online laundry services were primarily influenced by the effectiveness and efficiency of such services. It is simple to use and save time. As a result, an outcome of customers' behavior and attitude towards accepting this project was found.

The authors in [13] researched to develop Android-based laundry services that are more efficient in terms of time to process laundry pickup, records of incoming and outgoing garments, and information on their own laundry OXY. The method employed includes a literature review, interviews, questionnaires, design, and testing. The paper assisted in providing information such as price, type of service, and

preferred laundry branch. It also aided in the monitoring of applications and operations.

The fifth research paper is "Laundry Services Application" [14]. It shows a smart application that enhances the stipulation of a service that every home requires, mainly washing clothes and household items in specialized laundry centers, as their application facilitates linking the user to the nearest laundry center. It would be easy for them to communicate with each other and provide the laundry service online via an online request submitted by the user. To accomplish this, they created an Android application that works on smartphones connected to the Internet.

III. METHODOLOGY

This application has three types of mobile applications to help each user to complete those tasks efficiently, which are basically for shop owners, riders, and customers. The Android Studio is used as an android framework for development, and fire-base is used for the database framework. And the Google Cloud Platform to integrate Google Maps into the application.

A. Android Application

Shop Owner App: After logging into the system, the shop owners have the luxury too:

- add their products
- remove any product
- modify the products
- edit the price list

Fig. 1. Shop Owner App Diagram

Customer App: Customers must first create an account and log in to the system using their email or phone number. Customers can see a variety of shops and their names after logging into the system. Customers can edit their profiles by clicking my profile bar if they desire. They can then choose any payment method, such as card, mobile banking, or cash on delivery. Customers can view the order status after confirming their order.

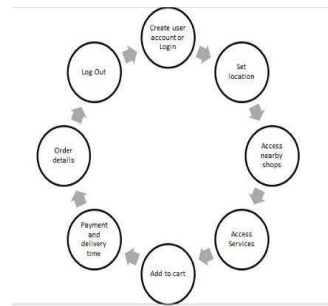

Fig. 2. Customer App Diagram

Rider App: When a customer orders, a notification will appear for the rider closest to that customer. The rider can then accept the pickup request. After picking up the products from the customer, the rider must deliver them to the shop chosen by the customer. After finishing the laundry, the shop owner can direct contact with the rider to provide the product to the

Fig. 3. Rider App Diagram

customer.

The details of the flow of different applications are given in Fig.1-Fig.3.

B. Web Based Application

The IronMan website will include a user panel with product showcasing, login and signup application, and a search of laundry shops nearby. On the other hand, there will be a Shop user panel where owners can decorate their shop by creating an account and adding all their services. These sections will have an administrator who will connect these users and enable the E-laundry service.

It all started with HTML and CSS as web development tools. Then React JS was used for the back-end operation. And Django as a framework. So that the HTML page of the website can easily create and stored the database in the Django administration, from there admin can control the whole website and do have access to read and write and modify anything. DialogFlow and Kommunicate is used to implement Chatbot.

For the machine learning model dataset, a survey was created with questions about people's opinions on the idea of an E-commerce-based laundry service [15]. Then the responses

were converted into CSV files and used as datasets. We convert all the categorical data into numeric data [16]. For Yes and No, 1 and 0 was set. Score set calculation is given in Fig.4

```

a=0
b=0
c=0
result = []
for score in finalScore:
    if score>8 :
        result.append('Sustainable')
    elif score>= 6 and score <= 8:
        result.append('Preferable')
    elif score<6:
        result.append('Not Sustainable')
    
```

Fig. 4. Score Set Code

The logistic regression model [17] was trained. 70 percent data were given into the train set and 30 percent data into the test set for training. The results from Logistic Regression with no regularization gives a test accuracy 86%. Fig.5 presents the confusion matrix.

Fig. 5. Confusion Matrix

TensorFlow Lite [18] and a teachable machine were used to implement image classification. In TensorFlow Lite, some models were deployed to classify the images. It is one kind of machine learning process to object detection. In the models, we have deployed some images related to a shirt, pants, t-shirt, etc. Then we converted the model, optimized it, and deployed that model in the android studio project. The datasets of images and imported the model were trained as .tflite in android studio. DialogFlow [19] is used to understand natural language that makes it easy to create and integrate a conversational user interface into a mobile app, web app

IV. RESULTS

It was discovered that our current work almost performs flawlessly after individually analyzing our system. It successfully implemented the prototype of the entire system, as

planned initially. We divided into two parts. The final application demonstration will be used for the result, to analyze this project, and also to conduct some qualitative research.

A. Analysis of Results of Web Development

For the website, the user has to create a signup page at first. Then after registering, the customer can sign in to the system.

Fig. 6. Sign Up Page

Fig. 7. Login Page

After logging into the website, customers can view the whole dashboard. There are different products from different custom laundry and iron shops.

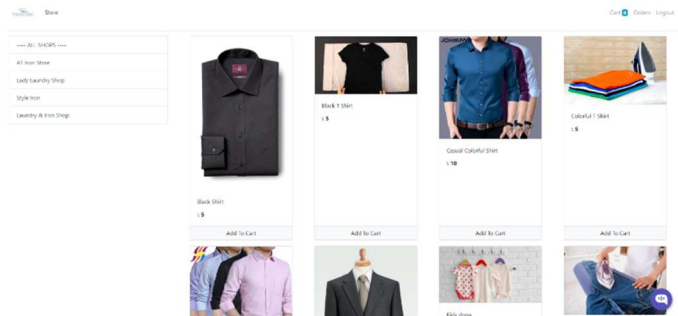

Fig. 8. Home Dashboard

Then the customer can select any products from any shops they like to order. They can increase or decrease the order. After ordering the products, they view them in the cart. The system will show the details like price, quantity, and total amount.

Sno.	Image	Product	Price	Quantity	Total
1		Black T-Shirt	₹ 5	2	₹ 10
2		Jeans	₹ 5	2	₹ 10
3		Shirt	₹ 15	2	₹ 30
Total					₹ 50

[Check out](#)

Fig. 9. Cart

After that, the customer can check out by giving the related information like their address and phone number.

Check Out Form

Address
Dhaka

Phone
01712981821

Check out

Fig. 10. Check Out Form

There is an order menu to view the orders or check the orders. From there, customers can view the products they ordered. Also, they can check the order status.

Your Orders

Sno.	Image	Product	Date	Price	Quantity	Total	Status
1		Black T Shirt	April 23, 2022	₳ 5	2	₳ 10	Pending
2		Jeans	April 23, 2022	₳ 5	2	₳ 10	Pending
3		Saree	April 23, 2022	₳ 15	2	₳ 30	Pending

Fig. 11. Order Status Pending

There is also a system where the admin can control the order status. If the order is done, the page will show the completed status.

Your Orders

Sno.	Image	Product	Date	Price	Quantity	Total	Status
1		Black T Shirt	April 23, 2022	₳ 5	2	₳ 10	Completed
2		Jeans	April 23, 2022	₳ 5	2	₳ 10	Completed
3		Saree	April 23, 2022	₳ 15	2	₳ 30	Completed

Fig. 12. Order Status Complete

All the steps from signup and order are described vividly through figures 6-12.

This application also has a Chabot where people can ask their queries (Fig.13).

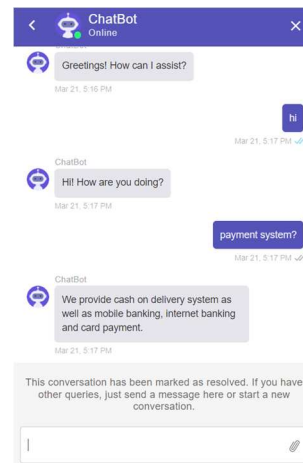

Fig. 13. Chatbot

B. Analysis of Result of Android Development

• Shop Owner App:

For Android development, the user has to create the shop owner app first. Any shop owner can register their shops by filling out the signing up page.

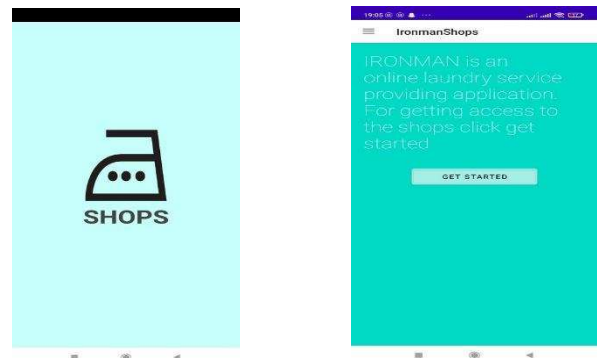

Fig. 14. Shop Owner App Interface

Shop owners can view their profiles as well as the orders. They can update the products and prices also. After updating, it will show the updated details on the product page. These are described in Fig14-15.

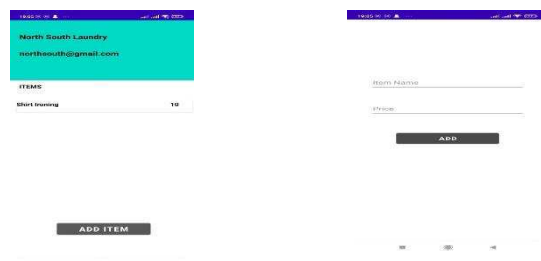

Fig. 15. Shop Owner Customizing Product

When the shop owner clicks on the 'Get Started' button, he can see the new page where he can update the products and their price. After filling those items, he must click on the 'Add' button. Then the product and its price will be updated.

• **Pricing of The Products:**

Initially, the shop owners can update the prices of the products according to their preferences. However, there has been made a template for updating the name of the products and prices. After registering in the app, shop owners have the authority to edit them. A survey was made asking different questions to different shop owners. They answered that they had set different prices for other products. They have asked us whether they could update the pricing as per their liking or not. This system assured them that that feature is available and flexible in the app.

• **Rider App:**

The next android application is for the rider. The rider will pick up the products from the customer's home, and after completing the ironing at the shops, he will deliver them to the customer. But firstly, the rider has to sign in to the app. Then he can see the orders that have come from the customers. After that, he can see the order details and prices through orders.

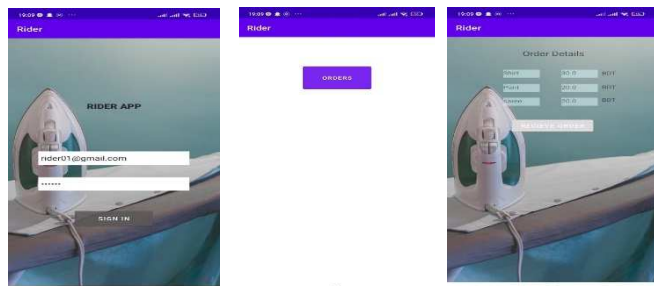

Fig. 16. Rider App Interfaces

The rider also has access to the image classification tool. He can check the clothes through image classification. It will assure the customer that their products will not be lost. Image classification will show the percentage of confidence whether that is the correct product.

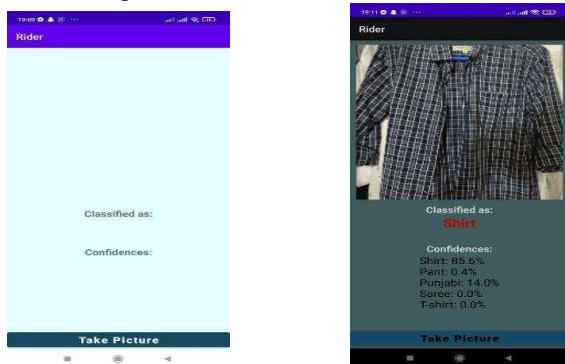

Fig. 17. Image Classification for Rider App

• **Customer App:**

There is also an app for the customer. Customers need to register through their mail, and then they can access their profile.

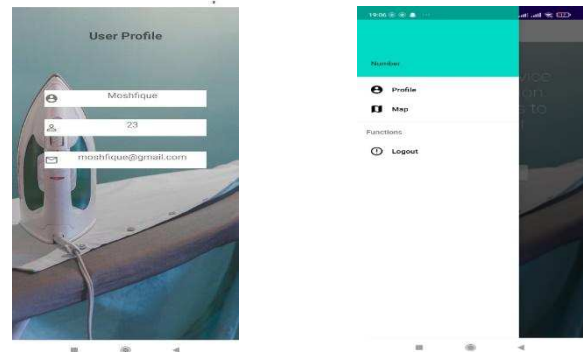

Fig. 18. Customer Profile

Customers can have access to Google Maps, where they will be able to see the current location. Also, they see different laundry shops that are registered through the app. Then they can choose any shop and order from that shop (Fig16-20).

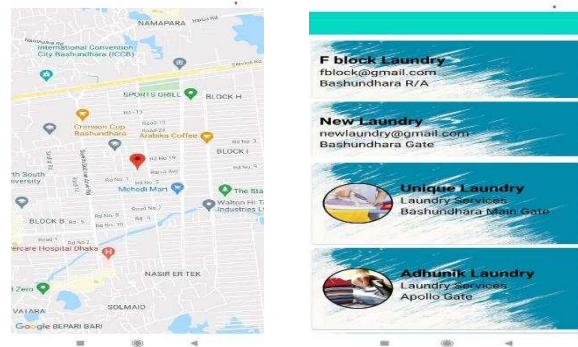

Fig. 19. Current Location and Registered Shops

After ordering from their particular liking shop, customers can view the cart and total amount of money.

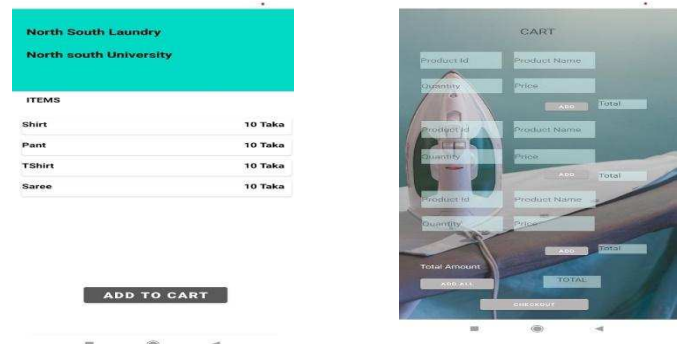

Fig. 20. Customer Cart

• **Image Detection:**

TensorFlow Lite is used for image classification. Our idea was to keep an image classifier in the rider app for instantly taking an image in real-time when picking order and adding the Image to the user's database for a future claim. The application has used machine learning to train the model by gathering images of categories like shirts, T-shirts, saree, Punjabi, etc. And then used TensorFlow Lite to add it to the Rider app and save the data to individual customer's databases using Firebase.

Image classification is an essential concern in which a set of target classes is defined, and a model is trained to identify them using labeled example photos. The system used numpy, Opencv, and PIL (Python Imaging Library) libraries for training.

Training the model requires the following steps[26]

1. First, it needs to provide the model with some training data.
2. Then the model tries to immaculate the provided images and labels.
3. After that, the model predicts the test sets.
4. Lastly, the model verifies whether the predictions match the labels or not.

The output of The Rider App is given in Fig.21.

Fig. 21. Image Classification

As shown in the above Fig. 21, after the rider takes a picture of items, the model can recognize the Shirt with 80.7% confidence, Punjabi with 100%, and Pant with 86.1%. The accuracy of the model will increase as more data gets added.

When the rider captures the images after taking the clothes from the customer, the photos will be saved to our database. When the rider is about to deliver the product back to the customer, he can check the product. The rider will click the images, and then the app will search the photos from the database. There will be the owner's name saved by their clothes images in the database. After that, the app will show the name of the owner of the clothes. Some snapshot of the image detection is given in Fig.22.

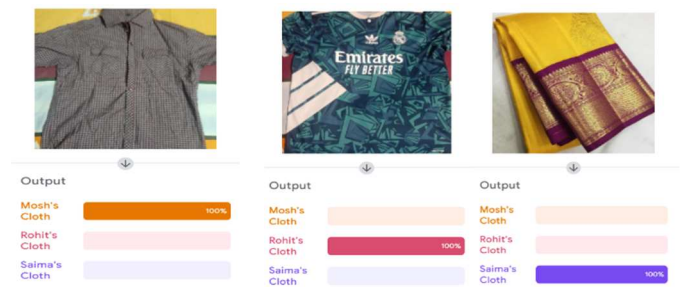

Fig. 22. Clothes Owner Image Detection

As shown in Fig. 22, the app will detect the owner's name through the database, then it will return the name of the owner matched by the Image of the clothes. After completing the ironing, the shop owner can check the owner of the clothes by using the feature of image detection from the database. Thus, every clothe will be scanned and will reach its actual owner, and there will not be any situation of mixing up any clothes.

V. QUALITATIVE SURVEY

The survey explains the view of the local laundry shop owners regarding the project 'IronMan.' We showed our demonstration of the application to them and asked them how they felt about our app. They were also asked about the sustainability of the project idea and if they are convenient and comfortable enough to use the mobile application.

After gathering the information and data from the different shop owners from other places, we realized that they were initially not sure or were not clear enough about the project process. They thought it would be an extra burden for them to appoint a delivery man, or some thought it would negatively impact their business. But when the method of the project was explained thoroughly, that is when they seemed clear about the project. So the majority of the shop owners are willing to participate in this project and appreciate the ideas. In short, the small shop owners see this as an opportunity to grow their business and set up a solid customer base. Whereas middle and large shop owners appreciate our project, they are currently not ready to be involved in our project. From the survey, an idea was found to appoint a go-between or delivery man, most of the shops are willing to be involved instantly. Overall, our current initiative seems sustainable to them. It is an excellent possibility that this project might be successful in the near future.

VI. CONCLUSION AND FUTURE WORK

Iron-Laundry Services is a service that is required regularly. People increasingly rely on e-commerce and internet-based jobs to help them manage their lives. This project aims to make laundry services more accessible to the general public. There has been developed e-commerce laundry services and brought all local laundry shops together on a single platform. In addition, the project contains Android and web-based applications. And to improve the user experience, it has been planned to add features related to big data analytics, intelligent

logistics management, and machine learning models. We have already taken people opinions on this project idea as a survey and turned them into datasets, which were used to train our logistic regression model and determine whether or not this work will be successful. To launch this as a pilot project, it needed to conduct qualitative research among local laundry shops to see if they are interested in such an idea or are ready to take their businesses online. This application needs to do fieldwork before launching as a pilot project. The main question, in the beginning, will be feasibility; will need to teach local shop owners how this project will work, its benefits and drawbacks, and so on. We hope that ecommerce based laundry can make a considerable change in the e-commerce industry.

Abstract—Internet of Things(IoT) is one of the emerging technology which connect billion of smart devices with minimum human interaction. Over the last decade, the Internet of Things has been increasingly used in applications like smart city, smart home, smart transportation, intelligent healthcare system, agriculture and smart grid. Traditional applications are becoming smarter and more automated as a result of the Internet of Things and some other emerging technologies. Due to resource constraint IoT devices are more vulnerable to the different attacks. To begin, this article identifies security problems in terms of design, data storage, and computation. Several researchers have already made significant contributions to this field of study. The authors of this study analyse the security challenges and available solutions to these challenges over the last five years. Finally, this article addressed the research problems and future technologies that would need to be integrated in order to meet the complex security risks associated with IoT applications.

Index Terms—Internet of Things, Security, Protocols, Privacy, Blockchain.

I. INTRODUCTION

Internet of Things (IoT) was first invented by Kevin Ashton, the Executive Director of Auto-ID Labs at MIT, in the year 1999 [1]. During his presentation for Procter Gamble supply chain system, he predicted that sooner than later computers or things will be able to collect information without human intervention. The Internet of Things (IoT) has emerged as one of the most promising research disciplines in the recent decade. Because of the smartness and real-time monitoring without human intervention, the IoT services have come as a huge relief to human life. IoT has a lot of applications such as smart home, smart transportation, intelligent lighting system, smart agriculture, supply chain system, smart metering and smart grids, smart healthcare system, industrial automation, smart retail: etc. IoT applications are frequently employed because they offer a high level of comfort, system automation, and efficiency. The large number of IoT devices and users are connected to the network which generates huge volumes of data. But it is also prone to basic security issues such as confidentiality, integrity and availability. To make successful

use of the ever-growing IoT applications, security, privacy, and trust must be addressed in order to secure IoT devices and user privacy from attackers.

Eight key research topics are identified by authors in [2], these are massive scaling, architecture and dependencies, creating knowledge and big data, robustness, openness, security, privacy, and human-in-the-loop for the future IoT. Similarly, security features of IoT are confidentiality, integrity, availability, identification authentication, privacy and trust are studied in [3], which are need to be addressed. When user information is shared over untrusted network, trust among users, and data privacy, as well as data confidentiality, are important factors. The traditional security mechanisms are not suitable for IoT environments. The number of devices connected are increased exponentially which rises to scalability issues. In IoT applications, devices are accessed remotely. The protocols used to connect smart devices are ZigBee, Bluetooth, 6LoWPAN, Message Queuing Telemetry Transport (MQTT), Constrained Application Protocol (CoAP), Extensible Messaging and Presence Protocol (XMPP), Near Field Communication (NFC), Routing protocol (RPL) Sigfox, LoRaWAN, or WiFi [9]. Each of these protocol is vulnerable to different types of attacks. The attacks are focuses on different type in IoT protocols like attacks on packets, attacks on the protocol and attacks on the whole system [10]. As most of the IoT architecture smart devices are connected through wireless manner, there is high risk of security vulnerabilities. The different attacks on wireless protocols are explained in [11] by the authors. The IoT is making the traditional applications into smart applications using the smart devices where processing and computation is done real time using fog computing or edge computing. Some of the applications like healthcare system, home automation system, smart city where sensitive information are share among different users if the attackers success to do any attacks then whole system become failed [12]. The IoT devices are vulnerable to various types of attacks due to lack of security protocols implementation [13]. Security

TABLE I
RECENT RELATED SURVEY ON IOT SECURITY

References	Year	Focus Point	Contribution
Y.Yang.et al. [4],	2017	Security and Privacy	The authors concentrate on the limitations of IoT devices and various attacks model. The authentication and access control mechanism of IoT applications are explained in details. The different layers of security vulnerabilities are also identified.
I. Stellios.et al. [5]	2018	Attacks on critical IoT infrastructure	Authors in this survey identify IoT-enabled cyber threats , verified IoT-enabled attacks in IoT applications. The solution approach of different direct and indirect attacks against important tagrets smart devices is explained. Finally, the authors discuss numerous problems associated with essential infrastructure and services in terms of IoT applications.
F.Meneghello.et al. [6]	2019	Security Vulnerabilities	The purpose of this article is to provide a high-level overview of the security dangers associated with the Internet of Things and to examine some potential countermeasures. To this goal, authors cover the specific security procedures used by the most prevalent IoT communication protocols after a fundamental introduction to security in the IoT area. Authors made comparison of the IoT technologies under consideration in terms of a set of qualifying security qualities, including integrity, anonymity, confidentiality, privacy, access control, authentication, authorization, resilience, and self-organization.
I. Butun.et al. [7]	2020	Vulnerabilities, Attacks, and Countermeasures	This paper provides a comprehensive overview of security attacks against WSNs and IoT, as well as approaches for preventing, detecting, and mitigating those attacks. In this article, attacks are classified and studied primarily in two categories: "Passive Attacks" and "Active Attacks." Understanding these threats and the security mechanisms connected with them will assist in constructing a secure road toward the spread and public adoption of IoT technology.
Euijong Lee.et al. [8]	2021	Interoperability and Security	Authors in this article work on interoperability and security in IoT applications. Additionally, authors looked at international standards bodies that have been producing standards for the Internet of Things in term of security and protocols used in IoT applications.

challenge like malicious behavior of smart device detection [14] or identifying the unrecognized information send from untrust devices need to be address. To make IoT applications secure and trustful where users integrity and privacy are taken care. So security challenges are need to be address properly. This paper’s summary is as follows:

Section II provides context for the study process. Section III discussed the security risks associated with IoT applications and the techniques employed to address them. The section IV highlighted and discussed the research that has already been conducted to address security concerns through the use of Blockchain Technology. The paper conclusion and future scope of research mentioned in Section V.

II. BACKGROUND STUDY OF RESEARCH METHOD

The initial study of the research method is shown in figure 1. Four major research database name IEEE Xplore, ScienceDirect, Springer and ACM digital are consider to collect the articles.

The relevant query was used to look for publications published between 2017 and 2021, which corresponds to the last five years’ databases. Along with the specified keywords, some filtering techniques are used to ensure that only English language journals with applications in computer science are evaluated. The total number of documents first downloaded is

2130. Following that, screening processes such as removing duplicate articles, deleting articles after reading the abstract and title, and finally reviewing the complete text are used to choose 60 articles for the survey.

III. SECURITY RISK ASSOCIATES IN IOT APPLICATION

Since the inception of IoT lots of applications are develop to monitor in real-time. The technology like machine learning, artificial intelligent and blockchain use to implement IoT applications [15]. As the number of smart devices are develop and deploy in numerous applications. These smart devices generate huge volume of data to be process, compute and store.

The layerwise attacks on IoT are shown in figure 2. Each of three layer in IoT have some attacks associated with it. The requirement to enhance the security of IoT systems is increasing. Users may choose not to use such systems if they become aware that adequate security measures are not in place [16].Recent advances in IoT security research have been facilitated by the availability of simulation tools, IoT modellers, and analysis platforms [17]. The security attacks, privacy issue, secure architecture design challenges, and protocols for secure communication are some of the important challenges exist in IoT applications are mentioned in paper [18]–[21]. The enormous privacy and security attacks associated with Internet-of-Things (IoT) devices, it appears desirable to encourage

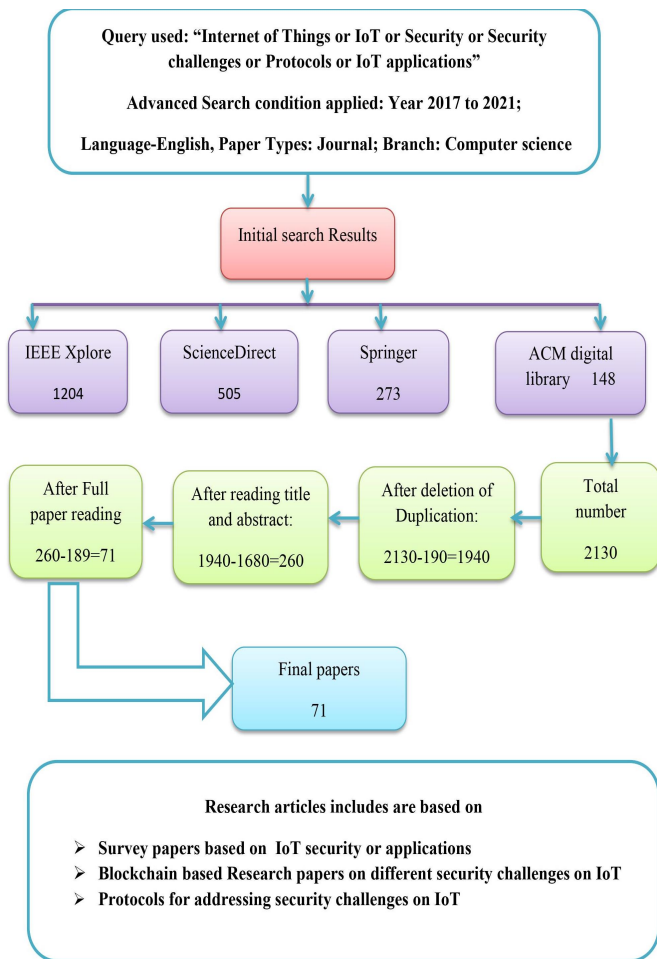

Fig. 1. Search criteria and final paper selection process

consumers to select more secure equipment and to factor privacy into their purchasing decisions [22]. The end user must build the trust to share his/her personal information to access different service provided by the IoT applications. In smart city applications there are many services which are available for the citizen. The citizen must have trust to share and access the service provided by the authority. Other wise the smart city ambition will not be full fill. To make the any applications usable to every user proper security measure must be build which will make the system reliable, secure and user friendly. When user information is shared over untrusted network, trust among users, and data privacy, as well as data confidentiality, are important factors. The traditional security mechanisms are not suitable for the IoT environment. The number of devices connected are increased significantly which rise to scalability issue, therefore lightweight, efficient and flexible protocols are needed to deal with the security attacks in IoT applications.

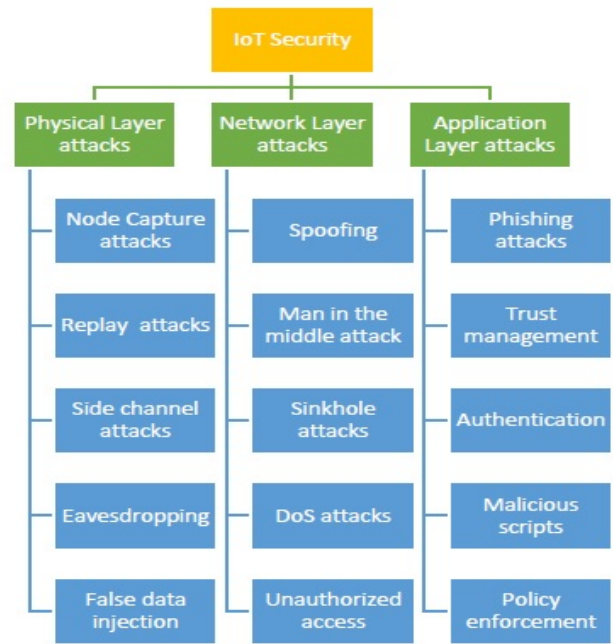

Fig. 2. Different layerwise security attacks in IoT [23]

Secure protocols in IoT applications is essential for rapid IoT adoption by the society. The security challenges in IoT may be active or passive type. Some of the security attacks and existing solution approach by different researcher are explained in Table II.

IV. BLOCKCHAIN FOR IoT SECURITY

In previous section that is section III, we have identified various potential risk and security attacks in IoT system. The emerging technology like Artificial intelligence (AI), Machine Learning(ML) and Blockchain are used to address different security and privacy challenges in IoT applications [15]. Blockchain technology consider as one of the secure platform because of it has some inherent security properties like immutable, distributed architecture. By utilising a peer-to-peer network, a Blockchain is totally decentralised. To be more exact, each node in the network keeps a copy of the ledger in order to avoid a single point of failure. All copies are simultaneously updated and confirmed. Blockchains can be private (permissioned) or public (non-permissioned) (public). The first category imposes limits on the contributors to the consensus. Only selected trustworthy actors are granted the authority to validate transactions. It does not involve much deliberation to reach a consensus, and thus is neither time- nor energy-consuming. Finally, it ensures the privacy of transactions by restricting access to them to authorised parties. The second type (public blockchains) makes use of an infinite amount of

TABLE II
SECURITY ATTACKS AND CORRESPONDING SOLUTION APPROACH

Attack Name	Reference	Solution approach/Methods Used
DOS	[24]–[27]	The DoS attacks is one of the significant security issues in IoT applications. The availability of services is one of primary aspect of intelligent gadgets as they monitor the items in real time. In IoT applications need dependable and effective data transmission with data delivery to the desire node. The numerous lightweight authentication communication protocols are developed to solve the misbehaviour of users’ or identify any anomaly in end to end communication.
MITM	[28]	Through various intermediary devices such as switches and controllers, smart devices are connected and deployed in diverse applications. Additionally, the majority of intelligent gadgets are connected via wireless communication protocols. If any of the network’s devices are compromised or an attacker obtains knowledge via an insecure channel. The Bloom lightweight countermeasure using Bloom filters protocol that is used to monitor the modification of packets in order to detect MITM attacks.
Trust Management	[29]–[31]	The heterogeneous nature of smart devices is a significant challenge for IoT design. Due to the variety of attacks on smart devices and the vulnerability of the majority of services to various types of attacks, trust management is a difficult issue for users’. Detection and prevention of malicious threats through the use of secure protocols builds user group confidence. The Blockchain-based secure platform addresses the issue of trust management in Internet of Things applications.
Malicious attacks	[32]–[39]	Malicious code is unrecognized software to gain the credential or information which will damage the device. IoT devices being the resource constraint are more vulnerable to the malicious attacks. The malicious node detection using different methods is essential to make the system security proof. The conventional security solutions are not enough to address all challenges like when detection of abnormality in the network and alert to the security administrator for handle the challenge are not suitable for IoT devices. Recently, researchers presented many schemes to handle malicious node detection in IoT applications, including index-based data provenance, a multi-agent and multi-layered game protocol, and a privacy-preserving game-based strategy.
routing attacks	[40]–[42]	Communication between smart devices might be decentralised, centralised, or dynamic in nature, depending on the routing protocols used in IoT applications. Security at the network level is a challenge in IoT networks due to the higher energy consumption of standard cryptography. Any IoT application is said to be using dense architecture since it makes use of a large number of smart devices to collect data and monitor the environment. The researcher addresses routing attacks by presenting a lightweight model based on machine learning algorithms.

anonymous nodes. Each actor can communicate safely using cryptography. Each node is identified by a pair of public/private keys. Any actor on the blockchain can read, write, and validate transactions. The blockchain is secure, and network consensus is achieved when at least 51% of nodes are honest. Typically, permissionless blockchains are energy and time intensive, as they require a certain amount of computing to ensure the system’s security. Blocks are used to group and store transactions based on their timestamps. These blocks are then connected (or chained) to form a chain of blocks, or blockchain. The blockchain employs elliptic curve cryptography (ECC) and the SHA-2 hashing algorithm to ensure the authenticity and integrity of data. The block data is fundamentally a list of all transactions and a hash to the preceding block. The blockchain maintains a complete record of all transactions and enables global distributed trust across borders. Trusted Third Parties (TTPs) or centralised authority and services can be infiltrated, hacked, or interrupted. They may also behave inappropriately and become corrupt in the future, even though they are currently trustworthy. Each transaction on the distributed public ledger is confirmed in blockchain by a majority consensus of miner nodes that are actively engaging in checking and validating transactions. Ethereum’s blockchain technology enables the storage of data and, more significantly, the execution of smart contracts. Nick Szabo originated the term smart contracts in 1994. A smart contract is, in essence, a computerised transaction protocol that carries out the contract’s terms. In a nutshell, smart contracts are user-created programmes that are uploaded and executed on the blockchain. Solidity is the scripting or programming language for smart contracts. It is similar to JavaScript. The Ethereum Blockchain enables the use of EVMs (Ethereum Virtual Machines), which are essentially miner nodes. These nodes are capable of enabling trustworthy execution and enforcement of these programmes or contracts in a cryptographically tamper-proof manner .

Design/architecture : Through protocols and gateways, the Internet of Things (IoT) architecture layers are utilised to track a system’s consistency. Due to the heterogeneity of IoT devices deployed in a variety of locations, managing connection, mobility, and interoperability within devices is challenging. As a result, certain attacks such as denial of service (DoS) attacks and malware attacks are a cause of worry. The authors of the publications identified the design issues and also discussed solution strategy [43]–[47].

Lightweight Protocols: The most of the IoT devices are resource constraint devices, so existing security protocols are not suitable to implement in IoT application. The lightweight computation algorithms are need to be develop which will be suitable for the smart devices. some of the research work already done on this regard [48]–[52].

Data Privacy: The data collected from different smart

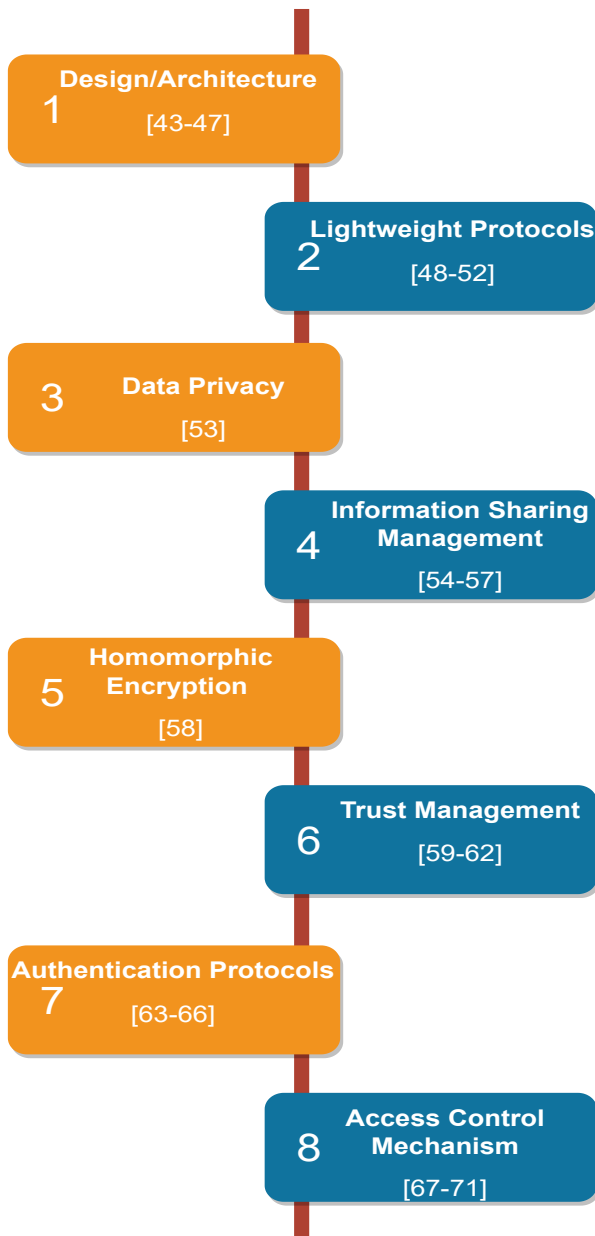

Fig. 3. Blockchain based solutions for various security issues of IoT.

devices are store in a centralized system for further processing in a IoT application. The end user access these data through various services to gain knowledge where user share lot of personal information to the network.If single point of failure occur or central server get compromise then privacy is a big concern as it is challenging to validate to IoT devices in untrusted IoT Network [53].

Information Sharing Management: Information security

management (ISM) establishes and manages the policies that an organisation must put in place to ensure that the confidentiality, integrity, and availability of information are protected from threats and vulnerabilities in a sensible manner.The system uses a double-chain approach that combines data and transaction blockchains, with distributed storage and tamper-proof data in the data blockchain and an upgraded practical Byzantine fault-tolerant (PBFT) mechanism consensus algorithm in the transaction blockchain. Through improved algorithms based on partial blind signature algorithms, data registration efficiency; resource and data transactions in the transaction blockchain are improved transaction efficiency and privacy protection [54]–[57].

Homomorphic Encryption: Homomorphic encryption is a type of encryption that allows you to do numerous operations on data while it's encrypted without compromising its security [58].A blockchain-based data aggregation framework and a cloud computing-based data aggregation framework are intended to improve security. A blockchain is used to record the transaction in the cloud. The cloud is also utilised to offload computations for smart metres with limited processing capability.

Trust Management: Tamper-proof data, more reliable trust information integrity verification, and improved privacy and availability during sharing and storage are all advantages of blockchain-based trust management [59]–[62]. The distributed network store record securely using cryptography protocols. Authentication, data encryption, digital signature and hashing ensure security. Once the security and privacy are ensure, end user build the trust to use different services in IoT application.

Authentication Protocols: Identity of users and smart devices in IoT applications is important aspect. Authentication is the process by which restriction can be put into the unauthorized users. The various cryptography authentication protocols are proposed by the researcher which are suitable for the lightweight devices. Blockchain based authentication protocols using one way hashing, multi server authentication, mutual authentication and smart contract in decentralized environment for smart devices [63]–[66].

Access Control Mechanism: It is a process designed to identify and prevent unwanted access while allowing authorised access to an information system or physical location. The attribute based encryption(ABE), Blockchain enable control, three factor based user access control scheme and ABE integration with Blockchain technique are different methods proposed by the researchers to make the system secure [67]–[71].

Some of the research challenges are still need to be address to make the IoT applications more usability. Scalability, localization of smart devices, deployment, smart device management, malware detection, and encryption of collected

information from smart sensors are various challenges need to be address to make the system security proof.

V. CONCLUSION

The authors of this paper begin mentioning the growth of IoT devices and development of various applications. The security risk associated with IoT layer wise are identified. Some of the attacks like DOS, MITM, Trust management, Malicious and Routing attacks and corresponding solution are identified. According to the finding, considerable research has already been conducted to solve the security challenges associated with Blockchain technology. Eight different challenges of IoT Security corresponding solution address by Blockchain technology are categorically explained. Lastly paper conclude with critical issue that must be addressed.

Abstract— *A great number of individuals suffer from spinal cord injuries which lead to drastic limitations to their daily life functions. Specifically, suffering from paraplegia and quadriplegia will deem the patient unable to move two limbs or all four limbs respectively. However, even if the spine is damaged, this does not stop the brain from functioning, and it will still have the ability to distinguish objects. Further, the implementation of Brain-Machine Interface (BMI)-based IoT system suffers from several challenges such as the issues of accurately translating the user intention. This paper presents a method for brain waves recognition using deep learning (DL) based on shapes and colors for use in merging concepts of the internet of things (IoT) and the brain computer interface (BCI) which we wish to call “Internet of Brain Controlled Things or (IoBCT) in short. The results showed an acceptable accuracy of 0.93 in the brain waves pattern’s recognition which opens the way towards designing a reliable IoBCT.*

Keywords: *Deep Learning, DL, EEG, IoT, Brain-Computer Interface, BCI, Brain-Machine Interface, BMI, IoBCT, LSTM.*

I. INTRODUCTION

The number of connected devices to the Internet is growing exponentially with over a 50 billion devices connected through Edge and Cloud computing. As a result, the Internet of Things (IoT) architecture is necessary to enable the connected devices to work efficiently and positively impact different domains such as healthcare, home automation system, transportation and other industries [1]. IoT provided internet for individual devices to control, connect and exchange data using smartphones, wearable devices or voice and gestures applications.

One of the methods used to support the interactions of individuals and electronic devices via brain waves is the concept of Brain-Machine Interface (BMI). BMI opened the door to control objects such as robots, prosthetics, and smart home appliances using human thoughts. BMI enables the interaction between machine and human through the establishment of a communication between an external device and the human brain [2]. Moreover, modern studies revealed that BMI is the way to translate human thinking

into physical actions such as Brain-controlled wheelchairs and IoT-enabled appliances [3], [4], and [5].

BMI provides many advantages such as brainwaves observation and human interactions with brain signals on runtime. One of the biggest challenges in BMI is signal accuracy. For example, the brain signals can be observed thorough several methods such as Electroencephalogram (EEG) [2], Functional Near-Infrared Spectroscopy (fNIR) [18], and Magnetoencephalography (MEG) [19]. Those methods can be negatively affected by several factors such as noise, environmental changes, and high brain concentration which makes the brain signal suffer from low signal to noise ratio and lack of temporal-spatial locality [6].

As presented in our previous work [6], the number of IoT devices is increasing rapidly at the edge of the network to be computed at the data centers, which is pushing network bandwidth requirements to the limit. We have also reported that the combination of BMI with the IoT results in a new concept coined as (IoBCT). IoBCT can offer great potentials to improve the quality of life of the disabled people who form about %15 of the world population [7]. Many applications can be operated using the concept of IoBCT such as controlling a smart home [8].

II. RELATED WORK

Deep learning is a fascinating tool used to analyze, process, and classify EEG data. The main obstacle in obtaining acceptable EEG dataset is the type of sensors or the EEG headsets used in the data acquisition stage, which usually are quite expensive and difficult to use [11]. L. Vezard et al. [12] have achieved 71.6% accuracy in a binary alertness states (BAS) prediction by applying the common spatial pattern (CSP) to extract the pattern feature. The methods in [13] and [14] have achieved accuracies of only 54.6 % and 56.76 % o, respectively, through applying multi-stage (CSP) for the EEG dataset feature extraction. While [15] took the power of deep learning networks and employed the recurrent neural network (RNN) to classify the EEG dataset and extract the features over time. The achieved accuracy was 85%.

Long-short term memory (LSTM) network has been used in [16], [17]. In [16] 84% accuracy of brainwave classification has been achieved. EEG dataset has been obtained while providing visual stimuli. High cost EEG headset has been used in [17] and therefore an accuracy of 98% has been achieved in classifying EEG dataset to learn human intentions to move eyes, feet and hands.

In this paper, low-cost EEG headset has been used to process and classify human brainwaves while looking at different images. LSTM-RNN has been selected to classify the brainwaves and extract temporal features from the time-series input signals with different frequencies and length. LSTM-RNN has improved the accuracy of EEG brainwave data classification. Moreover, the overfitting problem in the learning process has been avoided through analyzing and possessing the EEG dataset prior to getting them to the learning stage.

III. THE PROPOSED IoBCT SYSTEM

The brain produced signals (neural oscillations) have been recorded using the EPOC+ headset in this work which is manufactured by Emotiv company. Figure 1 shows the EPOC+ headset. Then it can be analyzed as an electroencephalogram or EEG. High beta, responsible for sensorimotor function and gamma, responsible for processing information from the senses, were the focus. During the EEG signals recording, an individual was looking to a PowerPoint slides containing black image which is the reset and control, and several successive slides of a Rorschach and a fractal images [9], [10]. The black image was presented before and after the Rorschach and a fractal images as a rest to start new recording or to stop the previous one. In addition to that, whenever the two images were presented, the 14 channel EEG signals were recorded using the Emotiv EPOC+ headset. Figure 2 and Figure 3 shows the Rorschach and a fractal images respectively.

Fig. 1: The Emotive EPOC+ EEG headset [5].

Figure 2: Rorschach image [9].

Figure 3: Fractal image [10].

A. Autonomic IoT- EEG based Framework

The framework is based on leveraging the classified brain waves which will be used as a control commands. Figure.4 shows the IoBCT framework, where we have different brain activities collected through IoT sensors. After the data is computed and processed, our framework will retrieve the output with the required action into the IoT destination such as Smart cities, smart hospitals, or smart homes.

Deep learning algorithms will be training and discovering the most important features from the brain signal that has high correlation. All the data will be trained during the offline model to discover the most sensitive features to latency, which then will be analyzed and stored in the database. On runtime, the online data would be analyzed and compared with the offline trained data to identify the higher priority features from the brain signal to optimize the latency.

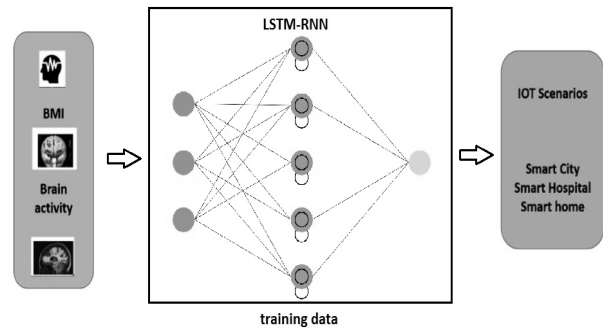

Figure 4: IOBCT framework

B. Deep learning based BMI

An LSTM network is a type of recurrent neural network (RNN) that can learn long-term dependencies between time steps of sequence data by memorizing the input features in RNN-cell memory. LSTM-RNN algorithm updates, forgets and outputs the RNN-cell memory information using multiple gated recurrent units (GRUs). The core components of an LSTM network are a sequence input layer and an LSTM layer. A sequence input layer inputs sequence or time series data into the network. An LSTM layer learns long-term dependencies between time steps of sequence data. The network starts with a sequence input layer followed by an LSTM layer. To predict class labels, the network ends with a fully connected layer, a soft-max layer, and a classification output layer. Figure 5 illustrate the chosen LSTM architecture.

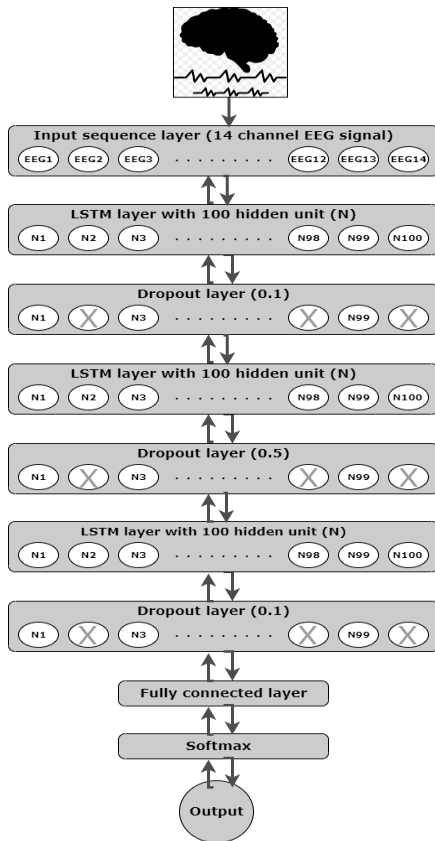

Figure 5: The architecture of LSTM network used to classify the EEG signals

The brain waves classification has been done using deep as follows:

• **Recording the EEG data:** Fourteen channel signals have been recorded using Emotive EPOC+ head seat during 25 sessions of looking to two different images (25 session for each image). The sessions of recording have been implemented by a 21 years old male while looking at Fractal

and Rorschach pictures. Ten seconds for each session with 10 seconds looking at black background image between each of them. Figure 6 depicts the recorded raw EEG signals set for the first session while looking to Rorschach picture.

Figure 6: Raw EEG signal set

• **Processing the EEG data:** Before training the LSTM network, the raw EEG signals data still need features extraction to enhance the accuracy of the output classification. The data has been divided to training and testing data (70% for training and 30% for testing). The EEG data has been recorded from 14 EEG sensor and it is consist of different frequencies with different amplitude range. Therefore, it was so important to normalize the EEG data to help to speed up the training process and obtain as much accurate results as possible. The training and testing data have been normalized by calculating the pre-feature mean and standard deviation for all the input sequences. Then, the mean value has been subtracted from each of the training and testing observation and the results for both of them have been divided by the standard deviation as follows:

$$EEG_{Normalised} = \frac{x - \mu}{\sigma}$$

Where (x) is the raw EEG signal, (μ) is the calculated mean value and (σ) is the calculated standard deviation for the recorded EEG dataset. After the normalization process, the data is now ready for the training process. Figure 7 shows the normalized 14 channel EEG signals for the recorded first session while looking to Rorschach picture.

Figure 7, normalized EEG signal set

•**Training LSTM network:** The processed data has been used later to train a deep learning model using Long Short-Term Memory (LSTM) network on MATLAB 2019a. Since we have a sequence of inputs (14 time series signals) and a vector output (vector of zeros for the Factual picture and vector of ones for the Rorschach picture), the LTMS network has been designed as sequence input to vector output and structured as follows: Sequence input layer with number of features equal to the number of channels of the recorded EEG data (14 channels), 3 LSTM layers with 100 hidden unit for each. To prevent overfitting, a regularization technique has been implemented by separating each of the 3 LSTM layers with a dropout layer. The dropout layers will randomly set 10%, 50% and 10% of the training parameters to zero in the first, second and third LSTM layer respectively (dropout ratios 0.1, 0.5 and 0.1). The network has been ended with a fully connected, softmax and a classification output layers with the number of class labels equal to the desired number of the outputs (2 outputs).

IV. RESULTS AND ANALYSIS

An accuracy of 0.93 has been achieved when testing the resulted LSTM network with the remaining 30% of the normalized EEG dataset. These results have been obtained with the help of the adaptive moment estimation (Adam) algorithm. Adam algorithm has been used as an optimization algorithm to tune the hyper-parameters of the LTSM-RNN model. After training the LSTM-RNN model on 70% of the recorded EEG dataset with a 100 max Epochs and 25 for mini batch size the above accuracy has been obtained. Figure 8 shows the model accuracy in the training stage. With the designed LSTM network, it was possible to achieve almost 93% accuracy to classify a normalized EEG dataset for two different activities while looking at two different pictures using low cost EEG headset.

Figure 8, LSTM accuracy after the training process

Table 1. Shows the predicted outputs for the designed LSTM-RNN network to classify the recorded EEG dataset (the test data) while looking to the Rorschach and Fractal images.

V. CONCLUSION AND FUTURE WORK

Although better accuracy has been achieved by other research work to classify the human brainwaves, this work proves the possibility of using a low cost EEG headset (such as Emotiv EPOC+) with the concept of deep learning to process and classify the human thoughts. With the concept of IoT, the classified brain thoughts can be used as a control command to help the disabled people around the world to improve the quality of their life. However, due to a lack in the interface software between the MATLAB and the Emotive EPOC+, all the testing and training stages have been implemented offline without an online execution. Further work will be conducted in the future using different EEG headset with the possibility of having online brain waves testing on MATLAB to assess the classification accuracy of the implemented LSTM model online. Moreover, more than one task will be implemented over the internet using the concept of IoT.

Abstract—The rapid development of battery-powered gadgets has made low-power design a priority in recent years. In addition, integrated SRAM units in contemporary soCs have become an essential component. The increased number of transistors in SRAM units and the increased leakage in scaled technology of the MOS transistors have turned the SRAM unit into a power block from dynamic and static perspectives. This memory circuitry consumes many chips and determines the system's overall power consumption. Typically, the primary 6T SRAM cell gives more power loss and delay. In this paper, various SRAM transistor cells have been built and analyzed from different topologies. A proposed low-power 9T SRAM cell area has improved reading and writing access time. As anticipated from the modeling findings, experimental results show a significant overall power decrease compared to traditional and previously published.

Index Terms—Dynamic Power, high speed, process analysis, SRAM, stability, static power.

I. INTRODUCTION

SRAM is intended to work in close collaboration with the central processor unit (CPU) and consumes less power to conserve battery life due to the fast proliferation of portable devices [1]- [5]. The speed and power parameters are critical in boosting the capabilities of electronic devices used in research and commercial facilities. With the growing need for low-power SRAMs, low-power design methodologies are concentrating their efforts on a few specific sources of power consumption [6]-[8]. Low-power methods of decreasing the SRAM cell's leakage current are necessary because of the increased leakage current associated with scaled technology. The high capacitance of the long interconnecting wires also contributes to the SRAM unit's large dynamic power consumption. Thus, the electronic industry's need for tiny and portable electronic gadgets with low power consumption and fast speed has developed significantly [9]-[13]. Therefore, designing an SRAM-based memory with optimum power and stability without sacrificing performance is tricky.

The traditional 6T cell design is relatively simple in various applications [14]-[18]. It has excellent conduction and performs well in terms of delay and power. The power dissipation of 6T, Comparatively high. The numerous types of SRAM cells, such as 7T SRAM [26], 8T SRAM, and 9T SRAM [26], are overviewed to the power consumption problem of the 6T SRAM. High static power is provided by the 6T SRAM cell [19]-[22]. An 8T is chosen and implemented to achieve low static power. The 8T SRAM cell is more stable and uses less power than the 6T SRAM cell. A new 9T SRAM cell has been proposed to overcome these limitations. The suggested SRAM has a lower power usage than a 6T SRAM [20]. Compared to a standard 6T cell, the proposed cell includes less outgoing current. Several techniques are discussed for reducing the SRAM cell's outgoing currents [23]-[25]. The power dissipation of the SRAM cell is particularly targeted.

The rest of the paper is structured as follows: The conventional SRAM cells are explained in Section II. Section III describes the proposed SRAM cell. Section IV presents and discusses the experimental results using the Cadence tool. The paper concludes with Section V.

II. STANDARD SRAM CELLS

SRAM is made up of two cross-coupled inverters in such a fashion that it store data and provide positive feedback. When powered, it functions as a volatile memory, storing data. It accelerates 'read' and 'write' operation using BL and BLB bit lines.

A. 6T SRAM Cell

The CMOS standard 6T SRAM cell has two PMOSs, two NMOSs, and two NMOSs as access transistors. Two data-storage inverters are manufactured and cross-coupled so that positive feedback is generated. The two inverters are P0, N0, and P1, N1. It also has vertically aligned Bit Lines

(BL and BLB) and a horizontally oriented Word Line (WL) [20]. SRAM has three modes of operation: standby, read, and write. Vdd is provided to BL during standby mode, and WL is switched off, causing the transistors connected to it to turn off as well.

Fig. 1: Schematic diagram of 6T SRAM cell.

The two cross-coupled inverters provide positive feedback since $BL = V_{dd}$, allowing data storage while power is supplied. Only read and write operations are permitted on the WL line, which controls the state of the access transistors.

Sense Amplifier: A sense amplifier is required for memory circuits to attain high performance, endurance, and usefulness. It is a part of the read circuitry responsible for reading data from memory. Its purpose is to monitor low-power signals from a bit line and convert the tiny voltage difference to full logic voltage, representing the data bit stored in a memory cell, thus significantly reducing read time. It includes voltage sensing, low-voltage amplification, delay reduction, power consumption [4] reduction, and signal restoration capabilities. They are mainly used to amplify the differential voltage across complementary bit lines during 'read' operations without flipping the stored cell data, enabling the data to be adequately handled by the memory's output circuitry. To function correctly, the SRAM cell must have a Static noise margin (SNM) since this determines the dependability of sensing data from the chosen cell [5]. Since the driving transistors do not need to discharge the bit lines completely, the inclusion of a sensing amplifier reduces the size of the memory cell. The sensing amplifier's design significantly impacts the read speed and power consumption.

It has seven transistors, two of which serve as differential input devices (N0 and N1). They function as driver transistors and accept inputs, while transistors P0 and P1 work as active current mirror loads, transistors N3 are current sources, and transistors P2 and N4 are inverter transistors (amplifier). The control circuit generates a sense enable

Fig. 2: Schematic diagram of Sense Amplifier.

signal (SE) to activate the sense amplifier. When this enabled signal is high, the sensing amplifier increases the differential voltage of the bit lines (active). Amplification of differential voltage results in a single-ended digital output reflecting one bit read from the SRAM array.

Pre-charge circuits: It is used to quickly and painlessly charge both bit-lines voltages to VDD before each read and write operation. The pre-charge circuit is shown. It comprises two pull-up PMOS transistors and an equalization that balances the voltages on both bit lines [4]. The pull-up transistors are controlled by the PR signal, which controls the transistor P3, an equalization signal that balances the voltage on both bit lines. The term "Vdd pre-charge" refers to the pre-charge. PMOS transistors are utilized in the pre-charge circuit because they are the most efficient at transmitting the Vdd level voltage to the bit lines.

Fig. 3: Schematic diagram of Pre-charge circuit.

When the word lines are activated, the memory cell nodes must raise the voltage on the bit lines to a level adequate to read the correct data value from memory during a read operation. Due to the high load capacitance of the bit lines in large memory arrays, charging and discharging them takes

a lengthy time. Waiting for the bit-line capacitance to drain before performing the next read operation may be an issue since it adds time to the 'read' process. Additionally, an error may result if the subsequent read operation occurs before the bit lines have been discharged. Consequently, a pre-charge circuit is required to provide a high current to bit lines to charge them fast. To do this, a pre-charge circuit is used to charge both bit-lines to a steady voltage Vdd. Since the voltage on both bit lines is known and steady, the voltage difference may be easily detected.

Write access time: The time interval between the positive edge of the word line reaching 50% Vdd and the junction of the two storage nodes Q and Qb are defined as the memory cell's write access time.

Read access time: The period between the positive edge of the word line hitting 100% Vdd and the sensing amplifier output reaching 100% of the stored value is the read access time of a memory cell.

B. 7T SRAM Cell

Before write operation, The 7T SRAM cell disables the feedback link between the two inverters inv1 and inv2. An additional NMOS transistor N5 handles feedback connection and disconnection, and the cell is completely reliant on the BL bar for a write operation.

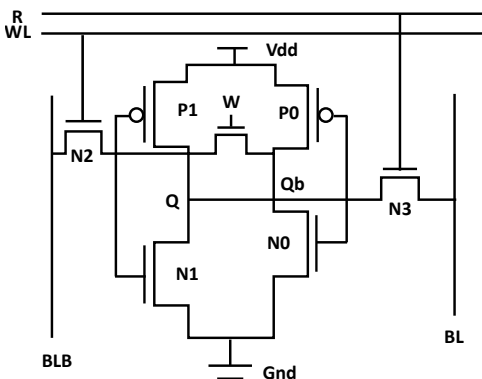

Fig. 4: Schematic diagram of 7T SRAM cell.

C. 8T SRAM Cell

The architecture of the 8T SRAM cell is depicted in the figure. It features two extra transistors N4 and N5 as compared to a standard 6T SRAM cell. Precharging BL is the first step in the read process. The reading is then initiated by setting RD to Vdd [3]. If bit 1 is stored in the cell, Q is at Vdd and Qb is at the ground. During the read process, the precharged BL begins to discharge via N4 and N5. Discharging should be fast enough to keep up with the

rate at which BL leaks through all of the unaccessed SRAM cells connected to it. As a consequence, the read circuit can correctly identify the data.

If bit 0 is stored in the cell, BL should not discharge and should stay at or near Vdd. In this case, the read circuit should calculate the value of BL before leakage reduces it considerably. To assist retain the value one in the bit line, we connected a weak pull-up to the read circuit. Because short bit lines have low capacitance, they facilitate the charging and discharging of SRAM cells and peripheral circuits [10]. As a consequence, transistor sizes are reduced, leakage is reduced, and reliability is enhanced.

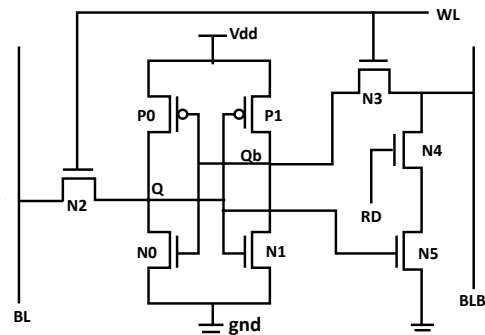

Fig. 5: Schematic diagram of 8T SRAM cell.

D. 9T SRAM Cell

The 9T SRAM's top circuit is identical to the 6T SRAM's but with fewer transistors. The two access transistors are controlled by the word line (W), and the data is stored in this subcircuit. A separate read signal (R) controls the bottom circuit, which consists of a single read access transistor [26].

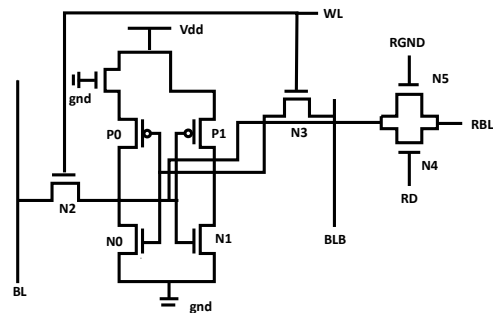

Fig. 6: Schematic diagram of 9T SRAM cell.

III. THE PROPOSED 9T SRAM CELL

A new 9T SRAM cell is being developed. Compared to a standard 6T SRAM cell, it has three more transistors, N4, N5, and N6. Figure 7 shows a single-sided read circuit. It

takes up less space and does not rely on the perfect timing of control signals, as the differential read of a typical sense amplifier circuit does. Figure 7 depicts the write circuit. One of these circuits is for BL, and the other receives the data bit and its inversion as input. Because PMOS transistors are larger than NMOS transistors, their pullup and pulldown currents are symmetrical, allowing the write circuit to drive both 0 and 1 to the bit lines. The reliability and static power

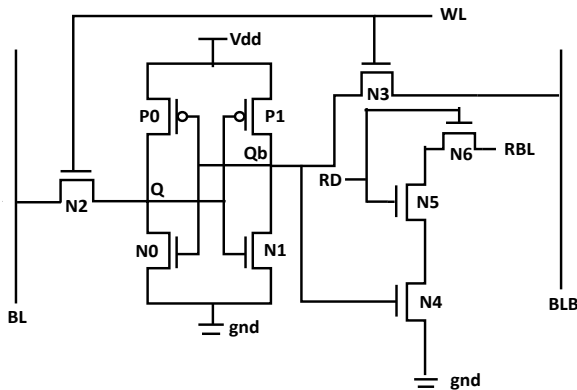

Fig. 7: Schematic diagram of Proposed 9T SRAM cell.

consumption of transistors are the primary determinants of transistor size. The dimensions used are listed in Table I. P0 and P1 have the narrowest widths allowed by the technology. Vdd leak currents are reduced as a result. In 6T SRAM, the pull-down NMOS transistors N0 and N1 are wider than the access transistors N2 and N3. This improves cell stability during read operations when 6T SRAM is most susceptible to undesirable state change. Because N2 and N3 are not used during read operations, the widths of the pull-down and access transistors in the proposed 9T SRAM have been flipped, making write operations faster and more reliable. The width of the N4, N5, and N6 of 9T SRAM decrease leakage.

IV. SIMULATION AND RESULT

The proposed 9T and other comparative SRAM cells are simulated at a 45-nm technology node in this work. The cadence virtuoso simulation tool is used for simulations.

A. Transient Response and Power Consumption

Power savings are significant in the proposed 9T cell structure, regardless of the stored value, i.e., whether the SRAM cell stores 0 or 1. When a bit cell in the 7T structure stores a 1, the PMOS is enabled, leading to significant power consumption in standby mode. When the bit cell stores a 0, the voltage difference between the drain and source raises the sub-threshold leakage via the PMOS. This grows

Fig. 8: Transient Responses of the proposed 9T SRAM cell.

Fig. 9: Power consumption of the Proposed 9T SRAM cell.

exponentially as the threshold voltage decreases, indicating a significant leakage current component in the off-state. The average standby power consumption of the 7T structure in Figure 4, the 8T structure in Figure 5, and the 9T structure in Figure 6, the proposed 9T structure in Figure 7 when the SRAM cell stores a 0 is shown in Figure for various power supply voltages, the proposed 9T cell achieve minimum power savings in each bit cell without sacrificing performance.

B. Analysis of Stability Using the N-Curve Method

The static noise margin (SNM) is a metric for the SRAM cell's stability. The read, write and hold modes of this SNM are used to get the read SNM, write SNM, and hold SNM, respectively. Generally, the butterfly method is employed to determine the SNM in various modes [26]. However, the disadvantage of the butterfly technique is that it only provides information about SNM; deriving SINM (Static Current Noise margin) requires mathematical calculations. Two distinct circuits must be examined to achieve read and write SNM. Another technique for determining SNM is the N-curve method, which provides both voltage and current information concurrently. The cell's read stability and write capabilities are also determined directly from the N-curve. The N-curves for all SRAM and planned SRAM cells are shown in fig. below. The values for SVNM, SINM, WTV, and WTI are as given in Table I.

C. Analysis of Stability Using the Butterfly Method

The SRAM cell's ability to store data against noise is measured in SNM. The SNM of SRAM is defined as

TABLE I: Comparative Analysis of SRAM cells

Parameters	Proposed 9T	6T [3]	7T [6]	8T [8]	9T [25]
Total Power Dissipation (μW)	0.09041	25.48	25.26	6.101	0.1154
Read Time Access (ns)	68.938	191.74	141.85	155.177	69
Write Time Access (ns)	78	92.562	70.5028	79.058	78
Static Voltage Noise Margin (mV)	423.32	369.094	371.581	359.41	393.51
Static Current Noise Margin (μA)	74	36.094	33.394	55.535	51.650
Write Trip Voltage (mV)	513.79	522.57	540.86	496.99	511.96
Write Trip Current (μA)	-12.208	-8.6711	-9.1072	-9.4437	-8.6705
Static Power Noise Margin (μW)	31.308	13.35	12.40	19.9598	20.325
Write Trip Power (μW)	-6.2723	-4.531	-4.9257	-4.6934	-4.439

Fig. 10: N-curve Analysis of Proposed 9T SRAM.

the minimum amount of noise voltage required to flip the state of a cell on the SRAM’s storing nodes. The static voltage transfer characteristics of the SRAM cell inverters are used in the graphical technique to determine the SNM. It multiplies one cell inverter’s voltage transfer characteristic (VTC) by the inverse VTC of the other inverter [14].

Fig. 11: Butterfly Curve Analysis of Proposed 9T SRAM cell.

The greater the SNM value, the better the read stability of the SRAM cell. The read stability of a cell with a lower RSNM is poor.

V. CONCLUSION

The performance of three SRAM cell topologies in terms of stability has been demonstrated. SRAM speeds will increase as process technologies advance, but devices will be more prone to mismatches, reducing the static noise margin of SRAM cells. The 6T SRAM’s RNM is relatively low. The width of the pull-down transistor must be raised to get a larger RSNM in 6T SRAM cells. However, this increases the area of the SRAM, which increases leakage currents. The read noise margin of an 8T SRAM cell is significantly higher. An 8T SRAM cell may fail during a write operation due to the asymmetric cell structure. Compared to 6T and 8T SRAM cells, 9T SRAM cells have stronger RSNM and WSNM, resulting in improved stability performance.

Smart Home Automation IoT System for Disabled and Elderly

Nesreen Alsbou and Naveen Mohan Thirunilath
 nalsbou@uco.edu, nmohan@uco.edu
 University of Central Oklahoma

Abstract— This paper provides a simulation based home automation system. The system is designed to be automated and controlled remotely through a cloud system. The proposed system enables the user to monitor and control the home environment including temperature, humidity, and detection of intruders. The system sends alerts via email and text messages to the user's phone for continuous monitoring. The cloud feature helps the user to read the data and control the functionality of different appliances at a home using mobile phone. This affordable system is best suited to remotely monitor and take care of disabled and elderly that are limited in movements.

Keywords – Internet of Things (IoT), Smart Home, Packet Tracer, Disabled, Elderly, and IoT Systems.

I. INTRODUCTION

Smart homes use home automation systems to control home appliances and provide automatic remote control inside and outside the home. Despite the comfort and ease of use of remote control, specific key problems must be addressed and improved, such as how to provide an intuitive and user-friendly remote-control scheme in IoT-based smart homes and can be accessed away from home [1]. In this system, using an MKR1000, connected devices are controlled, and data has been read and sent to the cloud in real-time. Various sensors that are kept in different areas of the house will read the values and send them into an Arduino. The Arduino is programmed and set up using the Arduino IoT cloud, which uses these values from the sensor to process and do necessary actions. An OLED display was also connected to the Arduino for the user to see real-time values from the sensors if the user does not want to check the phone.

This system can also be used for a COVID19 patient, which helps the patient to stay in a controlled environment and still would be able to control everything in fingertips. Values like room temperature, lawn soil humidity, light intensity, intruder detection, and appliances control are focused on in this project. In the proposed study, we are building a system with five sensors for data collection and

Two LEDs, a fan, and a buzzer for feedback. The temperature sensor will sense the temperature of the room, and after a certain limit on temperature value, a buzzer will go ON. The humidity sensor can be used to detect the humidity, and if it detects a value below a certain number, a fan will turn ON, which can be used as a lawn sprinkler. A rotary sensor is used to adjust the brightness of a LED. An ON/OFF switch is also added to the cloud dashboard to control a LED remotely. All the desired changes can be received as a notification via email and SMS text messages.

II. LITERATURE REVIEW

The topic of Internet of Things has been studied in various papers, and home automation is easy and popular among them. The main objective of IoT is to manage and control physical objects around us in a more intelligent and meaningful manner and improve quality of life by providing cost-effective living, including safety, security, and entertainment. Mandula introduced a simple Bluetooth-based home automation system in 2015. An Arduino ATMEGA238 was used for the study to control home appliances from user's mobile phones. The mobile is connected using a Bluetooth module HC-05, limited to a 10-meter range [2].

In 2013, Home automation using Zigbee stack had gone to get a faster communication to mobile phones. Their study investigates several methods to equip an Android device with a dongle capable of ZigBee communication. They proposed a scalable architecture with three abstraction layers that scales over multiple communication channels, such as the TCP channel for communication with the gateway, and the USB channel, for direct communication with devices through the dongle [3]. A similar study by B. Balaji in 2020 introduced a domestic home automation system in which an Arduino UNO is used to control home appliances. In the proposed study, an external Wi-Fi module had connected to get the Arduino connected to the Internet [4]. The system is designed again that only if the user is connected to the home network Wi-Fi the access to operate the system is granted.

III. PROPOSED SYSTEM

The proposed system's IoT architecture block diagram is shown in Figure 1. The smart thing we used in the system was Arduino MKR1000, and the sensors were connected to different sensors and actuators from the Arduino. The IoT gateway used in the study is Wi-Fi. The Arduino is connected to the cloud and Webhook via a Wi-Fi gateway. The Arduino IoT cloud is used to program the Arduino and to connect the Webhook Email client to the code. The smartphone will receive text messages and display the values of all connected devices in the dashboard through any available internet connection. The system block diagram is shown in Figure 1.

Fig. 1. System Block Diagram

IV. HARDWARE DESIGN

IoT is a structure in which objects, people are provided with an exclusive identity and the ability to move data through a network without requiring two-way inter-human to the human source, i.e., the destination or human interaction to the computer. IoT is a very promising development to optimize life based on intelligent sensors and smart appliances that work together over the Internet [1].

Arduino: Arduino MKR1000, as shown in Figure 1, is the main controller used in the project. The main advantage of this Arduino is the easy network connectivity and cross-platform advantage. The Arduino is open-source with extensible software support in different cloud platforms. It has a low-power ARM microcontroller which would be perfect for a long-life project like this. The device is equipped with 8 I/O pins and 12 PWM Pins which runs on an operating voltage of 3.3V. This will be perfect for connecting enough appliances and working for a relay for the fan in the proposed study. Arduino MKR1000 Wi-Fi is the board that has been chosen because this board has been designed especially for IoT. This board has a more powerful processor than Arduino Uno or Mega. Besides, it has a Wi-Fi WINC15000 chip to connect to the Internet, which allows sending data to devices from the Internet [5]. Different Sensors are used in the proposed system as

described below. Temperature Sensor: A groove temperature sensor that uses a thermistor resistance that varies according to temperature is used. The sensor is shown in Figure 2 and it is connected to the Analog pin A0 of the Arduino.

Fig. 2. Temperature Sensor

Light Sensor: The light sensor will detect the light intensity in the room and can be used to display the value on the dashboard for the Arduino IoT cloud, the sensor is shown in Figure 3.

Fig. 3. Light Sensor

Rotary Angle Sensor: The sensor will detect an angle from 0 to 300 degrees. This sensor is shown in Figure 4 and it is known as a potentiometer which is connected to Arduino to vary the light intensity of a LED.

Fig. 4. Rotary Angle Sensor

PIR Motion Sensor: The PIR (Passive Infrared) motion sensor will detect human movements in its range. Once the motion is detected, the sensor will output HIGH and will send that to the Arduino. The sensor is shown in Figure 5.

Fig. 5. PIR motion Sensor

Humidity Sensor: We are using a DHT11 humidity sensor that uses a capacitive humidity sensor to send Analog output to the Arduino. The sensor can be kept outside the house on the lawn to detect soil humidity. The sensor is shown in Figure 6.

Fig. 6. DHT11 Humidity Sensor

Buzzer: The buzzer is composed of a piezo buffer which emits a tone when the output pin is high. The buzzer will make a sound when the temperature is above a specific threshold value. The buzzer used is shown in Figure 7.

Fig. 7. Buzzer

OLED: Organic Light-emitting diode which is a grayscale 128x128 pixel, it is used to display the temperature and humidity values from the sensor as shown in Figure 8.

Fig. 8. OLED

V. SOFTWARE DESIGN

Smart Home is an application of a combination of technology and services devoted to the home environment with specific functions aimed at improving the safety, efficiency, and comfort of its inhabitants. The smart home system usually consists of monitoring tools, control devices, and automatic actuators. Several devices can be

accessed using a computer or smartphone connected to the Internet network [6-8]. For the proposed study, a simulation using packet tracer is done. All the appliances are placed on a two- bedroom apartment layout, as shown in Figure 9.

Fig. 9. Cisco Packet Tracer Simulation

Sensors are kept at the door to detect motion and to access the door. A humidity sensor is kept on the lawn to detect humidity and turn the sprinkler when needed. Light ON/OFF switch available on the smartphone. The wind detector will sense the wind and open/close the windows as per the conditions mentioned below in Table 1.

Table 1: Conditions on Cisco Packet Tracer

actions	Enabled	Name	Condition	Actions
E:R: Remote	Yes	Close Window 1	IoT18 Wind is true	Set IoT8 On to true
E:R: Remote	Yes	Door Open	MotionDet1 On is true	Set Door1 Lock to Unlock
E:R: Remote	Yes	Door Close	MotionDet1 On is false	Set Door1 Lock to Lock
E:R: Remote	Yes	Open Window	IoT18 Wind is false	Set IoT8 On to false
E:R: Remote	Yes	SprinklerOn	Humidity1 Number >= 55	Set Sprinkler Status to true
E:R: Remote	Yes	SprinklerOff	Humidity1 Number <= 55	Set Sprinkler Status to false
E:R: Remote	Yes	Motion Cam	MotionDet1 On is true	Set Cam On to true
E:R: Remote	Yes	MotionCam2	MotionDet2 On is false	Set Cam On to false
E:R: Remote	Yes	ScreenOn	SmartDet Level <= 0.52	Set Smart1 On to true
E:R: Remote	Yes	ScreenOff	SmartDet Level <= 0.52	Set Smart1 On to false
E:R: Remote	Yes	ACOn	Thermostat Temperature >= 19.0 °C	Set AC On to true
E:R: Remote	Yes	ACOff	Thermostat Temperature <= 19.0 °C	Set Furnace On to true
E:R: Remote	Yes	ACOff	Thermostat Temperature <= 19.0 °C	Set AC On to false
E:R: Remote	Yes	FurnaceOn	Thermostat Temperature >= 19.0 °C	Set Furnace On to false

The simulation also has a smoke sensor that detects smoke and will turn ON/OFF a siren after a specific value of smoke. Additionally, a Webcam is also placed at the door to detect people coming at the door. The simulation is a demo representation of how the home automation system will work in real life. On the packet tracer, all the components are added to the IoT home gateway network. This helps the user to access the devices from the smartphone.

VI. SECURITY FIREWALL

The goal of adding a IPv4 or IPv6 firewall to the network is to have every device assigned an IP address so that connections can be established directly between them instead of being behind on firewall. Adding a Cisco ASA (Adaptive Security Appliance) firewall to router will

improve the security and it stops threats before they spread through the network. This setup works best for a system which works on a cloud instead of adding just an IPv4 firewall for every device on the Cisco packet tracer. For the proposed study we are using an ASA 5505 on-board accelerator (Version 8.4(2)). The ASA is configured with domain ccnasecurity.com which is provided for the Cisco security network devices. The Cisco Packet Tracer Simulation for ASA firewall is shown in Figure 10.

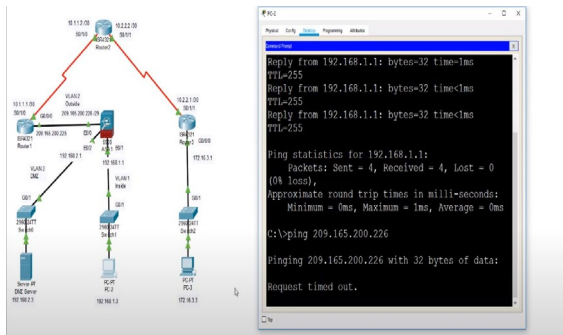

Fig. 10. Cisco Packet Tracer Simulation for ASA firewall

We setup VLAN 1 on the inside with the highest security level of 100 and VLAN 2 on the outside with the security level zero. This will provide the system interaction from lower security level and thereby securing system by any attacks outside from the network. On the figure we set up a demo system in which the ASA firewall will be connected to the router and the ping request from the lower security level is timed out when requested as shown in the figure.

VII. ARDUINO IOT CLOUD

The Web Editor platform on the Arduino IoT cloud was made use of for the programming of Arduino. This helps the user to have direct access to the cloud to make changes and reprogram it remotely. Arduino Create Agent client installed on the computer, which helps to communicate the hardware to the cloud and upload sketches. Things option on the IoT Arduino cloud dashboard is used to define the variables and to determine how they change according to the input. Necessary libraries are added during the coding for the different components added to the Arduino. IFTTT offers Webhook services that are used for email notification. Once the email is received, Gmail is set up to send a text notification to the desired number.

VIII. CONNECTION DIAGRAM

The overall circuit diagram for the proposed system is given in Figure 11. The pin diagram is connected in the circuit according to the program code in the IoT Arduino Cloud. The Arduino pins are soldered and placed on a

breadboard. The sensors and actuators are connected to the Arduino using connection wires.

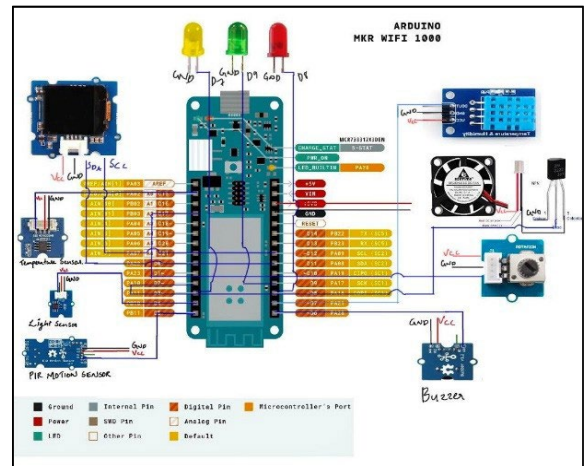

Fig. 11. Circuit Diagram and PIN Layout of MKR1000

IX. HARDWARE IMPLEMENTATION

Once the simulation is completed. The next step was to build the system and check its functionality. The goal was to implement the wireless sensors which can be connected to the Arduino to help the user easily place the sensors anywhere at their house with minimum to no wires. The final completed circuit of the system is shown in Figure 12 and the dashboard showing values detected and control buttons to monitor and control the home environment remotely as needed is shown in Figure 13 and Figure 14 shows text notifications of different events detected by the system.

Fig. 12. Final Circuit

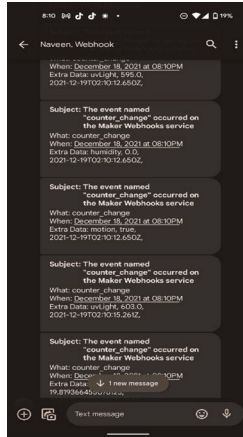

Fig. 13. IoT System Dashboard

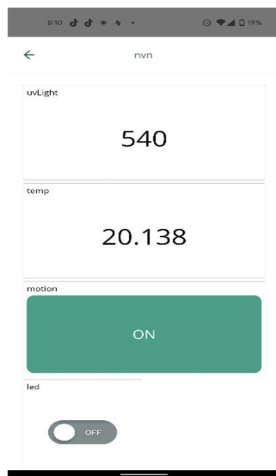

Fig. 14. IoT System Text Notification

X. CONCLUSION

This paper shows the simulation and implementation of an automated home to help the elderly using a low-powered home automation system that is user-accessible remotely. The projects enable the user to control appliances, read sensor values, and detect intruders from their mobile phones. The motion detector will detect any irregular motion in the house, the temperature sensor and humidity sensor will read and display the temperature and humidity values, respectively. The system is ready to use and needs to be connected to the home modem Wi-Fi. Once the necessary connections are completed, the home automation system is complete. Internet of things is a booming technology that brings all the technology together to make home automation possible in a simple and affordable way.

IoT-Based Smart Hospital using Cisco Packet Tracer Analysis

Nesreen Alsbou and Dakota Price
 nalsbou@uco.edu, dprice16@uco.edu
 University of Central Oklahoma

Abstract – Today's hospitals are outfitted with cutting-edge technology in order to save as many lives as possible. However, the hospital is missing one thing: IoT-based connectivity between vehicles such as ambulances and surrounding hospitals. WiFi or cellular data will be used to connect to the internet. An Arduino MKR1000 will be used in this IoT system, with sensors attached to the OBD II connector. These sensors will be used by the smart hospital to communicate live data collected from the patient on board to many hospitals at the same time. EMTs could examine the damage and speed up the time it takes for doctors to start treating patients once they arrive.

Keywords – Internet of Things (IoT), Smart Hospital, Packet Tracer, VANET, Vehicle-to-vehicle, and Security.

I. INTRODUCTION

The Internet of Things (IoT) is a network of interconnected, internet-connected items that can gather and transmit data without the need for human interaction across a wireless network [1]. Businesses are currently inspired by IoT and the potential for increased revenue, lower operational costs, and improved efficiency. Regulatory compliance is also a driving force for businesses. IoT device installations give the data and insights required to optimize workflows, visualize use trends, automate operations, satisfy regulatory needs, and compete more effectively in a changing business environment, regardless of the reasons. Physical things can exchange and gather data with minimum human interaction thanks to low-cost computers, the cloud, big data, analytics, and mobile technologies. Digital systems can record, monitor, and alter each interaction between linked items in today's hyper connected environment.

Packet Tracer is a visual cross-platform tool developed by Cisco Systems that employs simulations to assist users understand computer networking fundamentals. It can run on Linux, Windows, Android, and macOS. Many sorts of network (including IoT) devices may be added or removed using a simple drag-and-drop approach. It also enables students to conduct simulations in a basic manner using a variety of programming languages, including Javascript, Python, and Blockly [2].

IoT-based technologies are all over the world right now in many different applications. Smartphones are predicted to expand at a rate of 3% per year, whereas industry and smart

homes are likely to increase at a rate of 20% per year. The rapid expansion of this sector may result in fewer house invasions, vehicle accidents, and the time required for physicians to review arriving patients at emergency departments. Ambulances are anticipated to arrive within 15 minutes on average in the United States to treat persons with life-threatening diseases or injuries. Before arriving at the hospital, this time will be extended by another 15 to 30 minutes. This time frame might be utilized to gather all data from blood pressure, heart rate, respiratory rate, and pulse oximetry in 15 to 30 minutes. In this paper, we will be using multiple sensors included in a BeagleBone development kit, which also includes connections. Some of the kit's sensors and actuators will be used as external components for the vehicle. The information collected will be sent to the hospital so the physicians can keep track of it and plan the next step prior to arrival at the hospital and going to the emergency room.

II. METHODOLOGY

A. Design of Network Topology

A Local Region Network (LAN) – a small collection of sensor-equipped devices connected by wired (e.g., Ethernet) or wireless communication inside a constrained area is the smart hospital's suggested network design. Small-scale network applications are best served by LANs. The hospital will be linked to this, as well as a small onboard gadget on an ambulance. The Cisco Packet Tracer simulation was developed to demonstrate how this process would operate. You can add or delete a variety of network (including IoT) devices using a simple drag-and-drop approach. The diagram below depicts how the smart hospital connects to the internet before connecting to the server. The server establishes a connection with the mobile tower, and then connect with the smartphone.

B. Security Protocol Configuration

A network security device will be fitted with ICMP for increased security in the smart hospital. This limits the computer's ability to connect with other devices to merely browsing the internet. An IP address firewall is the other step. These guard the smart hospital against outside threats and let it connect to other IP addresses on the network. Figure 1 shows the server cluster with the low-security firewall configured on the router, PC, and switch. [1,3]

Fig. 1. Secure network topology.

C. Configuration of IoT Systems and Devices

The smart hospital is separated into three clusters for the different areas of the hospital. This allows to easily see the split up for clear analysis. The ambulance uses a smoke detector, window, LCD screen, alarm, fire detector, and water sprinkler as shown in Figure 2. These are all very important sensors and actuators that are essential in a hospital. The emergency entrance part of the smart hospital has a garage door, alarm, siren, smoke detector, trip wire, carbon monoxide monitor, and a water sprinkler. This can be seen in Figure 3 with all essential sensors and actuators an emergency entrance would include. The building portion of the smart hospital is shown in Figure 4 and it includes several monitors, a fan, alarm, trip wire, temperature sensor and light. These all correlate to each other, so when the trip wire is activated the light and fan activate. The microcontroller (MCU), which reads and transmits sensor data and outputs commands to IoT devices. All MCUs connect wirelessly to a central hospital gateway, which serves as a router to the PCs in the network, allowing users to view and control devices from the IoT monitor.

Three separate IoT systems were developed for the smart hospital design:

- Smart Ambulance: Located in the 'Vehicle Area' section in the smart hospital. The MCU takes the inputs from the different parts shown in Figure 2 and transmits them to the Gateway to be viewed on a connected PC in the hospital. These sensors read emergencies to activate the actuators and notify the IoT Monitor.
- Smart Emergency Entrance: This system warns users when the trip wire is activated to open the emergency door. This is also equipped with safety devices like fire sprinkler, monoxide monitor, and smoke sensor. This can be seen in Figure 3 and includes most essential sensors and actuators a garage would include.
- Smart Hospital: Includes a trip wire as input and light and fan as output. When motion is detected, the light and fan

turn on. This also includes an alarm, temperature sensor, and temperature monitor for viewing.

Figure 4 shows how the sensors and actuators are hard wired to the MCU, but some of these are connected wirelessly straight to the home gateway.

Fig. 2. WSN configuration of the ambulance in the smart hospital

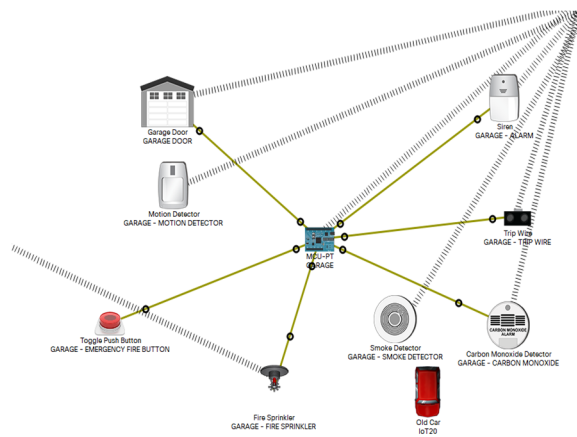

Fig. 3. WSN configuration of the emergency entrance of the smart hospital

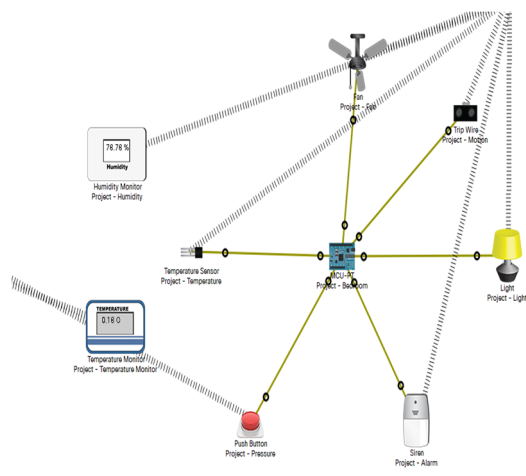

Fig. 4. WSN configuration of the building portion of the smart hospital

D. Packet Tracer Simulation and Testing

Cisco Packet Tracer is a simulation tool used for developing, testing, and troubleshooting networks [2, 3]. Packet Tracer allows users to program virtual IoT devices, sensors, and actuators, making the program a valuable tool for building and analyzing realistic IoT systems for smart cities. The network was first built and analyzed in Packet Tracer to ensure proper functioning [1].

E. Hardware Implementation and Testing

A hardware implementation of the smart hospital is being developed currently in the lab and will be tested. In addition to the functions design for the Packet Tracer simulation, this implementation includes the ability to send push notifications to user’s phone or send an email if sensor values pass user-determined thresholds.

III. PACKET TRACER SIMULATION AND ANALYSIS

A. Secure Network Communication

The ICMP Firewall is a protocol that network devices (e.g., routers) use to generate error messages when network issues are preventing IP packets from getting through. The Internet Control Message Protocol is one of the fundamental systems that make the internet work [3]. ICMP gives a little bit of feedback on communications when things go wrong. Figure 5 shows the command prompt pinging the IP address to show all connectivity is successful. The firewalls that are built are the ICMP and IP firewall. These allow the user to only browse, and not connect to other devices with the same IP address. This is a low security feature that allows users to continue safe browsing without disrupting other devices [1,3]. Figure 6 and Figure 7 show the Firewall Configuration and Firewall IP Configuration, respectively.

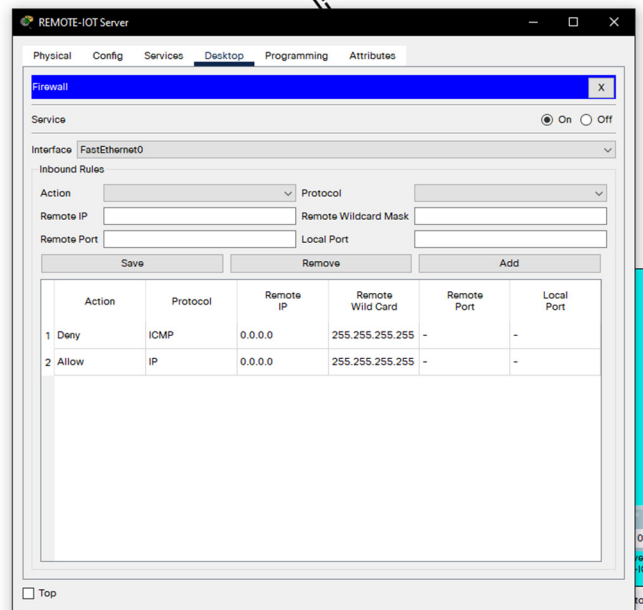

Fig. 6. Firewall Configuration

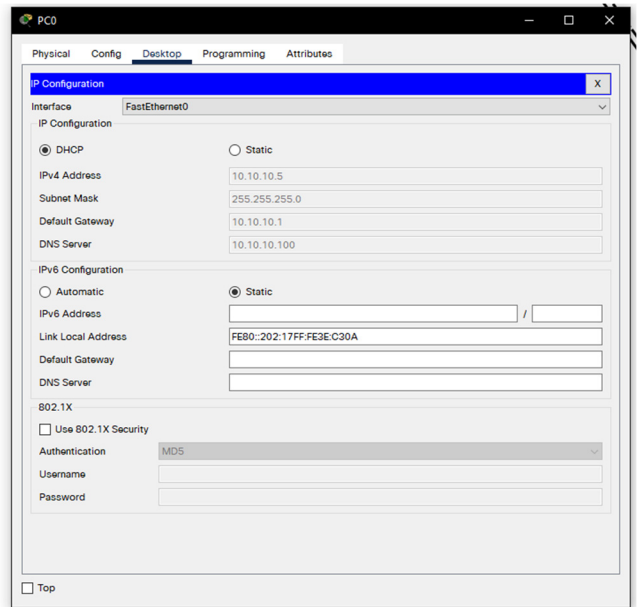

Fig. 7. Firewall IP Configuration

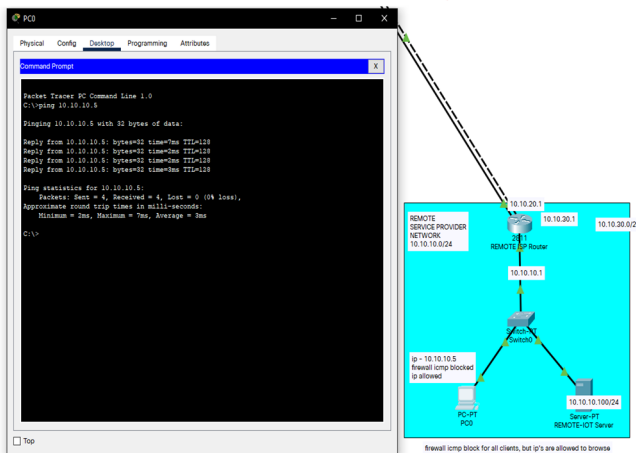

Fig. 5. Command Prompt pinging the IP address selected

B. IoT System Functions

- Smart Ambulance: Located in the ‘Vehicle Area’ section in smart hospital, this system consists of a LCD screen, window, fire monitor, alarm, fire sprinkler, and a smoke sensor. These sensors read emergencies to activate the actuators. This programming can be seen in Figure 8.

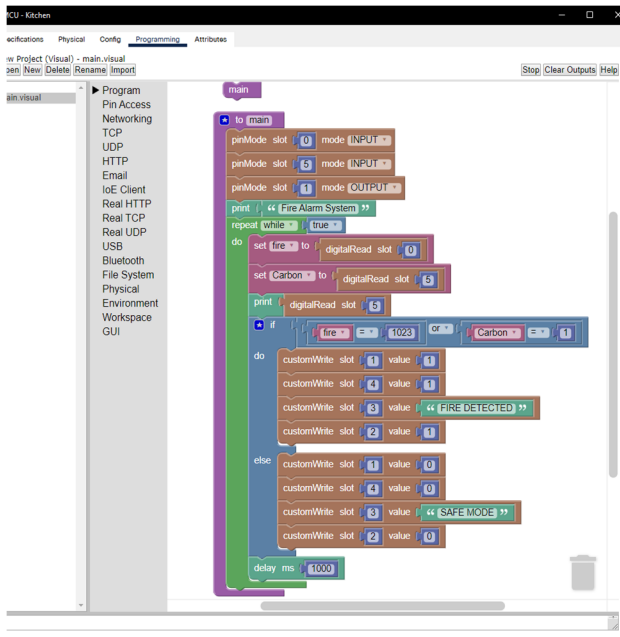

Fig. 8. Smart Ambulance – Blockly Programming

- **Smart Emergency Entrance:** This system warns users when the trip wire is activated to open the emergency door. This is also equipped with safety devices like fire sprinkler, monoxide monitor, and smoke sensor. The Blockly program for the sensors and actuators can be seen in Figure 9.

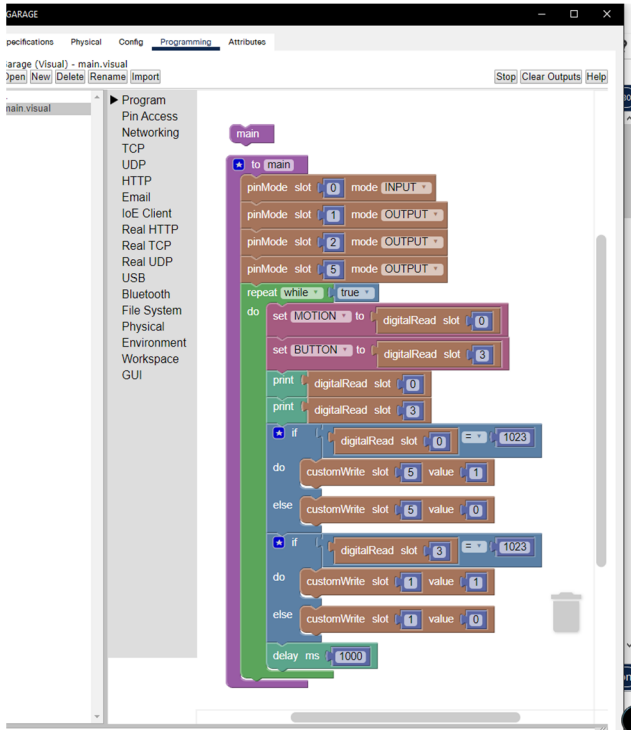

Fig. 9. Smart Emergency Entrance – Blockly Programmed

- **Smart Hospital:** Includes a trip wire as input and light and fan as output. When motion is detected, the light and fan turn on. This also includes an alarm, temperature

sensor, and temperature monitor for viewing. Figure 10 shows how the sensors and actuators are programmed with Blockly.

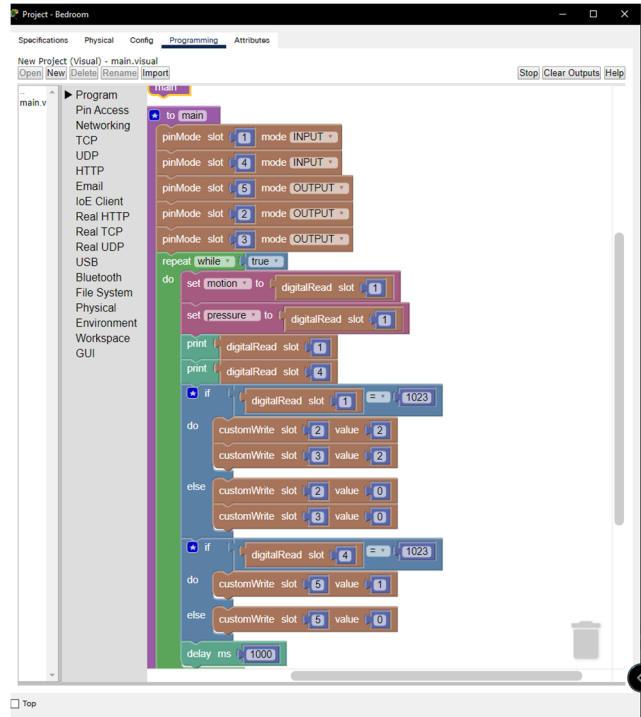

Fig. 10. Smart Bedroom – Blockly Programming

- **Remote-Access IoT Monitor**

Figure 11 shows all IoT devices that may be viewed or controlled remotely from a user PC’s IoT Monitor on Cisco Packet Tracer.

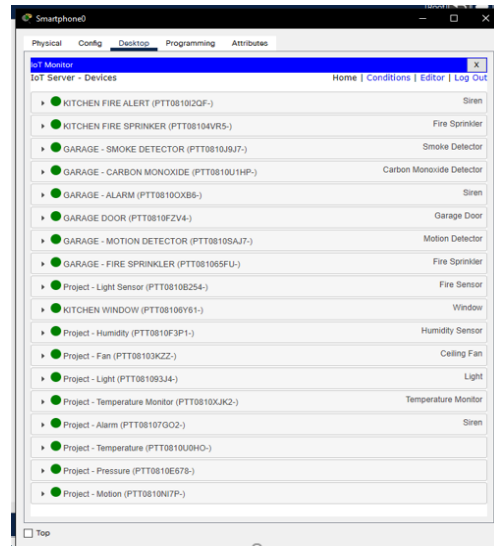

Fig. 11. All IoT devices accessible on the IoT Monitor.

IV. HARDWARE IMPLEMENTATION AND RESULTS

A. MCUs and Sensors

The smart hospital was created into three sections. This includes the smart ambulance, smart hospital, and smart

emergency entrance. These all connect with sensors and actuators and can be remotely controlled from the IoT Monitor.

Fig. 12. MKR1000 microcontroller with built-in WiFi Connectivity

The smart hospital system was implemented using an Arduino MKR1000 board and SparkFun OBD II. Sensors and actuators from the Grove Starter Kit for Seeed Studio BeagleBone® Green were used to monitor the various functions. These will be used to monitor the data remotely from the smart hospital.

B. *Arduino IoT Cloud*

The Arduino IoT cloud is a platform for creating Internet of Things (IoT) devices with Arduino and other microcontrollers. The Arduino IoT Cloud allows you to develop your own IoT devices using your existing Arduino skills. To make advantage of the cloud, you'll need to first learn some of its vocabulary. The "Thing" is the foundation of all Arduino IoT Cloud projects. The term "Thing" refers to a cloud-based virtual item. It is used to store variables and information about linked devices and networks in a safe manner. This needs a network connection details to the Thing. This will be the WiFi credentials, SSID, and password for most devices. Microcontrollers that link to the cloud are known as devices. It's likely that they are Arduino microcontrollers [4].

V. CONCLUSION

This paper provides a detailed explanation of an IoT-based smart hospital simulation. In this IoT system, an Arduino MKR1000 is utilized, with sensors connected to the OBD II port. In order to save as many lives as possible, today's hospitals are equipped with cutting-edge technology. One element is lacking from the hospital: IoT-based

communication between vehicles like ambulances and nearby hospitals. The internet will be accessed via WiFi or cellphone data. The smart hospital will employ these sensors to provide real-time patient data to other hospitals at the same time. EMTs might assess the situation and reduce the time it takes doctors to begin treating patients once they arrive. The internet will be accessed through WiFi and these sensors will be used by the smart hospital. The sensors are directly connected to the MKR1000. The MKR1000 has been calibrated to operate with all sensor data. The MKR1000 uses WiFi to send the data to the internet. This sends the data to the Arduino IoT Cloud through the internet. The data is subsequently transferred to the cloud, where IoT Analytics processes it. Before the data is uploaded to the Arduino IoT Remote, IoT Analytics examines it. This is the App component of the IoT system. Because it focuses just on the "Thing's" readings rather than all the Serial.prints and other units, the Arduino Dashboard is included in the IoT Analytics. This is a way of processing data so that graphs and gauges may be shown to monitor the patient remotely prior to arriving at the hospital.

Abstract— The Internet of Things (IoT) and Industrial Internet of Things (IIoT) are integrated systems that combine software and physical components. These integrated systems have experienced rapid growth over the past decade, from fields as disparate as telemedicine, smart manufacturing, autonomous vehicles, industrial control systems, smart power grids, remote laboratory environments, and many more. As IIoT becomes increasingly ubiquitous throughout supply chains, malicious attacks by hostile actors have grown exponentially in recent years. Attacks on critical national infrastructure (CNI) such as oil pipelines or electrical power grids have become commonplace, as increased connectivity to the public internet increases the attack surface of IIoT. This paper presents a review of the current academic literature describing the state of the art of the use of simulated environments and testbeds in the system development life cycle for IIoT environments, with a focus on the use of simulators for rapid iteration of security validation tests during the development process. As a new contribution, this paper also identifies outstanding challenges in the field, and maps selected challenges to potential solutions and/or opportunities for further research.

Keywords— *IoT Simulator, IIoT Testbed, Cyber-Physical Systems Design, Industry 4.0, IoT Cyber Range*

I. INTRODUCTION

The Industrial Internet of Things (IIoT) is comprised of integrated systems that combine software and physical components. IIoT systems have experienced exponential growth over the past decade, from fields as disparate as telemedicine, smart manufacturing, autonomous vehicles, industrial control systems, smart power grids, remote laboratory environments, and many more.

This research has been funded by the SUDOE Interreg Program -grant INUNDATIO-, by the Spanish Ministry of Economics and Industry, grant PID2020-112726RB-I00, by the Spanish Research Agency (AEI, Spain) under grant agreement RED2018-102312-T (IA-Biomed), and by the Ministry of Science and Innovation under CERVERA Excellence Network project CER-20211003 (IBERUS) and Missions Science and Innovation project MIG-20211008 (INMERBOT). Also, by Principado de Asturias, grant SV-PA-21-AYUD/2021/50994.

Academia tends to use the term Cyber-Physical System (CPS), while industry tends to use Internet of Things (IoT) for consumer-grade devices, and IIoT for industrial control systems (manufacturing, process control, etc.).

The consumer-focused IoT industry was born in an age when ubiquitous connectivity to an increasingly hostile Internet was assumed, which helped drive adoption of standardized communication protocols around TCP/IP, with integrated authentication and encryption functionality designed for the lightweight messaging protocols of devices assumed to have constrained processing power, battery life, and unreliable network connectivity.

However, the IIoT systems that are driving Industry 4.0 have product lifecycles measured in years or decades, and the historical design assumptions of operating in a fully trusted and air-gapped isolated environment, the traditional Industrial Control Systems (ICS) are much slower to adopt new technologies than their more agile counterparts in consumer-focused IoT devices that have product lifecycles measured in months to a few years.

This disparity in product lifecycles, as well as design considerations for life safety issues in IIoT design, has resulted in the consumer-focused IoT industry diverging from their IIoT counterparts. This paper focuses on the issues related to the design lifecycle of IIoT systems, with a focus on the use of simulators and testbed environments as a tool for non-destructive testing and validation of life safety and information security issues. In a typical corporate computer network, it is common to have a production environment that runs the organization, plus a parallel dev/test environment for testing changes and upgrades. However, dev/test environments are less common for IIoT systems, due to the expense and complexity of maintaining a parallel version of all the physical components in the IIoT system [1].

This fundamental difference in Information Technology (IT) networks and Operational Technology (OT) networks was largely ignored for decades, as OT networks were typically air-gapped from IT networks for reliability and availability reasons. However, Industry 4.0 has driven the merging of IT and OT networks, also commonly known as CPS or IIoT, exposing fundamental shortcomings in safely interconnecting IT and OT networks.

To address this issue, a number of simulation platforms [2-10] that have been developed specifically for researchers and practitioners to be able to test different facets of the IIoT system in an isolated non-production environment, which alleviates significant expense and life safety issues that could result from testing on a live system.

A common use case for a simulated IIoT systems environment is vulnerability assessments, which can involve potentially disruptive activities such as input fuzzing, man-in-the-middle (MitM) attacks, DDoS, false data injection, etc. Such activities performed on a live CPS may have significant financial and/or life safety consequences, which makes simulated environments attractive for testing [11]. Another common use case is for non-disruptive user training in a simulated environment, either on a parallel virtualized IIoT, or through the use of AR/VR (Augmented Reality / Virtual Reality) simulations.

Simulated or test environments are commonplace in software-only environments, due to widespread availability of server virtualization technologies than can inexpensively simulate large networks and applications. However, since IIoT environments are often customized and unique combinations of cyber and physical devices, a universal testbed or simulator has proved elusive, due to the myriad of hardware sensors and actuators in the marketplace.

II. LITERATURE ANALYSIS / RELATED WORK

Two of the commonly recurring themes in the available literature are the extreme heterogeneity of IIoT systems, and the lack of a formalized design methodology, leading to “reinventing the wheel”, which adds time and expense to the system development process. The use of simulators or testbeds during the IIoT development process can help minimize these costs, leading to shorter time to market and more robust designs.

Poudel et al [12] developed a simulator for smart power grids that focuses on testing overall grid reliability in the face of physical attacks on power lines and electrical transformers in a smart grid. Smart power grids are designed to be fault tolerant to environmental hazards such as lightning strikes, trees falling on power lines, vehicles striking transformers, etc. However, real-world testing on a power grid has significant economic and life safety consequences, making a simulated environment very attractive. There are various hardware vendors that serve the power grid industry with their own unique and proprietary sensors and actuators, so this simulator is valid only for testing very specific hardware environments.

The RITICS (Research Institute in Trustworthy Inter-connected Cyber-physical Systems) organization [13] is perhaps the leader in academic research in this area, a consortium of universities and industry partners that collaboratively develop simulators and testbeds for a broad range of CPS, with a focus on Industrial Control Networks (ICS), and their interactions with external corporate networks and the public internet.

RITICS has a particular focus on developing simulated environments with a high level of fidelity to the real-world system being emulated, as well as repeatability and accuracy of

test runs. This high degree of fidelity to the real-world counterpart leads to higher levels of confidence in the simulator as being reflective of the real world, which is often lacking in other implementations.

Wlazo et al [14] discuss the challenges of detecting man-in-the-middle (MitM) attacks in IIoT smart grid environments, which can allow malicious actors to create false data injection (FDI) and false command injection (FCI) to compromise the stability of the power grid. This research focus primarily on network traffic, which allows a large-scale emulated smart grid to run on virtualized hardware at low cost with high observability. While the use of an easily observable emulated environment did allow the researchers to use an off-the-shelf Intrusion Detection System (IDS) to detect MitM attacks, it suffered from poor accuracy in real-world environments, so has met with limited interest from industry.

Ani et al [15] developed a mapping framework for design considerations for building credible testbeds for IIoT / ICS environments, with specific focus on how effective design considerations for testbeds make possible the modeling and simulation of cybersecurity testing and physically destructive testing that is infeasible for financial or life safety issues on real-world IIoT systems. A key issue in testbed development is the credibility or confidence level that the testbed environment is an accurate simulation of the real environment, which is affected by trade-offs between fidelity of the testbed design and implementation costs, as well as the observability of the testbed environment during simulation tests.

Negi et al [16] performed case studies on several high-profile cybersecurity incidents that compromised IIoT environments running CNI, and how the use of testbeds to perform non-disruptive vulnerability assessments could have been used to mitigate the risks that lead to system compromises. Operators of CNI or IIoT systems are hesitant to perform Vulnerability Assessment and/or Penetration Testing (VAPT) on their own systems due to fear of disruption performance impact. Continuous availability has long been the primary goal of the operators of IIoT, which leads to a general avoidance of VAPT on live IIoT systems. Negi et al developed a testbed for a smart power grid comprised of a wide variety of heterogeneous physical equipment, with minimal use of virtualization or simulation to increase real-world fidelity, although on a smaller scale than a typical smart power grid. Through extensive VAPT, Negi et al were able to discover multiple communication protocol vulnerabilities that could be used to perform false data injection attacks on the power grid. These risks were then able to be mitigated on the live IIoT systems without disruptive testing.

Green et al [17] propose a high level model that defines a baseline for IIoT / ICS testbed development, utilizing the Purdue Enterprise Reference Architecture [18] to segment the IT/OT networks into four zones. The Safety Zone is for managing safety functions, the Control Zone for operational processes, the DeMilitarised Zone is a buffer between the Control Zone and Enterprise Zone, and the Enterprise Zone is the corporate IT network. This model encourages formal design specifications that forbid inputs from a lower-security zone being used in a higher-security zone, allowing a formal proof of the design, and eases real-world administration through the use of zone-based

firewalls to control access. This model has proven popular with academics due to its simplicity in generating formal proofs, but has received limited adoption in industry due to lack of fidelity with real-world environments.

III. SELECTED CHALLENGES

The field of IIoT is still quite young, but grew out of older industries such as cybernetics, industrial process control, and control logic. The rapid adoption of Industry 4.0 practices has grown in leaps and bounds over the past few decades, largely mirroring advancements in microprocessor technology, and the increased availability of high-speed wired and wireless networks. Due to rapid rate of change, IIoT has a number of outstanding challenges, a selection of which are described below.

Rapid obsolescence: The more modern consumer-focused IoT industry has been quicker to adopt a zero-trust model of information security, accepting the reality that they operate in a potentially hostile network environment, and embedding strong authentication and encryption protocols by default. Unfortunately, the rapid advancement of IoT means that product lifecycles are very short [19], making devices become obsolete quickly, leaving many “orphaned” devices without ongoing vendor support or upgrades to counter new security threats. While some vendors have included functionality for receiving trusted over-the-air updates to counter newly discovered threats, there are many IoT devices that entirely lack any sort of update functionality, leaving them permanently vulnerable to emerging threats.

Low quality research datasets: Another significant challenge is the availability of accurate and meaningful datasets from real-world environments. Conti et al [20] discuss the ongoing research challenge of obtaining useful datasets from IIoT systems for the testing of research questions. Due to privacy concerns, private industry and governmental organizations are reluctant to provide datasets from their own IIoT environments due to fears of inadvertent vulnerability disclosure and/or loss of competitive advantage in the marketplace. Most of the datasets currently being used for testbed validation have been generated by researchers in simulated environments, so have varying degrees of fidelity to real-world environments, which leads to less than optimal research outcomes. The use of honeynets [21-24] is a specialized use case for testbeds that are particularly useful for generating real-world data for research datasets for intrusion detection and AI modeling of threat detection.

Roblez-Durazno et al [25] recognize the lack of availability of accurate research datasets, and propose a hybrid testbed architecture that combines fully simulated testbeds with small-scale physical components to achieve greater fidelity to real-world environments as a means to obtain higher quality datasets for research. A fully virtualized or simulated testbed is attractive to academic researchers due to the low cost and ease of acquisition, but lacks real-world fidelity due to timing and performance inconsistencies introduced by the virtualization layer. Conversely, fully physical testbeds have greater fidelity to real-world environments, but are prohibitively expensive to

build at scale. By combining virtual and scaled-down physical testbeds into a hybrid model, more accurate testing of physical conditions such as vibration and temperature extremes can be more accurately tested, while the communication layer can take advantage of virtualization to minimize costs. A hybrid testbed will always be a trade-off between cost and real-world fidelity, which makes the development of an accurate model an ongoing challenge for researchers. Although wide variation exists across different testbeds, a common hybrid model will virtualize the sensor and actuator components to allow for flexible manipulation during experimentation, while using physical components for items such as Programmable Logic Controllers (PLC) and Human-Machine Interfaces (HMI) to achieve higher fidelity with real-world systems. Virtualization of the sensors and actuators in a testbed is particularly attractive to researchers, as it simplifies cybersecurity testing and validation early in the IIoT development life cycle, by providing visibility into network-based attacks such as ARP spoofing, MiTM, input fuzzing, password spraying, denial of service, etc. As OT networks are increasingly connected to IT networks, these network-based attacks have become more common, making cybersecurity testing increasingly important in the early phases of the IIoT development cycle.

Duplication of effort: Due to the extreme heterogeneity of IIoT systems, the case studies in this area are particularly interesting due to their extreme differences. The case studies [2-10] cover systems ranging from water treatment plants, oil pipelines, autonomous vehicles, power grids, and more. While this extreme heterogeneity makes the field ripe with different research opportunities, the lack of a common design framework or standardized communication protocols makes it difficult to leverage prior research and industry expertise to drive forward the current state of the art. In other words, the extreme heterogeneity tends to result in duplication of effort across both academia and industry, which slows advancement in the field.

Immature design models: Eckhart et al [26] recognizes that the software engineering discipline has a well-defined methodology for including security requirements in the earliest stages of the system development lifecycle, and that due to historical assumptions about operating on an isolated and trusted network, security was often ignored in ICS / SCADA networks. Eckhart et al propose a novel method of adopting similar techniques for security designs for CPS, referred to as Security Development Lifecycle for Cyber-Physical Production Systems (SDL-CPPS).

Rehman and Gruhn [27] build on the concepts of the SDL-CPPS, by developing a security requirements engineering framework for CPS that is designed to overcome the challenges of the highly heterogeneous nature of CPS with a unified general model, recognizing that fixing security issues in later stages of the system development lifecycle can increase costs exponentially.

Lack of consensus on best practices: Popisil et al [28] build on the work of Roblez-Durazno by developing a framework of best practices for the development of physical, simulated, virtual, and hybrid testbeds. Recognizing the extreme heterogeneity of IIoT environments, Popisil et al recognize the need for unique and custom testbeds to ensure fidelity to the

real-world system being tested, and therefore recommends against a generalized or universal model for accuracy reasons. This makes the datasets generated highly accurate for researchers to perform functional tests, intrusion detection, and training of AI models on that specific environment, but those datasets are of limited use to the greater research community due to their specialized nature. Further distinction is made by defining four categories of testbed, each of which has different intended audiences and objectives. The first testbed category is for cybersecurity analysis, which emphasizes network virtualization to simplify intrusion detection testing and forensic analysis of network-based attacks. The second category is testbeds designed for educational purposes, with emphasis on training students or operators in the day-to-day operations of the real-world system. The third category is testbeds designed for functional and performance testing, so will necessarily have more physical components than the other categories to ensure real-world fidelity, although at a scaled-down size. The final category is testbeds designed for standards development, with an emphasis on research and development of industry standards. Each category is sufficiently differentiated to provide value to its intended use case, making the added complexity of maintaining multiple custom testbed environments a worthwhile endeavour for both academia and industry.

Lack of standard reference architecture: Craggs et al [18] take the opposite approach of Popisil, aiming to develop a generalized reference architecture for IIoT testbeds, focusing on a highly virtualized environment used for cybersecurity testing. Little attention is given to the testbed fidelity with real-world systems, with the emphasis on development of a standardized approach for performing vulnerability analysis, generation of datasets for AI modeling, and big data analytics. While this approach provides value specifically for improving intrusion detection capabilities in IIoT, the lack of focus on real-world fidelity will limit industry adoption outside of the research community.

IV. CONCLUSIONS

As a relatively young (since 2006) field of study, the system development life cycle for IIoT environments is still maturing, with limited consensus for industry best practice or formal development methodologies. Due to historical design requirements inherited from legacy industrial control systems, IIoT environments typically place high priority on reliability and availability, but will often intentionally exclude even the most basic cybersecurity protections, due to historical assumptions of the IIoT environment being located on a fully isolated and trusted network. As IT and OT networks are joined together, these historical assumptions no longer hold true, resulting in cybersecurity measures being added to IIoT environments too late in the system development process, resulting in higher costs and lower effectiveness, resulting in the increasingly common compromise of IIoT environments from malicious actors.

Improved simulators: The use of simulated environments or testbeds for IIoT systems shows much promise for deeper integration of cybersecurity validation early in the system development life cycle, but is still hampered by the relative immaturity of IIoT testbeds, particularly relating to the fidelity

of a testbed environment when compared to the real-world system. Improvements in virtualization technology have helped simulated environments gain closer fidelity to their real-world counterparts, but the extreme heterogeneity of IIoT environments had made accurate simulation an elusive target.

Regulatory collaboration: The increasing frequency of state-sponsored attacks on CNI have created an urgency to developing more robust IIoT environments, leading to multiple governments to enact legislative requirements for minimal acceptable cybersecurity standards for CNI. The most widely recognized is the Cybersecurity in the EU Common Security and Defence Policy (CSDP) [29]. All EU member states agreed in principle to this common cybersecurity standard in 2016, but as of 2022, the process of integration into each member state sovereign legislation was still underway. This has resulted in inconsistent application of cybersecurity postures for CNI across national borders due to bureaucratic friction. Outside of EU member states, the UK and NATO have also agreed in principle to the CSDP, but have not enshrined those policy standards into law. While this cooperation is admirable in the face of shared threats from state-sponsored adversaries, there is considerable opportunity for accelerating the timeline for implementation.

Academia / industry collaboration: Opportunities for further development include increased collaboration between academia and industry, towards the development of a more formalized methodology for the end-to-end system development life cycle of IIoT, with a focus on increased use of standardized communication protocols and observability metrics to encourage a common testbed environment that can provide high fidelity with a real-world IIoT, allowing for more reliable testing and validation earlier in the system development life cycle.

Higher education: Recognizing a skills gap in cybersecurity skills for CNI / IIoT environments, Kamsanrong et al [30] recommends development of curricula for higher education to prepare students for the cybersecurity needs of industry controlling critical infrastructure. With stakeholders throughout the EU, Erasmus+ is an academic consortium performing fundamental research into solutions to the cyber skills gap for CNI, in collaboration with government and industry. Testbeds are a significant part of driving education to address this skills gap, and Erasmus+ develops both physical and virtual testbeds with a design objective of pedagogical instruction and curriculum development. This is one of the few organizations focused directly on raising the minimum acceptable standard of CNI security through educational development, and shows great promise for future development.

Abstract—Image captioning aims to make a textual short explanation of a given image. Despite the fact that it looks to be a straightforward task for human being, it is difficult for computers since it involves the ability to analyze the image and provide a human-like description. Encoder-decoder architectures have recently reached advanced outcomes in the form of picture captioning. With some existing datasets, e.g., Flickr_data, Flickr8k_token.txt, and heritage dataset, we build our model that can create captions from the images related to Bangladeshi culture, tradition and historical places. Bangladesh is enriched with great culture; many heritage places and cultural programs that attract travelers to visit our country. We try to relate our culture, place, and food, together with machine learning techniques by appropriate captioning and spread over our cultural strengths through proper captioning. Our image captioning tool can be very helpful for travel lovers who want to know more about Bangladesh.

Keywords—Encoder-decoder, datasets, LSTM, CNN, RNNs, ResNet-50, tensorflow & keras, RNN.

I. INTRODUCTION

Natural beauty is the key for rich lands in Bangladesh. There are many other natural features like rivers, beaches, hills, waterfalls etc. Some of our world heritage sites are Sundarban, Bagerhat's Historic Mosque, Ruins of the Buddhist Vihara at Paharpur. Many local and international tourists visit the mentioned locations to admire the natural beauty. However, due to some obstacles Bangladesh has been unable to establish itself as a tourism destination. By keeping that in mind, this paper empirically focuses on unleashing the natural beauty of Bangladesh among travelers using image captioning.

A. Background and Motivation

In our daily lives, images are pretty important. They are in people's homes, on the streets, on their jobs, and even in the internet. Stop signs in the street, artwork at the Louver museum hung behind protective glass, or

modified photos for enjoyment are accessible online. Regardless of their intended use, all photographs serve the same purpose: to communicate [1]. We want people worldwide to know about our country and its tradition, culture, and daily life, which worked as our motivation.

B. Study objective & Aspiration

Image captioning is known as the task of producing written explanations for photos. The earliest and most fundamental methodologies in picture captioning are pattern recognition based image labeling and framework-based captioning. There is a database of information in the system which has photographs and their accompanying captions or descriptions using this way. Before tying those concepts to a specified sentence template and proceeding, the system examines an image for visual ideas. This method still has a rigorous selection of words for photos with similar visual notions and minimal variability even after producing a more appropriate description method. It has proven that deep neural network-based approaches receive extraordinary outcomes on image captioning problems when large datasets are open. These methods depend laboriously on recurrent neural nets (stands for RNNs) and are powered often by a Long-Short-Term-Memory (stands for LSTM) segment [2,3].

This study experiments with the help of image captioning using TensorFlow, resnet, and flask based on the discussion above. We provided a complete assessment of the tourism industry's perspective using image captioning algorithms. In this paper, we looked at various existing raw image captioning techniques to see how they create new captions for unseen photos. We also compared and provided the results of our implementation of these models.

C. Cognitive Challenges

Extra layers are sometimes added in CNNs (for convolutional neural networks) to take care of challenges found in computer vision. These extra coatings support

the faster explanation of complex issues since the separate layers can be qualified for additional jobs to create accurate outcomes.

A deeper network can indicate the degradation issue, while the number of stacked layers might improve the model's qualities. If we put it in another way, as the number of layers in a neural network increases, the precision levels may become soaked and slowly decrease. Consequently, the model's performance spoils both training and testing data. Overfitting may not be the reason for this degeneration. It may be due to the network's initialization, optimization algorithm, or, more crucially, the problem of vanishing or ballooning slopes.

II. RELATED WORKS

Recently, encoder-decoder models for image captioning have been intensively investigated [4-12]. In its most raw version, the input image gets into the vector representation with the help of a CNN converter, and after that, the starting input gets into an RRN. The following word in the caption is speculated by RNN rooting on the preceding word without needing the secular vulnerability to be constricted to a pre-decided order, as n-gram methods do. In different ways the CNN image representation can be sent into RNN. A number of researchers [6, 10] compute the RNN's initial state, whereas others [5, 8] use that in every RNN repetition.

Attention-based image captioning was first suggested by Xu et al. [11]. The visual display of an image region incorporated by RNN position improvement. With RNN's starting state the picture region gets attended to. A rounded fusion of several area descriptors was presented, as well as a "hard" variant that uses only one region, which is used by a "soft" modification. Although one runs quite well, it is much harder to train and that to anti sampling procedure inside the condition update. The loci of attention in their method are locations in a convolutional CNN layer's activated grid. Each site is represented by the activation column that corresponds to it throughout the layer's channels.

Recently, there has been a lot of research into automatic image captioning. The research is divided into major categories: template-based, retrieval-based, and ways for creating original photo captions.

The goal of the template-based approach is to produce captions from preset templates with various blank areas. After recognizing the various objects, features, and actions, the empty spaces are filled. For example, in [13] a triplet of scene elements was used to fill the template slots in constructing image descriptions [13]. Li et al. [14] achieve this by extracting phrases relevant to specified objects. Kulkarni et al. [15] use a conditional random field (CRF) approach to infer the objects, characteristics, and prepositions. Template-based solutions can produce grammatically correct captions.

On the other hand, templates are preset, and description length cannot be modified.

The retrieval-based strategy seeks to generate a picture description by selecting the most conceptually comparable phrases from a phrase pool or duplicating terms from those other visibly similar pictures. For instance, Gong et al. [16] built visual descriptions from millions of badly labeled photos using a stacked auxiliary embedding method. Ordonez et al. [17] used the Flickr database to locate similar images in the millions of photographs and their associated descriptions, then returned the explanations of these extracted features to the query. Sun and his colleagues [18] grouped similar phrases and photos together first, then used captions from similar images in the same group to generate captions for image features. Hodosh and his associates [19] created a ranking-based framework for using sentence-based image descriptions as an information source. The authors in [19] developed a system that treats sentence-based picture description as a ranking of a set of captions for each test image. These techniques generate captions that are both general and syntactically correct. Creating image-specific and semantically appropriate captions, on the other hand, is difficult for them.

In contrast to the other two categories, novel caption creation methodologies rely heavily on deep learning and machine understanding to develop unique captions. This method is often implemented by analyzing the picture's visible information and utilizing a speech example to create picture captions from the optical material. Vinyals et al. [20], used CNN to generate the description sentence as an encoder for picture variety and LSTM as a decoder. Karpathy et al. investigated creating a natural language image description [21]. Their strategy looked for an intermodal link between the words in the description and the visual data in picture datasets with natural language descriptions. The first method aligns sentence fragments to visible places before combining them into a single description using multimodal embedding. A second recurrent neural network model is trained to construct captions using this description as training data. Xu and his associates used a convolutional neural network to extract feature maps, and an LSTM was used to characterize the input image with already extracted feature maps [22].

So, following the footsteps of these works, we implemented our image captioning project and tried to uphold the Bangladeshi culture in front of the world through images and appropriate captions. We try to use all the techniques of related works and set our dataset according to Bangladeshi heritage pictures, and try to generate the nearest possible captions in terms of many methods which we mentioned earlier [23-25].

III. RESEARCH PLAN

We develop our image captioning model by blending structures. It is also known as the RNN - CNN model. The CNN algorithm pulls features and all from a photo. We will use CNN information to help create an image caption by using the pre-trained model. Figure 1 describes it.

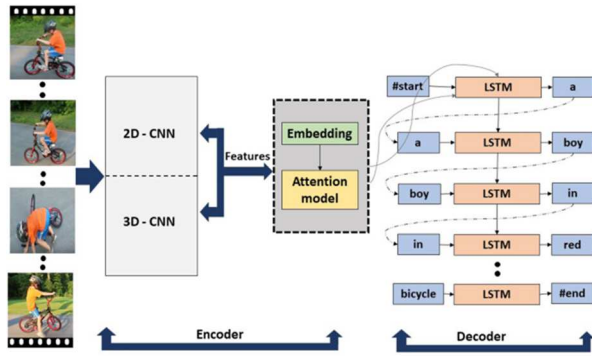

Figure 1: RNN-CNN Model [30]

We use the ResNet50 convolutional neural network (CNN), a profound network with 50 layers, to represent the image. For neural networks, web depth is critical, yet more in-depth networks are more challenging to train. ResNet50's topology facilitates network training and allows considerably more profound training, resulting in improved performance in various stirs. ResNet50 is not only more complicated than its "simple" contenders, but it also has a lesser number of parameters (weights). Consider the table below, which shows how many parameter comparisons VGG16 and ResNet-50 have. New evidence shows network depth is quite essential (Table 1).

CNN	Number of parameters
VGG16	138,357,544
ResNet50	23,587,712

Table 1: The entire number of VGG16 and ResNet50 parameters are compared.

The accuracy of networks proliferates as network deepness increases, unsurprising, and then swiftly diminishes (saturated). Overfitting does not cause this decline, and adding even more coatings increases the error of learning. ResNet50 may quickly obtain a deeper model that is comparable to the less deep network. It works by employing categories rather than layers to bypass the incoming signal without modifying it. ResNet50's higher levels must forecast the difference

between preceding layers' output and the objective function. They might simply skip the transmission by setting the scales to zero. Deep residual learning teaches the network to forecast divergences from past layers as a result.

IV. STUDY AREA

Our project target is studying the concepts of a CNN and LSTM model and then implementing the concepts of CNN and LSTM to develop a workable prototype of an image caption generator.

We will use CNN (Convolutional Neural Networks) and LSTM to construct the caption generator in this Python project. The image attributes are from Xception, a model with convolutional neural networks prepared on the flickr image dataset which is of course an imagenet database and then provided into the model which is LSTM and that's how the image illustrations will be generated [26].

Representing an image in 2D matrix is easy and CNN can do that as it is a neural web which is a type of in-depth web. Fig.2 describes it.

Mainly convolutional neural networks are used to identify the representation of an image, let us say it identifies if the image is a sky, water, living creatures etc. [26].

Figure 2: CNN Architecture [31]

For arranging/managing prediction challenges LSTM is being used. We can assume what the following word will be based on the prior section. It has transcended standard RNNs to overcome the constraints of RNNs with short-term memory. The LSTM may fetch out suitable data throughout the processing of intakes, and it can scrap non-related data using a forget gate [26].

This is how an LSTM cell appears [Fig.3]

Figure 3: LSTM [32]

TensorFlow is a line-to-line, open-source machine learning platform; for differentiable programming it's a framework coating. It combines four crucial skills: Low-level tensor operations on the CPU, GPU, or TPU are efficiently performed, calculating the growth of differentiable words at every given time, extending estimate to many machines, such as clumps of hundreds of GPUs, and shipping programs ("graphs") to servers and other external scripts, portable, browsers and inserted gadgets.

Keras: It is a high level API of tensorflow. It is an obliging, greatly-rich ally for decoding ML (machine learning) states, focusing on modern deep learning. It furnishes fundamental conceptions and formation unions to create and send machine-learning solutions with increased iteration momentum.

Keras designates architects and experimenters to benefit from TensorFlow's scalability and cross-platform abilities fully; Both on TPU and large groups of GPUs keras can be executed, and our keras patterns can be exported in order to carry out in both browsers and on a movable gadget[27].

ResNet-50 [28] is a 50-layer deep CNN. It is a pre-trained edition of the network which was trained on more than a million images that can be imported from the ImageNet database. It can classify objects into 1000 different categories. ResNet's variants operate on the identical vision but have distinct digits of coatings. 50 neural network layers can be identified by ResNet50 . [28].

Keras is a popular deep learning API because of how simple it is to create prototypes using it. Keras comes with a number of pre-trained prototypes, such as Resnet50, that can be used in experiments by anyone.

Creating a remaining network in Keras for computer image applications makes image categorization astonishingly simple. Essential steps to follow are described below:

#1: We must preferably run a code to define the essential blocks for modifying the convolutional neural networks into a remaining network and evolve the convolution coalition.

#2: By mixing both blocks we can build a 50 layer resnet model.

#3: Eventually, we must design the task's model. Keras assembles it simply to make a comprehensive summary of the web architecture we have created. For future use, this can be saved or printed [28].

V. DATA COLLECTION & PREPARATION

Datasets are groups of interconnected, separate parts of data that can be observed singly or together or handled as an individual unit.

Datasets are organized in a way where one can read the data easily and understand it. For example, for a car database there will be several rows and columns which will carry different entities, such as, car name, car model, engine model, horsepower etc. [29].

In our dataset, we picked the Flickr 8k dataset, where there are approximately 8k+ pictures and 40k+ captions. We have five different captions for each picture. So, there are two folders in our Flickr 8k dataset. Mainly the name is Flickr_Data. If we go inside that folder, we will see two more folders, and their names are Flickr_TextData & Images. In the folder Flickr_TextData, we are only using the file named Flickr_8k.token.txt as our captions for the images. If we open that file, we will see all the pictures with unique codes, and each picture has five captions. So basically, the images are not named randomly. These pictures are in perspective of Bangladesh Heritage. They are named according to a code name. They maintain a serial, and we can notice that if we look at the images in our dataset. We have used 1500 images to train our model due to memory issues.

VI. METHODOLOGY : LANGUAGE BASED MODEL

Image captioning is split into two components: an image-based sample that pulls the features and subtlety from our image and a linguistic/language model that transforms the elements and entities extracted by our image-based model into a meaningful phrase.

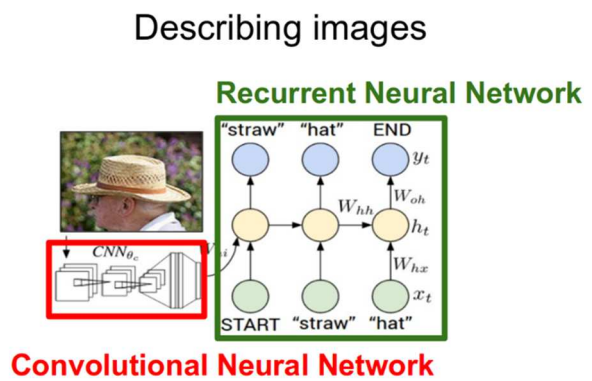

Figure 4: Image Description from [32]

In most cases, pre-trained CNN features are derived from our input data. The RNN/LSTM network's input dimension is continuously transformed to a particular dimension as the feature vector. We establish our label and target text before we train our LSTM model. This is done to ensure that our model recognizes the beginning

and conclusion of our labeled sequence [30]. By following the technique, we implement our Bangladeshi cultural and heritage dataset and train them to get the maximum value.

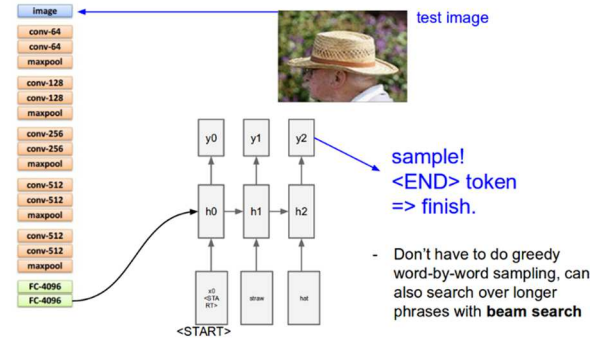

Figure 5: Machine Understanding Label Sequence [33]

VII. EXPERIMENT SETUP

A. Software Requirements

- VS code (Visual Studio)
- Jupyter Notebook

B. Model Train

First, we must import numpy, pandas, cv2, os, and glob, which are all straightforward imports. They will only be used to read and alter pictures. Then, using glob, we read the photos from our specified directory, only reading the .jpg image format. After that, we used matplotlib to display some image samples. Then we specified include_top=True and imported the resnet-50 model from keras. The input size is 224×224 , and the output size is 1000 classes, according to our model summary. This means it must anticipate 1000 different classes. The dense layer was then eliminated, allowing us to use avg pool as our final layer. After deleting the last layer, we built a new model called 'modele.' After that, we can observe that the size of our last output layer has increased to 2048. After that, we preprocessed our photos. We used the resnet model for all of our photos. We constructed an 'images feature' dictionary in which we preprocessed our images by iterating image names, values, and changing colors so that our machine could read them simply. Then, while preprocessing, we made sure that our image size was reduced. We used 1500 photos to help us improve our memory. We reshaped our image to make it easier for resnet to edit it, and we shrunk it down to 224 by 224 pixels. There are three color channels in total. The image is then altered one more time before being output as a 2048-pixel output.

The subtitles for the photographs were then pre-processed. To do so, we had to first include the caption path, and then build code to make the captions readable in our IDE. We chopped our caption dictionary so that we did not have to use the entire path name. After that,

we added the 'start of seq' and 'end of seq' strings. After that, vocabulary was added to the captions so that they could be converted into integer numbers. This indicates that the strings have been transformed to integers.

After that, we made three variables. One for storing picture attributes. Another is for holding the previous word, and the last is for holding the expected next word. We constructed a vocab size in which those three factors were used to improve our model training. Then we changed them all to numpy arrays to speed up the processing and ensure that everything works properly.

After that, we built our model and entered that data into it. We used libraries and packages that we imported. As evidenced by its code, it was a good-sized model. Then, before training, we plotted our model. Then we put our model through 150 epochs of training. The training took us nearly a day and a half to finish. Then we used the model to make predictions in which value was a key and key was a value. After that, we titled our weight files 'mine model weights.h5' and 'model.h5.' 'mine vocab.npy' was the name of the vocabulary file we used for our caption.

Verification

Unlike other machine learning assurance pipelines, in this case we will not guarantee our model against a particular matrix. Instead, we verified our model based on whether it produces the right captions, and, most importantly, whether it paid attention to the relevant features when producing those captions. We achieved this by covering the weight of the matrix of attention produced when we produced captions for a particular image in the image itself. This produced an image with specific areas that indicate what the network was paying attention to while generating captions.

Next Steps

We are trying out models on a different dataset, like the Flickr 8k dataset. We have built a new dataset based on Bangladesh's Cultural Heritage. Though we could not get far due to the lack of a high configuration PC, we did well enough to get a good caption.

C. Implementation to Website

We are creating a webpage using Python and Flask.

Flask is used to develop web applications faster. It has an easy to expand essence.

```
//importing flask
app = Flask(__name__)
def example_code():
```

```
return 'This is a test!'

if __name__ == '__main__':

    app.run()
```

Python, Programming language which allows us to work quickly and blend systems more virtually.

The presented model can be used using an illustrated a user interface that follows association:

- Authorizes the user to operate his or her trained model, choose a picture from the device.
- Generate and show a caption for a current image in the procedure defined in the design.

Numpy, cv2, os, glob, and other imported libraries were installed first. The flask was then fitted. After that, we developed the code for delivering our model's flask. We started with an elementary page for our website and then added other libraries to connect the flask to our model. We constructed captions by applying weight files and the vocab file to the exact pages.

VIII. RESULT & ANALYSIS

We built our model and entered that data into it. We have taken pictures in perspective of Bangladesh Heritage. Our system is described in Fig.6-Fig.9. We used libraries and packages that we imported. As evidenced by its code, it was a good-sized model. Then, before training, we plotted our model. Then we put our model through 150 epochs of training. The training took us nearly a day and a half to finish. Then we used the model to make predictions in which value was a key and key was a value. After that, we titled our weight files'mine model weights.h5' and'model.h5.' 'mine vocab.npy' was the name of the vocabulary file we used for our caption. The model accuracy was almost 89%.

Figure 6: Our website (Image uploading page)

In the figure 6 as we can see a website which is our BD Heritage Image captioning website and that is mainly our homepage where we can upload any picture for captioning.

Figure 7: After Prediction Page

After uploading the image, if we click on the button 'predict caption', it will take a little time and then the caption will be predicted just like in figure 7.

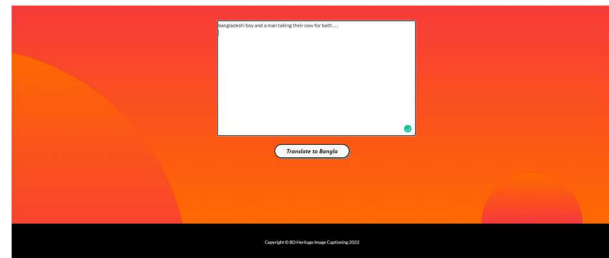

Figure 8: Translation box underneath the prediction

Then we can copy the predicted text and put it in the translation box as shown in figure 8.

Figure 9: Translated caption from the original caption

After pasting the predicted caption if we click on the button 'Translate to Bangla', it will translate the predicted caption to Bangla as shown in figure 9. For the translation part we used Google translator package.

IX. RESEARCH IMPACT

With this work, people worldwide will know more about our country. With that, we can attract more visitors, and they can enjoy the beauty of our county, which will strengthen our economic tourist site. We have gathered different types of Bangladesh heritage pictures from all around the sites. Captioned the pictures in 5 different scenarios.

There are so many places in Bangladesh which are very attractive and can blow anyone's mind with surprise. There are Sundarban, Sixty domed mosque, Paharpur, Shalbon Bihar, Maynamoti, Sonargone, Rangamati, Bandorbon, Cox's bazar etc. Every place has its own history, culture, and stories. If one digs into the history of these places then he can never react normally but be curious to know more about our country. Because that is how amazing Bangladesh's Heritage is!

If we look upon this generation then it's also beneficial towards the toddlers who have not yet got in touch with their motherland's heritage. They have to know and learn because we have to know about our beautiful motherland and therefore not only for the world but for the future generation in our country they have the right too to know everything and represent our country in the future when they will be grown up. So that they can say proudly "That's our country with its tradition and culture".

Figure 10: One of Bangladesh's Historical places

Simply we are having 5 captions for each of our images. So from those five captions we will be having one predicted by the machine and the caption will be set according to the picture as shown in the figure 10. So by this, whatever the picture related to Bangladesh's heritage a person can always get to know about Bangladesh and get curious to know more about the cultures, traditions, places, people, our daily life etc.

Our goal was to have decided to build this application in perspective to Bangladesh, to highlight that progress in machine learning, as there are many image caption sites but none in perspective to Bangladesh cultural domain. Our aim was to model train a full 8k dataset in perspective to Bangladesh culture.

X. CONCLUSION

Image captioning is the procedure of constructing natural language descriptions based on details observed in a picture to describe the situation that we visualize in

any kind of image. We have assembled all of the critical resources, including datasets. Our application had to deal with many issues: such as how we can build a model of predicting our country's heritage, finding good quality pictures related to our heritage, going places and collecting pictures, collecting datasets, editing datasets, increasing accuracy etc. We were able to overcome those obstructions. This program will be beneficial because it has a wide range of applications. We will continue to look at areas to improve our application and make the world know about our country. In the near future we plan to translate the auto generated caption into different languages so that even if someone who is not familiar with the English language can read the captions in their language.

Abstract—In 2018, Indonesia has 14,064 vocational school (SMK) with 14,989 computer laboratories. All these computer laboratories are mainly used to provide students with skill about office tasks, such as word processor, spreadsheet, and presentation, with little addition like programming and design skill. As the emerging trends of electronics especially the IoT, it would be prudent to provide such skill to students to understand how signal and system works. However, many measurement instruments are quite expensive and not affordable for many vocational schools. To answer this problem, this research provides a prototype for measurement instrument to show analog signal on audio band (20Hz-20kHz) that utilize the PC in computer laboratories. To ensure students are all have the same understanding on electronics devices, this research also design a lab guide for student's lab activity. To provide an audio band analog signal measurement instrument, authors use ADC (Analog to Digital Converter) within NodeMCU to create digital oscilloscope and spectrum analyzer.

Keywords—digital oscilloscope, spectrum analyzer, microcontroller, SMK practicum kit, analog audio signal, audio band, NodeMCU

I. INTRODUCTION

Based on the 2018 SMK or Sekolah Menengah Kejuruan (vocational school) Statistics document released by the Ministry of Education and Culture, Secretariat General of the Center for Education and Culture Data and Statistics, in Indonesia there are a total of 14,064 SMKs with a composition of 25.44% with state status and 74.56% private status. In total, all of these SMKs serve 5,009,265 students, with a composition of 43.64% being in State Vocational High Schools and 56.36% in Private Vocational Schools. Of the total number of SMKs available, there are a total of 21,942 laboratories with a composition of 8,284 laboratories at State Vocational High Schools and 13,658 laboratories at private SMKs. Of the total number of 21,942 laboratories, there are 14,989 computer laboratories with a composition of 4,701 computer laboratories at State Vocational High Schools and 10,288 computer laboratories at Private Vocational High Schools [1].

This research provides the development of a computer laboratory in SMK to also be able to provide electronics and IoT labs, and at the same time change the paradigm from a computer laboratory to an IoT laboratory.

The problem raised in this study is the lack of electronic laboratories in vocational schools where students can learn, one of which is about signals and systems that can support the acceleration of technological readiness, which is one of the pillars of development based on the Global Competitiveness Index of the World Economic Forum [2]. It is hoped that from this development, the computer laboratory will not only provide computer lab work, but also electronics and IoT practicums.

One of the measuring tools needed in electronics and IoT practicum is an oscilloscope and spectrum analyzer. Oscilloscopes help students understand the shape of the signal based on the time domain, while spectrum analyzers can help students understand the shape of the signal based on the frequency domain. Unfortunately, the investment price of oscilloscopes and spectrum analyzers is very expensive because they are feature-capable of capturing signals with very high frequencies up to the order of hundreds of Mega Hertz, while for practicum in vocational schools it only requires measuring instruments for the order of tens of kilo Hertz.

With the existence of computer laboratories that are widely available in each SMK, this research provides a solution for the empowerment of these laboratories to also be able to support electronics practicum by making analog signal measuring instruments prototypes in the form of oscilloscopes and spectrum analyzers.

The method used in realizing the proposed solution is through several stages:

1. begins with a market study related to similar devices (competitors) to seek development opportunities both in terms of features and economic value;
2. then proceed with prototype development and testing to prepare it for ready-to-use products.

The objectives of this research are:

1. implementation of a prototype analog signal measuring instrument on the audio band (20Hz - 20kHz) for Electronics and IoT practicum tools in SMK, including digital oscilloscope and spectrum analyzer

- in addition to prototyping, this research also provides a curriculum and syllabus for electronics and IoT practicums that will take advantage of this measuring device.

The research was broke down into 2 (two) stages, the market study stage and prototype development, and the prototype testing phase and its readiness to become ready-to-use products. In the first stage (this research), this research provides output in the form of a prototype device that can provide functions as an oscilloscope measuring device and spectrum analyzer to describe the audio signal to a television screen or monitor. Based on the TRL (Technology Readiness Level) [3], research in this first year includes TRL 2 to TRL 4, which is what is called the Research to Prove Feasibility phase and half of the Technology Development phase.

In the second stage (future research), this research prepares prototypes developed in the first stage to become ready-to-use products. So that the output from this second stage is in the form of prototypes that have been tested for their performance along with packaging design and plans for use in practicum. Based on the TRL (Technology Readiness Level), research in this second stage covers TRL 4 to TRL 6, which is what is called the Technology Development phase and half of the Technology Demonstration phase. Fig. 1 illustrates the relationship between the research plan and TRL.

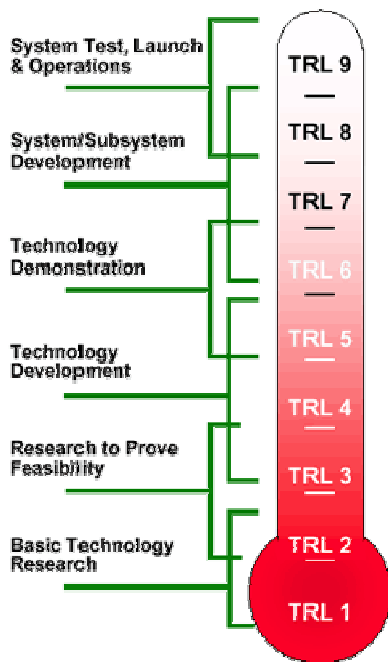

Fig. 1. Technology Readiness Level [3].

In accordance with the Indonesia government program for superior human resources, competence in electronics and IoT is one of the most needed competencies in Indonesia. This competency can be focused on vocational students who are indeed vocational schools so that they can have special skills. Skills in the field of electronics are greatly supported by a structured and applicable practicum with the help of measuring instruments as needed.

Based on the ITSM (IT Service Management) concept in Fig. 2, by definition, urgency is the time it takes for an event to have an impact on business and the environment. Therefore this research has a P2 (Important) level, namely impact =

HIGH because the existence of this measuring instrument affects the HR competence of SMK graduates throughout Indonesia, but urgency = NORMAL because this measuring tool, although it has several advantages such as low investment costs, it can be replaced with another device so that the time lag between the provision of this measuring instrument and the resulting impact is quite long.

		Impact		
		High	Medium	Low
Urgency	Urgent	P1 Critical	P2 Important	P3 Normal
	Normal	P2 Important	P3 Normal	P4 Low

Fig. 2. Relationship of Urgency and Impact (ITSM) [4].

II. RELATED RESEARCH

In his writing, Pereira [5] explained that an oscilloscope is a minimal or basic device that should be available in every electronics laboratory. There are 2 types of oscilloscopes, namely analog oscilloscopes and digital oscilloscopes. Digital oscilloscope itself is divided into 3 types, namely digital storage oscilloscope (DStO) which uses real-time sampling technique, digital sampling oscilloscope (DSaO) which uses time-equivalent sampling technique, and digital phosphor oscilloscope (DPO) which uses image and signal processing techniques. Pereira also explained that an oscilloscope has 5 main functions:

- Acquisition of electric input signal
- Signal conditioning (amplification or attenuation)
- Synchronization for a stable representation of the signal on the display media
- Visualization of the signal image on the display media
- The ability to measure and analyze signals and save and print the results of the analysis and measurements

By using the basic principles of the oscilloscope, this research also develops the prototype's ability to provide a function as a spectrum analyzer measuring device. This can be done with the help of Fourier transforms to convert from time domain to frequency domain.

Several aspects that affect the quality of the oscilloscope measurement results are the quality of the probe [6] and the sampling process [7]. The development of an oscilloscope that has economic value has also been built by utilizing a sound card available in a PC (Personal Computer) [8] and also building an external ADC (Analog to Digital Computer) device that displays the signal visualization on a PC monitor screen [9].

Most oscilloscope use built in display to show the signal to make it portable and more noise resistance. Even when the oscilloscope is using external display, they will go through a PC for processing and displaying the signal on the PC's monitor [9]. Even though all these approaches will give a low-cost oscilloscope, we need to balance between portability and features upgradability. The oscilloscope in this research will give both features, portability and displaying capability. The display capability can give the future opportunity for

knowledge discovery using online cloud-based dashboard [10].

III. SYSTEM DESIGN

According to market review, the provision of an oscilloscope measuring instrument with an economical price advantage does not yet provide the data processing capabilities required for further storage and processing, such as converting the ADC results from the time domain to the frequency domain. Fig. 3 explains the advantages of this study.

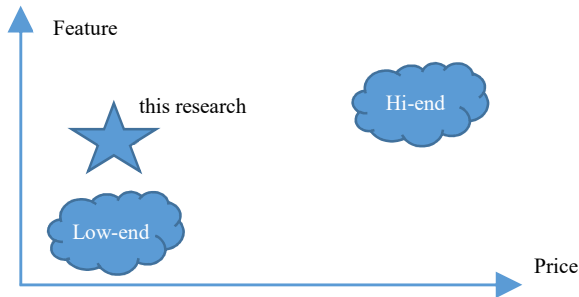

Fig. 3. Comparison of features against costs.

Hi-end oscilloscopes currently available have the ability to capture signals in the order of hundreds of Mega Hertz, so the investment price is very expensive. Meanwhile, for low-cost oscilloscopes according to literature reviews that use sound cards and also build external devices, the capabilities provided are also low, such as the limited maximum frequency that can be sampled and also require a separate computer for data processing.

Some of the well-known brands that have previously released hi-end oscilloscopes are Hewlett-Packard, Tektronix, and Hitachi. However, with a very high price, reaching tens or even hundreds of millions, it is the main obstacle for SMK schools to invest. This high price is due to the ability of the oscilloscope to be able to capture signals up to the Gigahertz order, whereas for practicum in the electronics and IoT laboratories at SMK, only an oscilloscope that is capable of capturing signals in the audio band is needed, which is the order of tens of kilohertz.

This research offers a prototype which besides being low cost, also has data processing features. This capability is also needed to add features to become a spectrum analyzer that requires Fourier transform processing.

This research uses NodeMCU for acquiring, processing, and sending sampled analog signal. There are five main reasons why authors choose NodeMCU, they are:

1. availability in Indonesia market,
2. (lower) price,
3. (bigger) memory capacity,
4. (smaller) power supply, the NodeMCU is powered through 3.3VDC, which in this prototype is supplied by 2 coin-batteries CR1025, and
5. built-in ESP8266 to transmit data via Wi-Fi.

Although, however, there are also two drawbacks on choosing NodeMCU for the system, they are:

1. (slightly) bigger size compared to, for example Arduino Nano, and
2. simpler ADC (Analog to Digital Converter) in terms of resolution (8-bit) and voltage range input.

The prototype was designed like an ordinary pen, with a sharp tip to capture the analog signal and at the other end is a cable with alligator clip to be connected to the same ground of the circuit being observed. The design is drawn in Fig. 4. The block diagram of the prototype is described in modules according to Fig. 5. Two probes, red as the sharp tip of the pen to capture the signal and black for the ground, just like regular digital oscilloscope, will determine which analog signal to be sampled. This analog signal is sampled using NodeMCU 8-bit ADC and could either stored in its RAM or sent directly to HTTP server or MQTT broker.

Fig. 4. Prototype design.

The prototype design in Fig. 4 shows a “start to capture” button. Student may press this button to capture the analog signal, once the sharp tip of the pen and alligator clip are already in place. The batteries in Fig. 5 were stored inside the pen. This is the reason the design is using coin batteries, so it can be easily stored inside the pen.

Fig. 5. Block diagram of the prototype.

Since the ADC resolution of the NodeMCU used in this research is 8 bit and the size of its usable RAM is around 50 KB then the system can store up to 50,000 samples. However, with the addition of timestamp and other additional information and for ease of addressing (data retrieval), the prototype is designed only to store 48,000 samples. If the prototype is going to sample a 20 kHz analog signal (the highest frequency in audio band), we need to sample the signal using at least 40,000 samples per second, which means the RAM is more than enough to capture a 1 second interval.

IV. TESTING AND MEASUREMENT

To ensure the oscilloscope can sample audio signal band, this research uses 2 signal generators:

1. A low-cost IC 555 timer in astable operation mode to generate a 20 kHz sawtooth periodic

signal, the maximum audible frequency, just like an audio analog signal,

2. A more sophisticated, yet rather expensive, XR2206 to simulate 20 kHz sine wave signal, the maximum audible frequency.

A. Sawtooth Signal Generator

Fig. 6 shows the IC 555 timer in astable operation, while the frequency is determined by the values of resistor R_a , resistor R_b , and ceramic capacitor C , while the duty cycle is determined by the values of resistors R_a and R_b [11].

Fig. 6. Timer 555 in astable operation to generate sawtooth signal [11].

Equation (1) describes the calculation of the output frequency for sawtooth signal generator in Fig.6 (for sawtooth signal, the output is taken from pin 6 of Timer 555), just as depicted from Fig. 7. With the value of resistor $R_a = 120 \Omega$, resistor $R_b = 300 \Omega$, and ceramic capacitor $C = 100 \text{ nF}$, we get frequency = 20 kHz, while using (2) we get Duty Cycle = 42%.

$$f = 1.44 / ((R_a + 2 * R_b) * C) \tag{1}$$

$$D = R_b / (R_a + 2 * R_b) \tag{2}$$

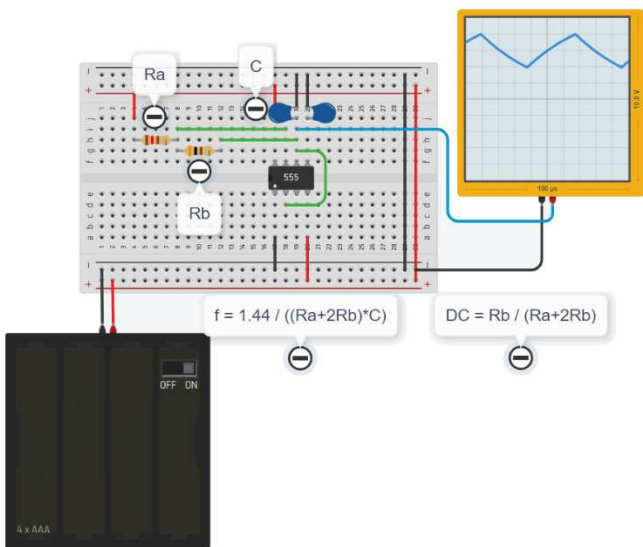

Fig. 7. Sawtooth signal for ADC input tester.

B. Sine Wave Signal Generator

For sine wave signal, we use XR 2206. Fig. 8 shows the circuit diagram for FSK (Frequency Shift Keying), which will give 2 frequencies, F_1 and F_2 , depending on the value on pin 9. Since we are going to use only sine wave with 1 frequency only, we are going to put pin 9 in open-circuited and use R_1 and C to determine the frequency using Equation (3) [12].

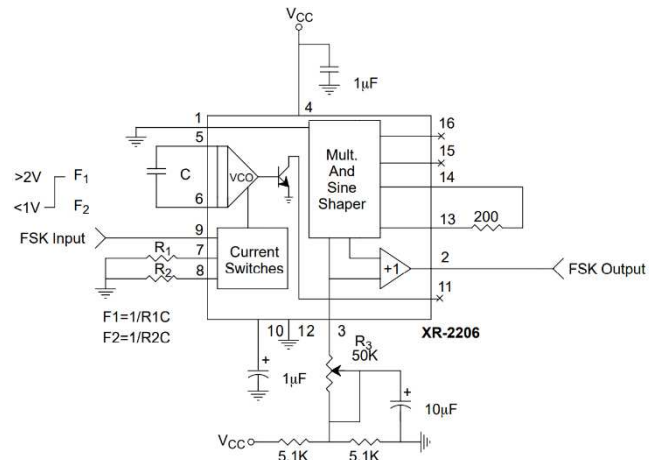

Fig. 8. XR 2206 generate sine wave signal [12].

$$f = 1 / (R_2 * C) \tag{3}$$

From Fig. 8 and Equation (3), to generate sine wave with a single 20 kHz frequency, we use $R_1 = 5 \text{ k}\Omega$ and $C = 10 \text{ nF}$.

C. Electrical Performance Analysis

Fig. 9 shows the sawtooth signal wave on a digital oscilloscope, while Fig. 10 shows the reconstructed signal from sampled signal taken previously using our prototype digital oscilloscope.

Fig. 9. Sawtooth signal from Timer 555.

Fig. 9 is taken by digital oscilloscope Tektronix TBS1052C with Timer 555 as the signal source. With a signal period of 64 µs shows the signal frequency of 15.625 kHz, lower than expected by the circuit, which supposed to provide 20 kHz. This happens due to the tolerance value of the resistor and the capacitor.

From the picture we can also see the pitch noise happened at the top peak and bottom peak of the signal, along with its shadowy signal. This happens probably due to the use of breadboard, instead of PCB (Printed Circuit Board).

Fig. 10 shows the sawtooth signal, sampled for 70 times by our prototype's ADC. The 70 sampled signal is printed out to the Serial Monitor and processed and plotted using Microsoft® Excel.

Fig. 10. Sawtooth signal from ADC of our digital oscilloscope prototype.

Fig. 11. Sawtooth signal comparison from ADC of our digital oscilloscope prototype and from theoretical formula.

Fig. 11 shows the comparison between the normalized sawtooth signal captured by the prototype with the theoretical approach (charging and discharging capacitor through resistor formula). Based on the comparison, we get $MSE = 0.29$.

Fig. 12 shows the sine wave signal on a digital oscilloscope, while Fig. 13 shows the reconstructed signal from sampled signal taken previously using our prototype digital oscilloscope.

Fig. 12. Sinusoidal signal from XR2206.

Just like in Fig. 9, Fig. 12 is also taken by digital oscilloscope Tektronix TBS1052C with XR2206 as the signal source. With a signal period of $52 \mu s$ shows the signal frequency of 19.231 kHz, a little bit lower than expected by the circuit, which supposed to provide 20 kHz. This happens due to the tolerance value of the resistor and the capacitor. From Fig. 12 we can also see 2 shadow signals made by unstable sampling noise.

Fig. 13. Sinewave signal from ADC of our digital oscilloscope prototype.

Fig. 14. Sinewave signal from ADC of our digital oscilloscope prototype.

Fig. 13 shows the comparison between the normalized sinewave signal captured by the prototype with the theoretical approach (sinusoidal formula). Based on the comparison, we get $MSE = 0.08$.

D. Price Analysis

The prototype is built using components listed in Table I. There are 4 components needed to build the prototype, 1 unit of NodeMCU, 1 unit of alligator clip, 20cm of copper cable, 1 unit of plastic casing (built by using 3D printer), and 1 unit solder tip.

TABLE I. COMPONENT LIST

No.	Component Name	Quantity	Price
1	NodeMCU Lolin	1 unit	Rp 32000
2	Alligator clip	1 unit	Rp 500
3	Copper Cable	20cm	Rp 100
4	Casing	1 unit	Rp 15000
5	Solder tip	1 unit	Rp 10000

Based on Table I, the total amount needed to build the prototype is Rp 57600 or approximately US\$ 4 each. This is affordable for many vocational schools to build the measurement instrument, in this case is digital oscilloscope, by their self.

V. CONCLUSION

The purpose of this research is to build a measurement instrument to capture signal just like a digital oscilloscope with the help of built in ADC (Analog to Digital Converter). The prototype should be small, affordable, and provide enough precision for any student in vocational school to help them understand analog signal and its application in audio range below 20 kHz. Based on our analysis, the prototype cost only Rp 57600 and gives MSE=0.29 for the sawtooth signal and MSE=0.08 for sinusoidal signal.

Abstract— The emergence of the novel SARS-CoV-2 (Covid-19) virus in 2019 has led to continuous monitoring of the outbreak attempting to generate accurate reports of people's health information to understand the pandemic's impact. It is likely that more variants will emerge since not all countries and populations have been vaccinated. Thus, with SARS-CoV-2's constant mutation, researchers need to collect individuals' health data to study these variants and vaccine efficacy, especially those who show symptoms. However, researchers have difficulties building comprehensive datasets because people are unwilling to release their health information or have no way to report their health statuses (i.e., at-home testing). This problem stems from a lack of complete control over who assesses their health data. Hence, they cannot guarantee the security, privacy, and integrity of the disclosed health information. As the problem of building secure databases persists, researchers find it challenging to accurately report any evolving variants within a short period. This problem has resulted in several new outbreaks of the pandemic. In this work, we propose a blockchain architecture that can guarantee patients' health data integrity, privacy, and security, encouraging individuals to disclose their health information freely. This solution gives patients complete control over who assesses their health information. The framework proposed access management to patients' health data for researchers and contact tracers. This solution classifies patient health information to different sensitivity levels and manages access based on this sensitivity. In case of unauthorized access, the proposed solution detects and prevents such access, thereby ensuring the patient's health information's security, integrity, and privacy. Based on the classification, contact tracers can quickly assess the information needed from patients while the patients will be confident that no sensitive information is disclosed, reducing the burden on contact tracers.

Keywords — Blockchain, Integrity, privacy, SARS-CoV-2 virus, Security, Privacy, Confidentiality, Public Health Information, Access Management.

I. INTRODUCTION

The outbreak of the SARS-CoV-2 (Covid-19) virus since 2019 has called for an urgent need for effective research and reports to curtail further spreading and deaths from the pandemic. Based on the studies, it is highly contagious and constantly spread around the globe [1]. The Covid-19 virus most often causes respiratory symptoms similar to cold, flu, or pneumonia. Since its discovery, more than 506 million cases have been reported worldwide and have accounted for 6.2 million deaths[2]. 80.7 million cases and more than 989 thousand deaths have been reported in

the USA[2]. Currently, about nine virus variants are being monitored, while three of the evolved variants (Delta, Omicron, and Ihu) are of great concern to researchers [3]. Due to its rapid mutation rate, researchers collect patients' health information to study and report new variants. Researchers failed to accurately study the variants despite their effort to collect updated health information. This is due to a lack of willingness from people that have been exposed to disclose health information. The problem stems from an inability of the patients to control who assesses their health data. Hence, they cannot guarantee the security, privacy, and integrity of the disclosed health data. As the problem persists, researchers find it cumbersome to give an updated report of new variants and vaccine efficacy. If no solution is provided, the problem might lead to an outbreak of another variant.

Academia and industrial researchers have put forward diverse blockchain applications to preserve the privacy and confidentiality of the health information collected by contact tracers and researchers. For instance, [3] proposed BeepTrace to bridge the user/patient and authorized solvers to desensitize the user ID and location information. A blockchain architecture that preserves the privacy of contact tracing Covid-19 patients was proposed in [4], while [5] evaluates the benefits of using Big data and blockchain technology to deal with the pandemic and some data quality issues that still present challenges to decision making. The authors in [6] proposed a blockchain architecture that enforces accountability and transparency to bridge the gap between the on-chain and off-chain user information collected by contact tracers.

Despite the numerous researches on privacy-preservation of individual health information, none of the available solutions focus on access management of the health information, hence the motivation to this work.

A. SARS-CoV-2 Virus researchers

These people are dedicated to monitoring the new variants symptoms to make an informed decision and recommendation to the government. These people study the symptoms to i). reports about the new variants, and ii) report the vaccine efficacies. To obtain accurate information based on the new or existing symptoms, they rely on information supplied by contact tracers. They can also request covid related health information from Covid isolation centers and treatment sites or healthcare providers and hospitals.

B. Contact Tracing

This is a process of identifying, assessing, and managing people who might have contact with Covid-19 infected person and subsequent collection of further information about these contacts[7]. The purpose of contact tracing is to minimize the spread of the virus. Contact tracing has been used and proven effective in minimizing the spread of infectious diseases in general. The contact tracing process relied heavily on recalling a list of people they have been in contact with over the previous weeks or locations the confirmed person has been. Letters, phone calls, or emails are being used to inform people who might be exposed. Thus, completeness and accuracy of the list and timeliness and efficiency of the tracing are limited by such a labor-intensive, traditional contact tracing approach. Recently, different digitized contracting through smartphone apps has been deployed to solve the labor-intensive problem. For instance, Singapore TraceTogether[8], GAEN[9], National Health Service (NHS) COVID-19 App [10], and China Health code system [11]. Researchers rely on contact tracing information to study the virus accurately.

C. Contribution

The proposed solution aims to develop a blockchain framework that can guarantee people's health information privacy, security, confidentiality, and integrity so that individuals will be willing to disclose necessary information to study and report new cases of Covid-19 variants. In addition, this framework promotes health equity by often engaging underserved communities. The specific aims of the solution are summarized below:

- **Guarantee PHI privacy, integrity, security, and confidentiality using access management:** One of the significant problems experienced by researchers in obtaining accurate information about the SARS-CoV-2 virus is that there is no way to guarantee privacy or integrity and confidentiality of the health information requested. As a result, individuals find it challenging to trust non-medical practitioners(e.g., Researchers, contact tracers, etc.) requesting their health information. Even if researchers turn to healthcare providers to obtain health information, they are restricted by government policies (e.g., HIPAA) about sharing health records with third parties. Our proposed solution combat this challenge by ensuring that patients have complete control over who accesses health records and that no sensitive health information is disclosed during this process.
- **Classifies individual health information based on its sensitivity.** People find it challenging to share their health information because there is no access control strategy to deter requesters from accessing more than requested information. This means there is no way patients can control the level of access once the health records have been shared. Our approach approached this challenge by classifying the health information based on

sensitivity and defining different access levels to enforce restrictions. Apart from creating these access levels, the architecture manages access to health information via verification, authentication, and permission steps.

- **Fosters SARS-CoV-2 virus research:** One of the reasons it is required to study and report the SARS-CoV-2 virus continuously is its constant mutation. This constant mutation has led to a strong need for a prompt and constant collection of health information to generate a dataset for compelling studies and reports. by implementing the proposed solution, people will be willing to release helpful information about their covid status without privacy and integrity breach concerns
- **Reduces the burden on Contact Tracing:** The bulk of the dataset building for effective studying of the variants relies on the information provided by contact tracing. It is often challenging to get accurate health information as people might be unwilling to talk or misrepresent their situation. Our architecture allows the individual's health providers (e.g., testing center) to upload accurate information to the blockchain network. Contact tracers can access this information from the blockchain platform by requesting a permit from the health data owner. In this case, both the contact tracer and owner are anonymous, and the contact tracer only accesses the permitted/required information.

This paper's remainder is organized as follows: Section II discusses the background and related works on blockchain applications for healthcare data access. Section III describes the proposed architecture's method. Section IV presents the preliminary results, and finally, section V presents the conclusions of this paper and possible future works.

II. BACKGROUND AND RELATED WORKS

Researchers have applied blockchain in diverse areas, including data security in healthcare, in the past years. The blockchain capabilities make the blockchain technology more secure than other distributed database platforms. Such features are attractive for their secure data collection and management, prompting other researchers to propose blockchain applications in sharing health information. For example, the authors in [1] proposed Gem Health Network, allowing different healthcare specialists to access the same health information from a shared infrastructure. The authors [2] proposed a user-centric health data sharing solution that utilizes a decentralized and permissioned blockchain. In their work, a mobile application is deployed to collect health data from personal wearable devices, manual input, and medical devices, and synchronize data

to the cloud for data sharing with healthcare providers and health insurance companies.

The authors in [3] proposed a conceptual design for sharing personal continuous dynamic health data using blockchain technology supplemented by cloud storage to share the health-related information in a secure and transparent manner. The primary goal of their proposed system is to enable users to own, control and share their personal health data securely. The solution also provides an efficient way for researchers and commercial data consumers to collect high quality personal health data for research and commercial purposes. A blockchain-supported architectural framework for secure control of personal data in a health information exchange by pairing user-generated acceptable use policies with smart contracts was proposed in [4]. In [5], the authors proposed blockchain-enabled IoMT to address the security and privacy concerns of IoMT systems to combat COVID-19. The authors in [6] presented a blockchain-enabled privacy-preserving contact tracing scheme, BeepTrace. Their work proposed adopting blockchain bridging the user/patient and the authorized solvers to desensitize the user ID and location information.

Our proposed application is unique from previous proposals in that it ensures data security with additional steps. Although the available solutions utilized the same blockchain platform to share personal health information, our approach introduced two specific, novel steps: i. our proposed solution classifies health information based on sensitivity for easy access management. ii. our application mounted an extra verification step on the existing blockchain framework to ensure that no unauthorized access is permitted. This mode of operations makes our approach different from existing blockchain applications in healthcare. The proposed architecture classifies and stores people's health information (PHI) then manages access based on the sensitivity and class of the requester, thereby guaranteeing the privacy, integrity, and security of an individual's health information. The requesters are classified (e.g., Researcher, Contact tracer, Physician, Nurse), and access to sensitive information is defined based on each class. Any entity that submits a request to access health data goes through verification steps. If the verification fails, the access is denied, and no health information is returned to the sender. Although the proposed framework can manage access from different requester classes, this work focuses on SARS-CoV-2 virus studies and reports.

III. METHODOLOGY

This approach aims to build a distributed database that guarantees health information security, privacy, and integrity by providing access management. The novel access management strategy encourages individuals to disclose their health information, enhancing covid-19

studies and vaccine efficacies testing. Figure 1 describes the high-level mode of operation. The key actors involved in the proposed approach are:

- **PHI generators:** These are health professionals that generate patient health information. An example is a Covid testing center, a healthcare provider etc. These entities send the PHI into the blockchain network[1] via a classification module(described below).
- **Owner:** The individual that owns the health information uploaded to the blockchain network. The owner approves whenever there is a request to access the stored health records. The owner grants or denies the access based on the request and sender's information. The request pushed to the owner is a successfully verified request.
- **Requesters:** These entities need health records for different purposes, e.g., research. They request health information relating to the Covid-19 virus to conduct better studies, make accurate reports, adjust the vaccines, evaluate the performance, advise government agencies like CDC, task-force on the pandemic, etc. Examples are SARS-CoV-2 virus researchers and contact tracers.

Apart from the above descriptions, the architecture can enable the inclusion of underrepresented populations, especially those whose health issues have been neglected in research

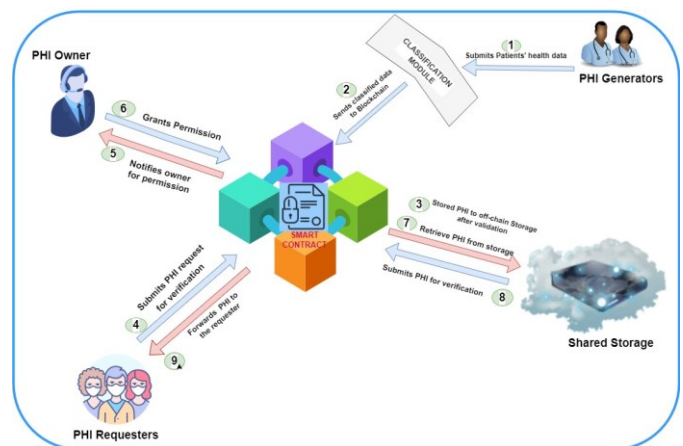

Fig. 1. The Proposed architecture

The architecture comprises a blockchain network that features a programmable smart contract and an off-chain storage system, e.g., IPFS. The main building blocks of the proposed architecture are shown in Fig. 2. The building blocks comprise a classification system, access management module, and storage system.

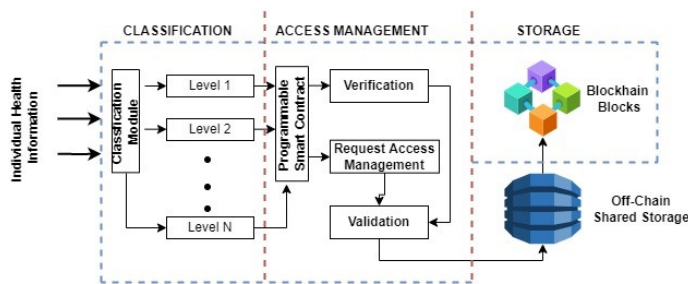

Fig. 2. Building blocks of the proposed architecture

1. Classification module

The classification module is an interactive script developed in a python programming language that identifies sensitive health information and groups them according to the sensitivity level. This module reformats the health record according to sensitivity features written in the smart contract. For the script to effectively classify ingress health records, it is required that the health record be sent in a particular format. Based on this format, the script interacts, extracts, and separates the information according to sensitivity. For proof-of-concept evaluated in this work, we defined three sensitivity levels:

- *Basic information:* The general or basic information about the individual is extracted here. An example of the information extracted includes name, age, date of birth, gender, weight, height, race, origin, etc. The basic information is accompanied by a tag that defines the sensitivity and access level.
- *Covid-19 information:* The health records here are Covid-19 and vaccines-related information. Individual Covid-19 related information is obtained and registered here. An example of the information extracted includes underlining health problems, age, gender, race, origin, vaccine status, Covid-19 symptoms, etc. The Covid-19 information is accompanied by a tag that defines who can access the information and the level of sensitivity
- *Other Health information.* The health information here is other health records not covid-related. Examples include health history from PCP, list of drugs, previous tests, etc. This information is not to be accessed by Covid-19 researchers or contact tracers. The health information is accompanied by a tag that defines the sensitivity and access level

Algorithm 1 below illustrates how the classification module script reads the incoming individual health information (IHI), classifies it, and sets the sensitivity level. To achieve this classification, the module matches the field of the received IHI to what it runs then retrieves the features.

```

Algorithm 1: Classification Module
1 Require:
2   Mapping(Incoming IHI ->struct) private Sensitivity;
3
4 Procedure: ReadIncomingIHI (Individual Health Information)
5   For ihi in IHI:
6     If ihi ∈ basic information
7       basic information ← ihi
8       Sensitivity => 1
9     else
10      If ihi ∈ covid-19 related information
11        covid-19 information ← ihi
12        Sensitivity => 2
13      else
14        other health information ← ihi
15        Sensitivity => 3
16      end If
17    end For loop
18  end procedure
    
```

Based on these classifications, the module prepares separate transactions. These transactions are digitally signed and submitted to the blockchain network for verification and validation. In addition to the information, the sending blockchain node submits its information for sender authentication.

2. Access Management Module

This module describes the verification, validation, and request access management of health information. The transaction sensitivity level, public keys, and authorized nodes' information are stored in the smart contract. The transaction owner is authenticated, and the submitted transactions are verified. Verification and request access control are managed on the server-side of the architecture, i.e., smart contract, while transaction validation is handled by blockchain consensus protocol. Thus, smart contract handles the following functions:

i. Node Authentication

The smart contract handles nodes authentication. The purpose of authenticating a node is to ensure that all transactions are sent from authorized nodes only. The smart contract retrieves the sender's information that accompanies the transaction and invokes a code that compares it with stored information. The information confirmed includes the transaction account, MAC and IP addresses, and the digital signature. We recognized that hackers could easily spoof the MAC and IP addresses in a highly unsecured environment; hence, we added a multifactor authentication process that involves verifying the sender's transaction account and digital signature in addition to the verified MAC and IP addresses. The pseudocode in Algorithm 1 describes the snippet of the smart contract that handles the node's authentication. The smart contract invokes the code that reads the sender's information. It verifies the digital signature using the owner's public key (o.pk) and confirms the transaction account, MAC,

and IP addresses. The algorithm invokes the transaction verification code if the node authentication is successful. For a node to be successfully authenticated, the sender must be an authorized node i.e., the digital signature and other information must be verified. If any of these fail, the node's transaction is dropped.

Algorithm 2: Node Authentication

```

1 Require:
2 Mapping (pubkey=>bytes32) public Keys;
3 Mapping (account => bytes32) public Account;
4 Mapping (ip_addr=>bytes32) public IP;
5 Mapping (mac_addr => bytes32) public MAC;
6
7 procedure: ReadOwnerData (Transaction tag)
8     Transaction.owner ←msg.sender
9     Transaction.account ← account
10    Transaction.pubkey ← o.pk
11    Transaction.ip ← ip_addr
12    Transaction.mac ←mac_addr
13    Return TRUE
14 end procedure
15
16 procedure: NodeAuthentication (OwnerData)
17     require (ip_addr ∈ IP)
18     require (mac_addr ∈ MAC)
19     require (pubkey ∈ Keys)
20     require (account ∈ Account)
21     require (o.pk verifies digital signature)
22     return successful authentication with timestamp
23 end procedure

```

ii. *Transaction verification*

One of the novelties of the proposed solution is the implementation of the verification stage. The verification stage ensures that any submitted transaction conforms with the agreed-upon format and contains the correct information. The verification step also ensures no leakage of sensitive information due to incorrect classification—the smart contract reviews and matches tags accompanying each transaction to its sensitivity level. A snippet from the smart contract runs through the submitted transaction to ensure no features are missing. Every authorized node sign its transaction with the private key, and a smart contract code verifies the digital signature using the known public keys whenever a transaction is submitted to the blockchain. For digital signature implementation, we generate key pairs with Digital Signature Algorithm (DSA) with 1024 bit-length using the command "*ssh-keygen -t dsa -b 1024*" and store the public key in the smart contract. The smart contract also stores the tag information accompanying each transaction to manage access. A snippet from the smart contract shows algorithm 3 pseudocode describing the transaction verification process. For transaction verification to be successful, the transaction must agree with the defined format, and the sensitivity level must match the information. If the sensitivity level does not match the

information, the sender is notified, and the transaction is dropped.

Algorithm 3: Transaction Verification

```

1 Require:
2 Mapping (transaction=>struct) public Sensitivity;
3 Mapping (transaction => struct) public Format;
4
5 procedure: ReadTransaction (format, tag)
6     Transaction.field ←format
7     Transaction.tag ← level
8     Return TRUE
9 end procedure
10
11 procedure: NodeAuthentication (OwnerData)
12     require (format != NULL)
13     require (level == tag[level])
14     return successful verification with timestamp
15 end procedure

```

iii. *Request Access Management*

Another novelty of this proposed work is its ability to enforce access control on the stored health information. The purpose of managing the requester's access is to ensure that a requester is assessing only the required information. We implement the access control function by defining a transaction retrieval policy that uses the transaction's sensitivity. We defined each class of requesters' information and wrote it into the smart contract. Every requester must submit the required information according to the access level requested. If a requester fails to provide the required information, access is denied. After the smart contract has successfully verified the requester, an access request is pushed to the owner for approval. If approved, the requester can access the information; else, access is denied. Algorithm 4 shows that for a request to be granted, a smart contract must verify the requester's information, the owner must approve the request, access level must match the requester level (e.g., a researcher requesting covid-19 related health information), and a sender cannot request multiple information (i.e., no cross-level request).

Algorithm 4: Access Management

```

1 Require:
2 Mapping(request => struct) public Request;
3 Mapping (requester_sender => struct) public Information
4
5 procedure: ReadRequest(requester)
6 Requester_info ← info
7 Requester_request ← health_info
8 Requester_level ← access_level
9 Return True
10 end procedure
11
12 procedure: RetrieveTransaction (Transaction)
13 require (access_level ∈ Tag[level])
14 require (info must be correct)
15 require(health.owner must approve)
16 require (request_info == 1)
17 Allow Access to Specified Information
18 end procedure
19 end procedure

```

3. Storage Module

i. Off-chain shared Storage

Owing to the massive amount of data accompanying patient health records, we introduce a decentralized off-chain shared storage medium called interplanetary File System(IPFS). One of the features of IPFS is that each stored file can be allocated a unique hash according to its content to identify it uniquely. So, if somebody uploads two files with the same hash value, IPFS pins them to the server and creates only one entry in the content addressed storage block. Due to this feature, IPFS has no access control, and files over IPFS can be directly accessed by their respective hash value [14]. Unlike [14], access to the IPFS is limited to the blockchain network. Blockchain network offloads health records to the IPFS after successful verification and authentication. A successfully verified transaction is pushed to the off-chain Storage, and reference to the location of this information is sent to the blockchain network for validation and Storage. The reference location of the newly added information undergoes a validation process and is added to the blockchain network blocks. Our previous works have extensively described the validation process [15-17].

ii. Blockchain Blocks

After successfully validating the location reference, the newly added block reflects on the ledger of all blockchain nodes, and the transaction is ready to be retrieved. All blockchain nodes receive the newly added block notification but do not access the block's content. The smart contract retrieves the transaction address after the requester has been successfully verified and the owner approves the request.

IV. RESULT

The on-going work is implemented on an Ethereum blockchain platform. We use *Solidity v 0.8.11*

implementation for smart contracts and *geth v 1.10.13* for Ethereum. For initial testing of the proof-of-concept, the private blockchain network is set up in the laboratory with five computers serving as blockchain nodes (Fig. 1) to evaluate the performance. We evaluated access management on the stored information, and the preliminary result was as described below. We also present the further work to be carried out.

A. Access Control/Management

We evaluate the access control function by implementing a node attempt to retrieve an unauthorized transaction. We submit a transaction using one of the blockchains. The submitted information was successfully verified and pushed to the off-chain Storage. The reference to the location was successfully verified and added to blocks. Another random node was used to query this stored information. The smart contract handles each transaction's access control by comparing the information of the requesting node to the authorized requester. The node queries the blockchain for the content of a newly added block that it is not privileged to download. We investigate further by querying the blockchain using a node that can retrieve the data. The node successfully downloads the block's content from the blockchain. No information was returned to the requester because the node is not privileged to retrieve the data.

V. CONCLUSION

We proposed a blockchain framework that can guarantee the privacy and integrity of shared patient's health information, thereby encouraging people to disclose more helpful health information to enhance the SARS-CoV-2 (Covid-19) virus study and monitor vaccine efficacies. Implementing the proposed architecture will foster the study and reporting of new SARS-CoV-2 variants. Due to its distributed database implementation, the proposed solution can enhance the inclusion of underrepresented populations, especially those whose health issues have been neglected in research.

Further works

As part of the further work, we plan to implement the following

- Add Off-chain shared storage medium to offload the Storage of health information from the blockchain
- Evaluate the effectiveness of the classification with real data
- Evaluate and present the results of the architecture's effectiveness towards guaranteeing privacy, integrity, confidentiality, and security of Individuals' public health information.
- Describes how the architecture achieves the user training module and inclusion of underserved populations

Abstract—Many cybersecurity attacks utilize Covert Timing Channels as a method to secretly transmit (steal) sensitive information from target networks such as untrusted Internet of Things (IoT) and 5G/6G networks. Such attacks aim to violate the confidentiality and privacy of the data that resides in the targeted networks by transmitting the stolen information in a stealth manner over a prolonged period of time to avoid detection by cyber defenses and anti-exfiltration tools.

In this work, we proposed a novel approach that utilize novel Artificial Intelligence (AI) algorithms, in particular, deep learning to detect and localize covert channels over cyber networks. Taking advantage of the rapidly improving deep learning algorithms in image processing, we convert the malicious and normal network traffic (or packets) inter-arrival times to colored images. Then, we implement an AI-based approach using the popular deep learning algorithm Convolutional Neural Network (CNN) to process images and detect the ones that contain malicious CTC activities. Finally, we design and conduct a set of experiments to evaluate the ability of our proposed system to detect and localize CTC-based privacy attacks. The conducted experiments show that our approach yielded a high accuracy of 96.75% in detecting stealth covert channels.

Keywords—Big data analytics, artificial intelligence, privacy-aware defense, covert timing channel detection, image processing, deep learning.

I. INTRODUCTION

Fifth-generation (5G) wireless communication networks have been deployed in many countries to date. 5G technology boosts mobile capacity and data rate. However, the advancements promised by 5G technologies go far beyond increasing the data rate for mobile users to the provision of massive inter-connectivity at a scale never witnessed before. The current volume of data exchanged over 5G networks shows explosive growth. Moreover, 5G technology transforms many services, including location-based services, given its location positioning accuracy. Coupling 5G accurate positioning and low latency capabilities with the Internet of Things (IoT) allows for a significant overhaul in inter-connectivity and automation, paving the way to new models of seamless and ubiquitous interactions [1]. Using IoT sensors, many companies, businesses, or even individuals would have the possibility of collecting and analyzing the massive amounts of data collected or provided by various IoT applications either directly or via other low power

technologies. The cohesion of IoT, 5G, and 6G, will transform many industries and move humanity many steps ahead on the road of realizing the vision of intelligent or smart cities. Nevertheless, given that global 5G implementation requires substantial investments in communications infrastructure, 6G is poised to augment the revolution in ubiquitous and cross-borders communications.

Industrial collaborative robots [2], holographic meetings and health [3], and metaverses' cross and external connectivity with real-world applications are some examples of the innovative applications and technologies be driven and enabled by 6G technology. The massive increase in data rate currently witnessed with 5G is poised to be at least ten folds more in 6G. This advancement in data rate will also extend to provide advances in service availability, increase reliability, and removing many of the current network and geographical boundaries currently experienced with 5G.

However, in addition to inheriting the security vulnerabilities of the IoT and the previous generations, 6G has its own set of challenges [4]. New radio technologies will introduce many unknown threat vectors; the physical location of ultra-massive MIMO systems will also be a concern and many other challenges such as quantum-safe communications and cyberattacks against pervasive intelligence. While network steganography is relatively not fully explored, the integration of billions of embedded devices that communicate to each other in 6G networks will open the door to several new covert timing channels (CTCs) attack. Given the CTCs' ability to evade traditional detection and prevention methods and the massive data rate capabilities of 6G networks, transmitting hidden data bits over 6G networks poses a serious security threat [5].

Traditional CTCs detection methods presented in [6]–[10] use anomaly-based detection techniques. Using these techniques, the statistical features of both the covert and normal traffic are extracted and analyzed to detect covert communication. However, the volume and variability of data provisioned in 6G networks hinder the effectiveness of CTCs statistical-based detection methods.

Recently, rather than focusing on non-visible features for CTC detection, our previous work [11] proposed a CTC

visualization and classification model to improve the accuracy of CTCs' detection. The visualization approach introduced a technique for converting traffic inter-arrival times to colored images and transforming CTC detection into an image classification problem. The CTC visualization method can handle the attack detection and localization problems, but it suffers from the high time cost needed for image feature extraction. Moreover, these feature extraction methods also demonstrate low efficiency when exposed to large datasets. Additionally, the quality of extracted features significantly affects the overall performance of classifiers, which satisfies specific criteria or assumptions. Therefore, the challenge for building CTC detection models is to find a means for extracting features effectively and automatically.

To this end, this work employs a convolutional neural network (CNN), one of the most common and powerful deep learning algorithms in computer vision. CNN can automatically extract image features and avoid the drawbacks of manually extracting inappropriate features for images classification. It is critical to have a quick and light technique for detecting CTC attacks with large data to make decisions appropriately. Moreover, discovering the covert part of the traffic containing covert messages is another essential objective. It provides the ability to drop only the malicious part of traffic flows while allowing the rest of the traffic flow to pass through. This precise detection allows alerting the existence of CTCs to start the mitigation defend mechanisms, which significantly improves the quality of service that gets impaired upon dropping the entire traffic flow.

The main contributions of this work are summarized as follows:

- Utilize the convolutional neural network to improve CTC detection accuracy.
- Determine the optimum model architecture that provides high-performance outcomes in CTC detection by evaluating model hyper-parameter effects and determining optimal parameter values.
- Use a variety of image-based datasets to evaluate the proposed model's effectiveness and quantitative performance.
- Propose a mechanism that uses the convolutional neural network to accurately pinpoint the covert part that contains covert messages within traffic flows.

The rest of this paper is organized as follows. Section II, illustrates the detection model. Section III, describes the experimental setup. Section IV shows the results and analysis of this research. Finally, Section V, concludes this work.

II. CTC DETECTION USING CNN APPROACH

This section provides a detailed description of our proposed detection approach and the methods used to accomplish the detection objective of covert traffic.

A. Collecting and Processing Network Data

Figure 1 overviews the major components of our proposed approach. First, we collect a dataset of network traffic induced by two processes 1) a normal (non-malicious) client-server packet exchange and 2) a malicious process that implements covert channels to steal information from the network. Then, we calculate and extract the inter-arrival times (IATs), the time duration between two packets, from our traffic flows. Once these IATs are extracted, we convert these numbers into colored images to utilize the advanced image processing techniques in the domain of deep learning. To convert IATs to colored images, we implemented a module that creates a 2D matrix of size $n \times n$ where n ranged from 16 to 128. More details about these sizes are provided in Section III. This module then systematically places each IAT in this matrix in a row by row manner. Intuitively, each stream of IAT numbers are placed in one matrix. Then, the module normalizes the numbers in each matrix into a range between 0 and 255 to represent a colored image. We used the matplotlib library [12] to create colored images from these 2D matrices.

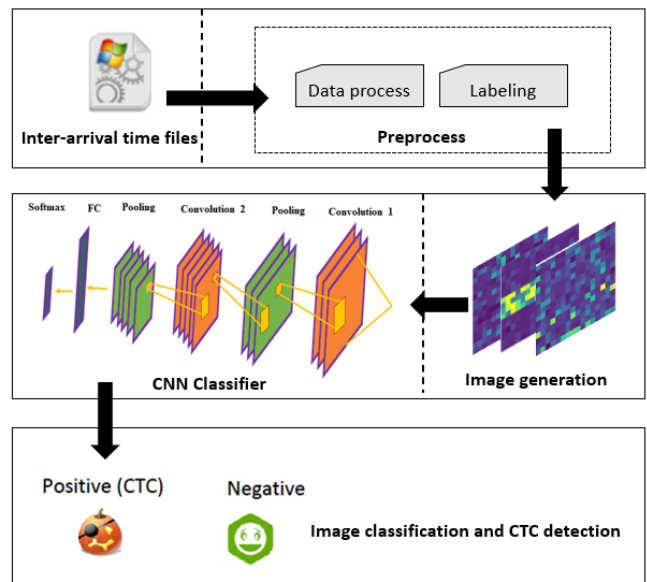

Figure 1: CNN framework.

B. Shallow CNN classifier

CNN uses weight sharing and pooling methods to reduce the number of parameters and decrease computation time and memory. This reduction allows the training depth model to be implemented. Deep CNNs have shown stellar performance in the field of image processing as demonstrated by AlexNet [13], and VGGNet [14]. However, CNN remains a time and memory-demanding algorithm due to its complicated learning network and network topologies that contain many parameters such as kernel size and layers. For instance, VGG16 contains 16 layers with more than a million parameters making it

a memory-demanding convolutional neural network model. Shallow CNN is underutilized, and research on such networks has lately gained interest.

To utilize deep learning in network security resources with limited memory and computation resources, we chose shallow CNN. The shallow CNN network has less layers and smaller convolution kernels, making it a lighter-weight model that places less demand on memory and computation.

C. CNN feature extraction and classification of images

The previous step yielded colored images such that some of these images resulted from a normal (non-malicious) traffic exchange, and the remainder of these images resulted from a malicious traffic exchange that used covert time channels to steal data from the victim network.

To construct a deep learning model that detects covert channels from these images, the first step is to extract effective features from these images. To this end, we used the feature extraction algorithm in CNN.

A colored image is essentially a matrix (or simply a set) of pixels. Once an image is fed into the CNN feature extraction module, the convolution layers and filters of a CNN produce feature maps. First, as shown by Algorithm 14, the model extracts 32 features to feed into the first hidden layer. Then, the second hidden layer utilizes 64 features for its learning. To reduce the computation requirements, the max-pool layers, which have the size of 2×2 , come after the second layer.

Then, the feature maps are normalized using CNN batch normalization [15] to adapt to the changing parameters during the training process. This adaptation increases the stability of the neural network and, in turn, improves classification accuracy. After the normalization process, the features are converted into one dimension for the fully connected layer. To reduce overfitting, dropout is used to improve the generalization of the model. Finally, the softmax classifier is used to identify the images into two categories, covert and overt.

III. EXPERIMENTAL SETUP

A. Experimental dataset

This work focuses on detecting one of the most sophisticated CTC attacks known as Cautious Covert Timing Channel (CCTC) [11]. CCTC is a cyberattack that attempts to mimic normal network traffic behavior to some extent, making it more difficult to detect by security detection methods such as firewalls and intrusion detection systems.

For the detection process, four CTC datasets have been built with 4000 streams (50% covert and 50% overt) in each dataset. The main difference between these datasets is the stream length (256, 1024, 4096, and 16384). Covert message size in each covert stream is 64 bits regardless of the length of the stream. The delay time used to generate CTCs in all datasets is 0.5μ where μ is the mean inter-arrival times of normal traffic, which equals 0.664 seconds. However, for each stream-based dataset

Algorithm 1 CNN Based CTC Detection Algorithm

Input: Training data and parameters

Output: Class label

Create classification model:

- 1: Generate the first convolutional layer, followed by batch normalization
- 2: Add max pooling layer
- 3: Generate the second convolutional layer, followed by batch normalization
- 4: Add max pooling layer
- 5: Add a dense layer

Model training:

LOOP Process

- 12: **end for**
- 13: Output the result according softmax classifier

Model testing:

- 14: Test the model using the test dataset
-

(256, 1024, 4096, and 16384), an image-based dataset version has been generated with different image dimensions ranging from small images with the dimensions of 16×16 pixels to large images with the dimensions of 128×128 pixels. Table II details the different image dimension that were used in our evaluation. In fact, for the detection process, the covert message is located in the middle of the stream, while in the localization process, it has been either in the beginning, middle, or end of the stream. Accordingly, a new dataset has been generated for the localization process of 6000 covert streams (2000 in each location) with 1024 bits length, which then it converted to an image of 32×32 pixels.

B. Experimental environment

To run the training and testing experiments of CTC detection and localization, we used a ThinkStation-P920 server running Linux version, with 24 cores and 62.42GB RAM. Python, the programming language with various libraries such as TensorFlow and Keras is used to implement the models and experiments.

C. Measures of CTC detection

In this paper, most common performance metrics have been used to evaluate approaches performance. Our evaluation aims of providing a comprehensive analysis measures to provide more details about CTC detection and localization process. The following list presents each one of these performance measures.

$$Accuracy = (TP + TN)/(TP + TN + FP + FN) \quad (1)$$

$$Precision = TP/(TP + FP) \quad (2)$$

$$Recall = TP/(TP + FN) \quad (3)$$

$$F_1score = \frac{2 \times (Precision \times Recall)}{(Precision + Recall)} \quad (4)$$

where True Positive (TP) is the number of image samples that are classified correctly as CTCs. True Negative (TN) is the number of image samples that are correctly identify as non-CTC. False Positive (FP) is the number of image samples that are incorrectly classified as CTCs. False Negative (FN) is the number of images that are incorrectly classified as non-CTC while, in fact, they are CTCs.

D. Choice of model hyperparameters

The CNN model has various hyper-parameters that determine the network structure (e.g., number of filters) and how the network model is trained (e.g., type of optimizer). The model performance can vary considerably according to the selected set of hyper-parameters. For example, the number of layers was ascertained after repeated experiments for designing the CNN model. The convolution layers were determined to be optimal with small kernels, in this work the kernel size of the convolution layers was determined at 3×3 .

We evaluated several model hyper-parameters to determine the best classification model. We adjusted and updated the model hyper-parameters in the search space and found the best value in the grid search. For example, we evaluate the model performance using the epochs range between 10-30. Based on the model results, we found that when the number of model epochs reaches 15, the model results did not continually improve, and the training time increased; based on that, the best number of epochs for the CNN proposed model is set as 15. The learning rate was another important hyper-parameter determining whether the objective function converges to a local minimum in the appropriate time and speeding up training in the early stages. In this study the learning rate was sit to 0.001 and the decay of the learning rate to 0.02. Moreover, the Adam optimizer and Cross-Entropy loss function are used with a 0.5 dropout probability for all model experiments.

IV. EXPERIMENTAL RESULTS EVALUATION

Our evaluation seeks to measure the performance of the proposed CNN approach in the following terms: (a) the effectiveness of the proposed approach to detect CTCs under different batch normalization configurations; (b) the efficiency of the proposed approach to detect CTCs using different hyper-parameters; (c) the impacts of various traffic image sizes and

shapes on the proposed approaches performance; d) compare the results of the proposed approach with different traditional machine learning and deep CNN classifiers based on their accuracy and interpret-ability in detecting CTC, and e) the ability of the proposed approach to pinpoint the covert part of the traffic flows.

The training and testing experiments were repeated ten times, and then the average of the findings was used as the final assessment value. 10-fold cross-validation is used to evaluate each classifier model in this work. We also used well-known metrics in the model's evaluation, including accuracy, precision, recall, and F_1 score.

A. Effects of using batch normalization on the CNN model performance

Our first set of evaluation results shows our approach's performance in detecting CTCs under different batch normalization (BN) configurations to demonstrate how BN may speed network training and enhance model performance. This section provides two CNN variation instances with two assumptions for utilizing BN, as shown in cases 1 and 2. The results of these two cases are compared with the CNN model that utilizes BN after each convolution layer.

case 1: Remove the BN technique after the first convolutional layer only and leaving all other layers and model parameters without any changing.

case 2: Remove BN techniques after the first and second convolutional layers, while all remaining layer parameters have no changes.

According to the experiment accuracy results, the CNN approach with BN after each convolutional layer achieved the higher accuracy of 96.75%, which is 0.3 % better than the proposed CNN approach in case 1 that obtained 96.45% of accuracy and 0.55 % higher than the CNN approach in case 2 with 96.20% of accuracy.

CNN with batch normalization technique have significantly quicker convergence than the results obtained with the standard parameterization without BN. The BN technique helps to normalize the parameters of each layer, making updating the model parameter process is more stable. This indicates that the CNN with BN can learn data characteristics more effectively and quickly. Consequently, we can infer that our classification accuracy obtains the best classification result when combining CNN with BN, proving the validity and efficiency of the proposed approach.

B. Effect of hyperparameters on CNN approach performance

Our second set of evaluation results shows our approach's performance using different model hyper-parameters, including the type and the number of layers with other activation functions. Table I shows the proposed CNN approach performance based on using three convolutional layers and one fully-connected layer with sigmoid, Tanh, and ReLU activation functions.

Table results show that the diverse activation functions affect the proposed approach’s performance and training time. The results demonstrate that the ReLU function is more time-saving than other functions, which is overall more effective in terms of approach performance with convolutional and fully connected layers. As shown by the table, the proposed CNN approach with sitting two convolutional layers and one fully-connected layer obtained the highest detection CTC accuracy of 96.75%, and the lowest training time, which is 5.03 seconds, where ReLU function is set for both types of layers.

Table I: Accuracy results of proposed model based on various hyperparameters.

Layer	Function	Accuracy	Training time(s)
Convolution 1	Sigmoid	95.10	5.50
	ReLU	95.51	4.00
Convolution 2	Sigmoid	96.60	7.22
	ReLU	96.75	5.03
Convolution 3	Sigmoid	96.20	9.50
	ReLU	96.55	6.20
Fully connected	Sigmoid	96.60	7.22

C. Image size effect on CNN model performance

Our third set of evaluation results shows the performance of our approach for detecting CTC using various image-based datasets. In the CNN technique, image size considers one of the crucial parameters affecting the approach classification results. The small size of the image could not help extracting enough information, which causes losing the attack properties. At the same time, using a large size of image would increase the computational time without any improvement in the accuracy of classification.

In this paper, we conducted a variety of experiments based on using different image sizes, including 16×16 , 32×32 , 64×64 , and 128×128 pixels as discussed in Section III-A. Fixed image size is used as required for CNN approach input. Figure 2 show the accuracy results of two classes classification using the four image sizes.

Also, Table II shows various performance metrics of using these same four image sizes. The results show the approach performance is increased when the image size is increased. However, a large image needs more training time. We noted that when the image size is getting more than 32×32 pixels, the approach performance does not significantly increase, and the training time is increased rapidly. For these reasons, we choose 32×32 pixels as the best size of input image-based data that can be used to achieve the best CTC classification and detection.

D. Image reshaping effect on CNN approach performance

This work also studies the effect of image shapes on the proposed approach performance. We used the traffic inter-arrival times to generate a non-square image with different dimensions. We choose the image size 16×16 , and then we

Figure 2: Accuracy results of using different image sizes.

Table II: Performance measures of CNN model using four image sizes.

Size of image	Precision	Recall	F_1 score	Time(s)
16×16	94.46	92.00	92.56	4.00
32×32	95.95	95.75	95.85	5.03
64×64	95.93	95.22	95.84	12.00
128×128	95.44	95.00	95.22	27.00

reshape it to three non-square image shapes, including 4×64 , 8×32 , and 2×128 pixels. The experiment results shown in Table III present the image shape of 64×4 obtained 94.451% of accuracy, 32×8 achieved of 94.455% accuracy, 128×2 achieved also 94.438% of accuracy, comparing to what is the model achieved 94.46% of accuracy for the 16×16 pixels.

Table III: Accuracy results using different image shapes.

Size of image	Accuracy
64×4	94.451
32×8	94.455
128×2	94.438
16×16	94.46

Based on the performance results, we noticed that changing the image shapes did not affect the classification approach’s performance, which means the width and height of the image did not affect the pattern of covert traffic in the image. Thus, a shallow convolution network with a small filter size and one stride would be worked well; the filter can correctly detect the split pattern in the covert images.

E. A comparison of the proposed approach with machine learning and deep CNN approaches

To validate the performance and efficiency of the proposed approach, we present our experimental results and compare them with various popular approaches. These detection approaches include traditional machine learning and deep CNN approaches, same as shown in Figure 3 and Table IV.

In this part, firstly, we compare our approach’s effectiveness in detecting covert channels with five traditional machine approaches, including Random Forest (RF), Multilayer Perceptron (MLP), Support Vector Machine (SVM), Decision Tree (DT), and Naive Bayes (NB). These approaches utilized

extracted image features to identify and detect CTCs. For this comparison, 32×32 image size was used. The results in Figure 3(a) and Table IV show the highest CTC detection accuracy is achieved by the CNN proposed approach, which achieved the accuracy of 96.75%. The second highest CTC detection was achieved by the MLP, which reached 94.1%. The SVM approach achieved third place with an accuracy of 93.7%, whereas the NB approach achieved the lowest accuracy of 90%.

Then, to verify the benefit of the proposed shallow CNN approach over deep CNN approaches, we compare the proposed shallow CNN approach with the most common other deep CNN approaches, including VGG16, AlexNet, and ResNet. These approaches were designed with a high number of convolution, and fully connected layers, such as the ResNet approach consists of 419 filters with 5x5 convolutions in the first layer only. Figure 3(b) shows the shallow proposed CNN approach with 32 and 64 filters in the first and second convolutional layers, outperforms the AlexNet approach by 6.74%, achieving an accuracy of 90.01%, and 9.73% and 8.75% more accurate than the VGG16 and ResNet approaches, with accuracies of 87.02% and 88%, respectively.

(a) Accuracy results with machine learning approaches

(b) Accuracy results with deep CNN approaches.

Figure 3: Accuracy results of proposed approach with machine machine learning (a) and deep CNN approaches (b).

Table IV also shows the shallow CNN proposed approach

is achieved the highest score of correct predictions with less training time compared with other deep CNN approaches. For instance, the AlexNet approach achieved the second level of precision, which can predict 89.02% of the CTC samples correctly. In contrast, the ResNet classifier is reached 85.50%, which is the lowest precision level after the VGG16 approach. In the final column of Table IV the convolutional layers are denoted by Conv in the last column of the table, while fully connected layers are denoted by Fc (including output layer).

Table IV: Classification results of CNN approach with shallow machine learning and deep CNN approaches.

Classifier	Precision	Recall	Training time(s)	Con./Fc
RF	92.11	90.00	63.30	-
MLP	93.01	93.00	36.02	-
SVM	92.00	89.00	73.96	-
DT	91.80	88.99	66.25	-
NB	90.00	90.88	25.10	-
AlexNet	89.02	86.00	25	5/3
VGG16	86.00	85.50	42	13/3
ResNet	85.50	87.00	35	7/1
CNN	95.95	95.75	5.03	2/2

F. Localization of CTC in traffic flows

As mentioned earlier, detecting a CTC attack is essential to prevent malicious applications that steal sensitive data over the network. The traffic will be dropped to stop the exfiltration data process by successfully detecting these covert data. Dropping traffic flows containing covert data is an effective defense against CTC, but it is also very disruptive to non-malicious applications' quality of Service of the non-malicious applications.

Finding the parts of traffic flows containing the covert data is an important goal, which provides the ability to drop only the malicious part while allowing the normal traffic to pass through. This accurate identification substantially reduces the disruptions of overt traffic caused by non-malicious applications.

This part of our study investigates and presents the proposed CNN approach's performance in pinpointing the location of covert data within traffic flows. To do this, we designed experiments in which the covert messages are injected into one of three locations: *beginning*, *middle*, and *end*. Then, we investigated our approach's performance to find the correct traffic flow segment that contained these covert data.

These location labels are generated automatically using the malicious agent. For instance, if the malicious agent injects the covert data into the beginning of traffic, it will also provide the label beginning to that traffic flow then generate the image with the same label of the inter-arrival times of that traffic flow. Further, it does the same with the other two labels, the middle and the end. This labeled image-based dataset of covert traffic flow is then used as input for training and testing CNN proposed approach.

As demonstrated in Table V, our proposed approach successfully identified the segments that contained the covert data

with an accuracy of 94.01%, and less false positive (FP) and false-negative (FN). We also ran machine learning and deep CNN approaches, including SVM, AlexNet, and Decision Tree (DT), to provide a baseline for comparison. Based on the table results, AlexNet achieved second place with the detection accuracy of 92.01%. The SVM achieved third place with an accuracy of 91.05%. DT came in last place with an accuracy of 90.54% and high FN.

Table V: Results of pinpointing covert messages within traffic flows using different approaches.

Classifier model	Accuracy	FP	FN
SVM	91.05	5.53	12.98
DT	90.54	5.13	14.39
AlexNet	92.01	4.29	12.29
CNN	94.01	3.17	6.72

V. CONCLUSION

Cyber attacks targeting the Internet of Things (IoT) and 5G/6G networks with the objective of stealing sensitive information have been rapidly increasing. Covert Timing Channels provides a maliciously effective method to steal data from the targeted networks in a defense evasive manner.

In this work, we presented a novel deep learning-based approach to detect and localize CTC-based cyber attacks at the exfiltration phase. First, we converted the traffic data (packets) to colored images, then we constructed a Convolutional Neural Network (CNN) model to classify those images to malicious or normal. Finally, we evaluated our CNN model using a set of comprehensive experiments and the model achieved an accuracy of 96.75% , a relatively high accuracy in this domain.

In addition, we evaluated the capability of the CNN model to pinpoint the location of covert data with traffic flows. The model achieved a high accuracy of 94.01% in pinpointing the stolen covert data in traffic flows.

In the future, we plan to extend this work by test the capability of our CNN model in detecting more advanced stealthy spyware utilizing port knocking. In this attack (e.g., Covert knocks), the malware sends signal packets to a closed network port to enable it and allow stolen information to flow through it. This attack is more difficult to detect as it can utilize multiple ports (even closed ones) to create covert channels. Detecting such distributed malicious activity will require a novel method that can investigate network traffic on each port as well as the aggregated traffic activity of multiple ports to detect advanced stealthy spyware.

Abstract—The ECG signals are one of the most important signals to check the human heart's condition. On monitoring the heart continuously, a large amount of ECG signal data will be produced. So, there is a need for efficient compression techniques. Discrete Anamorphic Stretch Transform (DAST) is one of the most efficient techniques. It is a one-dimensional complex transform that includes the phase recovery technique for recovering the phase from the magnitudes. This paper deals with implementing the phase recovery block in Field Programmable Gate Array (FPGA), which will recover the phase by using magnitudes. Phase recovery block plays a key role in reconstructing the phases from the magnitudes. First, the required signal is passed through the linear filter or phase recovery filter. Then the phase value is estimated using a non-iterative algorithm depending on the linearity and causality conditions. The new approach for the phase recovery block is also used for any complex signal transmission. The input ECG signal is taken from the MIT-BIH Arrhythmia database and implementation is carried out in Artix-7 NEXYS 4 DDR FPGA Board. The performance of the phase recovery block is quantified in terms of hardware and computational complexity.

Keywords—*Electrocardiogram; Discrete Anamorphic Stretch Transform; Coordinate Rotation Digital Compute; Phase Recovery; Field Programmable Gate Array.*

I. INTRODUCTION

The electrocardiogram (ECG) signals are generally used for detecting various heart diseases. They are recorded, processed, stored, and transmitted continuously through wired and wireless communication networks. Cardiac monitoring continuously over the long term is required in many cases such as monitoring patients in critical conditions,

detecting pathological events occurring sporadically over a long time, and continuous remote monitoring of the aged population. The enormous volume of ECG data is generated in these cases, resulting in a “BIG DATA” that needs to be transmitted and stored with less bandwidth and storage space. It requires a higher ECG data compression factor while maintaining a high degree of accuracy in the reconstructed signal. The millions of ECGs are taken yearly, thus putting a heavy burden on the physicians and cardiologists, who have to diagnose these ECGs manually. Big Data leads to challenges in acquisition, analysis, storage, and transmission [4]. Several wireless technologies such as Bluetooth, Zig bee, Wi-Fi, and GSM are used to transmit the ECG signals. The maximum signal rate limits all these technologies. So, to send at a lower rate than this, bandwidth should be reduced. Hence, a novel approach to data capture, compression, and transmission is required to deal with such data loads. A two-dimensional DAST is proposed for Image data compression in [4]. Application of the DAST for ECG data compression is proposed in [1-3]. The phase recovery for complex transform is simulated and verified in MATLAB in the literature [1] and [3]. Field Programmable Gate Arrays (FPGA) contain a large number of configurable logic blocks (CLBs) connected through programmable interconnects. Due to their programmable nature, FPGAs are best suited for various applications. Xilinx offers complete solutions comprising FPGA devices, advanced software, and configurable, ready-to-use IP cores [13]. The FPGA implementation of the phase recovery block is carried out first time in this paper. The phase recovery block contains many mathematical and trigonometric functions. The CORDIC algorithm is used to implement the trigonometric functions in FPGA [6-17].

II. PHASE RECOVERY TECHNIQUE SS

A. Discrete Anamorphic Stretch Transform

A complex one-dimensional (1D) DAST is presented in [1] as a pre-processor for ECG data compression. This preprocessing is achieved through a mathematical reshaping of the signal and non-iterative. But the sampling process is modified in Compressive sensing and needs feature detection and as well as iterative in nature. The complex 1D DAST of a 1D ECG signal $B[m]$ is denoted as $\tilde{e}[n]$ and is expressed by

$$\tilde{e}[n] = \sum_{m=-M}^M K[m].B[n-m] \quad (1)$$

where $K[m]$ is the 1D two-sided DAST kernel of length $2M+1$. $K[n]$ is defined as

$$K[n] = e^{i\Phi[n]} \quad (2)$$

$K[n] = 0$ for $n > M$ where $2M+1$ is the size of the kernel the DAST kernel phase profiles ($\Phi[n]$) can be obtained as

$$\text{Sublinear } \Phi[n] = a \left((n \cdot \text{atan}(b \cdot n)) - \frac{\ln((b^2 \cdot n^2) + 1)}{2 \cdot b} \right) \quad (3)$$

where \ln indicates the natural logarithm, \cos is the cosine function. After the suitable selection of the variable ‘a’, the resulting signal size is associated with the warping strength b . DAST is well suited for the pre-compression of the ECG signal for real-time transmission using channels with limited bandwidth [1].

B. Compression using Complex Transform

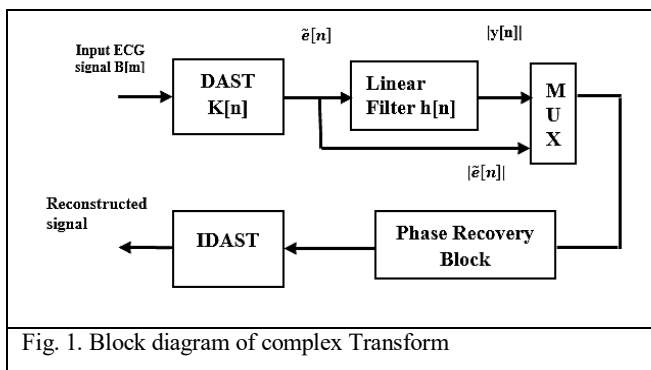

Fig. 1. Block diagram of complex Transform

The block diagram of ECG compression using complex transform is shown in Fig. 1. The input ECG signal $B[m]$ is convolved with DAST sublinear kernel $K[n]$ with kernel size 5.

To enable the phase recovery, the DAST performed complex ECG signal $\tilde{e}[n]$ is fed to a linear frequency filter (phase recovery filter) with impulse response $h[n]$. A two-tap all-pass filter with constant magnitude and the sum of the phases $\Phi_h[0]$ and $\Phi_h[1]$ equal to 180 degrees is proposed in [1] and is used here. Only the magnitude of the unfiltered signal $\tilde{e}[n]$ ($|\tilde{e}[n]|$) and filtered signal $y[n]$ ($|y[n]|$) are transmitted. At the receiver side, the phase of the signal is recovered using these two magnitudes in the phase recovery block. The ECG signal is properly reconstructed after performing the inverse DAST.

C. Phase Recovery using a linear filter

The procedure proposed in [1] and [5] for phase recovery is adopted in this work. $\Phi_e[n]$, the phase of $\tilde{e}[n]$ is given by

$$\Phi_e[n] = \cos^{-1} \left(\frac{|y[n]|^2 - |\tilde{e}[n]|^2 |h[0]|^2 - |A_i|^2}{2|\tilde{e}[n]||h[0]||A_i|} - \Phi_h[0] + \Phi_{A_i} \right) \quad (4)$$

where

$$y[n] = \sum_{m=0}^n \tilde{e}[m] h[n-m] \quad (5)$$

$$= \tilde{e}[n]h[0] + A_i \quad (6)$$

where

$$A_i = |A_i| e^{j\Phi_{A_i}} = \sum_{n=0}^{i-1} \tilde{e}[n] h[i-n] \quad (7)$$

From Fig. 2 it is noted that the phase of $e[n]$ is calculated using the previous sample $e[n-1]$. The $\Phi_e[n]$ is implemented in FPGA and the required DAST complex samples are generated using MATLAB.

III. FPGA IMPLEMENTATION OF PHASE RECOVERY

The MIT-BIH Arrhythmia database (mitdb) ECG signals are considered as the input [14]. The record 112 (V1) will have the voltage (mV) values with respect to time. A total of 300 samples (equivalent to 1 beat) are considered as the input data. The ECG signal is sampled at 360Hz and has an 11-bit resolution. Hardware results of the design are analyzed using Chip scope in the Xilinx platform.

The FPGA Specifications are FPGA Board: Artix-7 NEXYS 4 DDR, Clock frequency: 100MHz, Xilinx part number: XC7A100T-1CSG324C. It has 15,850 logic slices, 240 DSP slices, and 4,860 Kbits of fast block RAM.

The concept of phase recovery block is based on the propagation of the signal under test through a linear filter or phase recovery filter. The phase value is then calculated using a non-iterative algorithm based upon linearity and causality conditions. Equation (4) is implemented in FPGA. To design the phase recovery block in Xilinx, trigonometric functions like sine, cosine, inverse tangent, and inverse cosine are needed.

These advanced mathematical operations cannot be implemented directly. To implement these functions CORDIC algorithm is very much useful. CORDIC algorithm is used to implement these operations by using IP core in Xilinx ISE 14.4 tool.

A. Computation of Magnitude

The computation of magnitude is performed using the Non-Restoring Square Root algorithm. It is one of the effective ways to implement at a very fast clock rate. It mainly emphasizes the non-restoring on the “partial remainder”, with each iteration. It needs one normal adder/subtractor in each iteration and produces the correct value as well as in the last bit position. Next, using the last bit result, the accurate remainder is achieved immediately without any correction or addition operation. There are two advantages: i) fully pipelined high-performance operations. It may accept a new square-root instruction for each clock cycle with each pipeline stage. It requires a minimum number of gate counts. ii) low-cost operations that require simply a single adder/subtractor for iterative operation.

B. Computation of taninv using CORDIC

The CORDIC algorithm has two modes, vectoring (rectangular to polar) or rotation (polar to rectangular) modes. The vectoring is achieved by selecting α_i , such that θ' converges towards zero. It produces the scaled output Vector $Z_i * (X', Y')$. The rotation mode rotates the vector (X, Y) around the circle till the Y reaches zero. For the input vector (X, Y), magnitude X, and phase θ , are the outputs. It is achieved by choosing α_i in such a way that Y converges to zero. The outcomes of the CORDIC algorithm are corresponding to a vector rotation or vector translation that is scaled by a constant Z_i , where Z_i is the CORDIC scale factor. The concept adopted in [6-7] is applied here to get the required trigonometric functions. Vector rotation is expressed as a sequence of ‘n’ micro-rotations.

$$X' = \prod_{i=1}^n \cos(\text{atan}(2^{-i}))(X_i - \alpha_i Y_i 2^{-i}) \quad (8)$$

$$Y' = \prod_{i=1}^n \cos(\text{atan}(2^{-i}))(Y_i + \alpha_i X_i 2^{-i}) \quad (9)$$

$$\theta' = \prod_{i=1}^n \theta - (\alpha_i \cdot \text{atan}(2^{-i})) \quad (10)$$

$$\alpha_i = (+ \text{ or } -) 1.$$

Where α_i is the direction of rotation.

C. Computation of cosinv using taninv

The computation of the cos inverse function is done using the trigonometric identity

$$\cos^{-1}(x) = \tan^{-1}\left(\frac{\sqrt{1-x^2}}{x}\right) \quad (11)$$

D. Recovery of real and imaginary components

The real and imaginary components of the complex transform are recovered using the phase and magnitude of the samples. Consider the phase θ and the magnitude r , then the trigonometric identity is

$$r * e^{i\theta} = r * (\cos \theta + i * \sin \theta) \quad (12)$$

Hence the real part will be $r * (\cos \theta)$ and the imaginary part will be $r * (\sin \theta)$. Here $r = |\tilde{e}[n]|$ which one is transmitted and $\theta = \Phi_e[n]$ is calculated using a phase recovery block at the receiver side. Using $|\tilde{e}[n]|$ and $\Phi_e[n]$, the DAST ECG samples $\tilde{e}[n]$ is recovered.

E. Modular Hierarchy

The unfiltered signal magnitude and filtered signal magnitude applied to the phase recovery block is shown in Fig. 3. The corresponding real and imaginary portions of the complex numbers are generated. The Verilog code for the phase recovery block is written as in the above hierarchy. The inputs and outputs of the phase recovery block are 16 bits. Initially, input ECG signal samples are scaled by 1000, since the samples will be in mV (which are less than 1). To work in Verilog easily the samples are scaled with 1000 and descaled at the output samples. The input angle i in degree is scaled and descaled to work with the trigonometric functions by 31994. Since the angle ranges from 0 to 360 degrees is very small for working with 16-bit resolution.

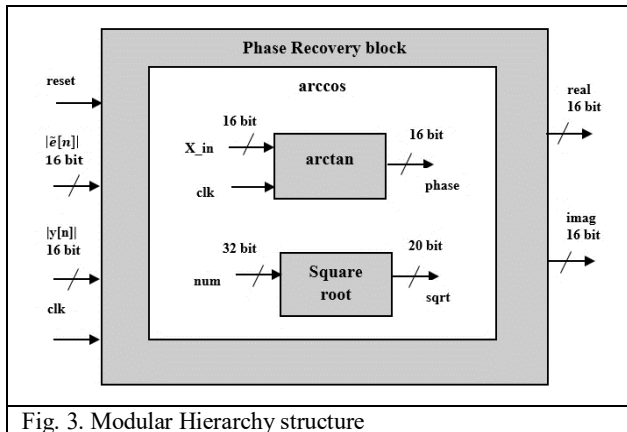

Fig. 3. Modular Hierarchy structure

F. Hardware blocks

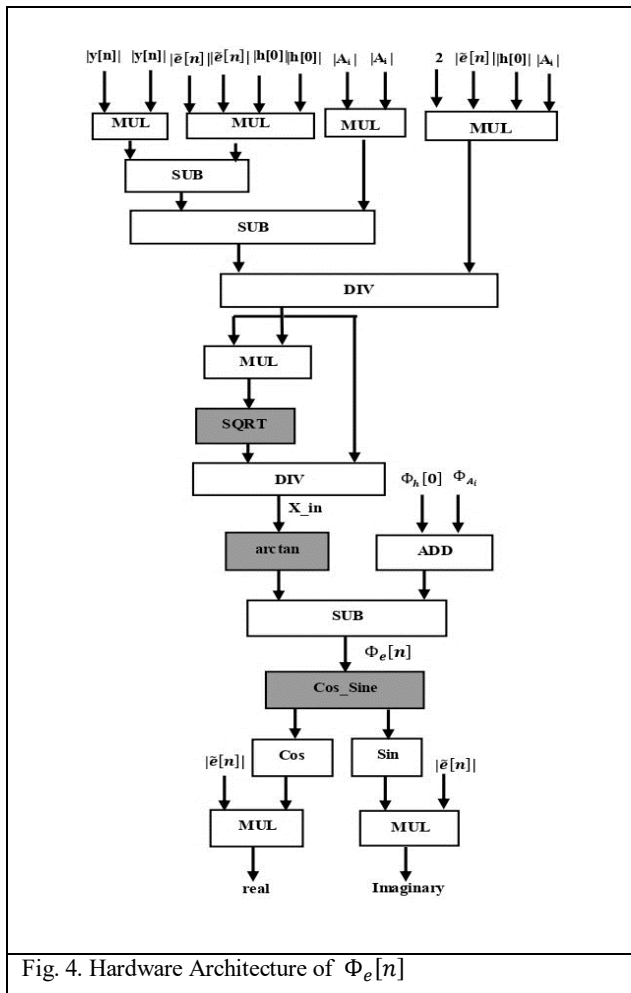

Fig. 4. Hardware Architecture of $\Phi_e[n]$

The different hardware blocks required for the phase recovery implementation are shown in Fig. 4. ADD and SUB indicate the 16-bit adder and subtractors respectively. The 16-bit multiplication blocks (MUL) and 16-bit division blocks (DIV) are also used. The block SQRT i.e. the square root function is implemented using the Non-Restoring Square Root algorithm. Arctan and cos_sine blocks are the trigonometric functions that are implemented using the CORDIC algorithm.

IV. SIMULATION AND RESULTS

All the modules are coded in Xilinx ISE 14.4 Design suite in Verilog HDL, simulated and synthesized using Xilinx Artix-7 FPGA device. Hardware results of the design are analyzed using Chipscope in the Xilinx platform. The filtered and unfiltered DAST ECG coefficient magnitudes are calculated using the Non-Restoring Square Root algorithm. It is implemented and verified with a simple example in Fig. 5. i.e $\sqrt{3^2 + 4^2} = \sqrt{25} = 5$. Each value is scaled by 1000. Cosine & Sine implementation is done with the CORDIC rotational mode in Verilog shown in Fig. 6. The input angle is specified in terms of $(2^{32} \cdot i) / 360$, where i indicates the input phase angle in degree. The output is scaled with a gain of 32000. Arccos is implemented using arctan by CORDIC vectoring mode in Verilog is shown in Fig. 7. $\arccos(x) = \arctan(\sqrt{1-x^2} / x)$. Input angle is specified in terms of $x \cdot 1000$, where x signifies input in radian. This gain is compensated in $(\sqrt{1-x^2} / x)$. The phase output is scaled with a gain of 342068275. The reconstructed complex DAST ECG sample is $esr + i esi$ recovered using the phase recovery block shown in Fig. 8. i.e $8 + i 619$ is recovered from two magnitudes. The hardware result for phases recovery block using chipscope is shown in Fig.9. The required number of adders, multipliers, and clock cycles are reported in Table I. For computing phase recovery for N samples, N + D clock cycles are required. Where D represents initial delay while computing trigonometric functions (sine, cosine, and arccos) using the CORDIC algorithm (Pipeline).

TABLE I. COMPUTATIONAL AND HARDWARE COMPLEXITY

Required Hardware Blocks	Number of blocks	Latency (cycles)
Adders / Subtractors	732	N + D
Multipliers	16	
Shifts	88	
Table lookup	44	

The hardware utilization details for the phase recovery block are reported in Table II.

V. CONCLUSION

The complex transforms are reported in the literature for improving the compression factor and reducing the reconstruction errors. The one-dimensional DAST is one of the complex transform used in ECG signal compression. Instead of sending real and imaginary parts separately, only the magnitudes are transmitted. At the receiver side, the necessary phase is recovered using these magnitudes. The proposed phase recovery block is effectively implemented in the ARTIX-7 FPGA board and the results are compared with MATLAB simulation results which is not reported in the literature. Advanced mathematical functions like square root and trigonometric functions are implemented using the CORDIC algorithm. Since it uses shift registers, adders, and look-up tables the Hardware requirement and the cost of a CORDIC processor are less. Working with the smaller values (less than one) in Verilog is a complex task. The problem is solved by multiplying the input samples by the scaling factor leads to error. The floating-point implementation may be considered in the future. FPGA implementation of real-Time ECG Signal processing can be carried out instead of the ECG signal database.

Abstract—In this paper, a real-time impulse noise removal (RTINR) algorithm and its hardware architecture are proposed for denoising images corrupted with fixed valued impulse noise. A decision-based algorithm is modified in the proposed RTINR algorithm where the corrupted pixel is first detected and is restored with median or previous pixel value depending on the number of corrupted pixels in the image. The proposed RTINR architecture has been designed to reduce the hardware complexity as it requires 21 comparators, 4 adders, and 2 line buffers which in turn improve the execution time. The proposed architecture results better in qualitative and quantitative performance in comparison to different denoising schemes while evaluated based on the following parameters: PSNR, IEF, MSE, EKI, SSIM, FOM, and visual quality. The proposed architecture has been simulated using the XC7VX330T-FFG1761 VIRTEX7 FPGA device and the reported maximum post place and route frequency is 360.88 MHz. The proposed RTINR architecture is capable of denoising images of size 512×512 at 686 frames per second. The architecture has also been synthesized using UMC 90 nm technology where 103 mW power is consumed at a clock frequency of 100 MHz with a gate count of 2.3K (NAND2) including two memory buffers.

Index Terms—Impulse noise, image denoising, filtering algorithms, image quality, PSNR, field programmable gate arrays.

I. INTRODUCTION

DIGITAL images are commonly corrupted with impulse noise due to faulty sensing, acquisition, transmission, and reception, leading to loss of information [1], [2]. The impulse noise is randomly distributed in the image, and it can either be fixed-valued or random-valued in nature. The fixed-valued impulse noise is referred to as salt-and-pepper noise, for which the image pixels can be altered into either black (graylevel = 0) or white (graylevel = 255) [3], [4]. Median filtering is widely used to eliminate such disturbances while maintaining image quality [5], [6]. The Standard Median Filter (SMF) alters both corrupted as well as uncorrupted pixels resulting in blurring of the output image [6]–[12]. To minimize blurring an improve image quality, the noisy pixels are detected and restored, while other pixels are kept unchanged. The Adaptive Median Filter (AMF) adjusts the processing window depending upon the noise density, however bigger window sizes result in increased blurring in the output image [13], [14]. Switching Median Filters (SWMF) restore noisy pixels by an immediate neighbour or the median value of the pixel neighbourhood while keeping the remaining pixels intact [15]–[20]. They perform well under various conditions, but are unable to restore images at high noise densities due to difficulties in determining impulse magnitude and impulse strength at sharp edges in the image. SWMFs

$P(i+1, j-1)$	$P(i+1, j)$	$P(i+1, j+1)$

with boundary discriminative noise detection (BDND) tackles this problem at the cost of increased execution time [21]–[23]. On the other hand, decision based algorithms (DBA) have lower complexity and can be executed in lesser time, but result in streaking effects at high noise densities [24]–[31]. A variety of techniques such as fuzzy based adaptive median filtering [32]–[39], genetic programming based filters [40], hypergraph-based algorithms [41], partial differential equation based filters [42], linear mean-median filters [30], noise elimination and edge preservation filters [43], interpolation based approaches [44], classified regularization approaches [45], and non-uniform sampling and autoregressive modelling based super-resolution techniques [46], Min-Max Average Pooling Based Filter for Impulse Noise Removal [47], An Adaptive Weighted Min-Mid-Max Value Based Filter [48], & Conditional Min Pooling and Restructured Convolutional Neural Network [49] have been used for impulse noise removal. These techniques involve significant computation on the corrupted images which is performed offline, making it difficult to get denoised images in real time. For real-time embedded applications involving impulse noise reduction from images, hardware implementations of such filtering algorithms is essential. Existing hardware implementations for impulse noise reduction are effective, but are not efficient occupying significantly large area [50]–[59]. We propose a modified decision based real time impulse noise removal (RTINR) algorithm along with its architecture to realize an efficient real time hardware design for portable systems. The algorithm and its implementation are evaluated based on parameters, such as, Peak Signal to Noise Ratio ($PSNR$), Mean Square Error (MSE), Image Enhancement Factor (IEF), Edge Keeping Index (EKI), Figure of Merit (FOM), Structural Similarity Index between Images ($SSIM$), and Mean Structural Similarity Index between Images ($MSSIM$) [1], [60], [61]. Above all the computation complexity is optimized and the processing time for the proposed algorithm is executed on a system with an Intel Core i7 processor at 3.1 GHz, equipped with 8GB RAM, running MATLAB 2012a. The remaining paper is organized as follows: Section II describes the proposed algorithm for the detection and reduction of impulse noise. The hardware architecture of the proposed algorithm and its VLSI implementation is detailed in Section III, Section IV deals with the performance analysis of the reconstructed image and Section IV draws the conclusions.

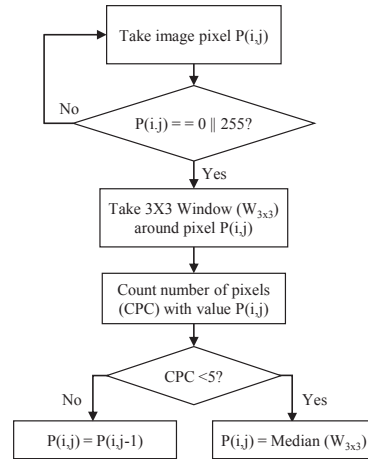

Fig. 1. Flowchart of the proposed algorithm (RTINR) for removing impulse noise from an image.

II. PROPOSED RTINR

Assume pixel values are changed in image I due to salt and pepper noise. For each pixel $P(i, j)$ in I , RTINR first detects the noisy pixel. If it is noisy, a window of size 3×3 ($W_{3 \times 3}$) is considered in Table I. Noisy pixel value is restored by the proposed RTINR depending on the number of corrupted pixel equals to $P(i, j)$ in $W_{3 \times 3}$. The algorithm and the flow chart of RTINR are given in Algorithm. 1 and in Fig. 1 respectively.

Algorithm 1 The RTINR Algorithm

- 1: **for** each pixel in the image **do**
 - 2: **if** pixel is noisy ($P(i, j) == 255 \parallel P(i, j) == 0$) **then**
 - 3: Take 3×3 Window ($W_{3 \times 3}$) around $P(i, j)$;

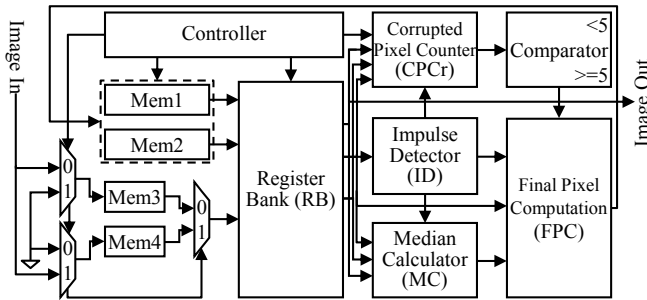

Fig. 2. Block level diagram of the VLSI architecture of RTINR.

III. VLSI IMPLEMENTATION OF THE PROPOSED ALGORITHM

Toward the objective of fast image processing for real time embedded applications, VLSI implementation of the RTINR architecture is proposed. Fig. 2 shows the block level diagram of the VLSI architecture of the proposed algorithm. The main building blocks of the architecture consist of Register Bank (RB), Impulse Detector (ID), Corrupted Pixel Counter (CPCr), Final Pixel Computation (FPC), Median Calculator (MC) and Controller. In the proposed RTINR three clock cycles are initially used to buffer the nine registers (R1 to R9) with image pixel values for $W_{3 \times 3}$ forming. After the latency of three clock cycles noise detection and restoration of each pixel in the corrupted image are taken place at each clock pulse. During the operation of noise cleaning, every processing pixel is read from, buffered with restored value into memory at each clock pulse. The hardware of RTINR requires only 21 comparators (CMP) and 4 adders along with two memory line buffer of size 512×8 each. Arithmetic operations like comparison and addition make it notably less complex in computation as compared to low-complexity noise removal (LCNR) technique [54]. A brief description of each block of RTINR for removing salt and pepper noise from image is presented below.

A. Register Bank (RB)

Fig. 3. Architecture of register bank in RTINR.

The register bank is made up of nine registers, R1 - R9, that are connected serially storing the pixel values, $P(i-1,j-1)$

- $P(i+1,j+1)$ of the current processing window $W_{3 \times 3}$. The architecture of the register bank is shown in Fig. 3 to process the entire image corrupted with salt and pepper noise. Denoising process starts when last pixel value $P(i+1, j+1)$ is buffered into the register R9. Current processing pixel $P(i, j)$ stored in register R5 is used to detect the noisy pixel and the type of corruption caused by either salt or pepper noise is also confirmed with the help of impulse detector (ID). The remaining pixels, stored in registers are then used simultaneously to determine the number of corrupted pixel as same type of $P(i, j)$ by subsequent corrupted pixel counter (CPCr). The replacement of the corrupted pixel $P(i, j)$ at register R5 with either median value or previous pixel $P(i, j-1)$ value is performed by final pixel computation (FPC).

In general, the restoration of corrupted pixel values in row_i for the subsequent image denoising process is performed by simultaneous read and write operations of RAM1 and RAM2. Image pixels are simultaneously read out from RAM1 as row_{i-1} and the values of row_i are written back into RAM1. In parallel to this, the values of pixel row_i are read out from RAM2 and at the same time the value of row_{i+1} are written back into RAM2. The data of third row is coming directly from input image as row_{i+1} .

B. Impulse Detector (ID)

Fig. 4 presents the architecture for impulse detector (ID) designed to detect the current processing pixel $P(i, j)$ disturbed with either salt or pepper noise in the proposed RTINR. Logical circuit diagrams for G1 and G2 in Fig. 4b and Fig. 4c are designed to determine grey level value of "255" and "0" for salt and pepper noise detection respectively. The type of noise is also determined from the output SN and PN of G1 and G2 respectively. Image pixel affected with salt noise is determined if all the bits of the register R5 is logically 1 i.e., the output SN of G1 is logic high. On the other hand image pixel is considered to be corrupted with pepper noise if all the bits of the register R5 attains logic value of 0 i.e., the output PN of G2 is logic high. One 5 input AND gate, one 4 input AND gate, one 5 input OR gate, one 4 input NOR gate and a 2 input OR gate are used to design the above architectures.

C. Corrupted Pixel Counter (CPCr)

The architecture for counting number of corrupted pixels (CPCr) or corrupted pixel counter (CPCr) is shown in Fig. 5. The output SN and PN from ID is used to determine the current processing pixel $P(i, j)$ corrupted with either salt or pepper noise. All the registers except R5 in RB are combined individually to perform bitwise AND and NOR operation for salt and pepper noise detection. Four adders are used to count the total number of pixels corrupted with either salt if SN is logic 1 or pepper if PN is logic 1.

Fig. 4. (a) Architecture for impulse detector, (b) salt noise (SN) detector and (c) pepper noise (PN) detector in RTINR.

Fig. 5. Architecture for counting number of corrupted pixels (CPCr) or corrupted pixel counter (CPCr).

D. Final Pixel Computation (FPC)

The value to be restored to the current processing pixel, $P(i, j)$, is determined based on the number of corrupted pixels (CPC) in the processing window. A simplified boolean expression is implemented to realize the output (RPSel) which selects either median or neighbour pixel value. If the number of corrupted pixels is less than 4 ($CPC < 4$), the processing pixel is replaced with the median pixel value ($P(i, j) = Median(W_{3 \times 3})$) otherwise ($CPC \geq 5$) by

Fig. 6. Architecture for Final Pixel Computation (FPC)

$C > B > A$	0	1	0	1	0	1	0	0	0

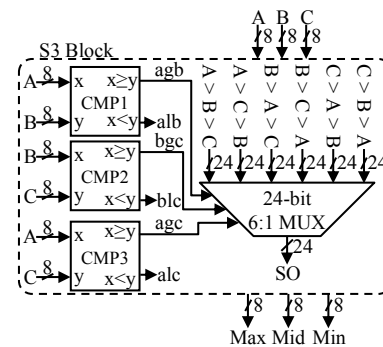

Fig. 7. Truth Table and architecture for sorting three numbers

previous value ($P(i, j) = P(i, j-1)$) in the processing window. Ultimately the final pixel value (FP) for each processing pixel is selected depending upon the value of ND which is shown in Fig. 6.

E. Median Calculator (MC)

Median value calculation is performed if CPC value is less than four ($CPC < 4$). Three steps are followed sequentially

Fig. 8. Architecture for median calculation in RTINR.

to calculate median value of 9 pixels stored in RB . First step is the sorting of rows of $W_{3 \times 3}$, columns of $W_{3 \times 3}$ are sorted in second step and in third step right diagonal sorting of 3 pixels [24] are performed to get the middle (Mid) value which is median of the 9 pixels of the processing window $W_{3 \times 3}$. Sorting of 3 numbers (Sorting Block or S3) is the basic building block shown in Fig. 7 required to determine median value. To achieve this a look up table based six sorting combinations for three numbers are presented in truth table Table III-D and is given as inputs to the 24-bits 6:1 MUX. Three selection lines of this MUX are the three binary outputs of three comparators namely CMP1, CMP2 and CMP3 used to determine the sorted output (SO). Therefore, seven S3 blocks are required to calculate the median value of current processing window $W_{3 \times 3}$. The architecture is shown in Fig. 8 implemented for calculating the median value of $W_{3 \times 3}$ in RTINR.

F. Controller

The controller module is designed to control the overall operations inside the architecture. The controller governs the read and write instructions for the data in the register bank is governed by the controller. The schedule for writing into and reading from memories RAM1 and RAM2 is guided by the controller module. In the architecture for proposed RTINR, an input reset signal initiates the process of impulse noise removal by activating the controller which directs all the steps from taking in a noisy image *ImageIn* to giving out a restored image *ImageOut*.

IV. IMPLEMENTATION RESULTS AND COMPARISONS

The qualitative and quantitative performances of the proposed algorithm RTINR is examined and analysed based on the following parameters: *PSNR*, *IEF*, *MSE*, *EKI*, *SSIM* and *FOM*. Five different gray scale images of size 512×512 such as Lena, Baboon, Boat, Goldhill, and Barbara are considered as reference images for testing.

To validate our proposed work we have taken five reference images like Lena, Baboon, Boat, Goldhill, and Barbara of size 512×512 with 8-bits gray value for simulation. The performance in terms of above mentioned parameters of the proposed algorithm has been evaluated and compared with the

existing noise cleaning algorithms at different noise densities in Fig. 9, Fig. 10, Fig. 11, Fig. 12 and Fig. 13 respectively. It is clear from the graph of Fig. 9 that upto 45% noise density, the *PSNR* value of our RTINR is greater than reported *PSNR* of existing methods. Other parameters like *IEF* and *SSIM* are also significantly higher compared to other noise removal techniques at 45% and 80% noise density respectively. It is also observed that proposed RTINR technique has lower *MSE* value with respect to other methods even upto 80% noise density. However, in comparison to other algorithms, there is no significant difference is observed in *FOM* at upto 60% noise density except CWMF method but at higher noise density RTINR outperforms the other methods. *EKI* of RTINR is very high with respect to SMF only. It also reveals that the RTINR outperforms the median filter based design not only at low noise density but also at higher noise density. It is observed from Fig. 10, Fig. 11, Fig. 12 and Fig. 13 that RTINR produces better quality of image even from different varieties of images corrupted with impulse noise. The performance of the proposed algorithm (RTINR) has also been verified with zero noise density of Lena image which is compared with different filtering algorithms in Table III. It is observed that RTINR has the capability even to restore noise free image without disturbing its pixel value. Fig. 9 shows the results of *PSNR* of 8-bits gray image of Lena (512×512) corrupted by impulse noise with a noise density varied from 10% to 90% after simulation in hardware of RTINR is compared with the reported results of SMF [7], decision based algorithm (DBA) [24], decision based adaptive filtering method [30], decision based switching median filtering (DBSMF) [31], fuzzy based adaptive switching median filtering [36], novel decision based adaptive weighted and trimmed median filter [28], iterative adaptive fuzzy filter using alpha-trimmed mean (IAFFUATM) [39], enhanced edge preserving impulse noise removal technique (EEPINRT) [56] and advanced modified decision based unsymmetric trimmed median filtering method [29]. In [30] the reported *PSNR* is greater than RTINR but the execution time of 20s is quite high. The architecture reported in [59] suffers from initial latency of 25 clock cycles and each pixel restoration is performed after 5 clock cycles. In the proposed RTINR architecture each pixel in the test image is restored in each clock cycle with a initial delay of 3 clock cycles. As the noise density increases IAFFUATM [39] gives better result but the iterations consume more time during filtering. Hardware implementation by Chuang *et al.* [53] for removal of impulse noise in RSEPD and SEPD is reported with a minimum number of false detection of corrupted image whereas in the proposed RTINR, the occurrence of false detection is zero. Although the platforms are different still two buffer lines of size 512×8 each and comparatively less area are required to implement it on hardware. The speed of the operation is also higher compared to other image denoising hardwares are tabulated in Table II. Execution times

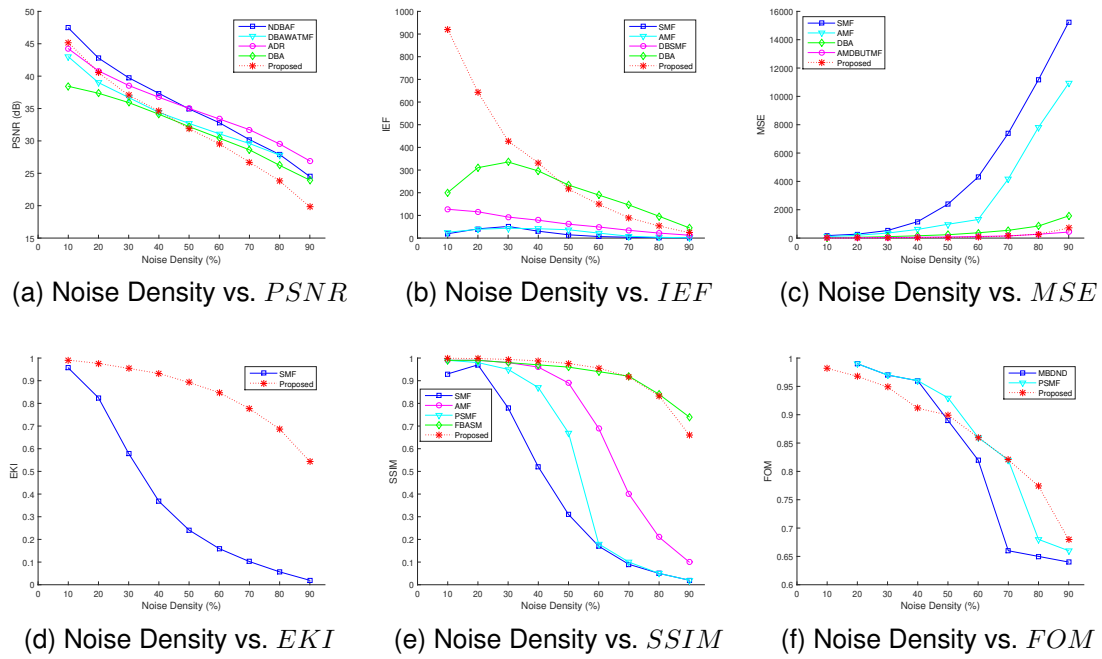

Fig. 9. Comparison of features of restored image in terms of $PSNR$, IEF , MSE , EKI , $SSIM$ and FOM for the 512×512 gray images of Lena with different noise densities using Matlab

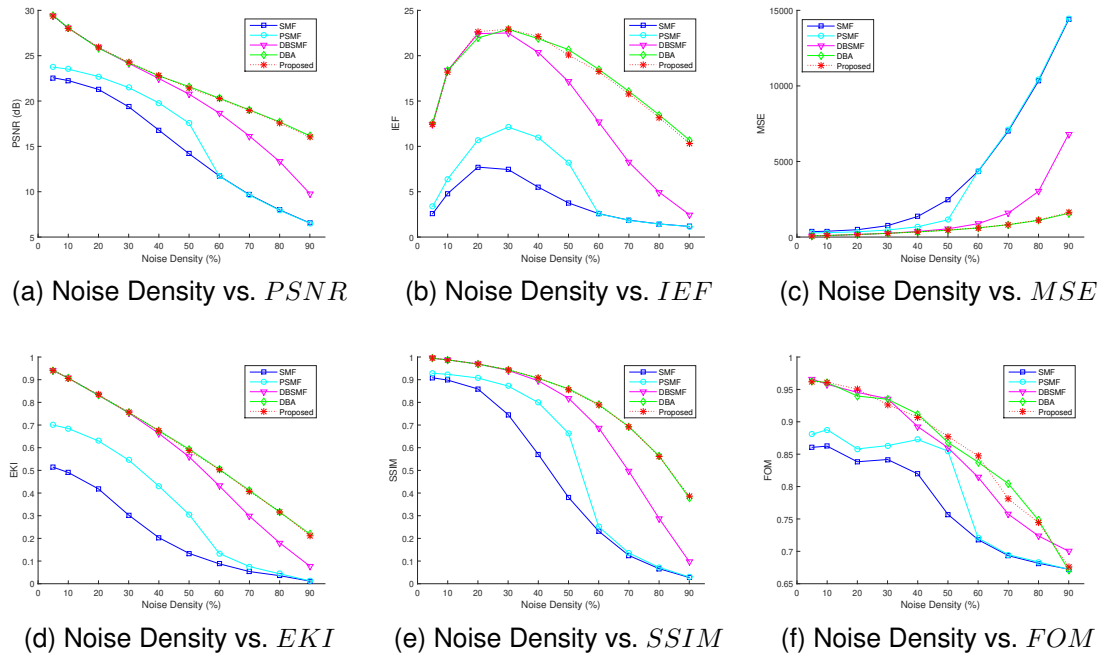

Fig. 10. Comparison of features of restored image in terms of $PSNR$, IEF , MSE , EKI , $SSIM$ and FOM for the 512×512 gray images of Baboon with different noise densities using Matlab

of different denoising algorithms are plotted with respect to different noise densities in Fig. IV which proves that RTINR can produce faster result. It is observed from Fig. IV that RT-

INR has higher $PSNR$ value compared to existing hardware based denoising techniques upto 30% noise density. Table IV shows the superiority of our RTINR in terms area and speed.

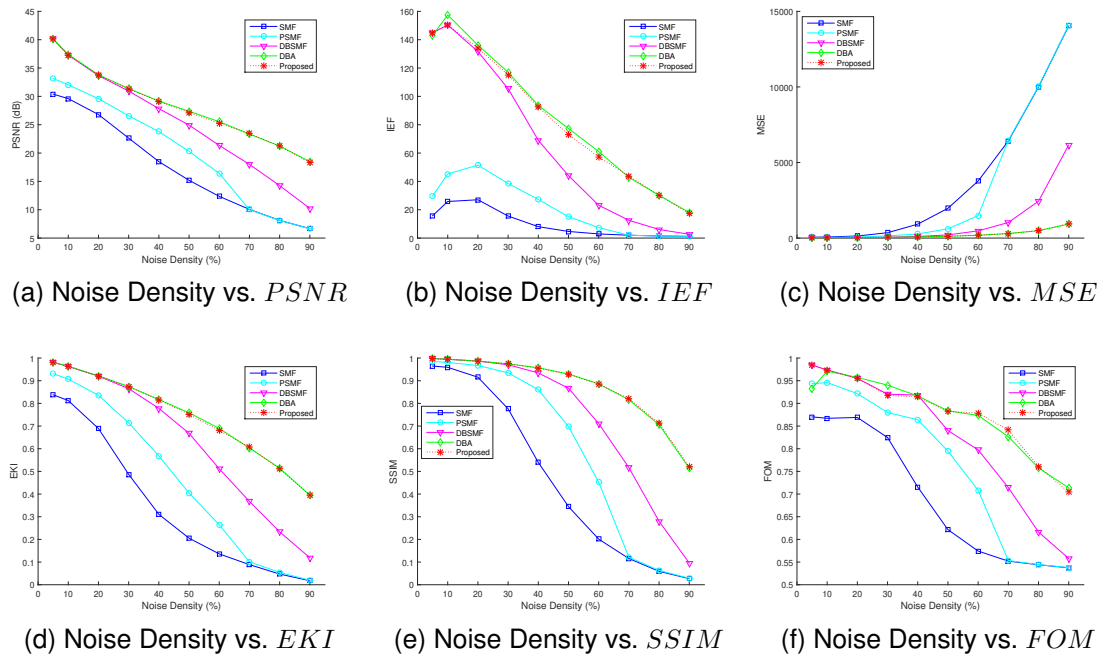

Fig. 11. Comparison of features of restored image in terms of $PSNR$, IEF , MSE , EKI , $SSIM$ and FOM for the 512×512 gray images of Boat with different noise densities using Matlab

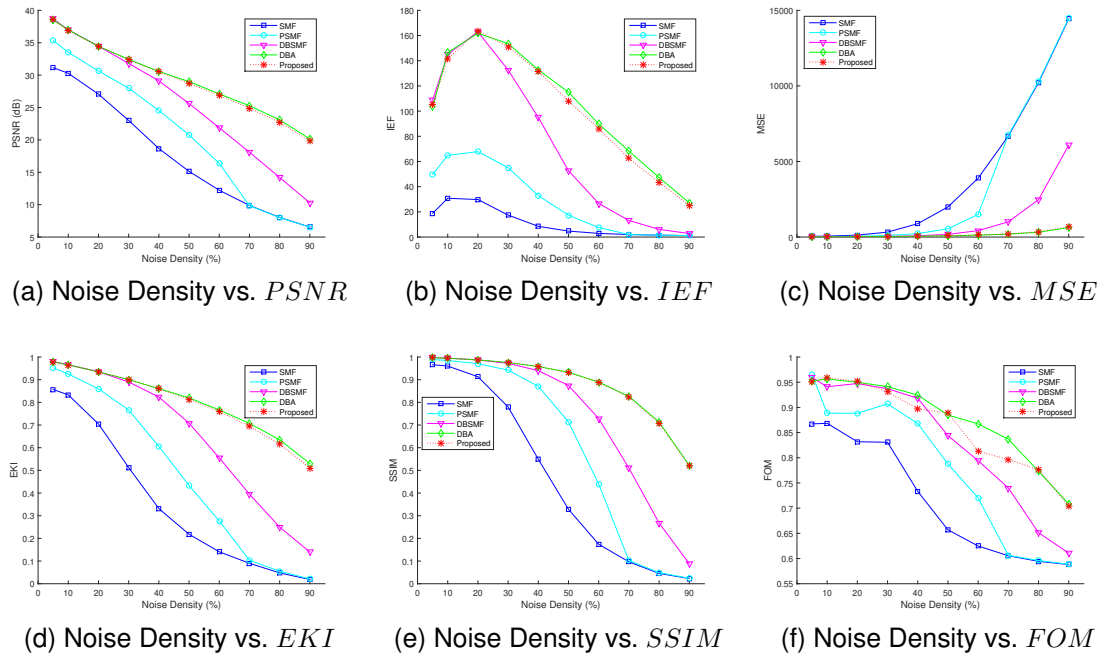

Fig. 12. Comparison of features of restored image in terms of $PSNR$, IEF , MSE , EKI , $SSIM$ and FOM for the 512×512 gray images of Goldhill with different noise densities using Matlab

The proposed architecture has also been simulated using XC7VX330T-FFG1761 VIRTEX7 device and the reported maximum frequency and device utilization after post place

and route synthesis using Xilinx ISE tool with version 14.7 has been tabulated in Table IV. The total power consumption of RTINR using XC7VX330T-FFG1761 FPGA is 178.52 mW

The architecture has also been implemented using UMC 90 nm CMOS process in Synopsys Design Compiler where 103 mW power is consumed at clock frequency of 100 MHz. The

total gate count of RTINR is 2.3K gates (NAND2) along with two memory buffer of size 512×8 each.

V. CONCLUSION

In this paper, a real time modified decision based algorithm and its architecture for removing fixed-valued impulse noise from the corrupted images has been implemented. The architecture has been simulated using Virtex7 device and the reported post-place and route simulation frequency is 205 MHz. During the process of noise elimination impulse detection of the current processing pixel is performed first. Corrupted pixel is then replaced with median or nearby value of the noise free pixel depending on the number of remaining eight pixels in 3×3 window. The execution time for noise cleaning of our proposed hardware at worst case supersedes with other reported denoising hardware. Comparative study of the contemporary techniques shows better performance in terms of *PSNR*, *IEF*, *EKI*, *MSE*, *SSIM* and *FOM* of our proposed work specifically at up to 50% noise density. Performance degradation of our proposed hardware is observed as the noise density increases from 60% to 90%. The speed, hardware cost of the proposed RTINR is also better in comparison to existing architectures.

Envisioning A Light-Based Quantum-Computational Nano-Cyborg

Dr Pravir Malik
 Deep Order Technologies
 San Francisco, USA

pravir.malik@deepordertechnologies.com

Abstract— By viewing light as a symmetrical, multi-layered construct, it is possible to envision a new genre of nano-cyborgs. In general cyborgs can be considered as a portmanteau of cybernetic and organic, and therefore as an entity consisting of both organic and mechatronic parts. However, in the multi-layered model of light subtle information existing in antecedent layers of light can be thought of as materializing through a process of quantization, that subsequently would require a nano-cyborg to interface with it, make sense of it, and act on it. Further quantum-level dynamics would necessitate nano-cyborgs of a tunneling type, annealing type, superposition type, and entanglement type, amongst others, that would have practical applications at nano-levels of different granularity. Such nano-cyborgs are envisioned to be built leveraging computational stratum at different levels of granularity ranging from the electromagnetic level, to the quantum particle level, to the level of atoms, to the level of molecular plans in cells. Immediate application areas of such light-based quantum-computational nano-cyborgs are envisioned to be in medical technology, material sciences, and alteration of genetic-type information, amongst others.

Keywords— *Quantum Computation, Cyborg, Symmetry of Light, Mechatronic, Nano*

I. INTRODUCTION

A cyborg is portmanteau of the words ‘cybernetic’ and ‘organic’ and is envisioned to be made up by both organic and mechatronic parts. This paper builds on the notion of ‘organic’ and ‘mechatronic’ to propose a new genre of cyborgs based on light-based quantum-computation.

Cyborgs themselves, are commonly categorized into mechanical cyborgs, intelligent cyborgs, and adaptive cyborgs, that leverage technologies such as robotics, algorithms, and machine learning respectively, that are therefore by definition limited by the current limits of AI.

As pointed out in ‘Limits of AI as Established by a Multi-Layered Symmetry-Based Model of Light’ [12] contemporary AI is based on mind-based processes such as memory, computation, sensing, and learning, that operate within a defined and limited conceptual space and are positioned to be substrate independent. This conceptual space and the operating principles that define it limit AI, which in its current incarnation will not

perceive the possibilities inherent in a multi-layered symmetry-based model of light, unless the notion of ‘substrate independence’ is anchored in the multi-layered symmetry-based model of light itself.

Note further, that even robots and androids as conceptualized to date are at best also based on similar mind-based processes, where a robot can be thought of as mechanical device or software program designed to do a specific task that would take more time by a human, and an android can be thought of as a robot designed to look like a human.

The light-based quantum-computational cyborg is going to be based on an enhanced notion of light as explored in a number of previous IEEE papers [8], based on the foundational Cosmology of Light work elaborated in a series of 10 books [3]. Such cyborgs, envisioned to operate at the scales of the electromagnetic spectrum, quantum particles, atoms, and molecular plans in cells, respectively, are further qualified to be nano-cyborgs.

Section I, A Quantum-Computation Model of Light, introduces a symmetrical, multi-layered light-based model. In this model quantization is proposed to connect the layers of light together so that as the layers cascade the vast amount of subtle information in the initiating layer progressively materializes in each subsequent layer.

Such cascading dynamism that is positioned to inform all materializations, as will be explored further, therefore also extends the notion of what it means to be ‘organic’, and Section II, Organic Surfacing in Matter and Life, suggests how layers of matter and life can be thought of as emergence due to a persistent quantum-computation. Such light-based quantum-computation pushes to the surface more of the information in light in forms of matter and life.

As such, an interface with these surfacings and an understanding of their structure will be central to the development of a light-based quantum-computational nano-cyborg being proposed here, and Section III, Light-Based Quantum-Computational Mechatronics, will suggest some technological mechanisms that must exist to access the information that is contained in light and that will be central to

the creation of this new genre of nano-cyborgs. It will also summarize the notion of alternative computational stratum at the electromagnetic, quantum particle, atom, and cellular levels that would be the foundation of the envisioned nano-cyborgs.

Section IV, Technological Extrapolations, will suggest a series of different kinds of nano-cyborgs and possible application areas.

Section V, Summary & Conclusion, will offer a summary and conclusion.

II. A QUANTUM-COMPUTATIONAL MODEL OF LIGHT

Light has a profound impact on how the nature of reality is experienced. Light traveling at speed c , 186,000 miles per second in a vacuum influences fundamentals such as space, time, and how the movement of objects may change [4]. It is possible to construct a multi-layered light-based model [10] [11] which can provide significant insight into the nature of quanta, by extrapolating on the necessity for light to move at a constant speed of c .

In this model the infinite information conceived were light to travel infinitely fast, is depicted by Equation (1), ‘Information When Light Travels Infinitely Fast’:

$$R_{C_\infty}: [Pr, Po, K, H] \quad (1)$$

This information (R_{C_∞}) is conceived as a set of four properties such that the element (Pr) represents the state of ‘presence’ formed because light is instantaneously present in whatever volume is being considered due to its infinite speed. The element (Po), ‘power’, is formed by the ability of light to overpower any other emergence not of the nature of light within the conceived volume. The element (K) represents ‘knowledge’, formed by the fabric of light being able to record any appearance or disappearance of an event in its substance. The element (H), ‘harmony’, is formed by everything that appears or disappears, being connected in the nature of such all-present light.

It is further conceived that the information summarized by (1) precipitates into material reality, represented by R_{C_U} and signifying a reality where light travels at speed c , referred to here as c_U , via intermediate realities where light is envisioned to exist at speeds slower than infinity, but faster than c_U . These intermediate realities are specified by R_{C_K} and R_{C_N} in (2) and (3) respectively, such that $c_U < c_N < c_K < c_\infty$, where c_x represents the speed of light at layer ‘x’. Note that while Einstein’s Theory of Relativity emphasizes that the acceleration to speed c from a slower speed that is not possible [16], it does not disallow speeds of light greater than c . Further, spaces with light speeds greater than c should be viewed as conceptual spaces made to vary were light to travel at different speeds. This is akin to the notion of property spaces, being separate from but influencing physical space as explored by Nobel Physicist Frank Wilczek [19].

Such precipitation itself is envisioned to take place via a series of quantization functions. The first quantization (\downarrow) is specified by ($\downarrow R_{C_K} = f(R_{C_\infty})$) and suggests that reality (R)

at c_K, R_{C_K} , is a function (f) of reality at c_∞, R_{C_∞} . Hence, the set specified by (1) is mathematically transformed into four large sets as specified by Equation (2), ‘Transformation into Four Sets’:

$$R_{C_K}: [S_{Pr}, S_{Po}, S_K, S_H] \quad (2)$$

In (2), S_{Pr} is the set of ‘presence’, S_{Po} is the set of ‘power’, S_K is the set of ‘knowledge’, and S_H is the set of ‘harmony’, respectively.

A further quantization takes place via ($\downarrow R_{C_N} = f(R_{C_K})$), and suggests that reality (R) at c_N, R_{C_N} , is a function (f) of reality at c_K, R_{C_K} .

Hence, elements from each of the four sets combine in unique combinations to create the basis of ‘seeds’, specified by Equation (3), ‘Creation of Unique Combinations’:

$$R_{C_N}: f(S_{Pr} \times S_{Po} \times S_K \times S_H) \quad (3)$$

In (3) hence, bases for a practically infinite number of unique seeds or functions are specified.

A final quantization, specified by ($\downarrow R_{C_U} = f(R_{C_N})$), suggests that reality (R) at c_U, R_{C_U} , is a function (f) of reality at c_N, R_{C_N} . This quantization results in material reality, specified by Equation (4), ‘Formation of Space, Time, Energy, and Gravity’:

$$R_{C_U}: [S, T, E, G] \quad (4)$$

In (4), ‘S’ refers to *Space*, ‘T’ refers to *Time*, ‘E’ refers to *Energy*, and ‘G’ refers to *Gravity*. Specifically, “Space” – is envisioned to be the arena for unique seeds specified by the subtle-seeds in (3); “Time” – ensuring that the possibilities in the seeds are worked out; “Energy” – associated with the conversion of seeds into concrete matter; and “Gravity” – specifying relationship between seed and seed and seeds and seeds thereby being the bases of future collectivities at different levels of granularity. Further, *Space*, being a repository of unique seeds - and therefore archetypes - represents light’s property of knowledge (K); *Time*, assuring maturity regardless of opposition represents light’s property of power (Po); *Energy*, fundamental to the process by which seeds accumulate presence, represents light’s property of presence (Pr); and *Gravity*, allowing relationship between seed and seed, represents light’s property of harmony (H) [9] [11].

Hence the multi-layered fourfold light-based model is summarized by Equation (5), ‘Multi-Layered Fourfold Light-Based Model’:

$$\left[\begin{array}{l} R_{C_\infty}: [Pr, Po, K, H] \\ (\downarrow R_{C_K} = f(R_{C_\infty})) \\ R_{C_K}: [S_{Pr}, S_{Po}, S_K, S_H] \\ (\downarrow R_{C_N} = f(R_{C_K})) \\ R_{C_N}: f(S_{Pr} \times S_{Po} \times S_K \times S_H) \\ (\downarrow R_{C_U} = f(R_{C_N})) \\ R_{C_U}: [S, T, E, G] \end{array} \right]_{\text{Light}} \quad (5)$$

In this model it is assumed that the deeper nature and activity at the quantum veil before matter is formed, is of the substance of *space-time-energy-gravity*. This is a logical outcome following the emergence of *space-time-energy-gravity* when light precipitates to speed *c*. Further, as proposed in ‘The Origins and Possibilities of Genetics’ [9], *space-time-energy-gravity* can also be thought of as the script used to write a “law” about any specific emergence. The aggregation of these “laws” determines the overall dynamics of *Space, Time, Energy, and Gravity* as experienced at the macro level. Note that the script writes more and more complex fourfold “law” into existence as evidenced by subsequent emergences of the electromagnetic spectrum, quantum particles, atoms, molecular plans, and so on [9] [13].

Note further that this model is entirely symmetrical, with the properties of light of *presence, power, knowledge, and harmony* conceived in the conceptual space were light to travel infinitely fast, showing up in different configurations of the same four properties in related conceptual spaces determined by proposed variation in speed of light. Such fourfold law is the basis of all that emerges including layers that are foundational to organic manifestation, as will be illustrated in the next section. Further, Such a view of organic manifestation necessitates a different kind of technology, that then becomes the basis of the mechatronics explored later in this paper.

III. ORGANIC SURFACINGS IN MATTER AND LIFE

The inherent fourfoldness of Light can be seen to form the foundation for the emergence of different layers of complexity of matter and life, starting at the field level and moving through the quantum, atomic, and cellular levels respectively, thereby also being the basis of organic manifestation.

Taking the first layer of emergent complexity, the Field Level, the four characteristics of light are expressed by the EM Spectrum (knowledge), its implicit energy-gradient (power), the speed *c* with which is propagated (harmony), and the potential for mass (presence) also implicit in it, respectively.

It can be surmised that the EM Spectrum itself is a repository of knowledge of a vast range of phenomena experienced in the Universe. This follows from the range of different types of waves from radio waves to gamma rays, determined as a function of frequency and wavelength of light, that form a set of archetypes. This relationship is indicated by Equation (6), ‘Knowledge Correlation in the EM Spectrum’:

$$Knowledge \propto [f(\nu) \& f(\lambda)] \tag{6}$$

It can also be seen that there is a large variation in energy or power implicit in the EM Spectrum. This is directly related to the large variance in the frequency of light in the EM Spectrum. This relationship is summarized by Equation (7), ‘Power Correlation in the EM Spectrum’, where ν is the frequency of the EM Spectrum:

$$Power \propto h\nu \tag{7}$$

The principle of harmony, as already suggested, is related to the speed of light at *U, c_U*. This is highlighted by Equation (8), ‘Harmony Correlation in the EM Spectrum’:

$$Harmony \propto c_U \tag{8}$$

Finally, Equation (9), ‘Presence Correlation in the EM Spectrum’, summarizes that mass-potential can be expressed as indicated, by combining $E = mc^2$ and the equivalence of *hν* with *E*, as in:

$$Presence \propto h\nu / c^2 \tag{9}$$

At the Quantum level it is suggested that quarks are a precipitation of the characteristic of knowledge. This is so because, protons, which determine atomic number, are composed of two “up” quarks and one “down” quark, and atomic number in turn uniquely identifies the element from the periodic table. So, an atomic number of 47, for example, specifies that the element is Silver. This implies that the unique properties of an element, the knowledge of what it is and how it will behave in the universe, is related to the quark. This is summarized by Equation (10), ‘Knowledge Correlation at the Quantum Particle Level’:

$$Knowledge \propto f(quarks) \tag{10}$$

Further, it can be surmised that electrons are a precipitation of the characteristic of energy. While quarks only exist in composite particles with other quarks, leptons are solitary particles. Leptons appear to be point-like particles without internal structure [14] with the best-known lepton being the electron. Arabatzis [1] in his article, “Representing Electrons: A Biographical Approach to Theoretical Entities”, details the characteristics of electrons. The electron may be considered as a surrogate for the lepton class. Importantly, the electron is associated with the flow of energy and power, amongst other properties. This is summarized by Equation (11), ‘Power Correlation at the Quantum Particle Level’:

$$Power|Energy \propto f(leptons) \tag{11}$$

Bosons can be thought of as force-carriers. It is due to them that all known matter particles interact. The three fundamental bosons in this category are the gluon, the photon, and the W and Z bosons. The gluon is the carrier particle of the strong nuclear force that holds quarks together. The carrier particle of the electromagnetic force is the photon. The carrier particle for the weak interactions, responsible for the decay of massive quarks and leptons into lighter quarks and leptons, are the W and Z bosons. Bosons, therefore, can be thought of as the precipitation of what creates relationship and harmony at the quantum level. This is why they can be thought of as the precipitation of harmony as summarized by Equation (12), ‘Harmony Correlation at the Quantum Particle Level’:

$$Harmony \propto f(bosons) \tag{12}$$

This leaves the Higgs-Boson: the other discovered fundamental particle. In ordinary matter the mass of an atom resides in the nucleus, made of protons and neutrons which are each made of three quarks. But it is the quarks that get their mass by interacting with the Higgs field [14]. Therefore, the Higgs-Boson can be thought of as the mass-giver, or that which gives presence to the quarks. This can be summarized by Equation (13), ‘Presence Correlation at the Quantum Particle Level’:

$$Presence \propto f(Higgs_boson) \quad (13)$$

Note that recent research at CERN [15] indicates that just as there are multiple particles in each of the other ‘families’ it is likely that there will be multiple particles in the Higgs-Boson family.

At the level of atoms, all atoms in the Periodic Table can be classified by the p-Group, d-Group, s-Group, and f-Group.

The p-Group of elements are those with a valence shell specified by the p-orbital. This indicated that the probability of the existence of an electron is equally likely on either side of the nucleus. Beyond elements such as Carbon, Nitrogen, Oxygen, and Silicon, there are elements of high significance in this group that are part of the metal, metalloid, non-metal, halogen, and noble gas sub-groupings. This grouping, therefore, can be thought to summarize many element possibilities within it. Perhaps it is the case that the possibility of ideas behind all elements has precipitated in this group. Hence one can hypothesize that this group may be a carrier or precipitation of light’s property of knowledge, forming archetypes from which all other elements are created.

Philosophically, the one probability cloud (s), to be discussed shortly, becoming two (p) signifies an essential polarity created within a unit space. Consider the hypothesis that the form is a ‘switching’ function that attracts function into form. If this is the case, then this dual manifestation may be viewed as the prerequisite condition by which a larger number of such ‘switches’ also come into being. This ‘essential two’ existing in three dimensions of space may then allow a threshold meta-function experimentation to come into being. But being the first instance of such variability in space it could therefore become an attractor for all the essential element-archetypes to precipitate.

To further reinforce this proposition, consider that the essential elements - Carbon and Silicon – both contained within this group, are what allows both thinking and virtual thinking machines to come into being. Carbon, after all, is the basis of DNA and of all life. The fact the Silicon (Si), directly below it in the periodic table and therefore sharing essential qualities, is considered the basis of all virtual thinking machines is therefore perhaps significant and may reinforce the notion that the p-Group is a precipitation of knowledge, as summarized by Equation (14), ‘Knowledge Correlation at the Atom Level’:

$$Knowledge \propto f(p_orbital) \quad (14)$$

In thinking about the d-Group, we know that it comprises the Transition Metals. These metals exhibit corrosive resistance, are generally hard and strong, and can be thought of as workhorse elements. Many industrial and well-known elements sit in this group: Copper, Zinc, Silver, Platinum Titanium, Chromium, Manganese, Iron, Cobalt, Nickel, and Gold, amongst others.

The d-orbital itself is a probability space characterized by four lobes around the nucleus. It is likely that four lobes occurring in 5 possible planes around the nucleus will create a space of stability, since there is a possibility of four lobes creating the four vertices of a tetrahedron that has been implicitly positioned as one of the most stable shapes [2]. Work

done in Crystal Field Theory [18] reinforces this concept. The general stability of the transition metals is reinforced by the d-orbital arrangement.

Note that most of the elements in this group easily lose one or more electrons to form a vast array of compounds. Further, much of the constructed world around us is created from these elements. It can therefore be surmised that these metals exist for service, to help bring about perfection in the constructed world, to help much of the machinery in which they are used, and to assist the processes dependent on them to be completed with diligence. We can conclude then that these transition metals appear to be a precipitation of Presence, as summarized by Equation (15), ‘Presence Correlation at the Atom Level’:

$$Presence \propto f(d_orbital) \quad (15)$$

Exploring the s-Group, one sees that it consists primarily of alkali earth metals and alkali metals. These groups are highly electropositive, easily losing electrons and forming positive ions, and releasing a lot of energy while doing so. Tweed [17] refers to these groups as the “violent world of the s-block”. Gray [5] points out that stars shine because they are transmuted vast amounts of hydrogen into helium. Note that both are s-block elements. This characteristic of easily released energy that the elements of this group share suggests that the s-Group is a precipitation of Power, as summarized by Equation (16), ‘Power Correlation at the Atom Level’:

$$Power \propto f(s_orbital) \quad (16)$$

Philosophically the s-orbital as a probability cloud indicates the equal likelihood that an electron can be anywhere in a symmetrical sphere around a nucleus. Since all other orbitals can be thought of as occurring within some fractal-like cloud as specified by the s-orbital, in therefore gives the sense of a space being created within which varied meta-functions can more easily precipitate to the level of U. In other words, the elements that are part of the s-Group may be thought of as the adventurers who venture forth to create some foundation by which all other element-creations can follow. The fact that H and He constitute 98% of the Universe [7] relative to other elements is significant in this view, since H and He provide the fuel with which the star-furnaces manufacture all other elements.

The f-Group comprises the Lanthanides and Actinides. Philosophically, the f-orbital, consisting of 6 probability lobes around the nucleus in 7 different planes suggests the attempt to build larger and larger bonds within a small space. This is clearly a dynamic reinforcing extended relationship and collectivity at the level of the atom. It is likely, therefore, that this group, continuing to draw the link with the quaternary architecture, is a precipitation of Harmony, as summarized by Equation (17), ‘Harmony Correlation at the Atom Level’:

$$Harmony \propto f(f_orbital) \quad (17)$$

At the cellular level, there are molecular machines that do the myriad things that distinguish living organisms. These machines are identical in all living cells [6] and uses four basic molecular plans with unique chemical personalities: nucleic acids, proteins, lipids, and polysaccharides.

Nucleic acids encode information. They store and transmit the genome, the hereditary information needed to keep the cell alive. They function as the cell's librarians and contain information on how to make proteins and when to make them. They are the keepers of a cell's knowledge, its wisdom, its ability to make laws. They are the vehicle to spread knowledge within cells and to the next generation of cells. It can be surmised then that nucleic acids are a precipitation of knowledge at the cellular level. This is summarized by Equation (18), 'Knowledge Correlation at the Cellular Level':

$$S_{K(cell)} \ni [Knowl., Wisdom, Law Making, Spread of Knowl. ...] \quad (18)$$

This relationship may also be summarized more simply by Equation (19), 'Knowledge Correlation (Simple) at the Cellular Level':

$$Knowledge \propto f(nucleic\ acids) \quad (19)$$

Proteins are known to be the cells work-horses. They are found in any part of the cell. They are built in thousands of shapes and sizes, each performing a different function. As described by Goodsell [6], some proteins are built simply to adopt a defined shape, assembling into rods, nets, hollow spheres, and tubes. Some proteins are molecular motors, using energy to rotate, or flex, or crawl. Many proteins are chemical catalysts that perform chemical reactions to transfer and transform chemical groups atom by atom, exactly as needed. With their wide potential for diversity, proteins are constructed to perform most of the tasks of the cells. In fact, there are as many as 30,000 different kinds of proteins in the human cell to execute on the diverse array of required cellular level tasks.

It may therefore be said that proteins exist for service. They bring about perfection at the level of the cell. They are characterized by extreme diligence and perseverance. Proteins, hence, can be thought of as a precipitation of presence at the cellular level as summarized by Equation (20), 'Presence Correlation at the Cellular Level':

$$S_{Pr(cell)} \ni [Service, Perfection, Diligence, Perseverance, ...] \quad (20)$$

This relationship may also be summarized more simply by Equation (21), 'Presence Correlation (Simple) at the Cellular Level':

$$Presence \propto f(proteins) \quad (21)$$

Lipids by themselves are tiny molecules. When they are grouped together though, they form the largest structures of the cell. When placed in water lipid molecules easily aggregate to form large waterproof sheets. These sheets naturally form boundaries at multiple levels, to allow concentrated interactions and work to be performed within a cell. The nucleus and the mitochondria, for example, are contained within lipid-defined compartments. Similarly, each cell itself is contained within a lipid-defined boundary.

Lipids can therefore be thought of as the promoters of relationship and of harmony in the cell. They can also be thought of as nurturing the cell-level division of labor and of allowing specialization and uniqueness to emerge. Even perhaps of exhibiting early forms of compassion and love. This

function of harmonization suggests that lipids are a precipitation of harmony at the cellular level as summarized by Equation (22), 'Harmony Correlation at the Cellular Level':

$$S_{H(cell)} \ni [Love, Compassion, Harmony, Relationship ...] \quad (22)$$

This relationship may also be summarized more simply, by Equation (23), 'Harmony Correlation (Simple) at the Cellular Level':

$$Harmony \propto f(lipids) \quad (23)$$

In contrast to lipids, polysaccharides are long branched chains of sugar molecules. Further, these are covered with hydroxyl groups, which associate to form storage containers. Because of this polysaccharides function as the storehouse of cell's energy. But also, polysaccharides are used to build some of the most durable biological structures. The stiff shell of insects is made of long polysaccharides, for example.

Polysaccharides therefor function to create energy, power, courage, and strength. They also ready the cell for adventure, amongst similar functional traits. Providing energy and strength, it can be surmised that polysaccharides are a precipitation of power at the cellular level as summarized by Equation (24), 'Power Correlation at the Cellular Level':

$$S_{Po(cell)} \ni [Power, Courage, Adventure, Justice, ...] \quad (24)$$

This relationship may also be summarized more simply by Equation (25), 'Power Correlation (Simple) at the Cellular Level':

$$Power \propto f(polysaccharides) \quad (25)$$

IV. LIGHT-BASED QUANTUM-COMPUTATIONAL MECHATRONICS

Equation (5), Multi-Layered Fourfold Light-Based Model, suggests a model at the core of the dynamic emergence of matter and life. This equation can be generalized to form Equation (26), Generalized Form of Light-Based Emergence, where x_U can be thought of as an initial output of (5) that iterates to create x_T such that the next x_U is the previous x_T :

$$x_T \leftarrow \left(\begin{array}{c} R_{C_{\infty}}: [Pr, Po, K, H] \\ (\downarrow R_{C_K} = f(R_{C_{\infty}})) \\ R_{C_K}: [S_{Pr}, S_{Po}, S_K, S_H] \\ (\downarrow R_{C_N} = f(R_{C_K})) \\ R_{C_N}: f(S_{Pr} \times S_{Po} \times S_K \times S_H) \\ (\downarrow R_{C_U} = f(R_{C_N})) \\ R_{C_U}: [S, T, E, G] \end{array} \right)_{x_U} \leftarrow_{<x_U: x_T>} \quad (26)$$

Hence the application of (26) will iteratively produce the fourfold light-based outputs as illustrated in the previous section: the electromagnetic spectrum, quantum particles, atoms, and molecular plans.

Such light-based output contrasts with the random, probabilistic output imagined to be true of the quantum-level in general. By a process of reverse extrapolation, and more importantly by a process of induction assuming Equations (5)

and (26) to be models of emergence, a different fundamental activity existing in the minutia of space must be considered a possibility.

Such innate activity will also necessitate that this fundamental core of organic-ness must be read differently, necessitating therefore, a different genre of mechatronic devices to read and respond to this activity. Such a device would need to be based on a different “sight” of the dynamics in the minutia of space, as suggested by (5) and (26).

As opposed to traditional computational devices based on binary-based logic, or mainstream quantum-computational devices as envisioned by industry leaders based on qubit logic, such a mechatronic device will need to be based on logic that recognized fourfoldness and have circuitry that can freely manipulate and build on the mathematical possibilities suggested by (5) and (26).

Mechatronic devices could leverage any of the fourfold light-based emergences as elaborated in Section III - the electromagnetic spectrum, quantum particles, atoms, and molecular plans. These emergences have been previously explored as possible computational strata [13] – with the ability to house memory, create logical gates, and seed wide functionality - and here the gist of it will be summarized.

Considering the electromagnetic spectrum level:

- **Memory:** The ability to house memory is suggested by the arising of many potential stable states manifest as different frequencies or wavelengths of light. This is further reinforced by the ability to easily change from one stable state to another.
- **Logical Gates:** The creation of logical gates can be enabled by constructive and destructive interference of wave. Conceptually, this will allow calculations and logic to be implemented.
- **Arbitrating Functionality:** From a consideration of (3) in combination with (6-9) it also becomes apparent how unique seeds or functional states can be created through leveraging the four aspects that architect the electromagnetic field - knowledge, presence, power, and harmony.

Considering the quantum particle level:

- **Memory:** Memory may be operationalized through the action of electrons in an atom. Hence, an electron in a particular orbit around an atom may represent one memory state while its existence in another orbit may represent another memory state.
- **Logical Gates:** Gates of various kinds may be constructed through combinations of orbits in atoms and the action of photons to flip the status of gates, to begin to implement broader functionality.
- **Arbitrating Functionality:** Stratum specific seeds housing unique functionality are envisioned to exist through the seed formulation introduced by Equation (3) in combination with (10 – 13).

Considering the level of atoms:

- **Memory:** Memory can be conceived by a mechanism involving some reversible reaction in which a particular atom in a molecular conglomerate has dominance, and therefore stability, subsequently yielding to another atom in the same conglomerate, and vice-versa.
- **Logical Gates:** Function may exist by implementing logical gates formed by a combination of different groups of atoms and stimuli, such that the atoms will always react in a predictable way under the influence of the same stimulus.
- **Arbitrating Functionality:** Equation (3) in combination with (14 – 17) suggests the potentially vast variety of function-based seeds that are possible, also hinting at the implicitly creative as opposed to constructive aspect of computation possible at this level.

Considering the level of molecular plans:

- **Memory:** Memory can be conceived as a function of one of the myriad types of cellular proteins that might exist in one or more stable states. The influence of an enzyme can predictably flip the protein from one state to another, thus allowing the operation of memory to come into existence.
- **Logical Gates:** Function may exist by implementing logical gates formed by the combination of different proteins and stimuli, such that a protein will always react in a predictable way under the influence of some stimulus.
- **Arbitrating Functionality:** Here too the creative as opposed to constructive aspect of computation becomes apparent when considering the formation of the potentially vast variety of function-based seeds as suggested by (3) in combination with (18 – 25).

V. TECHNOLOGICAL EXTRAPOLATIONS

The envisioned nano-cyborgs, leveraging off one or more of the mechatronic schemes suggested in the previous section, would be sensitive to information at the light-based interface that is positioned to exist in all emergences regardless of level, as suggested by Equation (26).

Hence such nano-cyborgs could be electromagnetic based, quantum particle based, atom based, or molecular plan based, in nature. Being open to the fundamental light-based dynamism that is positioned to be at the base of organic life, would potentially make these nano-cyborgs “organic” – provided they have the mechanism to make choice in real-time that does not in any way impede the natural organic-ness seeking to emerge. Fourfold logic emanating from (5) and leveraging flexible circuitry as suggested in the previous section, could assure this.

It is perhaps easiest to envision applications that may exist at the molecular-plan level in cells first, and then work backward from there.

At the cellular level hence, it can be posited that all health is based on the right functioning of a cell. In the cell not only do all four molecular plans need to play their part, but further all four molecular plans need to work with each other. The light-based quantum-computational nano-cyborgs, being essentially quantum mechanical in nature since they are operating at the level of the smallest fragments or packets of light, could be designed to generate quantum phenomenon such as superposition, entanglement, tunnelling, and annealing [20]. It would be possible to have such nano-cyborgs leverage one or all of the four quantum phenomenon to influence the health of a cell.

For example, a target set of molecules in an unhealthy cell could be urged into a state of health by superposition-causing nano-cyborgs so that the presiding seed-function, as summarized by Equation (3), could be activated in the target cells to thereby change their functioning. Or the action of a well-functioning protein could be tunneled into a set of cells by a tunnelling-causing nano-cyborg to alter growing dysfunction into function. Further, the effect of a group of healthy cells, using an annealing-causing nano-cyborg, could be made to change the functioning of unhealthy cells. Finally, an entanglement-causing nano-cyborg could combine the effect of two specific nutrients that would then be targeted at specific sets of cells or areas of the body.

At the level of atoms, specific light-based quantum computational entanglement-causing nano-cyborgs could entangle a set of meta-functions such as preside over the action of diverse elements, for example - gold, silicon, helium, and cerium - amongst other possibilities, targeting this at a light-based interface, to influence a process of crystallization that could be organized to take place on the other side interface. Such processes may also influence the field of material sciences to ground new properties or even new combinations of elements into unique materials. A similar process may also be applied to the way that quantum particles come together to create stable atoms.

At the level of the electromagnetic spectrum, light-based quantum-computational sensing nano-cyborgs may be designed to sense the rate of change in particular subtle frequencies and wavelengths to predict or even change the space-time-energy-gravity scripts, aka genetic-type information, of particular environments.

VI. SUMMARY & CONCLUSION

This paper has suggested a new genre of light-based quantum-computational nano-cyborgs. Such cyborgs are the natural outcome of modeling light as a quantum-computational, symmetrical, multi-layered construct. The quantum is seen to be a bridge mechanism between layers of light, and quantum-computation is seen as being a persistent process in which different possibilities originating in different layers of light are arbitrated into existence at every instant.

Since space-time-energy-gravity is envisioned as being a first outcome caused by light precipitating to speed c , and further, as the very script by which genetic-type information is encoded, cyborg sensitivity to particular kind of fourfoldness, perhaps at the subtle electromagnetic level, may imply that such cyborgs also be able to influence genetic-type script by sensing and shifting space-time-energy-gravity information in targeted micro-phenomenon.

In such a model organic-ness can be positioned as ubiquitous since even what is perceived as inanimate matter would have emerged through several quantum-computational iterations of the multi-layered light-model resulting in fourfold emergence at the space-time-energy-gravity level, the electromagnetic spectrum level, the quantum particle level, and the atom level, respectively. Something of the information in antecedent layers of light, is dynamic in everything which therefore offers all that emerges a sense of organic-ness. To be sensitive to such fourfold dynamism perhaps even implies that the sensing mechanism itself becomes organic.

But a particular kind of sensing mechanism and architecture that leverages natural computational stratum at different levels of granularity – the electromagnetic, quantum particle, atom, molecular plans in cells - would be required to interface with such organic-ness. Various mechatronic devices would encapsulate this ability.

The resulting nano-cyborgs would be of different kinds: Tunneling-nano-cyborgs, annealing-nano-cyborgs, entanglement-nano-cyborgs, superposition-nano-cyborgs. But then there would also be sensing-nano-cyborgs. Nano-cyborgs could also be enabled by machine learning and neural networking to learn and therefore sense differently.

Application areas of such nano-cyborgs would foreseeably be in the areas of cellular healing and medical technology, in material sciences, and in alteration of genetic-type information, amongst other possible areas.

Abstract— Smart farming is an evolving concept in the field of information and communications technology. In this, the IoT sensors and image processing is used to establish transparent mechanisms of feedback about the growth and productivity of crops and the environmental surrounding conditions. In this paper, the solution of the aforementioned problem statement in the form of an accountable live information system of the cultivated crops to yield efficiency has been presented. The feedback mechanism consists of monitoring parameters like temperature, humidity, weather, soil and crop moisture, crop health, etc. It provides the information between the planting phase and the harvesting phase to facilitate soil management and climate forecasting in real time. The proposed paper suggests the use of an open data platform, namely Adafruit IO, for visualizing and analyzing real-time in the IoT integrated system. Further, image processing approach has been used for crop remotely health monitoring for 2 widespread diseases namely, *Glomeralla Cingulata* and *Phaeoisariopsis Bataticola*. Owing to the economical nature and the ergonomic design of the proposed system, it has the feasibility of being implemented on a large scale in water scarce economies aiming to build a sustainable smart farming infrastructure by automating existing irrigation systems.

I. INTRODUCTION

The internet of things (IoT) comprises of all the physical electronic devices that are connected to the internet, all of which are actively collecting and sharing information. These devices are likely to be found embedded with sensors, software, and processors that enable them to connect with other devices and systems over numerous communication networks. IoT has been considered a misnomer, given that no device needs to be connected to the public accessed internet.

Today's smart computing is mostly based on the Internet of Things and over the 46% of the world population is using this technology. It plays a vital role in transforming conventional forms of technology into next generation technology. IoT has already gained a critical role in areas of research globally and specifically in the area of advanced wireless communication technology. It has seen exponential growth in usage in a very short period of time. In the view of

a normal user, IoT has laid the foundation for products that uses wireless technology extensively. For example, it is being used in products like smart living, smart education, automation, and process controls [1-3]. Commercially, it is being used in manufacturing, transportation, agriculture, and business management as well [4-7].

The future of agricultural technology is precision agriculture. The data that is being generated from multiple sensors on the field can be used for data analytics. Therefore, assisting farmers in improving crop yield. The aim of this paper is to design a working product which will enable farmers to access real time soil, crop, and environmental data.

The anticipated advantages of smart farming include remote monitoring for farmers, handling water supply and natural resource conservation. Real time data allows for necessary manipulations of variables that can be handled by man. Integrating an image processing mechanism guarantees information about crop diseases as well. This would allow the farmer to take quick action and stop the disease from spreading to other crops in the field.

Some disadvantages of smart farming are the requirements. Full-time availability of the internet is a major challenge in the rural areas. Unfortunately, most of the farming in India happens in rural areas. However, there has been a lot of improvement in last few years. Multiple segments of Indian states have been getting access to the public internet. The smart farming-based equipment require farmers to understand and learn the use of technology. A mobile application with a sophisticated user interface however might enable farmers to understand how this concept works.

Integration of image processing and computer vision enhances the potential of this system. With computer vision, the agricultural industry greatly benefits by further productivity along with lower capital costs surrounding production capacities [8]. This is done via the detection and analysis of objects and presenting valid hypotheses based on meaningful interpretations out of a sequence of images. Computer vision AI models have immeasurable uses in the

fields of planting, harvesting, analysis of weather, weeding and crop health detection and real time feedback for monitoring [9].

This paper presented an agricultural system with an IOT environment which requires adequate manpower. It employs IOT and cloud computing globally to remove the inadequacy and lack of management, which are considered to be the key factors responsible for the decline in quality agriculture.

II. METHODOLOGY

Varying crops require different levels of water levels for cultivation between the plantation and the harvesting phase depending upon the week of harvest. Based on the standardized template of the sample crops, information about the minimum threshold and maximum capacity of water required along with live feed of additional parameters like pesticides, seed monitoring, sunshine and humidity on the proposed automated irrigation network would be fed into the system. The water supply from the submersible water pump would be released at regular intervals based on the inputs from the sensors in the soil. Moreover, the quantity and the type of pesticides can be decided using the concepts of image processing approaches. The image processing techniques such as morphology, binarization and segmentation can be used for the identification of anomalies over a crop area to estimate and monitor plant growth.

III. PROPOSED SYSTEM DESIGN

The proposed system for smart irrigation is shown in Fig. 1. It consists of Sensors, Node MCU, LDR and camera. The principal framework comprises of a Wi-Fi Module, specifically, an ESP8266 Node MCU configured with numerous sensors such as the DHT11 humidity sensor, DS18B20 temperature sensor probe, soil moisture sensor, a light dependant resistor (LDR) and a water pump as shown in Fig. 1. The descriptions of each sensor implemented in this design are given below.

Fig. 1. Hardware Diagram

A. NodeMCU ESP8266

The ESP8266 is a low-cost Wi-Fi microchip, with built-in TCP/IP networking software, and microcontroller capability. This Wi-Fi module is used in the design to connect all the sensors to an online IO, Adafruit to share, collect and analyse the data.

Fig. 2. NodeMCU Module

B. Soil Moisture Sensor

Soil moisture sensors are globally used to estimate the content of water in the soil. The moisture sensor used in this system is a capacitive sensor. It calculates the change in capacitance caused due to the dielectric. It cannot measure moisture directly as pure water does not conduct electricity. Some advantages of using a capacitive sensor are that corrosion is avoided and gives an accurate reading of the moisture content in the soil.

Fig. 3. Capacitive Moisture Sensor

C. DHT11 Humidity Sensor

The DHT11 Sensor is the most frequently used temperature and humidity sensors in the field of IoT, owing to its extremely low price. It uses a capacitive humidity sensor and a thermistor to measure the air temperature. It also directly produces a digital signal without the need of an ADC.

Fig. 4. DHT11 Sensor

D. Light Dependent Resistor(LDR)

LDRs are also called photoresistors since the resistance produced is dependent on the amount of light. Hence, this module is used in our system to monitor the amount of sunlight during the day. The resistance of this LDR is indirectly proportional to the intensity of light, hence, when the light intensity increases, the resistance offered by the LDR decreases.

Fig. 5. Light Dependent Resistor

E. Water Pump

The mini water pump that is used in this model is a 3-5V DC Pump. It is programmed to turn on when the moisture content in the soil is lower than the configured value.

Fig. 6. Mini Water Pump

This model also employs an open-source Input/Output (I/O) cloud service, namely, Adafruit I/O. It is a platform that permits aggregation, visualisation, and analyzation of live information on the cloud. Adafruit I/O also enables motor controls and reading data via sensors. The cloud service has multiple feeds that are used to monitor various data being captured by the sensors. A minima and maxima are predefined during configuration, below or over which the farmer is notified for corrective measure.

The ESP8266 NodeMCU governs the communication between the sensors on the board and behaves as the IOT Gateway to the cloud. All the sensors detect the physical parameters and convert the analogue value into a digital value. This is achieved using an in-built Analog-Digital-Converter (ADC) in the sensor modules. The humidity sensor, DHT11, is used to compute the environmental humidity. The temperature sensor probe and the OpenWeatherAPI is used to monitor the soil temperature and get live environmental temperature, respectively. The soil moisture sensor is a capacitive sensor which estimates the amount of water in the soil. It works on the principle of open and short circuit. In simpler words, it acts as a switch with an ON/OFF mechanism [11]. Whether the output is high or low indicated by the in-built LED. When the soil is dry, the current is not conducted, hence, acting as an open circuit, with the output being high. When the soil is wet, the current flows from one terminal to the other and the circuit is shorted. Consequently, the output is low. Therefore, when the moisture sensed is below

threshold, the water pump turns on and provides continuous water flow till the threshold value is met [10].

The cloud service, Adafruit I/O, deployed in this system will provide a dashboard of multiple feeds depending on the parameters that have to be analysed. In this case, a total of 8-9 feeds are set up which include all the data acquired from the installed sensors. This will also comprise of a system which will alert the farmer or the user when the environmental factors are extreme. For example, whenever the temperature measured is above the set point, an output from a decision logic notifies the farmer. A model Adafruit I/O dashboard from an run is shown in Fig. 7.

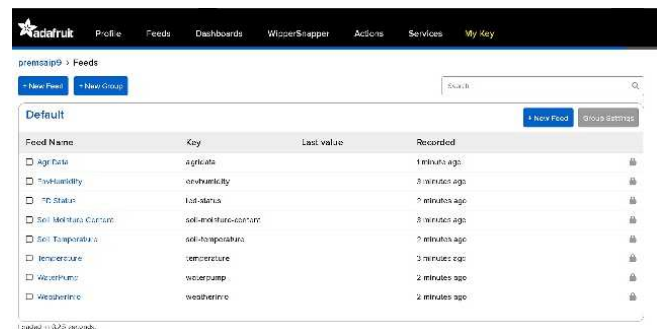

Fig. 7. Adafruit Dashboard

The IoT based system is implemented by using Arduino IDE. The sensing phase is concerned with the estimates of all the physical parameters which comprise of humidity, moisture, temperature, and light. Although the ESP8266 module acts as the IoT gateway, Arduino is used to program the sensors to it. The basic flow of the program is as follows:

Start

- Initialise all sensors
- Continuous sensing of data over regular time intervals
- Analogue to Digital conversion of data
- Set threshold values for physical parameters
 - If the value of acquired data is above threshold
 - LED glows on particular sensors
- Read weather forecast from OpenWeatherAPI
- Establish data on Adafruit dashboard

End

F. Image Processing

The following parameters can be broadly classified as the major criteria involved surrounding the productivity of crops and plants in 4 respective areas:

- Identifying Plant/Crop diseases
- Monitoring the growth of crop/plant
- Monitoring the health aspects of crop/plant throughout its plantation timeline

The following flowchart in Fig.8. lays down the foundations of the steps involved ranging from acquiring our image to the final classification of the disease detected:

Fig. 8. Basic Steps of Image Processing in Leaf Disease Detection

The Images of the target plants during their harvesting phase are captured via a webcam. The images are pre-processed in order to eliminate any distortions or impurities and noise which might be present in the images extracted and are prepared for the upcoming processing methods like extraction of features required in the later stages. Segmentation is primarily done to separate the respective area of interest by filtering out from the image captured. The basic purpose of segmentation is to create a collection of segments that are combined overall to represent the entire image into a set of contours which are obtained from the captured image.

Feature Extraction is mainly used to extract features from the processed image after which we use the respective features for classification purposes. Its main use is to reduce dimensions in the image and compress the data which is to be processed in order to target the specific features which help us in disease classification. This is done in order to filter out the input data and eliminate redundant data.

Classification is done on the basis of spectral features in the features created. And classification aids in the process of dividing the feature target space into various classes according to the input decision rule.

Initially after high resolution images of plants/crops are captured via a webcam, image pre-processing and processing techniques are implemented in order to get features which would be needed for analysis at a later time. The image, which is in the form of Red, Green and Blue (RGB) is converted to a Hue, Intensity, Saturation (HIS) model for increasing luminance of every frame of the image [11]. Further for the purpose of smoothening and filtering out noise. This is done by enhancing contrast in the image for increasing the accuracy of output and better implementation of segmentation on the image. Furthermore, Image segmentation is carried out using thresholding which is an efficient method in order to separate the background from the foreground and also masking pixels which are green indicative of healthy parts of a leaf or crop [12].

Segmentation is done using k means clustering, with standard Euclidean distance as the measuring parameter for

calculating extent of similarity, which is an unsupervised machine learning algorithm where k denotes the number of centroids (which represents the center of the cluster) that are present in our dataset. For our respective algorithm, a structure was created for color transformation which is based on the model proposed by Oo and Htun[13] in his research. This is done mainly to mask the green pixels of the leaf image which is to separate out parts of the image. Our proposed algorithm creates $k = 3$ clusters in no particular order- One cluster for separating out the leaf from the background, one cluster to segment out the healthy part of the leaf and the final cluster dedicated to segment out the infected and diseased part of the leaf, if there is any. Since k is small, the computational speed of the algorithm increases exponentially than hierarchal clustering. The Infected cluster is converted to HSI from the RGB format. In this work, the SVM (Support Vector Machine) classification method is used because it is much easier due to less processing time [14-17].

IV. EXPERIMENTAL RESULTS AND ANALYSIS

A. Irrigation System

The various reading has been taken from the design system to facilitate and validate the proposed system. It has been observed that the water pump starts automatically at the particular soil conditions. A prototype for monitoring the soil condition is shown in Fig. 9. The setup acquires the values of moisture, humidity and temperature and transmits it to the cloud via the NodeMCU Module.

Fig. 9 Physical Setup

Table 1 shows the status of the pump corresponding to the threshold value that has been set, along with other measured data. A tulsi plant was used for the purpose of testing and threshold range coded for moisture content used was between 60 to 63, i.e below 60% moisture, the motor is on and above 63%, the motor is turned off, between 60 and 63, there is no change in the motor status. However, the threshold values for light and moisture can be changed in the program according to the needs during field implementations. Fig. 10 to Fig. 13, the variation of soil Moisture, Soil Temperature, Environment Humidity, Environment Temperature, respectively.

TABLE 1. SENSOR MEASURED DATA DISTRIBUTED

S. No	Time	Soil Moisture (%)	Soil Temperature (Celsius)	Environment Humidity (%)	Environment Temperature (Celsius)	Pump Status
1.	11.00 AM	65.69	22	47	25	OFF
2.	12.00.10 PM	62.76	22	48	25	ON
3.	1.00.10 PM	60.8	22	47	25	ON

Fig 12. Soil Moisture data of over 8 hours

Fig 11. Environmental Humidity sensed over a period of 8 hours

The graphs attached above were obtained for a testing period of 8 hours. All the data was also published on the online service Adafruit. This has been shown in the Fig. 14 below.

Fig 14. Published data on Adafruit IO

B. Disease Detection using Image Processing

The presented model has been validated using the available dataset [18]. The images are initially pre-processed using the filter to remove the noise. After pre-processing edge extraction is carried out using canny edge detection approach to preserve main features and remove the remaining features as shown in Fig. 15. It is observed that Canny edge detection method performs better as compared Sobel approach. The feature extraction on the region of interest gives information whether the plant or crop is healthy or unhealthy. This work has been carried out for two widespread diseases – *Glomeralla Cingulate* and *Phaeoisariopsis Bataticola*. The various feature metrics then calculated and used as an input parameter for further classification. The various average values of parameters are shown in Table I.

TABLE 2. EXTRACTED FEATURES PARAMETERS

Features Parameters	Metric Values
Mean	41.1795
Standard Deviation	69.2234
Entropy	2.9503
RMS	8.50045
Variance	4583.02
Smoothness	1
Kurtosis	3.11504
Skewness	1.30558
IDM	255
Contrast	1.4293
Correlation	0.834972
Energy	0.467692
Homogeneity	0.91613

The leaf disease detection GUI is also shown in the figure below. The images captured have vertical resolution and horizontal resolution of 96 dpi with bit depth equal to 24. The dimensions of the captured image is resized in MATLAB for processing. The webcam to capture query images to test our model has the following specifications: Lenovo 300 FHD Flexible Mount Webcam FHD 1080P 2.1 Megapixel CMOS Camera.

V. CONCLUSION

This paper proposes and implements the smart farming-soil monitoring and disease detection system. The presented may be useful for automatic irrigation system which increases the efficiency of the harvesting process by tracking real time plant/crop growth. It enables the farmers at all times requiring his intervention in the process only in the case of any anomalies. The plant disease classifier classifies two diseases: *Glomeralla Cingulate* and *Phaeoisariopsis Bataticola*. The design can further be improved by increasing and training the dataset on new diseases and real time images. The proposed system reduces human labor and workload of the farmers. The process is economical owing to its low budget and highly feasible considering the processing of low-resolution images captured via webcam which implies its suitability for farmers’ uses.

Abstract— Efficient detection of acetone is important for a variety of applications in pharmaceutical, automotive industries, medical diagnosis etc. Surface modification is one of the potential method to enhance the sensitivity as well as selectivity of any sensors. In recent days, surface functionalization with bimetallic nanoparticles become attractive because of its enhanced catalytic properties and the possibility to form discrete heterojunctions. In this study, WO₃ flowered morphology was prepared by one step acid precipitation method and bimetallic nanoparticles of Au-Pd and Au-Pt were deposited on WO₃/GO hybrid layer by one-step dip-coating process and fabricated a back gated field effect transistor (FET) structured sensor. Various morphological and structural characterizations were performed to study the various properties of the hybrid sensing layer. I_D-V_{GS} characteristics and the acetone sensing performance were measured for both the sensors i.e., Au-Pd/WO₃/GO and Au-Pt/WO₃/GO at room temperature. Among the two sensors, Au-Pt/WO₃/GO FET sensor exhibited an appreciably high sensitivity of 56% towards 80 ppm acetone at room temperature under applied gate voltage (V_{GS}) of 1.2V. The lower detection limit of the Au-Pt/WO₃/GO FET sensor was 400 ppb of acetone where it showed a 3 % response. The sensing mechanism envisages that the bimetallic loading in the ternary form of the nanocomposite enhanced sensitivity significantly by the spill-over effect. Also, the application of an optimized gate voltage amplified the sensitivity of the FET structured sensors.

Keywords— noble metals/WO₃/GO, FET, acetone sensing, improved sensing properties

I. INTRODUCTION

A volatile organic compound like acetone is used in a variety of applications like purifying paraffin, dissolved plastic, laboratories and most attractively in noninvasive disease detection [1,2]. But, continuous inhalation of acetone causes illness and affects the nervous system so a highly sensitive acetone sensor is required to detect the traces of acetone [3]. Semiconducting Metal oxide nanostructure-based composites are most widely used in VOC sensing applications

due to their large specific surface area, high carrier mobility and good sensing properties [4,5]. Among them, WO₃ is n-type semiconducting material considered a promising candidate for VOC sensing because of its unique chemical and physical properties [5,6]. Pure WO₃ gas sensing properties were optimized by different research groups [7-10]. Chong wang et. Al. reported pure WO₃ flowered nanostructures for NO₂ sensing and showed a good response (152) at 80 ppm concentration at a slightly high operating temperature (90 °C) [9]. Marco Righettoni et al. reported a pure WO₃ sensor for breath acetone detection. The acetone sensor response was (4.63 at 600 ppb) at a high operating temperature (400 °C) in dry air [24]. Still, metal oxide sensors show some shortcomings such as high operating temperature, low response speed and low selectivity [2,11]. On the other hand, at low operating temperature metal oxide sensor shows poor sensitivity and low response and recovery time [12]. High operating temperature sensors require high power consumption and can cause device damage. In this scenario, 2D graphene Oxide (GO) emerges as an ideal channel material for gas sensing application due to its outstanding electrical and physical properties including large specific area, strong gas adsorption capacity, high electrical mobility and conductivity at room temperature [1,6,13-17]. GO composites with semiconducting metal oxides emerges with good sensing properties [2,4]. GO and WO₃ based nanocomposites attracted wide attention in VOC sensing applications [5,6,15]. Jinniu Zhang et al introduced GO-WO₃ composite nanofibers and showed the highest response of 35.9 to 100 ppm acetone at 375 °C, which was 4.3 times higher than pure WO₃ nanofibers [32]. However, the sensitivity and other sensing properties of developed nanostructures can be improved by the functionalization with noble metal nanoparticles [14, 15, 18-21]. Lu Chen and coworkers found that noble Pt nanoparticles decorated sensor exhibits a good selectivity and response (12.2) to 10 ppm acetone with a very fast gas response/recovery time (14.1/16.8 s) at the operating temperature of 200 °C [3].

In this work, we are reporting bimetallic (Au-Pd, Au-Pt) loaded WO₃ hybridized GO FET sensor systems. We synthesized flowered WO₃ nanostructures with one step chemical method and FET sensor systems were synthesized by spray coating. FESEM (field emission scanning electron microscopy), Raman spectroscopy and UV-Vis spectroscopy results were used to characterize the samples. Transfer

Fig. 2 (a) Raman spectra and (b) UV-Vis plot of pure WO₃, Au-Pd/WO₃/GO and Au-Pt/WO₃/GO samples.

characteristics of prepared FET sensors were optimized. The sensing properties of pure WO₃ and bimetallic (Au-Pd, Au-Pt) loaded WO₃/GO FET sensors were studied by gas measurement setup.

II. EXPERIMENTAL

A. Synthesis of WO₃ nanostructures

One step acid precipitation route was used to prepare WO₃ nanoflowers. The synthesis process includes 16.5 g Na₂WO₄·2H₂O dissolved in 125 ml HNO₃ and 125 ml deionized water to form a homogenous mixture. The resulting suspension was aged for 24 h followed by 4 h stirring at 25 °C. The resulting yellow precipitate was undergone the gravity filtration method to remove impurities and was cleaned multiple times with water and ethanol and then dried at 60 °C. Annealing of material was carried out at 500 °C for 3.5 h to remove the acidic impurities. Green-colored homogenous WO₃ solution was obtained by adding 600 mg WO₃ powder to 100 ml of DI water. The detailed procedure is given in our previous reports [15].

B. Synthesis of nanocomposites

All the chemicals are analytical grade with high purity. 0.2 wt% GO suspension was obtained by adding graphene oxide powder in DI water at room temperature with continuous stirring to maintain homogeneity. Similarly, 1MM noble metal nanoparticles (Au, Pd and Pt) solutions were prepared

by incorporating metallic salts (AuCl₃, PdCl₂ and H₄PtCl₆·xH₂O) in DI water at a stirring state and with this drop by drop hydrochloric acid was also added to the solution to reduce the aggregation of nanoparticles at room temperature. Boron-doped, ~500 μm thick <100> SiO₂/Si was used as a substrate for the sensor preparation. Nanocomposite samples were prepared by mixing nanoparticle solutions (Au-Pd and Au-Pt) separately with continuous sonication and then spray coated on previously deposited WO₃ and GO layer on SiO₂/Si substrate and dried at room temperature as shown in table 1. Thermal annealing was performed at 250 °C for 4 h in the air to maintain the thermal stability and crystallinity in samples.

Table 1. Specifications of all three samples.

Sample no.	Specification
S1	Pure WO ₃
S2	(1MM Au + 1 MM Pd) + WO ₃ + GO
S3	(1MM Au + 1 MM Pt) + WO ₃ + GO

C. Device fabrication

Au-Pd and Au-Pt/WO₃/GO FET sensors were fabricated by depositing top 150 nm thicker gold electrodes by using electron beam evaporation unit and Cu physical mask. HF etching was used to create back gate contact in FET devices

Fig. 3 I_D - V_{GS} characteristics of both FET sensors; Au-Pd/WO₃/GO and Au-Pt/WO₃/GO in air and 80 ppm acetone (a) and Response of all FET sensors in 80 ppm acetone measured at $V_{GS} = 0$ V and $V_{GS} \approx V_{dirac}$ (b) under $V_{DS} = 1$ V at room temperature.

Fig. 4 The transient curve of all sensors i.e., pure WO₃ (a), Au-Pd/WO₃/GO (b) and Au-Pt/WO₃/GO (c) in the acetone concentration range from 80 ppm to 400 ppb with applied individual gate voltages ($V_{GS} \approx V_{dirac}$) at room temperature.

by etching a window on the backside of (0.1cm×0.1cm) SiO₂ layer assisted by a negative photoresist.

D. Material characterizations

Prepared samples were optimized by different characterization techniques. FESEM (field effect scanning electron microscopy) was used to identify the morphology of all three samples at high magnifications. Defects and structural properties of samples were analyzed by Raman spectroscopy and the bandgap of prepared samples was calculated from UV-Vis spectroscopy data.

E. Sensing characterizations

A static gas sensing setup was used to analyze the sensing performance of prepared samples where the sensor was mounted inside a 600 ml volume sealed chamber. The VOC was injected by micro syringes (Hamilton 705RN 50UL SYR). The ppm level of injected VOC was measured by the formula; C (ppm) = $2.46 \times (V_i D / VM) \times 10^3$, where D (gm/mL) is the density of VOC, M (gm/mol) is the molecular weight of injected VOC and V (Lit) volume of sensing chamber [22,23]. The mass flow controller (MFC) was maintaining a 450 SCCM continuous flow of synthetic air to recover the sensors. Two source meters (Keithley 6487) were mounted to measure the FET characteristics and sensing behavior of fabricated

sensors. The response value of FET sensors towards acetone was calculated by RM (%) = $[(\Delta I) / I_v] \times 100$ where ΔI ($I_v - I_a$) is the change in the current of the sensor in VOC and air. The FET devices were optimized at a constant bias voltage ($V_{DS} = 1$ V) with varied gate voltages (V_{GS}). 90 % of the total change in the current value of the sensors was marked as a response and recovery time.

III. RESULTS AND DISCUSSION

A. Material Characterizations

Figure 1 is showing FESEM images of prepared all three samples. Pure WO₃ is showing a layered structure and these layers get aggregated with each other and show flowered morphology as shown in Fig. 1 (a). Fig. 1b is displaying Au and Pd nanoparticles distribution on WO₃ and GO film. GO was showing layered morphology and aggregation of these layers from the continuous film (Fig. 1b and c). Fig. 1c is showing the arrangement of Au and Pt nanoparticles on WO₃ and GO. We have found the uniform, compact and continuous arrangement of nanoparticles (Fig. 1b and c). The average size, 200 nm of the Au metal particle was the largest and Pt nanoparticles with 5 nm of the average size were found smallest in diameter and the Pd nanoparticles were 12 nm in

Table 1. Literature survey on the status of the work on GO based acetone sensor.

Sensing materials	Gas/VOC conc.	Operating temperature	Response (%)	Ref.
Gd-WO ₃ /RGO	50 ppm	200 °C	54	1
ZnO-GO	100 ppm	240 °C	35.8	2
Pt- WO ₃	10 ppm	200 °C	12.2	3
Au-Pt/WO ₃ /GO	80 ppm	RT	56.5	This work

in diameter as shown in Fig. 1b and c.

Raman spectroscopy scan is displayed in (Fig. 2a) to identify the presence of all materials and defect density in samples. Four characteristic peaks of WO₃ were found in all three samples and 2 peaks of GO in metal loaded WO₃/GO samples as shown in Fig. 2a. The four prominent Raman peaks at wavelength values of 131.7, 267.5, 697.9 and 806.2 cm⁻¹ were detected in the resulting samples (Fig. 2a). The peak at a lower wavelength of 131.7 cm⁻¹ is due to the lattice vibrations of WO₃. Other than peak at 267.5 cm⁻¹ is originated due to the δ (O-W-O) bending mode and the peaks at higher wavelength values 697.9 and 806.2 cm⁻¹ are corresponding to the W-O-W stretching vibration modes [6, 13, 15]. The samples with presence of graphene oxide showing the characteristic peaks of material at wavelengths 1336.9 and 1591.2 cm⁻¹ are related to the D band (defect density of GO) and G band (shows the restoration of pi conjugation) [16, 17, 24] as shown in Fig. 2a. The intensity ratio (D peak/G peak) was 1.1 and 1.4 for Au-Pd/WO₃/GO and Au-Pt/WO₃/GO, respectively.

UV-Vis spectroscopy results of all three samples is shown in Fig. 2b. The bandgap of the resulting hybrids were 3.16, 4.7, 4.87 eV for WO₃, Au-Pd/WO₃/GO and Au-Pt/WO₃/GO respectively which is measured from the UV-Vis data by the help of Tauc model and the final equation, αhv = A(hv - E_g)^{1/2} where, A is the material property coefficient, hv is photon energy and E_g is the bandgap. The schematic representation of calculated the bandgap was as shown in Fig. 2b.

B. I-V Characteristics of FET sensors

Fig. 3a is showing I_{DS}-V_{GS} characteristics of both the Au-Pd/WO₃/GO and Au-Pt/WO₃/GO FET sensor in air and 80 ppm acetone at room temperature. *p*-GO and *n*-WO₃ both are semiconducting materials and form discrete Schottky junctions [9, 16, 25]. Change in the baseline current and dirac point position from Au-Pd/WO₃/GO to Au-Pt/WO₃/GO FET sensor was due to the work function difference between materials (Fig. 3a). GO shows ambipolar behavior and when the positive gate bias is applied the device current start decreasing and at dirac point the charge carrier density of GO is very low and the minimum device current in both air and 80 ppm acetone ambient was observed as shown in Fig. 3a [14, 16, 26]. After the dirac point conductivity gets changed from *p* to *n*-type in FET sensors and due to this in I_D-V_{GS} of 80 ppm acetone before the dirac point current was low and after the dirac point current was high compared to I_D-V_{GS} of air as shown in Fig. 3a. Moreover, Au-Pd/WO₃/GO FET sensor was showing dirac point at 1 V and Au-Pt/WO₃/GO FET sensor at 1.2 V (Fig. 3a).

Fig. 3b is showing sensitivity curve of Au-Pd/WO₃/GO and Au-Pt/WO₃/GO at V_{GS} = 0 V and V_{GS} ≈ V_{dirac}. The sensitivity value of the sensors in 80 ppm acetone was ~6.52 % and ~4 % at V_{GS} = 0 V and 46.6 % and 56.5 % at V_{GS} ≈ V_{dirac} for Au-Pd/WO₃/GO and Au-Pt/WO₃/GO, respectively, at room temperature. Moreover, ~7 and ~14 times amplification in

the response magnitude was noted for Au-Pd/WO₃/GO and Au-Pt/WO₃/GO FET sensors at 80 ppm acetone under the influence of optimized gate voltages (V_{GS} ≈ V_{dirac}).

C. Transient behavior study of sensors

Transient behavior of all three sensors was examined towards the acetone concentration range 400 ppb to 80 ppm at room temperature shown in Fig. 4. WO₃ and two FET sensors; Au-Pd/WO₃/GO and Au-Pt/WO₃/GO transient study were performed under constant V_{DS} of 1 V and V_{GS} ≈ V_{dirac}. With the decrease in acetone concentration, the device current also gets decreased in all three sensors. The response for the WO₃ sensor for highest ppm (80) and lowest ppm (0.4) of acetone was 14.1 % and 2 %, respectively as shown in Fig. 4a. While Au-Pt/WO₃/GO FET sensor was showing 56.5 % and 3 % response for 80 ppm and 400 ppb at room temperature and at applied V_{GS} (Fig. 4c). Noble metal functionalized/WO₃/GO FET sensor was showing ~4 times higher response than pure WO₃ at room temperature. All three sensors showed good sensing responses with good stability and repeatability in pulses for a minimum amount of acetone concentration (0.4 ppm) (Fig. 4). Moreover, noble metal nanoparticle functionalization improved the overall sensing performance of FET devices by the electronic and chemical sensitization behavior [14,15,18,20].

Table 1 is the comparison of sensing properties of GO nanocomposites with different sensing materials for acetone detection [1-3]. The reported Au-Pt/WO₃/GO FET sensor have good comprehensive performances including high response and low operating temperature compared to other ones.

IV. CONCLUSION

In this work, we are proposing three sensor systems marked as; pure WO₃, Au-Pd/WO₃/GO FET and Au-Pt/WO₃/GO FET. Among all three sensors, the best acetone sensing properties were observed in Au-Pt/WO₃/GO FET sensor in the influence of noble metal functionalization and applied gate voltage at room temperature. FESEM images confirm the uniform and discrete decoration of noble metal nanoparticles on WO₃ Nanoflowers and GO layer. GO as a channel material was deposited in sheets without any aggregation and discontinuity. Raman spectroscopy results signify the presence of WO₃ and GO in both the Au-Pd/WO₃/GO and Au-Pt/WO₃/GO samples and UV-Vis spectroscopy result was showing a bandgap shift from WO₃ to Au-Pd/WO₃/GO and Au-Pt/WO₃/GO after incorporation of noble metal nanoparticles and GO. The I_D-V_{GS} characteristic study was showing the ambipolar nature of GO at room temperature. An amplified sensitivity was found in Au-Pd/WO₃/GO and Au-Pt/WO₃/GO FET sensors at V_{GS} = 1V and 1.2 V, respectively. Au-Pt/WO₃/GO FET as the best acetone sensor was showing ~14 times higher response for 80 ppm acetone than the response obtained in two-terminal configurations and ~4

times higher than the pure WO₃ sensor at the same operating conditions.

Intelligent Reflecting Surfaces in UAV-Assisted 6G Networks: An Approach for Enhanced Propagation and Spectral Characteristics

Mobasshir Mahbub*, Raed M. Shubair

Department of Electrical and Computer Engineering, New York University (NYU) Abu Dhabi, Abu Dhabi, UAE
 Email: mobasshir@ieee.org*, raed.shubair@nyu.edu

Abstract - Intelligent reflecting surfaces (IRSs) with the ability to reconfigure inherent electromagnetic reflection and absorption characteristics in real-time provide unparalleled prospects to improve wireless connectivity in adverse circumstances. Unmanned aerial vehicles (UAV)-assisted wireless networks are evolved as a reliable solution to combat non-line of sight (NLoS) scenarios. Thereby, the IRS-empowered UAV-assisted cellular networks will be a significant role-player to improve the coverage and user experiences. The paper aimed to minimize the path loss and maximize the achievable data rate in IRS-UAV-assisted networks. In this context, the work analyzed path loss and achievable rate utilizing millimeter wave (mmWave) carrier considering the conventional UAV model and IRS-empowered UAV communication model. The research obtained that the IRS-empowered UAV communications model can significantly minimize path loss and maximize the achievable data rate compared to the conventional UAV-assisted model.

Index Terms – 6G, mmWave, UAV, IRS, Path Loss.

I. INTRODUCTION

The data rate will immensely increase attributed to the prevalence of increased users in hotspot circumstances. To solve the challenge, 6G (sixth generation) systems must migrate to several sophisticated network enhancement techniques e.g. IRS [1], [2], THz communication [3], etc.

UAV technology is regarded as a critical component of 6G mobile networks [4]. In comparison to typical terrestrial cellular connectivity, UAVs can swiftly facilitate connections in coverage region due to their great mobility. It is also cost-effective in regions with insufficient coverage, such as remote or hilly locations. As a result, the design of 6G networks may transition from the stationary terrestrial infrastructure model to aerial mobile connectivity.

IRS [5], [6], also referred to as a metasurface [7], is a newly developed engineered material whose radiation characteristics, such as reflection, phase, absorption, and refraction can be electronically modified in real-time. Because these surfaces are low-cost to produce, they may be distributed globally, giving an unparalleled opportunity to manipulate the wireless multipath scenario both indoors and outdoors. As a result, IRS offers an entirely new avenue in mobile communications research countering the multipath. Indeed, numerous studies have recently proven that IRS-assisted solutions may increase the coverage, capacity, energy, spectral efficiency of contemporary mobile networks dramatically. Fig. 1 visualizes the IRS-empowered UAV-assisted network.

Fig. 1. IRS-empowered UAV-assisted wireless network

UAVs are becoming increasingly used for relaying, data collection, secure communication, and information distribution. Because of their great agility and versatility for on-demand implementation, UAVs have a high likelihood of having line-of-sight (LoS) transmission connections [4]. As a result, UAVs can be used as aerial communication mediums to augment the performance of current ground wireless transmission networks, such as mobile networks.

However, UAV communication confronts several problems, particularly in urban environments. One notable concern is obstruction created by ordinary things including buildings/infrastructure, forests/trees, and human bodies that can exacerbate coverage and connection issues [8]. The movement of both the UAV and the UE (user equipment), on the contrary, causes excessive temporal and spatial changes in the non-stationary communication channels.

To solve these issues, the intelligent reflecting surface (IRS) technology [9] has recently been proposed to avoid impediments and improve connectivity in UAV systems, referred to as IRS-empowered UAV network systems [10]. IRSs are installed in the open network environment to aid the connection between UAVs and users, according to the IRS-assisted UAV architecture. A blocked i.e. non-line of sight (NLoS) transmission channel can be mitigated by deploying the IRS enabling several LoS links, which considerably minimizes channel attenuation.

Therefore, the work targeted minimizing the path loss and maximizing the achievable data rate in IRS-UAV-assisted networks.

II. RELATIVE LITERATURE

The paper in this section briefed several prior works and literature relative to IRS-empowered UAV communication. Since IRS-assisted wireless communication is an emerging topic and research is ongoing, during the literature review the authors find that there is a limitation of literature relative to path loss measurement in the IRS-UAV communication scenario.

Ma et al. [11] analyzed the potential deployment of IRS in cellular communications with UAVs that suffer from degraded signal strength. The work considered the implementation of IRS on walls that can be configured remotely by base stations to coherently transmit the reflected signal towards corresponding UAVs to enhance signal strengths at the user end. Al-Jarrah et al. [12] presented the outage probability and symbol error rate (SER) analysis of multi-layer UAV-empowered wireless communications supported by the IRS. The research of Pang et al. [13] overviewed the amalgamation of UAV and IRS, by illustrating the applications of IRS and the advantages of UAV and describing the advantages of incorporating them in a combined manner in the wireless network. Then, the work investigated case studies namely the UAV trajectory, the passive beamforming in IRS, and the transmit beamforming at the base station are jointly optimized. Jiang et al. [14] proposed and analyzed a three-dimensional (3D) stochastic geometry-based channel model incorporating multiple-input multiple-output (MIMO) for IRS-aided UAV communications. Wei et al. [15] considering the application of IRS in UAV-assisted orthogonal frequency division multiple access (OFDMA) transmission systems first derived the expression to analyze composite channels and proposed an approximation approach to set a lower and an upper bound for the considered problem. Mahmoud et al. [16] investigated the deployment of IRS in UAV-empowered communications networks aiming to enhance the coverage and improve the reliability in terms of spectral efficiency considering the Internet of Things (IoT) paradigm. Specifically, the work first derived tractable analytic expressions and then analyzed the ergodic capacity, achievable SER, and outage probability. Cao et al. [17] proposed and analyzed a 3D non-stationary MIMO channel model for an IRS-assisted UAV communications network. Shafique et al. [18] presented and analyzed a theoretical framework of an IRS-integrated UAV relaying system.

III. MEASUREMENT MODEL

A. Conventional UAV-Assisted Communication Model

Contemplate a 3D geographic coverage region in which terrestrial base stations, UAVs, and user equipment are spanned in a 3D plane. A set of base stations \mathfrak{B} are deployed in the mentioned communication (or coverage) region along with \mathfrak{U} set of UAVs to enhance the coverage (in case of NLoS and obstacle-filled area) for a set of user \mathfrak{R} . Consider $u_i = (x_i^{uav}, y_i^{uav}, z_i^{uav})$ as the location (3D coordinates) of UAV i

$\in \mathfrak{U}$ and $(x_n^{UE}, y_n^{UE}, z_n^{UE})$ as the coordinates denoting the location of user $n \in \mathfrak{R}$. Therefore, according to the ITU (International Telecommunication Union), the path loss is formulated as (Eq. 1) [19],

$$PL = \left(\frac{4\pi f_c d_0}{c} \right)^2 \left(\frac{d_i}{d_0} \right)^2 u_{NLoS} \quad (1)$$

where u_{NLoS} denotes the attenuation factor. c denotes the speed of light in ms^{-1} . f_c indicates the carrier frequency in Hz. d_0 denotes the reference distance (free space). Here, $d_0 = 1$ m. $d_i = \sqrt{(x_n^{UE} - x_i^{uav})^2 + (y_n^{UE} - y_i^{uav})^2 + (z_n^{UE} - z_i^{uav})^2}$ indicates the distance between the UAV i and arbitrary user equipment (UE) located at $(x_n^{UE}, y_n^{UE}, z_n^{UE})$ coordinates. The received power thereby can be obtained as follows (Eq. 2),

$$\wp_r = \frac{\wp_t}{\mathcal{K}_0 d_i^2 u_{NLoS}} \quad (2)$$

where \wp_t is the transmit power and $\mathcal{K}_0 = \left(\frac{4\pi f_c d_0}{c} \right)^2$. The SNR (Signal to Noise Ratio) can be formulated by the following equation (Eq. 3),

$$\zeta = \frac{\wp_r}{\sigma^2} \quad (3)$$

where $\sigma^2 = -90$ dBm denotes the Gaussian noise power. The achievable data rate (bits/s/Hz/m²) by the user equipment can be determined by (Eq. 4),

$$\mathfrak{R} = \log_2 \left(1 + \frac{\wp_r}{\sigma^2} \right) \quad (4)$$

B. IRS-Embedded UAV-Assisted Communication Model

Incorporating the IRS in UAV the far-field beamforming model for determining the path loss in the case of IRS-enhanced UAV-assisted communication model is (Eq. 5) [20], [21],

$$PL_{IRS} = \frac{64\pi^3 (d_1 d_2)^2}{G_t G_r G M^2 N^2 d_x d_y \lambda^2 \cos(\theta_t) \cos(\theta_r) \mathcal{A}^2} \quad (5)$$

where $d_1 =$

$\sqrt{(x^{BS} - x_i^{uav(IRS)})^2 + (y^{BS} - y_i^{uav(IRS)})^2 + (z^{BS} - z_i^{uav(IRS)})^2}$ denotes the separation distance between the transmitter i.e. base station located at (x^{BS}, y^{BS}, z^{BS}) coordinates and IRS-embedded UAV located at $(x_i^{uav(IRS)}, y_i^{uav(IRS)}, z_i^{uav(IRS)})$ coordinates. $d_2 =$

$$\sqrt{(x_i^{uav(IRS)} - x_n^{UE})^2 + (y_i^{uav(IRS)} - y_n^{UE})^2 + (z_i^{uav(IRS)} - z_n^{UE})^2}$$

denotes the separation distance between the IRS and the UE located at $(x_n^{UE}, y_n^{UE}, z_n^{UE})$. G_t and G_r are the gains of the transmitter and receiver and $G = \frac{4\pi d_x d_y}{\lambda^2}$ is the scattering gain. M and N are the numbers of transmission and reception elements of the IRS. d_x and d_y are the length and width of each scattering element. λ denotes the wavelength of the transmitted signal. θ_t and θ_r are the transmitter and receiver angles with the IRS. \mathcal{A} denotes the amplitude relative to the reflection coefficient of unit cells of the IRS. Thereby, the received power at the UE can be formulated by (Eq. 6),

$$\rho_r^{IRS} = \frac{\rho_t G_t G_r G M^2 N^2 d_x d_y \lambda^2 \cos(\theta_t) \cos(\theta_r) \mathcal{A}^2}{64\pi^3 (d_1 d_2)^2} \quad (6)$$

The SNR can be measured by the following formula (Eq. 7),

$$\mathcal{S}_{IRS} = \frac{\rho_r^{IRS}}{\sigma^2} \quad (7)$$

The achievable can be calculated by the following equation (Eq. 8),

$$\mathfrak{R}^{IRS} = \log_2 \left(1 + \frac{\rho_r^{IRS}}{\sigma^2} \right) \quad (8)$$

IV. RESULTS AND DISCUSSIONS

This section includes the measurement results based on the measurement model utilizing MATLAB-based simulation and incorporates discussions on the derived simulation result. The research considered low-altitude UAV since it utilized mmWave carrier.

Fig. 2 (a) and (b) show the path loss in terms of transmitter-receiver separation distance with 2D and 3D figures respectively in the case of conventional UAV-assisted communication networks. $f_c = 100$ GHz, $(x_i^{uav}, y_i^{uav}, z_i^{uav}) = (0, 0, 40)$ m, $(x_n^{UE}, y_n^{UE}, z_n^{UE}) = (0-100, 0-100, 1.5)$ m, $u_{NLoS} = 23$ dB indicate the simulation parameters.

Fig. 5 (a) and (b) visualize the path loss with top view and 3D figures in terms of transmitter-receiver separation distance (from BS to IRS and IRS to UE) in the case of IRS-empowered UAV communication networks. θ_t & $\theta_r = 45^\circ$, $x_i^{uav(IRS)}$ & $y_i^{uav(IRS)}$ are varied only, (other parameters are as same as Fig. 4).

(a)

(b)

Fig. 5. (a) Tx-Rx separation vs. path loss (top view); (b) Tx-Rx separation vs. path loss (3D)

Fig. 6 represents the path losses in terms of the number of transmit-receive elements of IRS. \mathcal{M} & \mathcal{N} are varied only, (other parameters are as same as Fig. 4 & angles of Fig. 5).

Fig. 6. No. of Tx-Rx elements vs. path loss

Fig. 7 (a) shows the achievable data rate in terms of transmit-receive angle with a top view figure and Fig. 7 (b) shows the path loss in terms of 0° to 90° transmit-receive angles in the context of the IRS-empowered UAV communications model. $\rho_t = 2$ W (parameters are as same as Fig. 4).

(a)

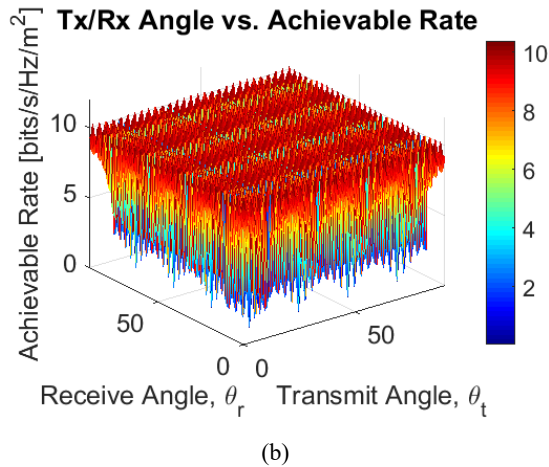

Fig. 7. (a) Tx-Rx angle vs. achievable data rate (top view); (b) Tx-Rx angle vs. achievable data rate (for angle 0° to 90°)

Fig. 8 (a) and (b) represent the achievable data rate with top view and 3D figures in terms of transmitter-receiver separation distance in the case of IRS-empowered UAV communication networks. $\rho_t = 2W$ (parameters are as same as Fig. 5).

Fig. 8. (a) Tx-Rx separation vs. achievable data rate (top view); (b) Tx-Rx separation vs. achievable data rate (3D)

Fig. 9 illustrates the achievable rate in terms of the number of transmit-receive elements of IRS. $\rho_t = 2W$ (parameters are as same as Fig. 6).

Fig. 9. No. of Tx-Rx elements vs. achievable data rate

Through the observation of Figs. 4 and 7, it is evident that 11°, 33°, 55°, and 77° angles exhibits the highest path loss and lowest achievable data rate. 0°, 22°, 44°, 66°, 88° angles of transmissions and reception produce the lowest path loss and highest achievable data rate. But the path loss is quite lower and the achievable rate is much higher than the case of the conventional UAV communication model. According to the prior research 30° to 60° transmit-receive angle [21], [22] is prominent for IRS communication.

It can be interpreted by examining Figs. 5 and 8 that, with the increase of transmitter-receiver separation distance the path loss increases and the achievable data rate gradually decreases. Since the IRS enables almost perfect reflection of the transmitted signal, reduces the absorption, and establishes an LoS condition a greater number of users can obtain a significantly favorable signal (in the considered coverage region) compared to the conventional UAV communication model (comparing with Figs. 2 and 3).

According to the observation of Figs. 6 and 9 it is comprehensible that, with the increase of the number of transmit-receive elements in IRS the path loss decreases, and the achievable data rate increases gradually.

Observing and comparing the figures finally it is evident that, the deployment of IRS reduces the path loss by around 70 – 100 dB and increases the achievable data rate up to 8 – 13 times approximately (according to the chosen network parameter).

An intriguing observation of this research is that by utilizing a lower transmit power a significantly higher achievable data rate can be obtained by deploying IRS-empowered UAV communication networks (2W) compared to the conventional UAV communication model (6W).

The research considered low altitude UAVs since it utilized mmWave carrier to minimize the significant attenuation of the carrier. Moreover, the work considered a limited interference scenario.

Furthermore, the research considered IRS (UAV) 3D location in the reference formula [20] which makes the measurement more precise.

V. CONCLUSION

The research work targeted minimizing the path loss and maximizing the achievable data rate of conventional UAV-assisted communication by deploying IRS-empowered UAV-assisted wireless networks. The work, therefore, analyzed and compared the deployment of IRS-UAV communication and conventional UAV communication considering the aforementioned measurement model. Performing MATLAB-based measurements the research obtained that IRS-empowered UAV communication networks minimize the path loss and maximize the achievable data rate significantly. Moreover, the IRS-UAV communication model reduces the energy consumption of the entire network. Further research can be performed on the analyzed model considering higher mmWave and THz-band carriers, multiple UAVs, higher altitude, etc. The research will be assistive to the scholars, researchers, and enthusiasts who are engaged in the relative research.

Intelligent Feature Selection on Multivariate Dataset using Advanced Data Profiling

¹ *Abstract*—The differential diagnosis of diseases which share similar clinical features is a real and difficult problem in medicine. This paper demonstrates the use of data mining (DM) techniques to augment standard data profiling methods and establishes an efficient approach for an intelligent feature selection method for disease that share similar features. The results from experiments returned show that by using DM techniques to select features as an additional layer on top of data profiling, there is considerable improvement in the performance of the prediction model built to predict a disease such as “Psoriasis”. A brief comparison between features selected by existing mining tools such as Weka and the proposed approach with respect to predictive accuracy is recorded in this paper. The proposed algorithm works as a promising tool for assisting diagnosis of disease like erythemato-squamous diseases, where the symptoms are overlapping. By combining data cleansing and knowledge discovery techniques, the algorithm aims to be “agnostic” and can be used on a wide variety of data standards with variable data quality.

I. INTRODUCTION

Machine learning models are built to capture relationships in an n -dataset (dataset of size n) between its $n-1$ features and the (n th) target feature in the dataset. Since such models are highly data-driven, their accuracy relies on how “good” the data is. “Goodness” of any dataset can be determined by understanding the data and preparing it so that it can be deemed “good”. Typically, repositories such as Data Lakes [15] store data in its raw form, which is eventually (pre)processed before it is used in a data mining model. To understand any given data in a dataset requires gathering information about that data, commonly known as metadata. Type of metadata depends on the application for which the data mining model is being designed. As an example, let us consider an application that requires educational data, such as student information, the courses they have completed and grades achieved in these courses. Metadata in this example can be as simple as the student’s name and age stored in its raw form, or it could require some calculation such as average age of students in this dataset. If described and managed well by big data repositories such as data lakes, such metadata can be exploited by analysts to discover underlying relationships between different features in a dataset, and thereby allow data mining models to be better informed about the dataset. Data profiling refers to this structured activity of creating small but informative summaries of a database [8]. Data profiling uses scientific methods to

explore, understand and collect statistics on raw data of a given dataset for detecting statistical distributions and structural patterns.

In a typical real-world scenario, data is integrated from various different sources, and this makes it challenging to provide consistent, clean and accurate data for machine learning models. Data profiling can be used as a pre-processing step in the process of data mining to evaluate datasets for consistency, uniqueness and quality of data. It is a well known fact that data mining models spend 70% of their time in the pre-processing step which clearly needs to be improved [15]. This paper proposes a data agnostic algorithm for data profiling. In this algorithm, a full understanding of the entire data set is not required. The algorithm uses data mining techniques to understand the data (we call it as intelligent data profiling) and use that to select features that could prove to have a higher impact on the accuracy of the final model that is being built. One may argue that the high cost of computational complexity of profiling large datasets may deter data enthusiasts from using it. But this can be overcome by leveraging massively parallel clusters and will not be addressed in this project. Our research aims to build an intelligent data profiling algorithm that evaluates and analyzes different attributes or features in the dataset, with an overall objective of selecting those features that are of good quality and that improve the accuracy of the predictive model built using these features.

This paper is organized in the following way: Section II explains the proposed methodology. Sections III illustrates the evaluation of the proposed algorithm. A literature review of the related work and their limitations is discussed in section IV. Section V presents the conclusions and proposes future work.

II. PROPOSED METHODOLOGY

This section presents the dataset used and proposed methodology for intelligent data profiling and feature selection.

A. The Dataset

The dataset used in this research is on dermatology and is taken from an open-source repository [4]. It includes 34 clinical and histopathological features that have been transformed in a variety of ways to suit this research.

¹978-1-6654-8684-2/22/\$31.00 ©2022 IEEE

1) *Rationale for using the dataset:* Diagnosing skin diseases such as 'Psoriasis' and 'lichen planus' is a real problem in dermatology [5]. Firstly, they all share the clinical features with very little differences. Secondly, there are too many features, some of them do not have enough values or have values that are not meaningful. Some diseases have overlapping features from another disease at the beginning stage and may have the characteristic features at the subsequent stages. In terms of data, the significance of the presence or absence of a feature in the dataset makes the analysis challenging. For example, given the features, it is difficult to differentiate between 'Psoriasis' or 'Lichen Planus' as they have overlapping features (for example, itching is a common feature in both). The proposed method intelligently selects only those features that have a significant impact on the accuracy of the predictive model that predicts the disease.

2) *Notation used :*

1) The following notation is used:

D = dataset

2) Each instance n of D is represented as a triplet:

$\forall_1^n i, (ca_i, ha_i, ta_i)$

where ca represents clinical attributes, ha represents histopathological attributes and ta represents the target attribute. $|x|$ indicates the cardinality or number of instances of x

3) D^T – dataset after transformation of attributes

4) $D_{profiled}^T$ - dataset after data profiling of the attributes

5) $D_{reduced}^T$ - optimal set of attributes used for prediction

B. Transformation of selected features in dataset D

In general, preprocessing is used to transform raw input data into appropriate formats for subsequent mining [14]. Real-world data is often inconsistent, has missing values and may have data that has errors. Data preprocessing is a technique that is used to resolve such issues.

The transformations on different attributes of D and the rationale for doing so are listed below.

1. The target attribute (ta) in the original dataset [4] has 6 classes. For simplicity, we transform ta to a binary class code problem, i.e. to 2 classes. We aim to predict if a person with several given symptoms (represented by a vector of clinical and histopathological attributes) has psoriasis (class code = 1) or not (class code = 2).

2. Attribute age is a clinical attribute (ca) that is continuous. In order to see the impact of age categories on the outcome (i.e. presence of psoriasis), we chose to discretize age into 5 different bins. This decision was a result of a few experiments with attribute age. Binning is a method to group a number of continuous values into a smaller number of "bins". This research creates bins using equal-width unsupervised discretization method (except for the last bin that is of a larger size than others) [10]. The bins created using this algorithm and their distribution with the target attribute are as follows:

Bin	Interval
1	[< 12.5]
2	[12.5 - 25]
3	[25 - 37.5]
4	[27.5 - 50]
5	[>= 50]

The third bin that caters to the age group 25 - 37.5 has the maximum count of patients among all bins, whereas age group less than 12.5 has the least. The graph in figure 1 shows the distribution of all age groups.

Figure 1. Discretization of Age into bins

3. All other clinical (ca) and histopathological (ha) attributes in the original dataset D can have any of the four values (0, 1, 2 or 3, where 0 indicates the absence of a symptom, 1, 2, 3 indicate the intensity of the symptom present, with 3 representing the highest intensity and 1 the lowest). All these attributes can be categorized as asymmetric attributes.

An asymmetric attribute is defined as an attribute in which the presence of one of the values (e.g. 1) is regarded as more significant than the other (e.g. 0), as opposed to a symmetric attribute in which the value 1 (or higher indicating presence of the attribute) is considered equally significant as its absence (0) [14]. For example, erythema in D is taken to be an asymmetric attribute in this research, where a value of 1 or higher indicates the presence of that symptom and 0 indicates its absence. In an asymmetric attribute, a 1-1 match of erythema in two rows is significant, whereas a 0-0 match has no significance (since 0 implies that the symptom is not present) and is ignored in the proposed method. On the contrary, an example of a symmetric attribute is gender, where 1 represents female and 0 represents male, then a 1-1 match (indicating a female-female match) is as significant as a 0-0 match (indicating a male-male match).

After the above transformation, our dataset now has:

- 11 clinical attributes: asymmetric
- 22 histopathological attributes: asymmetric
- 1 family income: binary symmetric attribute
- 4 binary asymmetric attributes: unique bin for age category

It is worth mentioning here that id numbers of patients are removed from the database in the original dataset D.

C. The proposed algorithm - Predicting Using Intelligent Feature Selection (PIFS)

Algorithm 1 lists the core steps of the proposed algorithm called PIFS (Predicting using Intelligent Feature Selection). Step 1 transforms the original dataset D to D^T . Section B defines the transformation on some of the attributes such as age and the target attribute (ta) and the rationale behind those transformations.

Step 2 performs the data profiling step to convert D^T to $D^T_{profiled}$. We did single-column profiling tasks in terms of the number of rows and uniqueness of the values [1]. Those features or columns that have 80% or more values as 0 (0 indicates absence of that symptom) were eliminated and not included in the new set $D^T_{profiled}$. At the end, the attributes selected for the next step were reduced to a new dataset ($D^T_{profiled}$).

Dataset $D^T_{profiled}$ is certainly more informed than D^T , however, many of its attributes still have a large number of zero values that indicate the absence of a symptom. In order to make our dataset more informed, this research runs an intelligent algorithm that is based on the distribution of different categorical values (0, 1, 2, 3) in each ca or ha attribute in $D^T_{profiled}$. Step 3 of PIFS (Algorithm 1) illustrates its details. Thresholds 1 and 2, selected by combining expert opinion with experiments, are given below. Here, \wedge represents AND; \vee represents the OR symbol.

$$\begin{aligned}
 & threshold_1 : |zeros| \geq 250 \\
 & threshold_2 : 150 < |zeros| < 250 \wedge \\
 & (|ones| \vee |twos| \vee |threes| > 50)
 \end{aligned}$$

These thresholds are determined by the attributes in the current dataset and by the different categorical values that these attributes can have. Figure 2 shows two attributes that do not meet these threshold values and therefore are not selected by PIFS. Figures 3 and 4 illustrate distribution for four attributes that were selected by the proposed algorithm. As can be seen, the number of zeros in both Erythema and Scaling (Figure 3) is negligible. Similarly, figure 3 shows two attributes that were filtered out by our algorithm since they do not meet the two thresholds.

Step 4 creates a predictive model using k-nearest neighbor algorithm to predict the target (psoriasis or not) given a vector from $D^T_{reduced}$. This research chose to use k-nearest-neighbor due to its simplicity. Its results were compared to decision tree model as well (as shown in the experimental section).

Figure 2. attributes not selected by PIFS

Figure 3. attributes selected by PIFS

Figure 4. additional attributes selected by PIFS

K-nearest-neighbor (k-nn) algorithm [14] typically takes 4 inputs in order to predict a target attribute: an integer k (k=number of neighbors), a set of training samples whose target attribute y is known, a test vector t and a similarity or distance function. It then predicts test sample of class label t by performing the following steps :

- 1) calculate similarity between a test vector t and all training samples using the chosen similarity function (as explained below)
- 2) sort these similarity values and pick the top k samples - these are the k nearest neighbors of test sample t
- 3) Use the values of ta of each of the k nearest neighbors of t to predict a value for t. If the total number of neighbors that have a 'Yes' as its target attribute is greater than the total number of neighbors that have a 'No', assign 'Yes' as the class label of t; otherwise assign a 'No'.

Jaccard's Coefficient (JC) works best with asymmetric attributes [14] and therefore is more applicable to this research. Jaccard's Coefficient (JC) between two vectors x and y is

measured as

$$JC(x, y) = \frac{f_{11}}{f_{11} + f_{10} + f_{01}} \quad (1)$$

where f_{11} is the frequency of 1-1 match in vectors x and y , f_{01} is the frequency of occurrence of 0 and 1 in x and y (non-matching pair) and f_{10} is the frequency of occurrence of 1 and 0 in x and y (non-matching pair). For example, if $x = [1, 0, 0, 1]$ and $y = [1, 0, 1, 0]$, then $JC(x, y) = 1/3$. Since all the attributes in D are categorical and asymmetric, the similarity function that we choose to use in the proposed algorithm PIFS is Jaccard's coefficient of similarity.

Algorithm 1: The proposed algorithm PIFS

1. Preprocess and prepare attributes in the original dataset D (call it D^T) - as explained in section 2.2
2. Perform SCP (single-column profiling) data profiling algorithm on D^T to get a new set of attributes (call it $D_{profiled}^T$) - as explained in section 2.3
3. Use an intelligent feature selection method to eliminate those that are (lets call it $D_{reduced}^T$) - as explained in section 2.3

```

for each attribute  $i$  in  $D_{profiled}^T$  do
    find the distribution of its different categories
    if  $|zeros| < threshold_1$  then
        Add  $i$  to  $D_{reduced}^T$ 
    else
        if  $|two| > threshold_2$  OR  $|three| > threshold_2$ : then
            Add  $i$  to  $D_{reduced}^T$ 
        end
    end
end

```

4. Create a predictive model to predict the target attribute (presence or absence of psoriasis) - as explained in section 2.3
- Divide data into 2 subsets using an 80-20 split: training (80% - $D_{reduced}^{Training}$) and test (20% - $D_{reduced}^{Test}$).
- Training dataset is used to build the model, whereas test is used to test the model.
- Build a model by applying a prediction algorithm such as k-nearest-neighbors on the training dataset $D_{reduced}^{Training}$.
- Apply the model to each vector in the test dataset $D_{reduced}^{Test}$ to predict its ta values.

	Features selected by Weka	Number of zeros
1	Erythema	4
2	Itching	116
3	Scaling	8
4	Follicular-Papules	325
5	PNL-filtrate	229
6	Fibrosis of the papillary dermis	308
7	Clubbing of the rete ridges	248
8	Thinning of the supra-papillary epidermis	249
9	Follicular horn plug	336
10	Perifollicular parakeratosis	337

Table I
FEATURES SELECTED BY WEKA

	Features selected by PIFS	Number of zeros
1	Erythema	4
2	Itching	116
3	Scaling	8
4	Definite Borders	55
5	Exytosis	117
6	Acanthosis	9
7	Parakeratosis	85
8	Inflammatory mononuclear infiltrate	9
9	Spongiosis	195
10	Age	Categorical

Table II
FEATURES SELECTED BY PIFS

III. EVALUATION OF PIFS

The proposed algorithm is evaluated by the following criteria: (1) feature selection (steps 1, 2 and 3 of PIFS) (2) performance of the prediction algorithm (step 4 of PIFS) using measures such as accuracy, recall and fscore [11].

A. Feature selection

Intelligent feature selection is a core step of PIFS, as described in section 2. The selected features are compared with features selected by Weka [16]. Weka is a collection of machine learning algorithms for data mining tasks such as data preparation, feature selection, prediction and clustering.

The features (also referred to as attributes in this paper) selected by Weka using its feature selection algorithm (cfs-SubsetEval + BestFirst) and the number of zeros in each of the selected feature is shown in table I. Note that zeros in this dataset indicate the absence of a feature (or a symptom) of the target disease being predicted (e.g., Psoriasis). All features other than Erythema and Scaling have a very high number of zeros. This implies that Weka is not able to accurately distinguish between the features as they are extremely similar and overlapping – this finding concurs with the claim made by the creators of the dermatology dataset D[4]. Attributes selected by PIFS are shown in table II. The selected features in this table have less number of zeros (0 indicates absence of symptoms) than the features selected by Weka.

B. Performance measurement:

Accuracy measures the ability of the model to match the actual value of the target attribute with its predicted one (e.g.

"Yes" predicted as "Yes"). Accuracy alone is not always a deterministic measure, especially when dealing with target attribute values that are imbalanced or uncommon. For example, let's assume that in a dataset with 100 samples, there are 10 people with target attribute = "Yes" and 90 with a target attribute = "No". Also assume that the model predicts 1 out of 10 people correctly as "Yes", and 90 out of 90 as "No", then the accuracy of the model according to its definition (equation 2) will be calculated as high as 91%. However, this result is misleading as the model is not at all accurate in predicting one of the target attribute values (in this case "Yes"). Other measures that are used to evaluate predictive models are precision and recall. Most models achieve a trade-off between precision and recall, since it is very challenging to keep both the measures high. F-score is a combined measure that assesses this trade-off between precision and recall. Figures 6 and 7 show high values of accuracy and fscore for the proposed model.

$$accuracy = \frac{ActualTrueValuesPredictedCorrectly}{NumberOfPredictions} \quad (2)$$

$$precision = \frac{ActualTrueValuesPredictedCorrectly}{PredictedTrueValues} \quad (3)$$

$$recall = \frac{ActualTrueValuesPredictedCorrectly}{ActualTrueValues} \quad (4)$$

$$f\ score = \frac{2}{\frac{1}{r} + \frac{1}{p}} \quad (5)$$

Performance of PIFS is compared with the models created using Weka. Weka gives over 98% accuracy with classification models such as Naïve Bayes, iBK and J48 (decision tree) using the selected attributes shown in table I. Most likely, this is because weka is unable to distinguish between the presence or absence of a feature (symptom). We also compared the accuracy of PIFS using selected features and all 34 features in the original dataset D. PIFS accuracy with the selected features is as high as 92%, as compared to 60% when all features are used, as shown in figure 5, asserting that PIFS selects its features intelligently. Figure 5 also shows that the accuracy is highest at k = 7 with PIFS features.

IV. RELATED WORKS

In this section, existing work on data profiling and their limitations are discussed. We first describe the different applications of data profiling and thereafter describe the recent works done to cater to these applications. Commonly, data profiling is the set of actions required to determine metadata about a given dataset. Determining metadata requires computation on rows of the given dataset (e.g. finding rows that have missing values such as identifiers) or more commonly on columns in the dataset (single or multiple). In a survey on data

Figure 5. Accuracy of PIFS using intelligent features

Figure 6. Accuracy of kNN model

Figure 7. Fscore of kNN model

profiling [1], the authors classify data profiling tasks as single-column and multi-column profiling, depending on the use case of the task. A traditional application of profiling is in data exploration. Most times, database experts including researchers are faced with a collection of data with not much information about the data due to the proliferation of data generated by

machines. Two main challenges in data exploration are as follows: (1) to assume that the data to be explored is in a well-structured format [12] and (2) to use manual methods such as data gazing to explore data. Data gazing [3], involves experts manually skimming through the dataset to understand its characteristics. In order to do this in an automated way, experts need to know databases well, so that they can run SQL queries to get better insight of the data. But this poses an additional constraint that explorers always have to be database experts [7]. Gathering statistics about the data (typically called as metadata in DBMS) is a common task done by DBMS. Metadata could be on single columns (e.g. number of unique values) or on multiple columns (e.g. find pairs or groups of columns that can be used to optimize queries by DBMS). Such metadata is also useful in doing reverse database engineering (e.g. creating ER models from an existing dataset) [6][1]. The most common application of data profiling is data integration, where data from different sources and with possible different formats are integrated into a single source. When performing integration, columns or features of two schema from different sources are compared to find the matching ones [13]. Data cleansing is considered as an essential step in the process of knowledge discovery and data mining and the need to collect insight into data (using data profiling techniques) is inevitable [9]. Besides these applications, data profiling is extremely useful in Big Data analytics [2]. Operations such as storing and fetching big data are much more expensive than traditional structured systems. Since the data here is typically huge and heterogeneous, gaining an insight into the data and cleaning it before using it to store or query gives some hope to big data researchers [1]. Most of the methods of data profiling listed above follow the traditional cycle of extracting metadata and then using it towards an application.

The methods described above fail to address the volume and heterogeneity of datasets today. If traditional data profiling methods are followed, it would take days to achieve any significant information about the data. To keep up with these challenges, keeping in mind the computational cost of profiling is covered, this paper proposes a progressive algorithm that blends the traditional methods with state-of-the-art data mining methods (particularly supervised mining) to extract metadata. The proposed method is extensible and scalable and can be applied to very large datasets to generate results in a timely manner.

V. CONCLUSION AND FUTURE WORK

The importance of data profiling as a pre-processing step of machine learning models is well known. In this paper, we demonstrate that layering supervised data mining techniques to data profiling, thereby building intelligence in the feature selection process, results in higher accuracy of prediction of differential diagnosis of diseases where there are several overlapping features. The intelligent feature selection algorithm PIFS selects features from a dataset based on the data and its

distribution. No prior knowledge of the dataset is needed. The algorithm safely ignores “noisy data” and selects an optimal and reduced set of features that yields a highly accurate predictive model.

As future work, we plan to test and train the algorithm to achieve better accuracy for a variety of multivariate datasets where differential diagnosis of disease pose a challenge due to overlapping features. The proposed algorithm can also be extended to multiple classes in order to discriminate between other diseases.

Abstract—In this work, we performed gated Kelvin Probe Force Microscopy on reduced graphene oxide thin-film transistors with time transient. This enabled us to probe the electronic density of states around the charge neutrality point in reduced graphene oxide thin film. The charge neutrality point is of significance to know the nature of the intrinsic doping of the thin film and the switching of the majority carriers in the transistor devices. We measured the transfer characteristics of the reduced graphene oxide transistor devices to estimate the intrinsic charge neutrality point. The results were in good agreement with the time-resolved gated surface potential measurements obtained using Kelvin probe force microscopy. We propose that gated time-resolved measurement of these semi-metals can be an effective tool to study the nature of electronic states.

Keywords—reduced graphene oxide, gated KPFM, DFT, density of states

I. INTRODUCTION

The discovery of a process to yield graphene from bulk graphite has led to an immense amount of research in this field [1]. Even after such extensive study, an effective method to grow large-area pristine graphene toward electronic application is not viable till now. In order to compensate for this, a derivative called reduced Graphene Oxide (rGO) with similar electrical properties to that of graphene was investigated [3]. Though the production of graphitic oxide from graphite has been around for about a century, the adoption of the Hummer's method [10] to yield a one-molecule-thick version of the substance known as graphene oxide [2] and its reduction to get graphene-like material was made only in later years after the experimental discovery of graphene. Hence, there is considerable interest in graphene oxide

(GO) and rGO for application in multiple fields [11]–[14]. Though there is a lot of research in this field, a better understanding of the electrical properties of the rGO is needed for its effective application in the field of electronics. The hysteresis in the transfer characteristics of Field Effect Transistor(FET) devices made of these materials as the active layer is one of the undesired properties. In order to understand the source and mechanisms involved with the hysteresis in these graphene-based FETs, various techniques have been explored towards realizing hysteresis-free devices in the future [15], [16]. However, there are very few efforts made towards the improvement of rGO based FETs though it finds application in many areas which demand a hysteresis-free device operation.

We make use of KPFM to probe information around the charge neutrality point, which corresponds to the minimum current point in the transfer characteristics of rGO based transistors. We employ an external gating to the thin film in the KPFM set up to capture the time transients of the change in work function for the applied change in gate voltage which we will call the g-KPFM.

The gate voltage was applied in steps of 1V, and the contact potential difference between the rGO film and the AFM cantilever probe was measured continuously. This is a direct measure of the change in work function due to the applied gate voltage stress. The obtained transients reflect that the charges are not able to respond instantaneously to the applied change in gate voltage which is also a signature of the rGO based transistors. The hysteresis in the transfer characteristics of these transistors has been reported and observed in our rGO

thin film transistor that was studied in this work.

II. EXPERIMENT

The fabrication starts with the deposition of the back aluminum gate after SiO_2 etching on the backside by protecting the top gate oxide with photoresist of $\text{SiO}_2/\text{p-Si}$ substrate. After this, the photoresist was removed with hot acetone and dried. The rGO film was coated using a two-step wet chemical method. The procedure involves the spin coating of GO dispersion in methanol followed by a vapor phase reduction in a closed environment of Hydriodic acid and acetic acid mixture for 12 hours. The rGO channel ($100\mu\text{m} \times 259\mu\text{m}$) formation along with top metal contacts (source/drain) follows the procedure reported elsewhere [24].

For g-KPFM measurements, the SiO_2/Si with aluminum back contact on the common gate silicon side and rGO coating on the SiO_2 gate oxide side was used. On top of rGO, a Chromium/Gold ($20/100\mu\text{m}$) pad was evaporated through a shadow mask onto the rGO surface to get the top contact grounding for the g-KPFM measurements as shown in appendix Fig. A1. The back Al gate is connected to a variable dc voltage source through the common ground. The frequency modulated (FM) KPFM was performed to probe the surface topography and the surface contact potential difference (V_{CPD}) of the rGO film. The working of FM-KPFM requires two ac voltage signals of different frequencies coupled with two lock-in amplifiers. These ac signals were applied along with the dc control voltage to the tip. The control voltage along with the z-piezo scanner was modulated to compensate for the change in the two ac voltages. The corresponding measure obtained at their resonant frequencies gives the topography and that obtained with dc control voltage correction gives the contact potential difference of the sample surface from that of the tip. A simplified schematic of the lock-in circuitry loop for measuring the V_{CPD} is shown in Fig. A1 in the appendix. The measurements were done with the Park NX10 system operated in the non-contact FM-KPFM mode. We used a standard conducting tip made of silicon coated with Chromium and Platinum of thicknesses 5nm and 30nm respectively as procured from Parksystems with the commercial name Multi-75E which has a resonant frequency of 70kHz (used to capture the topography). The second lock-in amplifier for measuring V_{CPD} was operated at a much lower frequency of 17kHz . Initial calibration of the tip work function was done with a freshly cleaved surface of highly oriented pyrolytic graphite standard whose work function is fixed at 4.5eV . The calculated work functions were obtained

using the relation $\phi_{tip} - \phi_{sample} = qV_{CPD}$, where ϕ_{tip} & ϕ_{sample} are the work function of tip and the sample respectively and V_{CPD} represents the contact potential difference obtained from the second lock-in circuitry. All the measurements were done at room temperature and pressure in a controlled Nitrogen ambient inside a glove box setup. The relative humidity levels were maintained below 5% during all the measurements.

III. COMPUTATIONAL METHODS

All the density functional theory (DFT) based calculations for obtaining the density of states were done with Quantum Espresso package [19], [20]. A simplified rGO model consisting of a hexagonal honeycomb carbon sheet with oxygen atom attachments to account for the semi-reduced complex functional group linkages as described elsewhere [5], [6] was adopted for this study. A top view of its ball-stick model is shown in Fig. 1(b). A dense k-point grid of 72×72 along the in-plane direction with Generalised Gradient approximation was considered [21]. The crystal structure was relaxed with Broyden–Fletcher–Goldfarb–Shanno algorithm [18] through self-consistent calculations.

The obtained density of state curves were fitted at and around the experimentally obtained charge neutrality point (V_{CNP}) data (refer Fig. 2) in the range 7V to 8V. The fitting to conserve the charges was performed with the condition describe in (1).

$$\frac{\Delta Q}{\Delta V_g} = \text{constant} \quad (1)$$

Here ΔQ is the change in induced charges due to the change in applied gate voltage ΔV_g . This implies that the total charge obtained by integrating the area under the density of states curve should be a constant for an equal change in gate voltage. The ΔQ obtained by integrating the area between the work functions measured at 7V and 8V under steady-state was kept as the reference. The work function values corresponding to other voltage step were obtained by fitting onto the curve by preserving the value of ΔQ , which equals the area under the curve bounded by the corresponding vertical lines in Fig. 1. The estimated position of the Fermi level as a function of the applied discrete voltage steps is in good agreement with the gate voltage-dependent change in work function measured under the steady-state condition, which confirms the reliability of the DFT calculations. The slopes at these fitting points were obtained and plotted against the corresponding experimental g-KPFM measurements after normalization at the peak value at the 7V to 8V step, as shown in Fig. 3.

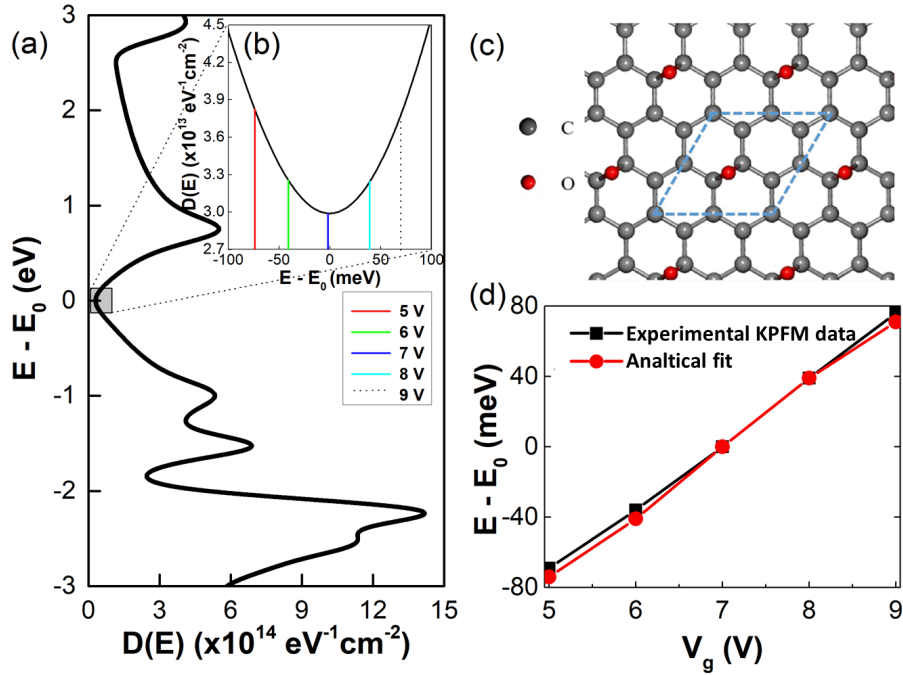

Fig. 1. DFT calculation and analytical modelling results: (a) density of states distribution obtained with DFT calculations ($E - E_0$ is the relative energy with respect the Dirac point (E_0) equivalent of graphene, E being the absolute energy); (b) enlarged image of the highlighted rectangular region in (a) along with the fitted points for $V_g = 5$ to 9 V sequentially represented by red, green, blue, cyan and dotted black vertical lines; (c) ball-stick representation of the rGO model used for DFT calculations; (d) relative work function at V_g from 5 V to 9 V obtained experimentally with FM-KPFM (black) and theoretically (red) with fitting shown in (b)

Further, a projection of these obtained energy values from reduced graphene oxide density of states onto that of graphene (obtained using DFT: Gr- DFT), i.e., the inverse of the slope corresponding to the steady-state energy was estimated and plotted in Fig. 4. In addition, tight binding approximations based on Huckel's model were calculated. Of the two tight-binding fittings shown in Fig. 4, one corresponds to Cerda Graphitic carbon (Gr - TB1), and the other being Hoffmann basis sets (Gr - TB2).

IV. RESULTS AND DISCUSSIONS

The transfer characteristics of the rGO channel-based FET is as shown in Fig. 2 under an applied drain to source voltage of $10V$. It shows a minimum current corresponding to the charge neutrality point (V_{CNP}) of the material between $7V$ and $8V$. The sweeping rates were set to $300mV/s$ and the starting voltage at $\pm 20V$ so that the forward and the reverse sweep almost match, implying that there was enough time to overcome the effect of hysteresis. Thus obtained hysteresis free transfer

characteristics can give the intrinsic doping of the rGO independent of the field-induced transient effects. A positive V_{CNP} at about $+7V$ indicates an intrinsic n-type doping of the rGO [7]–[9]. Further, the presence of hysteresis was observed in the transistor devices by repeating the measurement at faster rates which shows a clear shift in the V_{CNP} point in opposite directions during the forward and backward sweeps away from the former V_{CNP} value. These shifts indicates the inability of the states to respond to the fast-changing applied gate voltages, which accumulate over the previous voltage stresses [16] and leads to the hysteresis effects. The source of this might be the traps or defects present in the system. Hence a lower voltage rate was used to extract the intrinsic V_{CNP} signature from the transfer characteristics of the film, which signifies the ambipolar switching behavior in these materials.

In the g-KPFM analysis, the instance of the time transient right after the applied step voltage change ($t = 0^+$) was considered to remove the effect of slow responding

Fig. 2. The black curve represents the I_d vs. V_g double sweep / transfer characteristics on rGO FET measured over a range of ± 20 V and the red curve corresponds to the $\Delta I_d / \Delta V_g$. The highlighted area shows the range of interest for this study

trap/defect states and probe only the intrinsic states of rGO film. The transient g-KPFM on rGO film was done with switching the voltage in steps of $+1V$ transitions and recording the V_{CPD} continuously as a function of time. Fig. 3 shows the change in work function as a time transient for the applied unit step voltage change for different initial voltages. The applied gate voltage switching was very steep of values less than 1 V/ms. The transient shows a dependence on the voltage switching regime, which might be a reflection of the difference in the density of the states to be filled/emptied and to arrive in equilibrium with the change in applied gate voltage. The slope near the edge of the switching point will reflect the nature of the voltage stress and the effects of nature of the distribution of intrinsic states in rGO film. The initial slopes at $t = 0^+$ were plotted against the initial equilibrium gate voltage values and are shown in Fig. 4.

The comparison of the experimental and the theoretical values in Fig. 3(a) can be explained as follows. The experimentally obtained normalized change in work function (Normalized $\Delta\phi_f$ in Fig. 1b) corresponds to $\Delta\phi_f / \Delta t$ which for a small Δt at $t = 0^+$, where the effect of the applied step voltage change will be dominant. Hence, the rate of change of measured work function is proportional to the number density of states at that instant, which needs to be filled/emptied assuming the amount of induced charge is fixed for all unit step voltage independent of the initial gate voltage. The DFT fitting data was obtained by taking the inverse of the slope at the fitted points on the density of states curve, which equals $\Delta\phi_f / \Delta D(E)$ where $D(E)$ is the absolute density

of states. $D(E)$ can be related to the absolute charge as $Q = qN(E)$ where q is the charge of an electron equals 1.6×10^{19} eV and $N(E)$ is the number of states obtained by integrating the area under $D(E)$. Thus for a fixed $\Delta D(E)$ one can estimate the $\Delta\phi_f$ corresponding to the fixed change in induced charges which is then normalized against the experimental $\Delta\phi_f$ at the peak point of 7V - 8V step.

Table I lists the absolute values of the voltage, energy, and density of states obtained by curve fitting onto the DFT and tight-binding model-based data by projecting the experimental data as stated in the previous section. These data points correspond to the five vertical lines in Fig. 1c and those encircled points in Fig. 1d.

The amplitude of the normalized $\Delta\phi_f$ increases till the 7V - 8V and then decreases, implying that the number of states decreases and then increases clearly reflecting the V_{CNP} point similar to the data obtained with the transfer characteristics of the fabricated rGO transistor devices. The estimates corresponding to the pristine Graphene sheet also show similar trends. The tight-binding models (Gr - TB1 & TB2) show almost symmetric results with a slight deviation from those obtained with first principle calculations (Gr - DFT). However, the tight-binding approximation showed more deviations from the experimental measure as expected due to their pronounced approximation for simplicity, unlike the DFT-based calculations. This implies that the states of the oxygenated bulk of the rGO film do not contribute to the slow responding trap states; rather, it should be from the surface, interface, or gate oxide.

V. CONCLUSION

With the help of the g-KPFM measurements, we were able to capture the time transients of the surface potential of rGO film with the applied change in gate voltages. These measurements clearly show a varying response

that depends on the difference between the applied gate voltage and the voltage corresponding to the intrinsic charge neutrality point of the rGO film over the general operating range of these devices. We have performed density functional theory based calculations with analytical fitting to support the observed experimental data on the states around charge neutrality point in reduced graphene oxide thin films, and they are in good agreement with each other. The fabricated transistor devices on these films showed a transfer characteristic behavior with the charge neutrality point in agreement with that obtained from the transient g-KPFM measurements.

APPENDIX

The general schematic of the circuitry and instrumentation employed for g-KPFM measurements is shown in appendix Fig. A1. A step voltage setup was used in the transient measurements at the source V_g .

Appendix Fig. A1. Schematic representation of g-KPFM measurement setup employing frequency modulation technique for non-contact measurements

Appendix Fig. A2 shows the Energy Dispersion analysis with peaks at Atomic numbers of carbon and oxygen,

which forms the composition in the rGO film understudy. The signal from the SiO₂/Si substrate is corrected by post-processing with the modified form of the model described by Pinos et al [22]. The modification imposed to this random walk simulation of backscattered electron (BSE) assumes no significant contribution from the rGO, which might attribute to 3-5% error for 5 nm thick rGO film. Further, a discrete boundary between SiO₂ and Si was taken at 90 nm (represented by the dashed vertical black line in appendix Fig. A2b-inset) to account for the few nanometer thick SiO_x resulting from the thermal growth process. In the case of a solid-solid interface, it can be assumed that there is no secondary electron emission from silicon. Hence, it has been estimated that the recesses of the total energy for 90 nm thick oxide from that of infinite thickness contribute to BSE in Si. In the case of SiO₂, the effective atomic number was taken as the weighted average of atomic numbers of oxygen and silicon corresponding to their stoichiometry. From the results of this analysis, a concoction of carbon and oxygen in the ratio of 8:1 as represented by the unit cell in Fig. 1b to account for the 10-15% of oxygen-based functional group in them, for the DFT calculations of rGO films. Appendix Fig. A2c-inset shows the AFM height profile of the rGO film on SiO₂/Si substrate. The topographic image was obtained after oxygen plasma-assisted patterning through a metal masking layer deposited on the film followed by metal etching with wet chemicals method to get the rGO step.

ACKNOWLEDGMENT

We thank the financial support from the Ministry of Human Resource and Development (MHRD), Ministry of New and Renewable Energy (MNRE), and TATA Steel Pvt. Ltd., India. We also acknowledge the fabrication and characterization facility provided by the Center for NEMS and Nano-Photonics (CNNP) and Microelectronics Laboratory at IIT Madras. Abstract- Two arms of Microstrip Dipole antenna are printed on the same side of a substrate. But two arms of the Printed Dipole Antenna (PDA) are printed on the opposite sides and hence contain no ground plane. The Return Loss (RL) Bandwidth (BW) of PDA is much higher compared to Microstrip Dipole as it does not contain ground plane like the Microstrip Dipole and therefore Q value is low which results in large RL bandwidth. The PDA is fed by printed version of two wire transmission line. The cross polar discrimination is high as width to length ratio of the arm is very small. In general the width is kept below $0.05\lambda_0$. A novel design of PDA is reported in which the antenna arms have been widened to make it a Flag shaped to achieve large RL bandwidth. The -10dB RL bandwidth as high as 76% is achieved. Due to widening of the arms the fundamental resonant frequency and its first harmonic is stagger tuned to result a high RL. Three antennas are designed and simulated in MOM based simulator IE3D. One of them has been fabricated for experimental verification. The experimental result is in good agreement with the simulated results.

Keywords- printed dipole antenna (PDA), return loss bandwidth, broadband, flag shaped antenna.

I. INTRODUCTION

Two arms of PDA are printed on the two sides of a dielectric substrate and also known as Double Sided Printed Dipole Antenna (DSPDA) [1]. The DSPDA is fed by the printed version of two wire transmission line and is extensively analysed by the Wheeler [2].The structure of the DSPDA along with its feed structure is shown in Fig.-1[1].The closed form expression for the resonant frequency of the antenna is investigated by R.P. Ghosh, et. al. and is given in Equation-1[3].

$$f_r = \frac{c}{4\sqrt{\epsilon_r} L_0} * \frac{1}{(0.6463 e^{-0.4792 \epsilon_r} + 0.5453 e^{-0.01283 \epsilon_r})} \quad (1)$$

Where L_0 is the length of the antenna and ϵ_r is the relative dielectric constant of the medium.

The arm width of the antenna is typically kept less than $0.05\lambda_0$ [1]. This results in low transverse current component and hence cross polar discrimination is too high. The antenna has no ground plane and hence

no field confinement takes place, so the Q value is low compared to other form of Microstrip Antennas. The patch antenna in its basic and simple form provides 2-5% of -10dB RL bandwidth [1], whereas the RL bandwidth of DSPDA in its basic structure is nearly 15-18% [3].This has created immense interest among the researchers to use the PDA for wideband applications like medical imaging, high speed data applications, real time navigation etc. The research has been carried out to increase the RL bandwidth further using various techniques like integrated BALUN, flaring arms, parasitic elements, introducing slots on arms for gradual impedance transformation [4-10]. But these techniques of boarding the RL bandwidth have increased the complexity of the structure of the DSPDA.

In this communication the broad band DSPDA is reported with large impedance bandwidth (RL). The broadband is achieved by widening the arm's width making it a Flag shaped. The widening of arms stagger tunes the fundamental frequency and the first harmonic to provide large RL bandwidth. No BALUN, parasitic element or any other impedance matching technique is used to design the DSPDA. It is also found that cross polar discrimination is relatively high (more than 20dB) in spite of widening the arm width. Thus antennas are simply structured and fabrication of these is easy. Three antennas are designed and reported with highest 10dB RL bandwidth of 76%. All antennas are designed and simulated in MoM based simulator IE3D [11]. A DSPDA is experimentally verified and is in good agreement with the simulated data.

Fig.-1: Double Sided Printed Dipole Antenna (DSPDA) along with its feed structure [1].

II. PARAMETRIC STUDY TO DESIGN BROADBAND DSPDA

The DSPDAs consist of two arms known as active radial and ground radial which are printed on opposite faces of dielectric material. The length of the DSPDA for the resonant frequency is determined by the Equation-1.

$$f_r = \frac{c}{4\sqrt{\epsilon_r} L_0} * \frac{1}{(0.6463 e^{-0.4792 \epsilon_r} + 0.5453 e^{-0.01283 \epsilon_r})} \quad (1)$$

Where L_0 is the length of the antenna and ϵ_r is the relative dielectric constant of the medium. In case of DSPDA no field confinement takes place and hence there exists no fringing field. So the length correction is not required. The arm width of the DSPDA is usually kept less than $0.05\lambda_0$. Initially antenna is designed with the arm width much less than the prescribed value. But it is gradually increased and is found to increase the RL bandwidth. A parametric study is carried out to find the increase of bandwidth with increasing arm width. The common area as described by R.P.Ghosh et. al. [3] is also adjusted to get optimum RL bandwidth. A parametric study is also carried out to get the optimum RL bandwidth with the variation of common area.

An antenna is designed initially with the following specifications to carry out the parametric study. Dielectric Constant (ϵ_r) = 2.4, Length of each arm (L_0) = 130mm, Height of the substrate (h) = 1.524mm, Arm width = 6mm.

According to Equation-1, the DSPDA resonates at 0.5GHz. The arm width is kept well below the $0.05\lambda_0$. The variation of RL band width with the variation of common area is shown in Fig.-2. And the variation of bandwidth with the widening arm width is shown in Fig.-3.

Fig.-2: Variation of RL bandwidth with common area of the DSPDA.

Fig.-3: The variation of BW with arm width.

So from the above parametric study it is concluded that the common area and the arm width may be simultaneously adjusted to get broad RL bandwidth of DSPDA. It is also found that the cross polar discrimination is well above the acceptable limit even after the widening the arm's width.

III. DESIGN OF BROADBAND DSPDA

Following the observations of the above parametric studies, three broad band DSPDAs has been designed. The DSPDAs resonate at 0.5GHz, 1.0GHz and 1.5GHz. All three antennas are designed and simulated in MOM based simulator IE3D. In all three DSPDAs it is found that the maximum RL bandwidth is obtained at the arm width of $0.1\lambda_0$ and with no common area. In each case, the fundamental frequency and its first harmonic is staggered tuned to produce large RL bandwidth. The cross polar discrimination is above 20 dB which is well above the acceptable limit. The DSPDA whose resonant frequency is 1.0GHz is fabricated for experimental verification. The experimental values agree with the simulated results.

IV. RESULTS

A. DSPDA-1

The DSPDA-1 operates at the frequency 0.5GHz. The antenna arms are flattened to $0.1\lambda_0$ to stagger tune the fundamental mode and first harmonic. It provides RL bandwidth of 62% with cross polar discrimination more than 20dB. The top and back view of the antenna are shown in Fig.-4(a,b). The antenna dimensions are given by Dielectric Constant (ϵ_r) = 2.4, Length of each arm (L_0) = 130mm,

Height of the substrate (h) = 1.524mm,
 Arm width = 60mm.
 Common area between arms = 0 mm.

B. DSPDA-2:

The DSPDA-2 operates at the frequency 1.0 GHz and arms are flattened to $0.1\lambda_0$. It provides RL bandwidth of 69% with cross polar discrimination more than 20dB. The top and back view of the antenna are shown in Fig.-10 (a,b). The antenna is fabricated and experimentally verified. The antenna dimensions are given by

- Dielectric Constant (ϵ_r) = 2.4,
- Length of each arm (L_0) = 66 mm,
- Height of the substrate (h) = 1.524mm,
- Arm width = 30mm.

Common area between arms = 0 mm.

The top and back views of the designed antenna along with all dimensions are shown in Fig.- 10. The photograph of the fabricated antenna is shown in Fig.-11.

C. DSPDA-3

DSPDA-3 is also designed to operate at 1.5GHz with the following dimensions. The antenna provides impedance bandwidth of 76%.

Dielectric Constant (ϵ_r) = 2.4,
 Length of each arm (L_0) = 44 mm,
 Height of the substrate (h) = 1.524mm,
 Arm width = 20mm.

Common area between arms = 0 mm.

V. CONCLUSIONS

Three broadband DSPDAs are developed with the fundamental frequency of 0.5GHz, 1.0GHz and 1.5GHz. In each case, the fundamental and first harmonic is staggered tuned when the antenna arms are widened to $0.1\lambda_0$. It makes the antenna Flag shaped. The Q value of the antenna is lowered at both the frequency due to the increase of arm’s width and results in high RL bandwidth. The DSPDAs provide RL bandwidth of 62%, 69% and 76%. The antennas are simply designed. No complicated antenna design techniques are used to achieve large RL bandwidth. Even no BALUN or complicated impedance matching techniques are used. The cross polar discrimination is well above 20dB in each case even after widening the arm width. A generalised design procedure may be adopted to design the broad band

DSPDA. At first, calculate the arm length for any resonating frequency (fundamental frequency) using the Equation-1 and then widen the antenna arm to $0.1\lambda_0$. In the process, the fundamental frequency and its first harmonic will be staggered tuned to provide large RL bandwidth. All the three antennas have been designed following this method.

Abstract—In this work, we derive the semantics of a given English query and convert it into its equivalent SQL query. Instead of using neural networks for semantic analysis of English queries, we opt for a Context Free Grammar approach. Most neural-network-based systems can handle only one semantic at a time, whereas, because of the flexibility offered by our CFG approach, our system manages to handle simultaneous usage of conjunctive, disjunctive, and negative semantics. It also handles complex statements comprising of main as well as dependent clauses. In addition, the system also takes into account aggregate functions and constructs the required GROUP-BY and HAVING clauses. We describe how the system analyzes English queries by understanding the role that each part-of-speech has to play in constructing SQL queries. Numerous examples demonstrate the effectiveness of our approach where state-of-the-art techniques relying on deep learning algorithms fail to deliver.

Keywords—*chatbots, natural language processing, semantic analysis*

I. INTRODUCTION

Traditionally, relational databases have relied on a standard query language (SQL), a powerful tool for extracting data. But, often times this can be very challenging, specifically for non-technical users. Even for power users, expertise is still required to understand the specific schemas, and entity relationships further add to the complexity of using SQL. However, in the real-world, many people use natural languages such as English to ask questions and find solutions to their problems. Programs, for example, Chatbots, have been developed to answer queries or deliver personalized responses to various requests. Chatbots, a word derived from “chat robots”, have dramatically revolutionized how people interact with online information and services, a trend that requires a rethinking of user needs during the development of chatbots [1]. Chatbots are also known by other names, for example: virtual assistants, conversational agents, dialogue systems, personal assistants and conversational interfaces [2]. In recent times, Chatbot adoption in many applications is on the rise due to automation of labor-intensive tasks at low costs, improved customer experiences, and other benefits [3].

According to recent research [4], the global Chatbot market is predicted to grow at the rate of 31 percent by 2024 across different sectors such as healthcare, retail, travel and BFSI (Banking, financial services, and insurance services). Additionally, the retail sector is projected to spend \$142 billion worldwide by leveraging chatbots [5]. These trends are not driven only by technological advancements but largely by the desire to improve customer service and delivery experiences on ubiquitous devices, social media, customer relationship management and more [6]. With the increase in demand by

consumers, the Chatbot ecosystem is rapidly expanding, providing more opportunities to develop technological-focused platforms.

The primary goal of this paper is to develop a Chatbot system that provides non-technical users with an interface to interact with RDBMS using English-like, human-readable statements. In this paper, we propose an SQL-Chatbot System (SCB) consisting of mainly three steps. In the first step, the given English query is decomposed into granular components (individual keywords). In the second step, the equivalent SQL query is built. In the final step, the query is executed to return the results back to the user. To the best of our knowledge, our system is the first to use Context Free Grammar (CFG) for an SQL-based Chatbot platform. Our system leverages Context Free Grammar (CFG) to generate semantically equivalent SQL queries while contextualizing the role of parts-of-speech (POS).

II. RELATED WORK

One early attempt to connect casual users to relational databases using natural languages was the RENDEZVOUS project [7]. With the increase of both structured and unstructured data, a resurgence in this field has attracted research interest in understanding how to convert natural-language statements to machine readable form, such as semantic parsing. One approach is to use table-based semantic parsing on large databases. For example, Seq2sql used reinforcement learning [8], SPIDER leveraged multiple tables and contains multiple SQL queries [9]. Other works have investigated more challenging database structures such as relational databases. These approaches include RAT-SQL[10], which translates relational structure in the database schema, evaluation on multiple datasets using neural text-to-SQL systems [11], ToTTo for summarization [12], Table2Vec for retrieval tasks [13], and HybridQA for question-answering [14].

With the recent rise of the importance of neural networks in natural-language processing, some natural-language database interfaces have incorporated these networks into their systems in some way. For example, the authors of [15] created a speech-based interface based on semantic matching that used a convolutional neural network as part of the design. As another example, in [16], the authors used a word embedding based on a neural network in order to enable semantic queries to a database. However, we decided not to incorporate neural networks in this work because when it comes to semantic analysis, we found that our CFG approach offers more flexibility as compared to deep-learning approaches.

A recent survey of NLIDB with Deep learning evaluated 349 articles with a focus on text-to-SQL tasks across well-known

datasets such as Spider, ATIS, GeoQuery, Sparc and WIKISQL [17]. For example, the use of “Group By” and “Order by” SQL clauses remains a challenging task for deep learning applications due to limited availability of large datasets, varying schema information and cross-domain adoptability [17]. Another limitation for NLP-based SQL methods is the representation of queries into intermediate language [17]. In contrast, our CFG-based algorithm handles the challenging tasks of constructing clauses such as “GROUP BY” and “HAVING” and generating semantic queries while contextualizing the role of parts-of-speech in the use of SQL ChatBots.

Previous research in neural networks has attempted to map NLP to SQL queries to solve problems based on popular crowd-sourced datasets such as WikiSQL and Seq2SQL [8]. Another approach used autoregressive generative models trained on WikiSQL, ATIS, and GeoQuery datasets[18]. This method used execution guided-decoding of SQL leveraged on the semantics of SQL. Our work leverages Context Free Grammars (CFG) by applying a Framing Procedure (FP), a Grouping Algorithm (GA), and a Clause-Construction Algorithm to construct associative SQL clauses. The objective of this work, therefore, is to create a novel SCB system that allows even naïve users to interact with chatbots by specifying ad-hoc queries. We introduce a SQL-Chabot system built on CFG for semantic parsing to automatically map English queries to their corresponding SQL queries. Further details about the SCB system are discussed in the methodology section.

III. SYSTEM OVERVIEW

SCB system has mainly three built-in components used for query’s analysis purpose: thesaurus, lists of delimiters and connectors. Delimiters and connectors are used for English query’s decomposition purpose (to be discussed later); whereas inbuilt thesaurus is used for query expansion purpose, where if a user enters any word synonymous to any attribute or value, then with the help of thesaurus the system is able to map it back to the original keyword. In addition, after a particular database is connected to our system, the system will automatically generate an inverted index, based on the underlying schema and data graph.

Thereafter, when an English query (text or voice format) is submitted to the system, the parsing process takes place, and the English sentence is decomposed to construct an SQL query. The system first builds a sub-graph (candidate network) that represents a path between relations having all the query keywords. To locate such involved relations, our search engine uses depth first search technique for traversing the schema graph, which further results into the construction of FROM clause of SQL query. The system also uses inverted index for lookup purpose; i.e. for a given keyword it can retrieve the attributes and tables to which the keyword belongs to, in the underlying database. These table and attribute pairs (associated with the query-keywords) together forms the SELECT clause. Construction of WHERE clause involves a couple of components as shown in Fig.1, which depicts key steps

involved in execution or working of our search system. A brief overview of main components is provided below. They will be further explained in detail in methodology section.

The system processes English queries iteratively until all the sub-queries within a given query are not processed/parsed. Working of this system is mainly based on a Context Free Grammar (CFG).

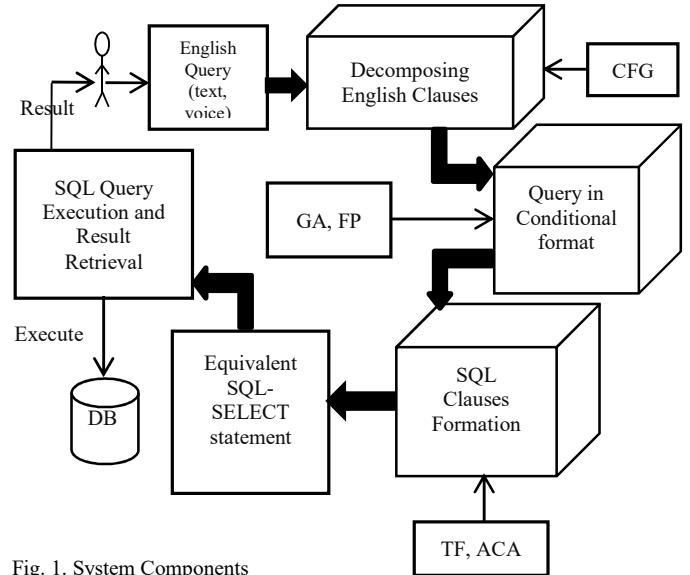

Fig. 1. System Components

Based on the list of delimiters, the query is first divided into sub-queries (main clause and subordinate clauses). Based on the list of connectors, each clause is then divided into subject and predicate, and is further analyzed from left-to-right to identify the attributes and values which in turn form the conditions. Also, every condition is associated with its neighboring condition by a logical operator. By applying the grouping algorithm (GA), conditions within each sub-query are grouped in such a way that the precedence and associativity of the involved logical operators is preserved. The precedence of such logical operator is determined by the number of parenthesis surrounding the condition of which it is being part of. GA works iteratively to produce parenthesized form for each clause. All the subordinate clauses, based on the Framing procedure (FP), are then eventually associated with the main clause so as to get the representation of the entire query in parenthesized or conditioned (attribute-value pair) format. This conditional format of the given English query is further converted to tabular format (TF). Tabular format makes it easier for search engine to deduce SQL’s SELECT, FROM and WHERE clauses.

Additionally, Clause-Construction Algorithm is used to detect whether or not the given English query has any aggregate functions involved or not; if in case it does, then it helps in identifying the attributes associated with aggregate functions, and the ones around which the grouping has to be done. The algorithm further constructs a data structure called Attribute-Clause-Association (ACA), which is used for the construction

of SQL’s GROUP-BY and HAVING clauses. All the SQL-clauses are then concatenated to get the entire SQL statement, which is further executed on the underlying database so as to fetch and display the results to the user. Also, to understand the semantics of the query, we have considered the roles of parts-of-speech that they play in breaking down the given English query and then in construction of its equivalent SQL query.

The strategy implied by the search system, therefore consists mainly of two phases: decomposition and construction phases. In the decomposition-phase, the English query is decomposed by using CFG to the smallest possible granularities. In the construction-phase, GA along with FP are used to parenthesize the parsed query, from the above phase, in a way so as get semantically equivalent parenthesized format of the original English query. Also, whenever needed, ACA algorithm is applied to take care of aggregate-functions, and then ensures the construction of GROUP-BY and HAVING clause. Throughout these phases, the given query is skimmed over in order to retain just the needed information, as per the CFG’s requirement; rest is discarded. Eventually, with the support of data-structures and algorithms, the parenthesized (conditional) format is converted into SQL’s SELECT statement for execution purpose.

IV. METHODOLOGY

A. Sentence Components

Fig. 2 below, illustrates the roles that various parts-of-speech have to offer in constructing SQL statement, for a given English query. It also helps in understanding how the components of English sentences comprise the WHERE clause (conditions) of SQL statement. In this diagram the dotted line represents that within a clause the conditions, if not stated explicitly, are implicitly connected through logical operator (AND).

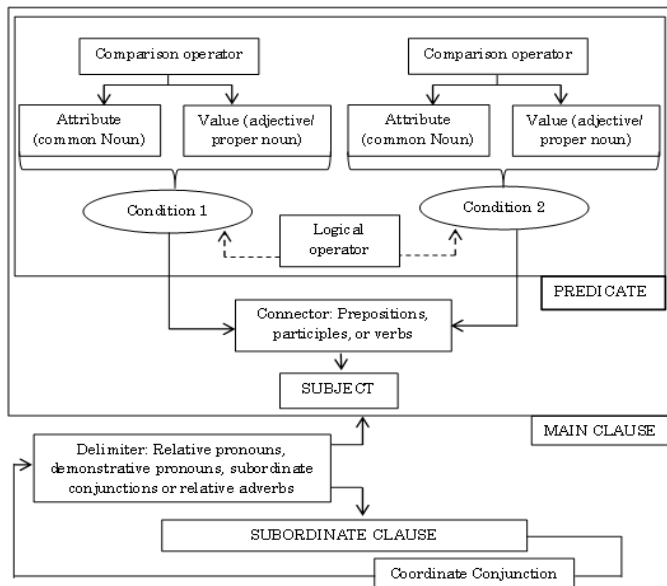

Fig. 2. Sentence Components

In addition, the conditions are individually associated with the subject in a clause through *connectors*, indicated by the solid line. Similar to the conditions, subordinate clauses introduced by delimiters, are also connected with each other by the help of coordinate conjunctions, and then are individually associated with main clauses.

B. Context Free Grammar (CFG)

Decomposition of the English query by Search engine is carried out through the Context Free Grammar (CFG) shown in Table-1.

Table 1. Context Free Grammar (CFG)

Grammar $G = (N, \Sigma, P, Q)$, where-
The non-terminal symbols are: $N = \{\text{Query, Main-Clause, Subordinate-Clause, Subject, Predicate, Condition}\};$
The terminal symbols are: $\Sigma = \{\text{attribute, value, delimiter, connector, logical-operator, coordinate-conjunction, comparison-operator, wrapper}\};$
‘Query’ = is the starting symbol, and
Query \rightarrow Main-Clause Main-Clause Subordinate-Clauses
Subordinate-Clauses \rightarrow Subordinate-Clause (coordinate-conjunction Subordinate-Clause)*
Main-Clause \rightarrow Subject connector Predicate
Subordinate-Clause \rightarrow delimiter connector Predicate
Predicate \rightarrow (Condition) (logical-operator Condition connector Condition logical-operator connector Condition)*
Subject \rightarrow (Condition) (logical-operator Condition)*
Condition \rightarrow (attribute comparison-operator value value comparison-operator attribute)*
Condition \rightarrow (attribute)* (value wrapper)* (value attribute)

From the CFG we can see that the delimiters are used to introduce subordinate clause into the sentence. Connectors are used to connect subject and predicate within a given clause (main or subordinate). Coordinating conjunctions like ‘or, and’ in the query, usually act as logical operators which connects the conditions within the subject or predicate of a clause, but additionally can also be used to connect subordinate clauses. Examples to be encountered in the paper, shall assert the fact of immense flexibility being offered by this CFG.

Wrappers are no different from logical operators, except that they operate on the values belonging to the same attribute domain. For example in the query, ‘car having red or green color’, both values (red, green) belong to the same attribute (color) and hence the operator ‘or’ is treated as a wrapper by the search system. The reason for such distinction is to give higher

preference for wrappers over other logical operators. The following example illustrates how the CFG decomposes the given query into smaller components:

Query-1: Look for a red color Toyota Camry that has price < \$8000 or which has been manufactured in year 2012 with mpg > 25. Here,

Main Clause (M): Look for a red color Toyota Camry
 Subordinate Clause (S1): that has price < \$8000 or
 Subordinate Clause (S2): which has been manufactured in year 2012 with mpg > 25.

C. Grouping Algorithm

After the query is decomposed by CFG, the next step is to group the conditions in a way so as to retain the precedence of involved operators. This job of retaining the semantics of query is done by GA. Parentheses, alongside the operands, are used to decide the preference of operators. The output of above CFG’s phase is given as an input to GA. GA processes each clause in an individual manner. Grouping Algorithm plays a crucial part as it helps in construction of WHERE clause, where the precedence of operators needs to be preserved. The grouping algorithm is summarized in Fig. 3.

Algorithm: Grouping Algorithm (GA)
 Input: un-parenthesized sub-query and its Attribute Domain Information (ADI)
 Output: parenthesized sub-query
 Procedure:

- (a) Wrappers are given higher priority than Logical operators.
- (b) As per the precedence rule, the logical operators are prioritized in the following order: NOT, AND, OR
- (c) If the same operator is repeated, then the priority is determined through Associativity rule: the left hand side operator is dealt first.

Grouping Algorithm satisfies the above priority rules, by building the following different cases. In each case, grouping of the operands takes place based on the attribute domain information (ADI) and the operator at hand:

- (1) AND, OR wrapper: If they act as wrappers, then group the values on which they operate
- (2) AND operator: If it operates on values belonging to different attribute domain then the values can be grouped, else not
- (3) OR operator: If it operates on the values belonging to the same attribute domain then the values can be grouped, else not
- (4) NOT operator: Either acts as a delimiter or as an unary operator

CASE A: As a delimiter

NOT (A operator B) --[Where “A” and “B” are values]

CASE B: As an unary operator

(NOT A) operator (NOT B)

Fig. 3. Grouping Algorithm

After the output of CFG is fed as input to GA, it generates the following query conditions:

Main Clause: ((color=red) and (manufacturer=Toyota) and (model=Camry))

Subordinate Clause-1: (price<\$8000)
 Subordinate Clause-2: ((production_year=2012) and (mpg >25))

After having the composed version of the English query from GA, Framing Procedure (FP) then applies propositional logic (particularly associative, commutative, and distributive rules) so that each subordinate clause can be separately associated with the main clause, and yet retaining the semantics of the original English-query. Along with GA, FP basically helps in constructing the parenthesized-format (intermediate representation) of the given English query. For the example in consideration, the conditions are grouped in the following way to construct the parenthesized format:

((color=red) and (manufacturer=Toyota) and (model=Camry))
and (price<\$8000))
OR (((color=red) and (manufacturer=Toyota) and (model=Camry))
and ((production_year=2012) and (mpg >25)))

The output of the above step represents the WHERE clause. For construction of SELECT and FROM clause, our system refers to the inbuilt inverted index; i.e., for every value involved in the query, the system derives its attribute and table name to which it belongs to. Based on this information and from parenthesized format of the query, we deduce the tabular format as shown in Table 2. Note, R.O. represents relational-operators.

Table 2: Tabular Format Of Parenthesized Query

open	table	attribute	R. O.	value	close	logical operator
((Table 1	Color	=	Red)	And
(Table 2	Manufacturer	=	Toyota)	And
(Table 4	Model	=	Camry))	And
(Table 1	Price	<	8000))	Or
((Table 6	Color	=	Red)	And
(Table 6	Manufacturer	=	Toyota)	And
(Table 5	Model	=	Camry))	And
((Table 5	production_year	=	2012)	And
(Table 3	Mpg	>	25)))	

Here, the name of tables in column2 will form the FROM clause, and the name of attributes in column3 will form the SELECT clause. In addition, each row represents a condition; so appending all the rows from above table will result in construction of WHERE clause. SCB also offers more flexibility

to users by allowing them to incorporate the aggregate functions into their query. The formation of GROUP-BY clause and HAVING clause is elucidated below.

D. Clause Construction Algorithm

Clause Construction Algorithm is used to deal with aggregate functions in the user’s English query, and hence responsible for construction of GROUP-BY and HAVING clauses in the background.

We now present the clause construction algorithm in Fig. 7, which parses the given English sentence to check for the presence of any aggregate function; if yes, then based on the following rules it constructs the data structure ACA, which is responsible for the construction of GROUP-BY and HAVING clause.

- (1) If any attribute in the English statement is preceded by aggregate function, our search engine infers that such attribute will be part of SELECT clause.
 - (a) Furthermore, such attributes together with aggregate functions, if in case do have any conditions imposed on them, then such condition shall be part of HAVING clause, and not of WHERE clause instead.
- (2) If any attribute is complemented by any value so as to form an attribute-value pair, then such attribute-value pair shall be part of WHERE clause, and not of the HAVING clause.
- (3) If any other attributes are mentioned in the *subject of a query* which neither have any associated value nor is preceded by any aggregate function (type-4) then such attributes shall be part of GROUP-BY and SELECT clause, and not of the WHERE and HAVING clauses instead.
- (4) Type-4 attributes that represent *objects in the predicate of a query* don’t make it to the SELECT and GROUP-BY clauses, unless explicitly stated; by default they can be only be the part of WHERE clause if accompanied by a value, or of HAVING clause if accompanied by both value and an aggregate function.

Fig. 4. Clause Construction Algorithm

After executing this algorithm, our system generates the *Attribute-Clause Association (ACA)* data structure. For illustration purpose, consider Query 2.

Query 2: Display the list of students in computer science branch whose/having average score greater than 75.

Here, the attribute ‘score’ has not only an aggregate function preceding it but also a condition that follows it. Therefore, such condition ‘avg(score)>75’ belongs to HAVING clause and not WHERE clause. ‘Students’ form the subject of the sentence, and as there is no aggregate function associated, it is part of SELECT as well as GROUP-BY clause. The ACA for this query is shown in Table 3

Table 3: ACA For Query-2

Attribute	Aggregate Function	Select Clause	Group-by Clause	Where Clause	Having Clause
Students	N/A	Present	Present	Absent	Absent
Branch	N/A	Absent	Absent	Present	Absent
Score	Average	Present	Absent	Absent	Present

The SQL query generated for Query-2 is:
 Select students, avg(score) from Table-t1
 where branch= ‘computer science’
 group by(students)
 having avg(score)>75.

Query 3: Find customers and their total/sum expenditure at Walmart organization, in the month of January 2012.

Here, the attribute preceded by aggregate function is ‘expenditure’. As it has no conditions imposed on it, it shall be just part of SELECT clause and not of the HAVING clause. Further, the attributes organization, month and year have been specified with the values of ‘Walmart’, ‘January’ and ‘2012’ respectively. As a result, those attributes along with their values will be part of the WHERE clause condition. Now for the attribute ‘customers’, based on the rules 3&4, search engine knows that ‘customers’ is subject and should be a part of the GROUP-BY clause. ACA for Query-3 is shown in Table 4.

Table 4: ACA For Query-3

attribute	aggregate function	select clause	group by clause	where clause	having clause
customers	n/a	present	present	absent	absent
expenditure	sum	present	absent	absent	absent
organization	n/a	absent	absent	present	absent
month	n/a	absent	absent	present	absent
year	n/a	absent	absent	present	absent

The SQL query generated for Query-3 is:
 Select customers, sum(expenditure)
 from Table-t2
 where (organization= ‘Walmart’ and month = ‘January’
 and year = ‘2012’)
 group by(customers)

Furthermore, there can be some cases where user might explicitly specify the attributes around which the grouping should be done. For instance, adjective words such as: each,

every, make it possible for users to be absolute or certain about the attributes that demands inclusion in the GROUP-BY clause. For example, consider Query 4.

Query 4: Count number of employees for each department in the company XYZ.

Here, the subject of sentence is ‘employees’ and hence is a part of the SELECT clause; whereas, when it comes to ‘department’ attribute, it even though being the object of the sentence still makes it to the GROUP-BY clause, since here the user is explicitly stating its inclusion through the use of adjective ‘each’. The ACA for Query 4 is shown in Table 5.

Table 5: ACA For Query-4

Attribute	Aggregate function	Select clause	grouby clause	Where clause	Having clause
Employees	Count	present	Absent	absent	absent
department	N/A	present	Present	absent	absent
Company	N/A	absent	Absent	present	absent

The SQL query generated for Query-4 is:

```
Select department, count(employees)
from Table-t3 where (company= 'XYZ')
group by(department)
```

Note that when it comes to English queries constructed by user, they are either of interrogative or imperative nature. As a result, most of the queries shall begin with a ‘verb’. Our search engine ignores such initial verbs (and prepositions) until the subject has being encountered. Also, the aggregate functions in the English query will only be taken into account, if the user is specifying them explicitly, and not implicitly otherwise.

V. EXPERIMENTS & RESULTS

Sample queries executed by SCB system are shown from Fig.6 to Fig.9. The schema graph of the underlying database (on which the queries were executed) is shown in Fig. 5.

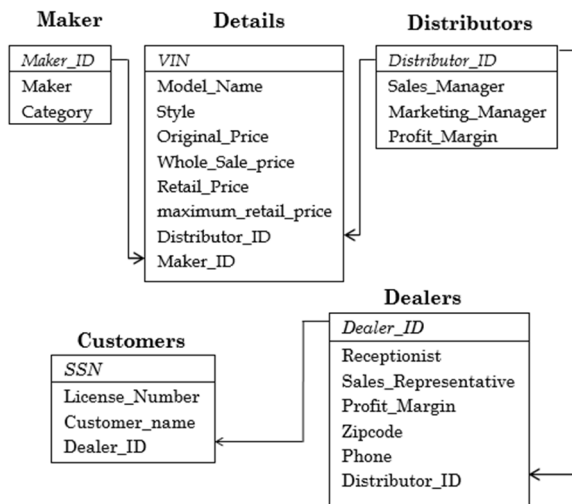

Fig. 5. Schema Diagram

Enter an English Statement Query:-
Count number of vehicles possessed by each dealer, located in Nebraska

----- OUTPUT -----

dealer_name	Count(vehicles)
Baxter	12350
Woodhouse	19180
Edmunds	21005

Fig. 6. Output for Query-5

Enter an English Statement Query:-
Find Honda model having the least/minimum price at Baxter

----- OUTPUT -----

Model	Min(Price)
Civic	\$10000

Fig. 7. Output for Query-6

Enter an English Statement Query:-
Find maximum mileage associated (5000 MILES ON THEM) with each car maker at Woodhouse

----- OUTPUT -----

Maker	Max(mileage)
Ford	23000
Honda	2800
Toyota	250000
Chrysler	20

Fig. 8. Output for Query-7

Enter an English Statement Query:-
Count number of coupe style cars sold in Omaha for year 2012

----- OUTPUT -----

Count(cars)
30560

Fig. 9. Output for Query-8

VI. CONCLUSION & FUTURE WORK

As discussed, the extended keyword search facility in our search engine initially deduces the structure of an English query with the help of CFG. Conditions within the original query are then grouped/parenthesized in a way so as to preserve the precedence of the involved operators, and hence the overall semantics of a query. The Framing Procedure goes a step ahead to deal with queries having more than one subordinate clause by informing the search engine of the way clauses of complex English queries can be associated. Roles played by parts of speech in composing English statements are understood and applied in the context or terminology of relational databases so as to construct their equivalent SQL query. The paper also illustrates the technique used to identify and further map the variety of attributes used in the English query statements to their SQL counterparts. The Clause-Construction algorithm is then

introduced to detect the presence of any aggregate functions in the query, and if needed, to construct the required GROUP-BY and HAVING clauses. By default, the search system allows the simultaneous use of disjunctive (OR), conjunctive (AND), negative (NOT) semantics, along with the possible combinations of NAND and NOR. Thus, the semantics derived by GA are used to construct the WHERE clause. The construction mechanism of SELECT and FROM clauses works in a way that is similar to traditional DBKWS. This paper also refines and exploits the list of delimiters and connectors used for decomposing the English queries. Overall, the paper demonstrates how the CFG approach enables extended keyword search and benefits DBKWS and NLIDB by capturing contextual information in English queries.

In upcoming work, we plan to explore and compare the performance in construction of queries of deep-learning approaches using sentiment-analysis against our SCB system.

Abstract—This paper introduces an optimal controller for the power electronics loads (PELs) based on the goal attainment multi objective optimization and linear quadratic regulator (LQR) architecture. Optimal set point of the PEL is derived to regulate the desired load demand while maximizing the input bus voltage of the PEL. Then a LQR controller is developed to drive the PEL state to the optimal equilibrium. Dynamic modeling of the PEL is done in the energy and admittance domain. Simulations were carried out to demonstrate the effectiveness and the applicability of the proposed method.

Keywords—DC microgrids, multi objective optimization, optimal control, power electronic converters

I. INTRODUCTION

To fulfil the ever increasing electricity demand due to the population growth and the technological advancement, energy authorities and policy planners are focusing on finding more reliable and flexible power systems. Over the years traditional power generation systems used to supply the electricity demands of the consumers [1], [2]. Due to the increased demand for electricity, high penetration of renewable energy sources into the existing grid and having a unidirectional passive distribution network [2], [3], these traditional power systems require significant re-modification in infrastructure in order to fulfil the future power system requirements which consist of bidirectional active distribution network [3], [4].

Contrary to large scale power systems, small scale power systems (SSPS) consist of localized generation, loads, storage systems and control systems [5]. Power systems of naval ships and communication centers and Micro-grids (MGs) are some of the examples for SSPS [6]. By implementing SSPSs such as MGs can offer many benefits to both electricity utility and the users. With the utilization of many distribution generations in MGs, transmission losses can be reduced as the power flow reduced in transmission and distribution lines. In addition to that improvement of network and power quality, reduction in emissions and cost are some other advantages provided by the MGs [7].

Typical MG consists of distributed generation sources, distribution systems, storage systems and communication and control systems [8]. Having low voltage operational networks

and capability of operating in different configurations such as grid connected mode and islanding mode are some of the special features in these SSPSs [7], [9]. MGs under SSPSs can be broadly categorized as AC, DC and hybrid MGs [10]. Compared to the AC MGs, DC MGs are becoming more popular due to the rapid growth in DC loads, DC based distributed generations such as solar PV, fuel cell and DC based energy storage technologies [11]. Efficiency improvement and reduction in losses due to the abatement of converters used for DC loads; smooth integration of distributed energy resources such as solar PV and energy storages are some of the benefits provided by the DCMGs [10]. Considering these factors, this paper focuses on the DCMGs.

Since the loads and sources in a DCMG have multiple objectives, MG control problem can be identified as a coupled multi objective optimization (MOO) problem. For example, sources try to maintain their load bus voltage around the desired voltage while loads try to regulate their input power at the desired value. Further, as an interconnected system, both loads and sources attempt to maintain the system stability while minimizing system losses. Game theoretic control and optimal control are two major control architectures which can be brought in to develop controllers that can solve MOO problems [12].

In game theoretic controllers, the active components in the system has to be modelled as players. Any constituent that influences the energy flow of the system such as loads, sources is considered as a player and objective function for each player should be defined [6], [13], [14]. On the contrary, optimal control is a tradeoff between requirements of the loads and the requirements of the sources [15]. Broadly speaking, in the optimal control, active components try to find the best possible transient path in the startup or subjected to a disturbance which minimizes a given cost function or individual cost functions by maneuvering their own control inputs [16].

In this paper, goal attainment MOO technique is employed to obtain the optimal set point of the PEL which minimizes set of multi objectives. Active power regulation and bus voltage maximization has been considered as the multi objectives in the modeling. Then, to maneuver the PEL state to this optimal set point, a LQR optimal controller is also proposed.

Rest of the paper is organized as follows. In the next section, PELs are modeled as an adaptive admittance. In section III, multi-objective problem for optimal PEL control is formulated. Section IV describes the solution for the multi-objective problem formulated. Then the PELs are modeled dynamically in the admittance domain in Section V. Section VI describes the optimal control sequence required. Simulation results are presented in Section VII and the paper is concluded in section VIII.

II. ADAPTIVE ADMITTANCE REPRESENTATION OF PELS

Power and impedance are the common parameters used to represent a power system load. In MG domain, End Loads (ELs) and power grid are connected through a Power Electronic Converter (PEC) as shown in Fig. 1 (a). PEC acts as an intermediate device between MG and EL. MG comprises of interconnected sources and loads while the ELs can be single or multiple loads with either constant impedance or current or power.

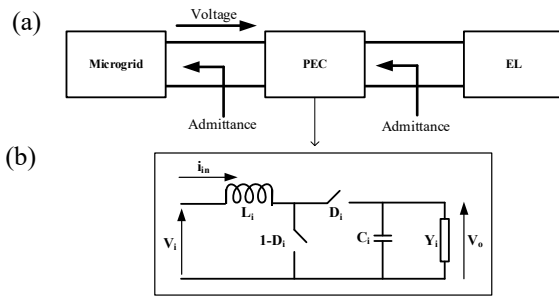

Fig.1 (a) Power electronic converter as an interface between the power system and end load (b) boost converter as a power electronic converter

Any DC-DC converter topology can be used as a PEC. Consider an average mode boost converter as the PEC as shown in Fig. 1 (b). EL properties can be varied by controlling the PEC input characteristics as the PEC works as a voltage and impedance translator between the MG and EL. In Fig. 1 (b), V_i , i_{in} , V_o and D_i represent the input voltage, input current, output voltage and duty cycle respectively. For any time, MG sees the input admittance of the PEC as,

$$y_i = \frac{i_{in}}{V_i} \quad (1)$$

If the PEC is assumed to be lossless, from the power balance,

$$V_i^2 y_i = V_o^2 Y_i \quad (2)$$

where Y_i represents the equivalent admittance of the EL. From (1) and (2), the input admittance of the boost converter based PEL can be shown as,

$$y_i = \frac{Y_i}{D_i^2}; \quad D_i \in [0,1] \quad (3)$$

This representation yields that the PEC based load can be modeled as an adaptive admittance and it acts as a member of the power system as a single quantity.

III. MULTIOBJECTIVES IN POWER SYSTEMS

A. Multiobjective formulation for Optimal PEL Control

There can be multiple different conflicting objectives in SSPSs control point of view. However, in DCMG perspective, active power and voltage regulation have paramount importance and will be the focus of this paper. Each PEL has the desire to regulate its active power input from the grid and it will be considered as the first objective in this paper as,

$$f_{1,i}(x_i) = (y_i V_i^2 - P_i)^2 \quad (4)$$

where, $x_i = [y_i \ V_i]$ is the decision variable vector, y_i , V_i and P_i are the input admittance, input voltage and active power demand of the i^{th} PEL. When the load demand increases, its terminal voltage decreases. Therefore, PEL would like to regulate its input voltage closer to the nominal value. However, regulation of both power and voltage could leads to unsatisfactory results since there is an inverse conflicting nature between the objectives. Hence, to overcome this issue and to satisfy voltage uplift, the second objective of the PEL is considered as maximization of its input voltage. Converting the maximization problem into a minimization problem yields,

$$f_{2,i}(x_i) = -V_i \quad (5)$$

In turn, minimization of this objective supports to increase the overall grid voltage which will be an extra advantage. The final MOO problem of the i^{th} PEL can be represented as follows.

$$\min F_i(x_i) = [f_{1,i}(x_i) \ f_{2,i}(x_i)] \quad (6)$$

subjected to: $\gamma_i^L \leq \gamma_i \leq \gamma_i^U$

where, γ_i contains all the constraints bounded between the lower and upper limits given by γ_i^L and γ_i^U respectively. This constraint vector includes the allowable maximum and minimum values of the decision variables and load demands.

Despite the fact that the input voltage is a function of PEL input admittance, and other power system parameters, it is treated as a variable in this implementation. Reason for this modification is to make the optimization problem decentralized and less complex. Even though input voltage is highly coupled and depends on other parameters which are not available to the local PEL, its value can be always measured locally. Hence, an additional constraint is included when solving the MOO problem to satisfy the equality of the measured input voltage and calculated optimal input voltage.

The MOO algorithm computes the optimal input admittance (y_i^*) and optimal input voltage (V_i^*) of the PEL as,

$$x_i^* = [y_i^* \ V_i^*] = \arg \min_{x_i} F_i(x_i) \quad (7)$$

subjected to: $\gamma_i^L \leq \gamma_i \leq \gamma_i^U$

Then the optimal control algorithm discussed in section V and VI utilizes the optimal input admittance and measure the corresponding input voltage in the steady state. This measured value must be the same as the optimal value computed from the MOO algorithm. This process continues until it finds a local optimal solution which satisfies both objectives and all the constraints. Solution to the defined MOO problem will be discussed in the next section.

IV. SOLUTION TO THE MULTIOBJECTIVE OPTIMIZATION PROBLEM

Optimization problem is a mathematical model with the main objective of maximizing desirable attributes or minimizing undesirable attributes [17]. One way of categorizing optimization methods is single objective optimization (SOO) and multi objective optimization (MOO). In SOO, solution is found considering a single objective function while in MOO, two or more objective functions are utilized to solve the problem [18]. Most of the realistic optimization problems have multi objective nature [19]. The best way to solve a MOO problem is obtaining the corresponding Pareto optimal front by simultaneous minimization of the objectives and then extracting a compromise solution [18]. Weighted sum approach [20], global criterion method [21], complex method [22] and goal attainment [23] are classical methods of MOO. Intelligent methods like simulated annealing [24], fuzzy logic approach [25] and genetic algorithms [26] are also used in MOO. In this paper, goal attainment is used to solve the multi objective problem.

Goal attainment method can be used in nonlinear programming problems. This method has a set of design goals $F_i^* = \{F_1^*, F_2^*, \dots, F_n^*\}$ associated with a set of objectives $F(x) = \{F_1(x), F_2(x), \dots, F_n(x)\}$. The solution is obtained by formulating the optimization problem such that the objective vector to be relatively imprecise about the design goal vector. The weighting coefficient vector $w = \{w_1, w_2, \dots, w_n\}$ is introduced to control the relative degree of over or underachievement of goals. This can be expressed as a standard optimization problem [23].

Minimize γ ; subject to,

$$F_i(x) - w_i\gamma \leq F_i^* ; i = 1, 2, \dots, n \quad (8)$$

The slackness term $w_i\gamma$ is introduced which otherwise goals to be rigidly met. In MATLAB fgoalattain multi objective solver is used to solve (7) in this paper.

V. DYNAMIC MODELING OF PELS IN ADMITTANCE DOMAIN

Dynamic modeling of the PELs in admittance and energy domain is discussed in this section. Derivation is given for the PEL based on the boost PEC. However, same procedure can be extended to any other DC-DC PEC. Consider the average mode boost PEC dynamic model given by,

$$L_i \frac{di_{in}}{dt} = V_i - D_i V_o \quad (9)$$

$$C_i \frac{dV_i}{dt} = D_i i_{in} - V_o Y_i \quad (10)$$

where L_i and C_i represent the inductance of the inductor and capacitance of the capacitor of the boost converter respectively. Define two new states, capacitor energy storage ($w_i = \frac{1}{2} C_i V_o^2$) and input admittance ($y_i = \frac{i_{in}}{V_i}$). In the context of these two states, the dynamic model can be reformulated as [12],

$$\frac{dw_i}{dt} = V_i^2 y_i - \frac{2}{R_i C_i} w_i \quad (11)$$

$$\frac{dy_i}{dt} = u_i \quad (12)$$

Here the control input u_i is given by,

$$u_i = \frac{1}{L_i} \left[1 - \frac{D_i}{V_i} \sqrt{\frac{2w_i}{C_i}} \right] \quad (13)$$

Once the optimal control input u_i^* is obtained, the optimal duty cycle can be extracted as,

$$D_i^* = (1 - L_i u_i^*) V_i^* \sqrt{\frac{C_i}{2w_i^*}} \quad (14)$$

In order to convert the control problem to an optimal control problem, error system dynamic model is obtained by defining the new state $\xi_i = [w_i - w_i^* \quad y_i - y_i^*]^T$. Here the optimal capacitor energy storage is derived from the desired EL voltage which is the output voltage of the converter. A boost PEC with the desired output voltage of v_d is considered in this paper and hence the optimal capacitor energy storage can be derived as,

$$w_i^* = \frac{1}{2} C_i v_d^2 \quad (15)$$

Under this state transformation, the obtained state space model of the PEL can be shown as,

$$\frac{d\xi_i}{dt} = \alpha_i \xi_i + \beta_i u_i \quad (16)$$

where, the system matrix and the control effectiveness matrix are given by,

$$\alpha_i = \begin{bmatrix} -\frac{2}{R_i C_i} & V_i^2 \\ 0 & 0 \end{bmatrix} \quad (17)$$

$$\beta_i = [0 \quad 1]^T \quad (18)$$

Since the system matrix contains the input PEL voltage, this dynamic is not linear. However, compared to the input admittance and capacitor energy storage state dynamics, input voltage variation is relatively slow. Hence, in the modeling input voltage is measured and assumed constant for a small time interval δt . This time interval is in the range of milliseconds and it's a reasonable assumption. In this period, the system matrix is constant, and dynamics can be treated as linear. The optimal control law is derived for this short δt period. After that, the input voltage is measured again, and the optimal control problem is solved for the next δt period with the updated input voltage. Optimal control problem and the solution is discussed in the next section.

VI. OPTIMAL MANEUVER OF PELS

Once the optimal states are computed as explained in the sections III and IV, the goal will be to drive the system states to those desired values. Finding out the best possible control sequence which can maneuver the system from a given initial state to the optimal values will be the focus of this section. The best control sequence for a given dynamic objective function is defined by the optimal control law. Since the simplified dynamics given by (16) in the linear form for a short δt period,

linear quadratic regulator (LQR) is employed to obtain the optimal dynamic behavior.

In the LQR control architecture, the optimal feedback control signal is obtained as,

$$u_i^* = -K_i \xi_i^* \quad (19)$$

which minimizes the performance index from the initial time t_0 to $t_0 + \delta t$,

$$J_i = \int_{t_0}^{t_0+\delta t} \xi_i^T Q_i \xi_i + u_i^T \rho_i u_i \, dt \quad (20)$$

Here, Q_i and ρ_i are positive definite diagonal gain matrices. In this paper, considered dynamical system is a single input system, ρ_i is a scalar constant. The optimal feedback gain matrix is given by K_i . The optimal cost of the performance index is a quadratic function of the optimal state as,

$$J_i^* = \xi_i^{*T} \psi_i \xi_i^* \quad (21)$$

where, ψ_i is the solution of the Lyapunov equation given by

$$(\alpha_i - \beta_i K_i)^T \psi_i + \psi_i (\alpha_i - \beta_i K_i) + Q_i + K^T \rho_i K_i = 0 \quad (22)$$

The solution of the LQR problem is associated with the algebraic Riccati equation (ARE) shown below.

$$\alpha_i^T \psi_i + \psi_i \alpha_i + Q_i - \psi_i \beta_i \rho_i^{-1} \beta_i^T \psi_i = 0 \quad (23)$$

The optimal feedback gain matrix is updated with the solution of the ARE as,

$$K_i = \rho_i^{-1} \beta_i^T \psi_i \quad (24)$$

There exist multiple ways of solving the ARE and this paper utilizes the Matlab LQR.

VII. SIMULATION RESULTS

Simulations were carried out considering the IEEE 9 bus test system [27]. A PEL was connected at bus 5 and two resistive loads with $20 \, \Omega$ were considered at buses 6 and 8. Nominal DC grid voltage was set to 120 V and the desired end load voltage (v_d) was considered as 230 V. The demand, inductance, capacitance and load resistance of the PEL were considered as 1 kW, 1 mH, 500 μF and 10 Ω respectively. In the goal attainment, equal unity weights were chosen for both the objectives with 0 and -120 goal values for objective 1 and 2 respectively. The lower and upper bounds for the input admittance were set to 0 S and 10 S while the corresponding values for the input voltage were 110 V and 130 V. First simulation started with no load initial conditions with zero input current and hence the input admittance is zero. Second simulation demonstrates a load change from 1 kW to 3 kW. The LQR controller parameters were considered as $\delta t = 1 \, \text{ms}$, $Q_i = 2 \times 2$ identity matrix, $\rho_i = 1$. Matlab LQR function has been used here to obtain the optimal feedback gains.

A. No Load Initial Transient

With the load demand of 1kW and under the constraints, the optimal input admittance and the input voltages of the PEL were found as 0.0720 S and 117.7654 V. The dynamic response of the LQR controller is shown in Fig. 2 to Fig.5.

Fig. 2 shows that the optimal states of input admittance and capacitor energy storage have reached the steady values of 0.07 S and 13.8 J respectively after 0.1 s. Starting values for both states were zero. According to Fig. 3, input voltage has reached 117.75 V within 0.1 s while the power of the PEL has reached the expected 1 kW value within the same time duration. Fig. 4 shows that the optimal control input has gone to zero after 0.1 s duration and the corresponding optimal duty ratio has reached 0.51 within the same time duration. Starting value for optimal control input was 2.5 and for duty ratio, it was 0.75. Then the optimal gains have reached 0.0399 and 33.3 as shown in Fig. 5. Time taken to reach the steady value is 0.1 s. Initial values for gains were 0.0409 and 34.2.

B. Load Change Scenario

In this simulation, the load demand was changed from 1 kW to 3 kW and corresponding optimal solution and variations in the states are shown below. The step load change was initiated after 300 ms from the startup. After the load change, the optimal input admittance and the input voltage of the PEL was found as 0.2283 S and 114.5890 V respectively. Due to the demand increase, the input admittance is increased to allow more current into the PEL. On the other hand, the terminal voltage drops to a lower value as a consequence of the load increment. The optimal dynamic response of the states, input voltage, power, control input and duty cycle are shown in Fig. 6 to Fig. 8.

Fig. 2 Variation of the optimal states, (a) input admittance, (b) capacitor energy storage.

Fig. 3 Variation of the input voltage and power of the PEL, (a) input voltage, (b) input power.

Fig. 4 variation of the optimal control input and the duty cycle, (a) optimal control input (u), (b) optimal duty cycle.

Fig. 5 Variation of the optimal feedback gains, (a) K_1 , (b) K_2 .

When considering Fig. 6, during the initial load demand of 1 kW, input admittance has reached 0.075 S and capacitor energy has reached 13 J. After changing the load demand to 3 kW, admittance has risen to 0.225 S within 0.1 s while the capacitor energy storage has shown a dip of 7 J minimum value for 0.1s and again reached the steady value of 13 J.

According to Fig. 7, input voltage has reached 117.8 V steady value from the starting value of 119 V within 0.1 s for 1 kW load demand. After increasing the load demand to 3 kW, input voltage has further reduced to 114.6 V steady value within 0.1 s. Furthermore, the power of PEL has reached 1 kW and 3 kW steady values according to the load demand changes.

Fig. 8 demonstrates that the optimal control input has reached zero value from the starting value of 3 within 0.1 s. After changing the load demand to 3 kW, the optimal control input has increased to 5 as a large control effort is required to get the voltage and power back to the desired values. After 0.1 s, again the optimal control input has reached zero steady value. The corresponding optimal duty ratio has started from 1 at 1 kW load starting transient and reached the steady value of 0.51 within 0.1

s. Then, at the moment of changing the load demand, there is a sudden increment up to 0.61 and after 0.1 s it has reached back the steady value of 0.4.

Fig. 6 Variation of the optimal states subjected to a load change, (a) input admittance, (b) capacitor energy storage.

Fig. 7 Variation of the input voltage and power of the PEL subjected to a load change, (a) input voltage, (b) input power.

Fig. 8 variation of the optimal control input and the duty cycle subjected to a load change, (a) optimal control input (u), (b) optimal duty cycle.

VIII. CONCLUSION

This paper has presented a multi objective optimal control methodology to obtain the optimal control input and states of power electronic loads in small scale power systems. PEL in SSPS was modelled using the adaptive admittance representation of power electronic loads. Active power input regulation from the grid and maximization of input voltage of the PEL were considered as the multi objectives . Then, goal attainment method has been used to solve the MOO problem to obtain the optimal input admittance for each PEL. With the introduction of two new states, capacitor storage and input admittance, dynamic model of the PEL was obtained to develop an optimal controller to drive the system to the calculated optimal desired input admittance. Subsequently, LQR method was utilized to solve the developed optimal control problem. Simulations of the system were carried out considering the IEEE 9 bus test system and two scenarios were used to demonstrate the effectiveness of the proposed concept. According to the results it can be seen that the proposed methodology is capable of regulating the PEL demand while maximizing its input bus voltage. Experimental verification of the proposed concept would be the major future direction of this work.

Abstract—Modeling the interaction of a mobile robot's wheels with the ground, is a key element in evaluating its performance. In this paper, to evaluate vehicle performance in a simulation environment, research studies were conducted to capture the physics in a mathematical framework. Vehicle performance can be directly correlated to forces and moments between the tire and the ground, and indirectly related to terrain variations such as sinking. The main objective of this paper is to propose a mathematical model describing the dynamic behavior of the robot wheel navigating a deformable soil. This model is validated using experimental data obtained from a test bench of a lunar wheel.

Keywords—mobile robot, the performance of the vehicle, tire, soil, ground.

I. INTRODUCTION

The modeling and control of the robot depends on the type of mission it must accomplish and the environment it must face [1–4]. Therefore, it is essential to know as much as possible what happens at the wheel-ground interaction in order to characterize and exploit useful information. The study of this interaction has been the subject of much research, with the objective of determining patterns and factors affecting the behavior of vehicles intended to travel over any terrain [5]. Tires are perhaps the most important component, but the most difficult to model. Not only do tires support the vehicle and dampen road irregularities, but they also provide the longitudinal and lateral forces necessary to change the speed and direction of the vehicle. These forces are produced by the deformation of the tire where it comes into contact with the road during acceleration, braking and navigation. In the literature we distinguish the Rigid Ground modeling, which presents the studies that include the effects of wheeled vehicles on undeformable ground. The main constraint is the study of the behavior of the vehicle on the road and the characterization of the wheel-ground interaction.

Over the years, a wide variety of models have been developed to formulate and simulate the wheel-soil interaction. The degree of complexity of these models is based on the application, accuracy and computational cost of development as elaborated in the Pacejka Model [6], the Bross

Model [7], the Gim Model [8], the Dugoff Model [9], the Kiench/Buchhardt Model [10] and the Linear Model [11]. The theory of deformable soil or Terra-mechanics which is defined as the science of studying the properties of the soil when interacting with both tracked and wheeled vehicles. As mentioned earlier, the main challenge in studying off-road vehicle behavior is the characterization of the wheel-ground interaction. This interaction is shown in literature as elaborated in the WES VCI model [12], the WES numerical mobility model [13], the Deere & Company Technical Center Models [14], the STIREMOD model [15], the VTIM Model (Vehicle Terrain Interaction Model) [16], the discrete element method (DEM) [17], the NWVPM model [18], the VDANL model [19], the SCM model [20] and the FTire model (Flexible Ring Tire Model) [16].

The main objective of this paper is to propose a mathematical model describing the dynamic behavior of the robot wheels navigating a deformable ground. This model is experimentally validated and gives good results. In this perspective, we will present in the second paragraph the dynamic analysis using the classical Bekker model which we will discuss the modeling hypothesis and the classical model which include the semi empirical equations. the third part. is dedicated give the explicit form of the laws of Bekker and the validation. At the end of this paper, we will summarize the results that we have reached, in order to reuse it in the next papers.

II. DYNAMIC ANALYSIS USING THE CLASSICAL BEKKER MODEL

A. Modeling hypothesis

To simplify the model, simplifying assumptions are adopted:

- The wheel is rigid and assimilated to a perfect smooth cylinder.
- The point contact is located on the plane of the trajectory.
- The ground is plastically deformed.
- The indentation is assumed to be negligible with respect to the wheel radius.

- The point contact is located on the plane of the trajectory.
- The wheels remain in contact with the road.
- The variation of the radius of the rolling wheel is neglected.
- In practice, the roll and pitch angles, as well as the tire angles are small, so we assume small angles.

B. Fundamental Basics

In this paragraph, we present some fundamental notions for the modeling of the wheel-ground contact using the classical Bekker model. These concepts are discussed as follows:

Figure 1. The geometric model adopted for the wheel-ground contact

- In the case where the robot moves on a trajectory :
The wheel can only produce thrust if $\dot{\phi}_i = \frac{V_x}{R}$
This phenomenon is called wheel slip rate, symbolized by s such that :

$$s = \begin{cases} \frac{R\dot{\phi}_i - V_x}{R\dot{\phi}_i} & \text{During acceleration} \\ \frac{R\dot{\phi}_i - V_x}{V_x} & \text{During braking} \end{cases} \quad (1)$$

- As in a curve, the vehicle has a lateral velocity can drive in relation to an angle called the slip angle defined by the expression above:

$$\beta = \text{atan} \left(\frac{V_y}{V_x} \right) \quad (2)$$

- The wheel motion causes the development of normal and shear stresses along the wheel-ground interface between θ_f and θ_r . That's why Bekker came to characterize the soil types, and to measure the properties of the soil using the bevametre technique. The latter allows for penetration tests (normal displacement stress) and shear tests (displacement shear stress).
- Using experimental tests and the bevameter technique, the researchers have developed functions to describe the stress distribution along the wheel-ground interface.

Figure 2. Geometric modeling of wheel-ground contact stresses in motion

Wong and Reece in [21], developed a form of the normal pressure at the wheel-soil interface using the results of plate penetration tests:

$$\sigma(\varphi_i) = \left(\frac{k_c}{w} + k_\phi \right) z^n(\varphi_i) \quad (3)$$

In which;

$$z(\varphi_i) = \begin{cases} R(\cos(\varphi_i) - \cos(\theta_f)) & \text{if } \theta_m < \varphi_i < \theta_f \\ R(\cos(\theta_e) - \cos(\theta_f)) & \text{if } \theta_r < \varphi_i < \theta_m \end{cases}$$

$$\theta_e = \theta_f - (\varphi_i - \theta_r)(\theta_f - \theta_m)/(\theta_m - \theta_r)$$

While;

- φ_i is the rotation angle of the wheel
- w the width of the wheel
- k_c, k_ϕ and n are respectively the modulus of cohesion, the modulus of friction and the exponent of sinking (bevametre)
- $z(\varphi_i)$ is the sinking of the soil along the wheel-soil interface

θ_f is the entry angle at which the wheel begins to touch the ground

θ_r is the exit angle at which the wheel loses contact with the ground, which is defined by :

$$\theta_r = (b_0 + b_1 s)\theta_f$$

θ_m is the maximum stress angle, which is defined as:

$$\theta_m = (a_0 + a_1 s)\theta_f$$

In which;

a_0, a_1, b_0 and b_1 Are soil constants.

The lateral shear rate is defined by :

$$V_{JL}(\varphi_i) = V_y \quad (4)$$

The tangential shear rate is defined by :

$$V_{Jt}(\theta) = R\dot{\varphi}_i - V_x \cos(\varphi_i) \quad (5)$$

The compression speed is defined by :

$$V_{Jn}(\varphi_i) = V_x \sin(\varphi_i) \quad (6)$$

The shear deformation of the soil can be defined as :

$$j_k(\varphi_i) = \int_{\theta}^{\theta_f} V_{Jk}(\varphi_i) \frac{1}{\dot{\varphi}_i} d\varphi_i \quad \text{in} \quad (7)$$

which ; $k=t,L$

Hence;

$$j_t(\varphi_i) = R(\theta_f - \varphi_i) - (1 - s)(\sin(\theta_f) - \sin(\varphi_i)) \quad (8)$$

And;

$$j_L(\varphi_i) = R(1 - s)(\theta_f - \varphi_i) \tan(\beta) \quad (9)$$

In the case of a plastic soil, Janosi, Hanamoto and Bekker developed an experimental behavior law that determines the shear stress:

$$\tau_k(\varphi_i) = \tau_{max} \tau_{base1} \quad k=t,L \quad (10)$$

In which;

$$\tau_{max} = C + \sigma(\varphi_i) \tan(\phi)$$

$$\tau_{base1} = 1 - \exp\left(-\frac{j_k}{K}\right) \quad k=t,L$$

While;

C : Soil cohesion

ϕ : Soil internal friction angle

K : Shear strain parameter (measures the amount of shear displacement required for the development of maximum shear stress). These values are given in the following table:

Table 1 The values of the shear modulus K(cm)

Soil type	K (cm)
Sandy loam	2.5 - 2.54
Snow	4
Clay	0.6 - 2.54
Sand	1 - 2.5

By linearizing, L_f et L_r are small in front of R. we obtain

The normal constraint is shown as follows:

$$\sigma(\varphi_i) = \begin{cases} \sigma_m \frac{\theta_f - \varphi_i}{\theta_f - \theta_m} & \text{if } \theta_m < \varphi_i < \theta_f \\ \sigma_m \frac{\varphi_i - \theta_r}{\theta_m - \theta_r} & \text{if } \theta_r < \varphi_i < \theta_m \end{cases} \quad (11)$$

While;

$$\sigma_m = \left(\frac{k_c}{b} + k_\phi\right) R^n (\cos(\theta_m) - \cos(\theta_f))^n$$

And the shear stress is :

$$\tau_k(\varphi_i) = \begin{cases} \tau_{m,k} \frac{\theta_f - \varphi_i}{\theta_f - \theta_m} & \text{if } \theta_m < \varphi_i < \theta_f \\ \tau_{m,k} \frac{\varphi_i - \theta_r}{\theta_m - \theta_r} & \text{if } \theta_r < \varphi_i < \theta_m \end{cases} \quad (12)$$

$k=L,t$

While;

$$\tau_{m,k} = (C + \sigma_m \tan(\phi))(1 - \exp\left(-\frac{j_k(\theta_m)}{K}\right)) \quad k=L,t$$

The reaction between the tire and the roadway is described by three forces and three moments, as modeled by the diagram defined below:

Figure 3 Modeling of wheel-ground contact forces

Net pulling force

(Drawbar pull) F_x : This force corresponds to the push force generating the wheel motion, which is equal to the difference between the drawbar pull and the resultant of the wheel resistances. Using the normal force $\sigma(\varphi_i)$ and the shear force $\tau_t(\varphi_i)$, the net tensile force (drawbar pull) acting in the direction from the ground to the wheel is calculated by integrating the input angle θ_f to the output angle θ_r , and is given by

$$F_x = R w \int_{\theta_r}^{\theta_f} (-\sigma(\varphi_i) \sin(\varphi_i) + \tau_t(\varphi_i) \cos(\varphi_i)) d\varphi_i \quad (13)$$

The lateral force

F_y : The authors modeled the force that acts along the lateral direction of the wheel when the vehicle makes a steering maneuver; as follows:

$$F_y = F_{sy} + F_{by} \quad (14)$$

While;

- F_{sy} is the force produced by $\tau_L(\varphi_i)$ under the wheel, is defined by :

$$F_{sy} = R w \int_{\theta_r}^{\theta_f} \tau_L(\varphi_i) d\varphi_i \quad (15)$$

- F_{by} Is the bulldozing resistance that is developed when a considerable mass of soil is moved by the wheel. This type of resistance is common when the wheel compresses the surface layers of the soil and pushes the compressed soil in front of and behind the tire. The phenomenon of bulldozing has appeared in the case of a

wide wheel (approx. 34 cm wheel width), crossing very loose soils. This phenomenon is estimated to cause a significant increase in the overall resistance to movement for values of depression greater than 6% of the wheel diameter. This force is defined as follows:

$$F_{by} = \int_{\theta_r}^{\theta_f} dF_b(\varphi_i) d\varphi_i \quad (16)$$

The vertical force

F_z : is obtained by the same method as for the longitudinal force F_x . The necessary condition for this force is that it must be equal to the normal load on the wheel. It is given by the following equation:

$$F_z = R w \int_{\theta_r}^{\theta_f} (\sigma(\varphi_i) \cos(\varphi_i) + \tau_t(\varphi_i) \sin(\varphi_i)) d\varphi_i \quad (17)$$

The moment of overturning

M_x : is present when the reaction of the ground on the tire F_{zr} (oriented upwards) is not aligned with the vertical load F_z (oriented downwards), It is given by the following equation:

$$M_x = -R^2 w \int_{\theta_r}^{\theta_f} \tau_L(\varphi_i) \cos(\varphi_i) d\varphi_i \quad (18)$$

Le moment de résistance au roulement

M_y : is the resistance to the forward motion of a free rolling tire with almost zero longitudinal slip. The rolling resistance is present as soon as the tires start to roll forward. This moment is defined as:

$$M_y = R^2 w \int_{\theta_r}^{\theta_f} \tau_t(\varphi_i) d\varphi_i \quad (19)$$

The moment of self-alignment

M_z : tends to rotate the tire about its z axis and align the x axis with the direction of the wheel speed vector. This moment always tends to reduce the drift angle α . It is due to the displacement of the lateral force behind the center of the contact area, It is given by the following equation:

$$M_z = -R^2 w \int_{\theta_r}^{\theta_f} \tau_L(\varphi_i) \sin(\varphi_i) d\varphi_i \quad (20)$$

III. ELABRATION OF THE EXTENDED BEKKER MODEL

A. Simplification of forces

Taking the condition L_f et L_r are \ll in front of R. And by linearizing .we find the following equations :

$$F_z = R w \tau_{m,L} \left(\frac{\cos(\theta_m) - \cos(\theta_r)}{\theta_m - \theta_r} + \frac{\cos(\theta_m) - \cos(\theta_f)}{\theta_f - \theta_m} \right) - R w \sigma_m \left(\frac{\sin(\theta_m) - \sin(\theta_r)}{\theta_m - \theta_r} + \frac{\sin(\theta_m) - \sin(\theta_f)}{\theta_f - \theta_m} \right) \quad (21)$$

$$F_y = R w \tau_{m,L} \frac{\theta_f - \theta_r}{2} + 2k_p c \left(\frac{\theta_f - \theta_r}{2} + \frac{\sin(2\theta_f) - \sin(2\theta_r)}{4} + \sin(\theta_r) - \sin(\theta_f) \right) + \frac{1}{2} \rho g k_p R^3 \left(\theta_f - \theta_r + \frac{\sin(2\theta_f) - \sin(2\theta_r)}{2} + \frac{\sin(3\theta_f) - \sin(3\theta_r)}{12} + \frac{7}{4} (\sin(\theta_f) - \sin(\theta_r)) \right) \quad (22)$$

$$F_z = R w \sigma_m \left(\frac{\cos(\theta_m) - \cos(\theta_r)}{\theta_m - \theta_r} + \frac{\cos(\theta_m) - \cos(\theta_f)}{\theta_f - \theta_m} \right) + R w \tau_{m,L} \left(\frac{\sin(\theta_m) - \sin(\theta_r)}{\theta_m - \theta_r} + \frac{\sin(\theta_m) - \sin(\theta_f)}{\theta_f - \theta_m} \right) \quad (23)$$

$$M_x = -R^2 w \tau_{m,L} \left(\frac{\cos(\theta_m) - \cos(\theta_r)}{\theta_m - \theta_r} + \frac{\cos(\theta_m) - \cos(\theta_f)}{\theta_f - \theta_m} \right) \quad (24)$$

$$M_y = R^2 w \tau_{m,L} \frac{\theta_f - \theta_r}{2} \quad (25)$$

$$M_z = -R^2 w \tau_{m,L} \left(\frac{\sin(\theta_m) - \sin(\theta_r)}{\theta_m - \theta_r} + \frac{\sin(\theta_m) - \sin(\theta_f)}{\theta_f - \theta_m} \right) \quad (26)$$

To simplify the model, we take: $\theta_r = -\theta_f$ and $\theta_m = 0$

Hence, we find;

$$F_z = 2R w \sigma_m \left(\frac{1 - \cos(\theta_f)}{\theta_f} \right) \approx R w \sigma_m \theta_f \quad (27)$$

While;

$$\sigma_m = \left(\frac{k_c}{w} + k_\phi \right) R^n (1 - \cos(\theta_f))^n \approx \left(\frac{k_c}{w} + k_\phi \right) R^n \left(\frac{\theta_f^2}{2} \right)^n \quad (28)$$

It is the expression of a non-linear spring because it is of the form $F_z = K_0 z^n$

While ;

$$z = R^{(1+\frac{1}{n})} \theta_f^{(2+\frac{1}{n})} \quad \text{Et} \quad K_0 = w \left(\frac{k_c}{w} + k_\phi \right)$$

This model is not valid in the transient regime.

To approach the real model Crahn [22] has developed a model that takes into account the sinking speed of particles in a granular soil after several penetration measurements.

Then, we obtain:

$$\sigma(\varphi_i) = \left(\frac{k_c}{w} + k_\phi \right) z^n(\varphi_i) K_q \dot{z}^q(\varphi_i) \quad (29)$$

Therefore, we added the term $\dot{z}^q(\varphi_i)$ a Where q is a new parameter characterizing the soil, which is called the soil penetration speed exponent. K_q is a positive coefficient, whose values are given in Table as follows:

Table 2 Soil penetration speed exponent

Soil type	q	K _q
compact Soil	0.30	2.86
Soft sand	0.30	2.86
Sandy loam	0.12	1

The problem occurs when $\dot{z} = 0$

Hence;

$$\sigma(\varphi_i) = \left(\frac{k_c}{w} + k_\phi\right) z^n(\varphi_i)(1 + K_q \dot{z}^q(\varphi_i)) \quad (30)$$

With this model, when the wheel is rotating, without normal component of the hub speed. We have:

$$\dot{z}(\varphi_i) = R\dot{\varphi}_i \sin(\varphi_i) \approx R\dot{\varphi}_i \varphi_i \quad (31)$$

Hence;

$$\sigma(\varphi_i) = \left(\frac{k_c}{w} + k_\phi\right) z^n(\varphi_i)(1 + K_q (R\dot{\varphi}_i \varphi_i)^q) \quad (32)$$

$$\sigma_m = \left(\frac{k_c}{w} + k_\phi\right) R^n \left(\frac{\theta_f^2}{2}\right)^n (1 + K_q (R\dot{\varphi}_i \theta_f)^q) \quad (33)$$

- the normal force is given in the following expression:

$$F_z \approx R w \theta_f \left(\frac{k_c}{w} + k_\phi\right) R^n \left(\frac{\theta_f^2}{2}\right)^n (1 + K_q (R\dot{\varphi}_i \theta_f)^q) \quad (34)$$

- The lateral force is given by:

$$F_y \approx R w \tau_{m,t} \theta_f \quad (35)$$

While;

$$\tau_{m,t} = (C + \left(\frac{k_c}{w} + k_\phi\right) R^n \left(\frac{\theta_f^2}{2}\right)^n (1 + K_q (R\dot{\varphi}_i \theta_f)^q) \tan(\phi)) \left(1 - \exp\left(-\frac{R(1-s)\theta_f \tan(\beta)}{K}\right)\right)$$

- The net traction is given in :

$$F_x = 2R w \tau_{m,t} \left(\frac{1 - \cos(\theta_f)}{\theta_f}\right) \approx R w \tau_{m,t} \theta_f \quad (36)$$

While;

$$\tau_{m,t} = (C + \left(\frac{k_c}{w} + k_\phi\right) R^n \left(\frac{\theta_f^2}{2}\right)^n (1 + K_q (R\dot{\varphi}_i \theta_f)^q) \tan(\phi)) \left(1 - \exp\left(-\frac{R \theta_f s}{K}\right)\right)$$

- The overturning moment is given in:

$$M_x = -2R^2 w \tau_{m,t} \left(\frac{1 - \cos(\theta_f)}{\theta_f}\right) \approx -R^2 w \tau_{m,t} \theta_f \quad (37)$$

While;

$$\tau_{m,t} = (C + \left(\frac{k_c}{w} + k_\phi\right) R^n \left(\frac{\theta_f^2}{2}\right)^n (1 + K_q (R\dot{\varphi}_i \theta_f)^q) \tan(\phi)) \left(1 - \exp\left(-\frac{R(1-s)\theta_f \tan(\beta)}{K}\right)\right)$$

- The rolling resistance moment is given by:

$$M_y \approx R^2 w \tau_{m,t} \theta_f \quad (38)$$

In which:

$$\tau_{m,t} = (C + \left(\frac{k_c}{w} + k_\phi\right) R^n \left(\frac{\theta_f^2}{2}\right)^n (1 + K_q (R\dot{\varphi}_i \theta_f)^q) \tan(\phi)) \left(1 - \exp\left(-\frac{R \theta_f s}{K}\right)\right)$$

- The self-aligning moment is given by :

$$M_z \approx 0 \quad (39)$$

B. Model validation

The use of this model respects the algorithm as discussed below:

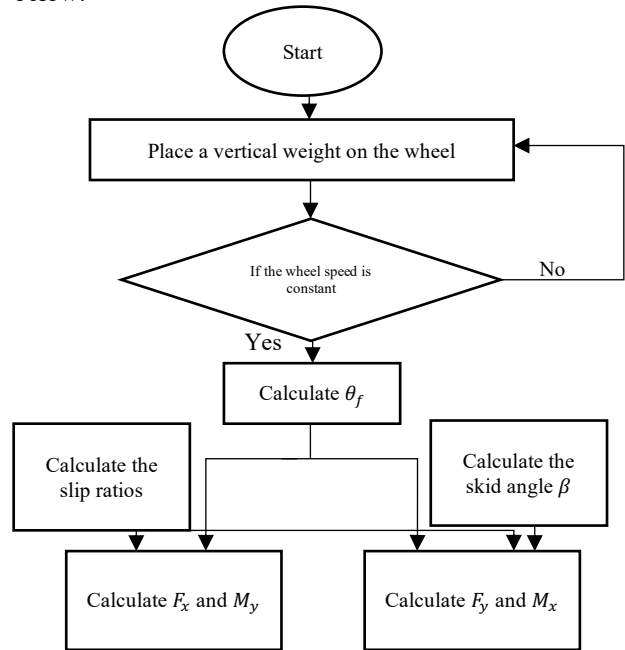

Figure 4. Algorithm for calculating forces and moments according to the extended Bekker's law

The numerical simulation procedure to obtain the forces and moments, introducing the normal load W of the wheel, the slip ratio s and the slip angle β. This Load allows us to calculate the input angle at which the wheel begins to touch the ground θ_f from the equilibrium relationship between W and F_z (equation (27)), to finally determine the traction force F_x and the lateral force F_y using equations (35) and (36).

To validate the wheel-ground contact model, we use the experimental data previously performed by Yoshida and Ishigami in [23]. This experiment was carried out on a single wheel test rig (wheel of a lunar vehicle) (Figure 5). The characteristic parameters of the model are defined in the table below:

Table 3 Parameters of the wheel of the lunar vehicle used as well as the parameters of the ground used during the experiment

Parameters	Value
C (KPa)	0.8
ϕ (deg)	37.2
k _c (N/m ⁿ⁺¹)	1.37 × 10 ³
k _ϕ (N/m ⁿ⁺²)	81.4 × 10 ⁴
N	1
K (m)	0.1
R (m)	0.09
w (m)	0.1
K _q	0
β (deg)	25

Figure 5 The Yoshida and Ishigami test rig [23]

The average variation of longitudinal and lateral force as a function of slip variation obtained experimentally after collecting about 100 force measurements at a given slip rate, are represented in concert with our model results as discussed in the following figures:

Figure 6. The traction force as a function of the slip

Figure 7. Lateral force as a function of slip

The Figure 6 shows that the tractive force increases with the slip ratio. This behavior is explained by the fact that the soil deformation (shear stress) in the longitudinal direction of the wheel increases with the slip ratio; this results in a large soil deformation which, in turn, generates a large tensile force on the drawbar. Also, the differences between the experimental and theoretical values are relatively small in the range of slip ratios above 0.4; however, relatively larger differences are observed for smaller slip ratios.

The Figure 7 shows that the lateral force decreases with the slip rate. In addition, it is observed that the lateral force whose maximum value is $s = 0$; this is due to the fact that the lateral velocity, proportionally to the longitudinal velocity. The theoretical curves show a relatively small difference, so we can deduce that the theory agrees well with the experimental results plotted.

These results confirm that the wheel-ground contact model proposed in this section is capable of representing the wheel motion behavior and contact/traction forces with appropriate accuracy.

IV. CONCLUSION

The main objective of the paper is to propose a mathematical model describing the dynamic behavior of the robot wheel navigating a deformable ground. This model is experimentally validated and gives good results.

The adaptation of the ground navigation model of the "Agri-Eco-Robot" robot will be the subject of future work.

ACKNOWLEDGMENT

The authors of this paper are thankful to the Ministry of Higher Education and Scientific Research of Morocco (MESRSFC), and the National Center for Scientific and Technical Research of Morocco (CNRST) for financing this project.

Abstract— The oil industry has become a significant industry that promotes the economy of North America. Finding the optimal inventory strategy and matching transportation methods have become a critical challenge in the oil industry to increase revenue while minimizing overhead costs. This paper focuses on the midstream and downstream sectors in the oil industry. The primary objective of this paper is to use discrete event simulation to find the optimal combination of transportation methods and the optimal inventory policy. Using a conceptual supply chain model and real data collection, experimentally, we can see that the best policy is using pipeline speed 1m/s with reorder point 500L and reorder quantity 35000L. Various pilot and production runs have been implemented.

Keywords— *Oil Transportation, Inventory Policy, Simulation, Conceptual Modeling, Optimization*

I. INTRODUCTION

The oil industry has become a significant industry that promotes the economy of North America. In 2020 Canada's three biggest oil companies (Imperial Oil, Husky Energy, and Suncor Energy) brought in record profits of \$11.75 billion. Most Canadian petroleum production, approximately 283,000 cubic meters per day (1,780,000 bbl/d), is exported, and Canada is the largest single source of oil imports into the United States [1]. The oil industry is divided into three components: Upstream, midstream, and downstream. The upstream is commonly known as the exploration and production sector, which includes searching for potential oil/gas fields, drilling wells, etc. The midstream sector involves transportation and wholesale marketing of refined petroleum products. The downstream involves refining, marketing, and distribution issues and more frequently targets end consumers through products such as gasoline, diesel, heating oil, etc. [2]-[5]. In this paper, we focus on the midstream and downstream sectors in the oil industry. The problem addressed in this paper includes the supply chain management of logistics and inventory. Two transportation schemes are discussed from the logistic perspective, pipeline and truck transportation. Different transportation methods will lead to different costs and time (lead time), affecting management decisions and demand satisfaction. From the inventory perspective, when a certain volume of oil product is ordered and stocked in a specific region to be sold, there will be a holding cost [6]-[9]. The high inventory will lead to high holding costs, and low inventory will risk the stock out. The proper trade-off between over-stocking and low-stocking levels

will reduce the cost and increase the profit. The best combination of transportation schemes and optimal inventory policy contributes to the least cost for corporation operations and improves efficiency in the supply chain sector. The primary objective of this paper is to find the optimal combination of transportation schemes and the optimal inventory policy using Discrete Event Simulation (DES) [10]-[12]. In this paper, the logistics methods (i.e., truck transportation, pipeline transportation), inventory level, reorder point, and transportation time affect the final cost result. We used different parameters for these criteria to find the optimal strategy to achieve a minimum cost. From the simulation results, inventory levels in different locations (distribution centers and local gas stations) will be collected to estimate the inventory cost. The number of times that the truck runs will also be collected to calculate the logistic cost. The best policy is using pipeline speed 1m/s with reorder point 500L and reorder quantity 35000L. The rest of this paper is organized as follows: Section 2 discusses the Canadian oil industry. The DES conceptual model is discussed in section 3. Various data requirements are discussed in section 4. Section 5 presents the proposed simulation model. The pilot and production runs of the model are discussed in sections 6 and 7, respectively. Finally, conclusions and future directions are summarized in Section 8..

II. THE CANADIAN OIL INDUSTRY

To fully present the oil industry's real supply chain model, research on the Canadian Oil industry is conducted from the supply, logistic, and end-user market perspective. Alberta is the largest producer of conventional crude oil, synthetic crude, and natural gas and gas products in the supply sector in Canada. Two of the largest producers of petrochemicals in North America are located in central and north-central Alberta. The total refined product produced in Alberta is about 20414 thousand cubic meters. From the logistics perspective, Pipeline transportation is an important sector of the Canadian economy. Canada is a significant energy producer globally, and pipeline transportation is a practical and economical way of moving large quantities of crude oil and natural gas. Transmission pipelines transport nearly 97% of Canadian natural gas and crude oil production. The network of pipelines in Canada is shown in Fig.1. We can see that the pipeline is applied in long-distance transportation. Hence in our model, from the Alberta to Toronto hub, the major transportation will be the pipeline.

Oil pipelines are made from steel or plastic tubes with an inner diameter of 4 to 48 inches (100 to 1,200 mm). Most pipelines are buried at about 3 to 6 feet (0.91 to 1.8 m). Various methods protect pipes from impact, abrasion, and corrosion, including wood lagging (wood slats), concrete coating, rock shield, high-density polyethylene, imported sand padding, and padding machines. The oil is kept in motion by pump stations along the pipeline and usually flows at about 1 to 6 meters per second (3.3 to 20 ft/s). The different flow rates lead to different volumes of oil products. The estimated unit cost for Oil Pipeline transportation [2] is illustrated in Table 1.

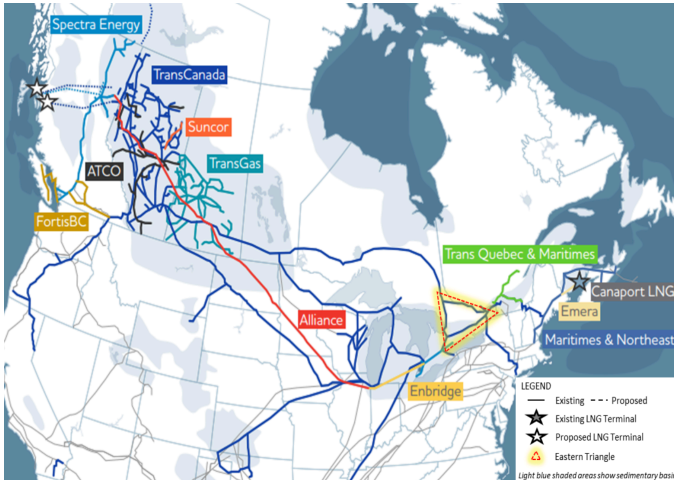

Fig. 1 Canadian Energy Pipeline Association, 2016.

Table 1: Estimated Unit Cost for Oil Pipeline Transportation (\$ per cubic meter-kilometre)

	Low	Base	High
Oil Unit Cost	\$0.011415	\$0.011968	\$0.012521

The oil tank truck will be applied for short-distance transportation due to its relatively low fixed cost and flexibility compared to the pipeline. Large trucks typically have capacities ranging from 20,800 to 43,900 Liters. Smaller tank trucks with less than 11,000 L are generally used to deal with light liquid cargo within a local community. Another common use is to deliver fuel with a capacity of 3,800 Liters. The truck operational cost in Canada from East to West Corridor LNG consists of the following cost components: Tire cost, Repair cost, Licensing Cleaning cost, driver cost, equipment ownership, administration, and interest costs. The collected cost data includes only the driver's wages, such that we can estimate the total truck cost [3].

III. THE CONCEPTUAL MODEL

The simulated supply chain system contains entities such as suppliers, distributors, retailers, and customers. To simplify the model, we assume only one manufacturer, distributor, and retailer in the supply chain. The process in this model can be described as follows: the supplier produces the products. The distributor delivers the products to the retailer when the retailer orders a specific quantity from the manufacturer. Each day,

customers come to the retailer with particular demands. When the inventory decreases to a certain point, the retailer will make the order. Fig.2 illustrates the material flow from left to right and the information flow (order) from right to left in the proposed conceptual model. We propose a conceptual supply chain model from the supplier to the end customer, as shown in Fig.3.

Fig. 2 Material Flow in the Supply Chain Model.

Fig. 3 The Supply Chain Conceptual Model.

We assume the supplier is located in Alberta, an oil production hub in Canada. The oil will be transferred from Alberta to Toronto via pipeline. A fuel tank truck will be used for short-distance transportation from Toronto to Waterloo local gas station. The Toronto distribution center and Waterloo local gas station will have a warehouse to stock a certain amount of gasoline. When the gasoline product's inventory level reduces to a specific threshold, which will be different for different locations, the staff will place an order for the upper level and wait for the order refill.

A. Assumptions

- We proposed one completed supply chain rather than a Multi-Echelon Model.
- We have focused on the perspective of inventory fluctuation rather than the queuing model; hence, we aggregate servers into one server.
- We have estimated the cost based on the data we collected from [2][3].
- We assumed the customer demand is based on the fuel capacity of the cars, and we estimated the average fuel capacity for three major types of vehicles in the market based on the market share statistic report published by the government [5].

IV. DATA REQUIREMENTS

In our model, four primary data sources are needed, including the inter-arrival time of cars entering a single gas station, the distribution of different types of vehicles entering the station, the average service time of each vehicle at the gas station, and the cost of transporting gas from Toronto to Waterloo. A real-data collection process took place at the ESSO gas station at King St. North and Weber St. in Waterloo, Ontario, each day from 11 am-12 pm and 5 pm to 6 pm and collected the inter-arrival time. We categorize vehicles into three types, small cars, SUVs, and Trucks. We received the sales data from the manufacturer's website, i.e., Ford, Chevy, Toyota, and Honda. We also calculated the service time for each car. Finally, we have collected an estimate for the truck transportation price and

pipeline transportation cost [2][3]. We have fit the inter-arrival data (Fig.4) to multiple distributions (Fig.5). We can see that the best fitting distribution of the data is exponential with rate=1/7.3197. A Kolmogorov-Smirnov test is performed to test this hypothesis. Based on the p-value, we did not reject the Null Hypothesis that the data follows the exponential distribution with a mean inter-arrival time of 7.3197 minutes. We have followed the same procedure in checking the distributions of other variables.

V. OIL TRANSPORTATION: A DISCRETE EVENT SIMULATION MODEL

Based on our conceptual model, we use two tanks to represent the main supplier of gas (Alberta) and the distributor (Toronto) (simplified version), as shown in Fig. 6. The simulation is conducted using SIMUL8 [6]. The flow rate between tanks is determined in the VL box. We determined the (s, S) policy inside the VL box to ensure that the flow is allowed when the lower tank level falls below a certain amount.

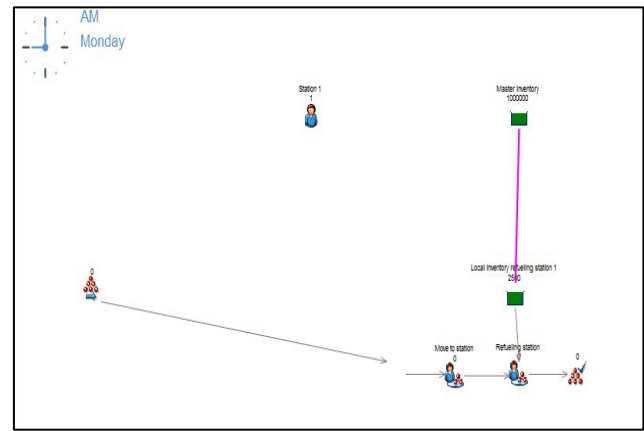

Fig. 6. The DES Model using Simul8

The tank object cannot clearly show the inventory level time by time. However, there should be a gap between the distributor, and the local gas station, which costs a delay since the transportation and the order must take some time. To create a more accurate model, we add an extra activity as a distributor and a new queue as the local station's inventory (Fig.7).

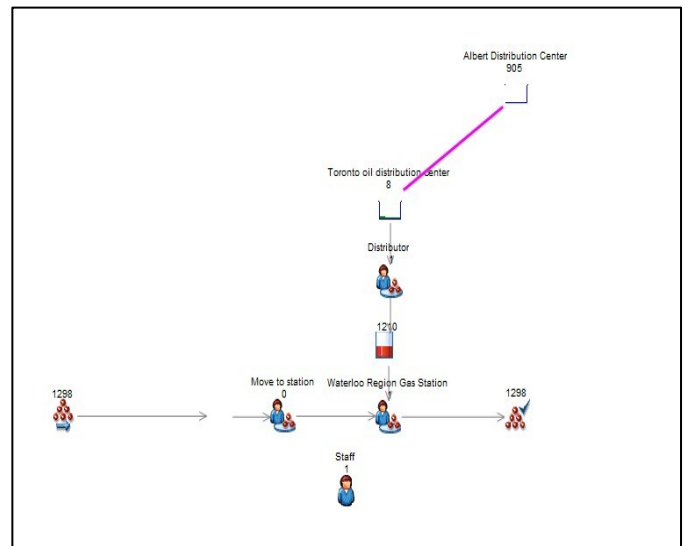

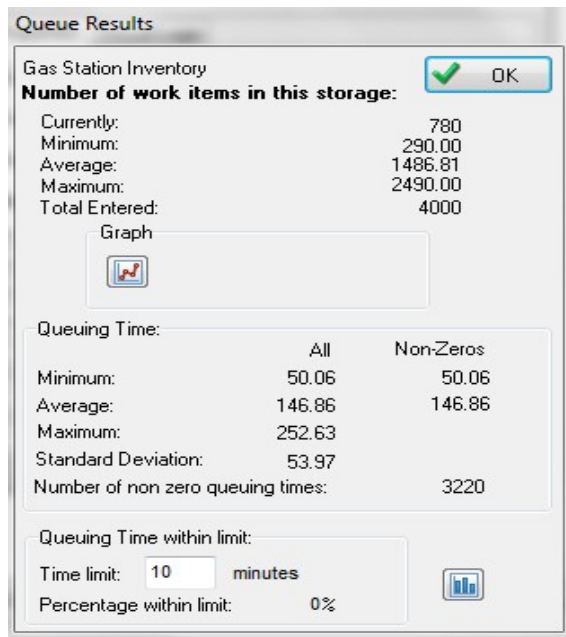

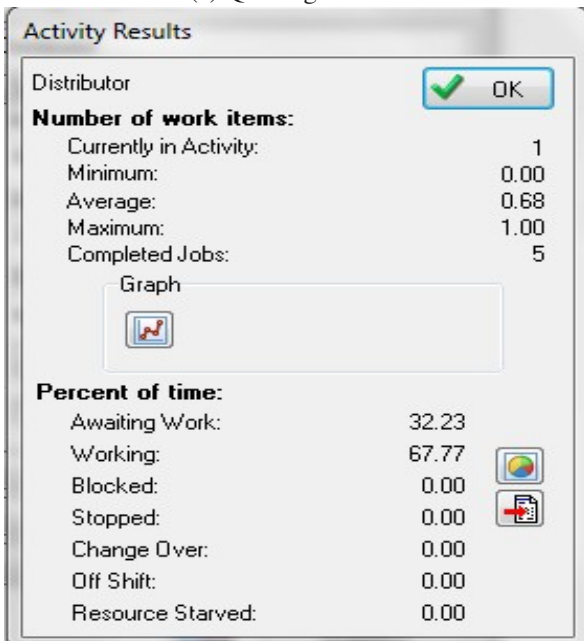

Fig. 7. The DES Model using Simul8 (Modified)

VI. PILOT RUNS

We input the distribution of the inter-arrival time of the car into the start point and the service time of the single machine into the Waterloo Region Gas Station WorkCentre. However, after a short time running, a serious problem happened: an unexpected long queue outside the gas station. We noticed at least eight servers at a single station in real life. Thus, the working rate is much lower in our model. We then refine the distribution based on the average servers each station has (8), adjust the parameters, and decide the distributor's batch size to be 1000 based on the normal capacity of a truck. To compare the cost between different policies based on different reorder levels, we calculated the average queuing size in the local tank queue object and the total times of order resulting in the Toronto distributor, as shown in Fig.8.

(a) Queuing Results

(b) Activity Results

Fig. 8. The Queuing and Activity Results

VII. PRODUCTION RUNS

We noticed that we cannot use one server to adequately represent the multiple servers' utilization since the working rate of the single equilibrium server is always lower or equal to the multiple sets. As the multiple servers' optimal policy should have a larger reorder quantity, the final model is designed, as illustrated in Fig.9. To calculate the total cost of a gas station with six servers, we used the following variables: pipeline speed, reorder point and reorder quantity. Thus, our goal is to compare the total cost based on different variable levels and find the lowest cost policy. We choose the decision variable levels. (R, Q, Speed) (Table 2).

Table 2: Decision Variable Levels

R	Q	Speed
500,1000 /L	10000,15000,20000,25000,30000,35000,40000 /L	1, 5 m/s

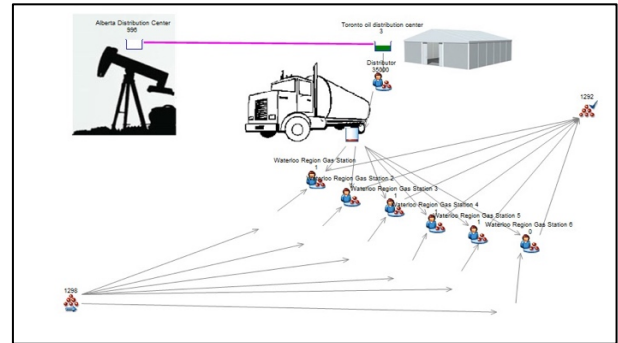

Fig. 9. The Complete Simulated Supply-Chain Model

We run a single month on the modified model to determine which policy level is optimal, i.e., has the lowest cost. For example, for reorder point 500L, reorder quantity 10000L with pipeline speed 1m/s, the inventory quantity graph is shown in Fig.10. Looks like a typical EOQ model. The statistics of the queue and the distributor are illustrated in Fig.11.

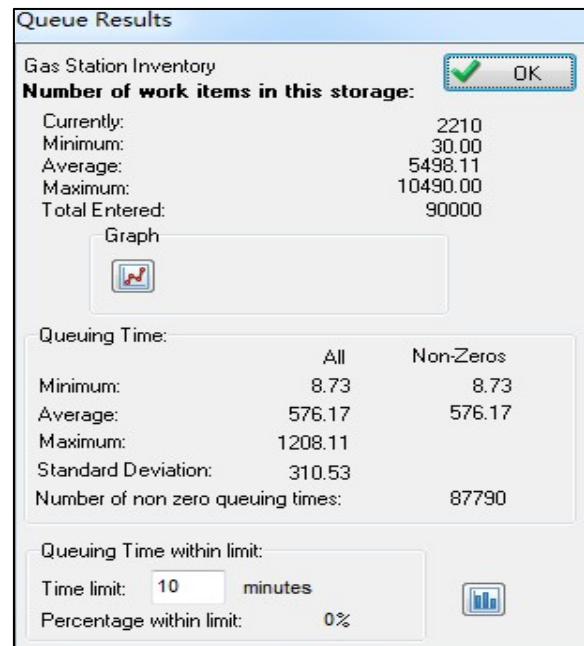

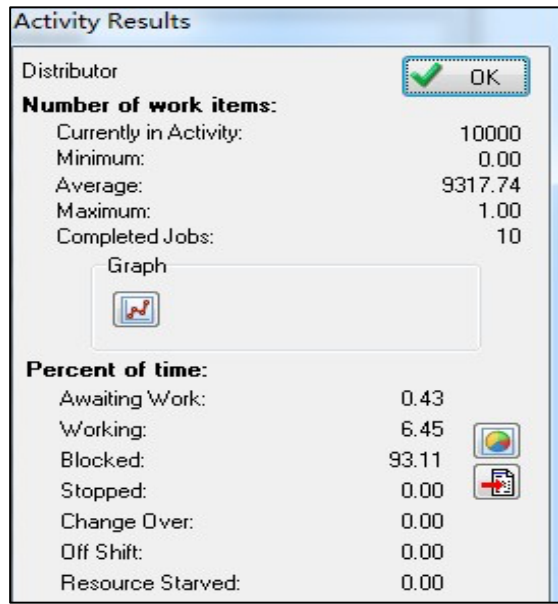

Fig. 10. The Inventory Quantity Graph

(a)

(b)

Fig. 11. The Queue and Activities (Distributor)

The status of each queue in the simulation period is shown in Fig.12. The green part of the distributor means the number of orders made during the whole period, and the green part of the waterloo gas station represents the fraction of stock out in the period. The tank volume during the simulation is illustrated in Fig.13. We can see that the minimum of the tank is never 0, which means we never faced the stock out of the simulation during the whole period.

Name	Completed Jobs	Current State	Utilization (%)
Distributor	4	Blocked	
Waterloo Region Gas Station	1298	Waiting	

Fig. 12. The Queue and Activities (Distributor)

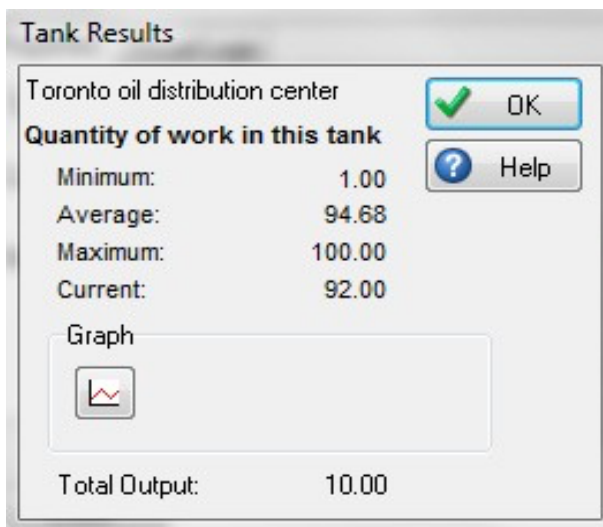

Fig. 13. The Tank Volume

Ten orders are made in a single month on simulation, so the cost is Pipeline cost+Holding rate*Average of inventory+number of orders*order cost. The cost of different policies is shown below: (for speed = 1m/s).

Table 3: Optimal Policy Levels

Quantity	Reorder	
	500	1000
10000	42656.73918	42662.93509
15000	42436.38504	42441.60887
20000	42388.02882	42393.73799
25000	42334.07632	42342.47215
30000	42273.40715	42277.89205
35000	42317.13049	42323.3408
40000	42342.6808	42349.28826

Table 4: Optimal Policy Levels

Quantity	Reorder	
	500	1000
10000	42738.15635	43329.86965
15000	42520.19496	42528.14132
20000	42384.58025	42390.78049
25000	42330.37035	42336.70882
30000	42356.11782	42365.76382
35000	42308.85685	42316.15549
40000	42346.06166	42352.15465

In the chart shown in Table 3, we see that the optimal policy for speed 1m/s is (500, 30000). Thus, the best order policy for our problem is (1m/s, 500L, 30000L). Then we run the full model to see if our prediction is correct. We use the same methodology as the simplified one, and after all the calculations, the final result is shown below in Table 4. We can see that the best reorder quantity now is 35000, greater than the simplified model and as we predicted initially. However, there is another issue if all the server is fully utilized at this current point. We checked the utilization graph of each working server, as shown in Fig 14. We can see that there is a substantial portion for each server to wait. In our model, we do not consider the maintenance fee of those servers, so more servers lead to a shorter waiting time for the cars but lots of idle time for the servers. Once the maintenance fee is considered, we should adjust current server numbers since it could cost a lot of loss because of its inefficiency. Also, in the simulation, we didn't see any stock-out situation happening in the Toronto oil distribution center. Thus, the pipeline speed doesn't need to increase since increasing the speed will increase the total cost but not improve the work rate. Overall, the best policy for the current problem is (1m/s, 500L, and 35000L). The result follows the classic EOQ assumption, a tradeoff between holding the asset and ordering goods. The best policy is using pipeline speed 1m/s with reorder point 500L and reorder quantity 35000L. The result differs slightly from what we have

proposed at the beginning. Some variables do not affect the result, like the pipeline speed and the tank capacity. In general, we can achieve a suboptimal solution as to the original goal of our project. If we could use a more extended time window, the model could be much more realistic as we can introduce more real-life factors such as idle cost and other cities. What is vital to the simulation is that the simulation should represent reality as close as possible.

Fig. 14. The Utilization of working servers.

VIII. CONCLUSION AND FUTURE DIRECTIONS

The main objective of this paper is to use discrete event simulation to find the optimal combination of transportation methods and the optimal inventory policy. In this paper, we will focus on the midstream and downstream sectors in the oil industry. Various pilot and production runs have been implemented. Using a conceptual supply chain model and real data collection, experimentally, the best policy is using pipeline speed 1m/s with reorder point 500L and reorder quantity 35000L. Future direction involves the investigation of a longer time window and different assumptions about probability distributions. Combining machine learning [13]-[15] in

transportation systems, including supervised methods [16][17] and deep learning methods [18]-[22] with simulation to increase accuracy is a future extension of the current research.

Abstract—Since there is a cost associated with providing 24/7 support, it is also common to divide user support into tiers where a group focused on usability and training of the software provides tier 1 support and another group, consisting of mainly developers, is focused on feature development, software bug fixing, and related issues work separately in a different tier. This paper focuses on software organizations where the developer tier operates from just one part of the world under a single time zone. This group is not available on a 24/7 basis, but the Tier 1 group works in different regions – and hence time zones - throughout the world to deal with user problems and questions. Users can be internal or external, depending on the purpose of the software. This paper discusses only internal users (developers, users and help desk employees who work for the same company) and the delays in support when dealing with these users who may be working in different regions and/or time zones. Tier 1 support is available around the clock due to hiring help desk resources in different locations under different time zones. If an issue cannot be resolved, the Tier 1 workers escalate the issue to the next tier (the developers), who work regular hours in one region under one time zone. This paper uses discrete event simulation modelling to provide insights for a company with a similar structure to better understand possible software support delays. These delays can be reduced, and better overall support can be provided in the future.

Keywords—Software Support, Simulation, DES, Performance.

I. INTRODUCTION

Customer support has become an integral part of software organizations. Companies tend to divide the support work into tiers to provide software support more effectively. It is common to place developers in a later tier so that tiers can handle user training and usability issues with non-developers. Anytime the support needs to be escalated to the developer tier and they are not available, a ticket is created so that the developers tier can handle the issue as soon as they are available at work [1]. With this concept, though it is ideal to have all types of resources available 24/7, for various reasons, that situation becomes challenging, especially when a tier of support is operational only under one time zone for a set number of hours. If the customer support or help desk (non-developer) tier is available around the clock to attend to the calls, the only concern would be the delay involved when issues are escalated to the development tier. In this paper, to learn more about service delays in software support, a model is created to simulate a company structure with the two-tier backing: Tier 1 – help desk tier, hired to provide 24/7 support at different branches around the world and Tier 2 - developer tier that operates only from North America under the

one-time zone. For simplicity, the model does not include overtime hours or on-call support options and excludes daylight savings time adjustments. Users of the software can be internal or external, depending on the purpose of the software. In most cases, external users do not interact directly with the developer tier; thus, we will focus on internal users alone. These users work for the same company as the help desk and developers, and they utilize the software to help run various processes or tasks within the company from different parts of the world. When they encounter an issue using the software, they may call the help desk available 24/7. If a software feature modification or alteration is required, the help desk forwards the requesting user to developers if they are available; otherwise, the user request goes to a queue waiting for the developers to be available to provide a resolution. This paper uses discrete event simulation (DES) modelling to provide insights for a company with a similar structure to better understand possible software support delays. These delays can be reduced, and better overall support can be provided in the future. We look at the latter queue to learn about the different parameters that influence the number of requests sitting in the queue and the overall time the requests spend in the system before the requests are resolved. These tasks and goals are achieved using discrete event simulation. This paper is structured as follows: related work is discussed in section 2. The conceptual model is presented in section 3. Section 4 discusses the validation and verification methods. Section 5 shows the experimental results along with pilot runs. The paper is concluded in section 6 with future directions.

II. RELATED WORK

As providing tech support on a 24/7 basis is becoming increasingly important to software companies, it makes sense that there is some related research on global support and collaboration and even examples of actual companies providing tiered service to businesses [1]. Most of the literature on this topic covers the challenges involved with support and collaboration in a global business environment. Authors in [2] examined the challenges of working with a virtual team versus working with a team in the same physical location. The challenges that affected relationships and communication involved working with a virtual team included different time zones, cultural differences, requirements creep, management leadership style, and the lack of clear responsibilities and roles. In [3], the authors studied issues that may arise when individuals work with each within a virtual team. This study interviewed sixty-five employees, including managers, senior executives,

team leaders, and team members. Some of the challenges discovered included building a sense of cohesiveness, trust, and specific team identity. Another issue that came up during this study is the issue of overcoming a sense of isolation that may arise from working in a virtual environment. A study of trends and practices for the Australian business sector [4] offers insight into the contact center offshore industry – a service often utilized by software companies. More specifically, they suggest that companies are experiencing cost savings and more business flexibility by choosing to employ offshore call center support. Some of the challenges faced with outsourcing these endeavors include employee recruitment and retention. In [5], they examined the additional benefits and challenges of outsourcing work to other countries. To arrive at their answers, a variety of companies were surveyed. With respect to the challenges, data security, intellectual property rights, and political risks were the top concerns. That said, 68% of the survey respondents were satisfied with their outsourcing arrangements, and just over 25% of the respondents were also unsatisfied or very unsatisfied with the arrangement. As most unsatisfied companies had been outsourcing work for less than a year, they suggested outsourcing is more of a long-term investment. For actual companies offering tiered tech support to other businesses, one example is a company called Harmonic [6]. Users with issues or questions contact Harmonic’s centralized Technical Assistance Center (TAC) for assistance. The staff employed at the TAC are located in multiple locations throughout the world, including the United States, Israel, Hong Kong, Singapore, and England. Available on a 24x7 basis, the TAC provides multiple-level tech support to users. Specifically, users first talk to a customer service agent and then are transferred to a technical support engineer. Suppose the initial issue cannot be resolved with the engineer. In that case, the problem is assigned to a Level 2 tech support engineer and specialists for further investigation (located throughout the world) and an eventual resolution to the problem. ExactTarget [7] is another example of a company that offers 24/7 global technical support to businesses. Once again, this company boasts of an international presence with offices located in Canada, the United States, England, Germany, France, Sweden, Singapore, Australia, and South America. With its standard support package, users call a Global Support Center and then relay their issues to one of the company’s technical support specialists. The issue is resolved or transferred to a Tier 2 advanced-level technician for resolution. ExactTarget also offers two other levels of technical support. The premium support package provides direct access to advanced-level technical support specialists. In contrast, the platinum support package offers specialized support from tech support experts who are extremely familiar with a business’ tech and business challenges [8]. Recently, discrete event simulation (DES) [9]-[11] shows a great protentional in providing insights for companies to better understand possible outcomes.

III. THE CONCEPTUAL MODEL

To design a conceptual model of the intended organization, the following four regions are considered: North America, Latin America, Asia and Europe. Four different cities are picked randomly under these four regions – Toronto for North America, London for Europe, Rio de Janeiro for Latin America and Singapore for Asia. A software company with branches in all

four regions hires a resource team for the developer tier in North America alone for the model in hand. Employees in North America are assumed to be available from 8 am – 6 pm EST. From the working hours in North America (Toronto), the associated times are highlighted in Fig.1 [1].

Fig. 1. Working hours in Toronto and how it overlaps with the rest [1]

North America will be the main reference point for this model when calculating hours covered around the clock for support or resource availability. This covers 8 am – 6 pm EST North America time, and both the help desk and developer tier are available to cover ten hours a day. The slider is moved towards the right to display the working hours in Europe (London), and the corresponding hours in North America (Toronto) are also highlighted in Fig.2.

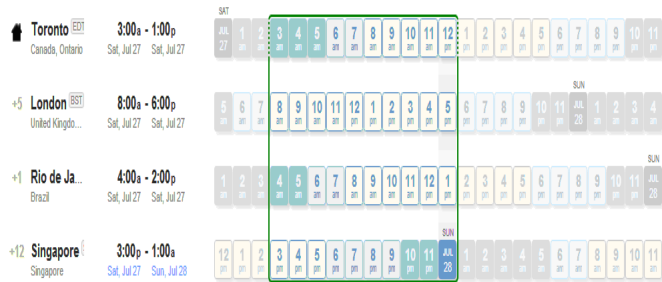

Fig. 2. Working hours in London and how it overlaps with the rest [1]

Here, it is visible that the European hours cover 3 am – 1 pm EST of North American time. During this time, the help desk team in Europe is available, and the help desk and development tier in North America. However, it must be noted that the North America support is only available for five hours – namely from 8 am – 1 pm EST. In other words, Europe can cover five hours of daily tier 1 support when North America’s support is not available. Similarly, the available working hours in Latin America (Rio de Janeiro) tell us that the region covers only one hour when North America is unavailable. From Fig.3, this region is available from 7 am – to 5 pm North American time. The only hour they can cover for North America overlaps with the Europe region (12 pm – 1 pm in London). Therefore, hiring resources in Latin America to provide 24/7 support is less efficient for this model when the cost is not included. Asia’s last region can cover a generous ten hours of the day for North America, as shown in Fig.4. Asia’s (Singapore) regular working hours fall under the 8 pm – 6 am EST time slot in North America, and Singapore’s help desk support is available from this region. As one may assume, this region is very important for any North American-based software company since this region

overlaps with the time when the North America support is unavailable.

Fig. 3. Working hours in Rio de Janeiro and how it overlaps with the rest [1]

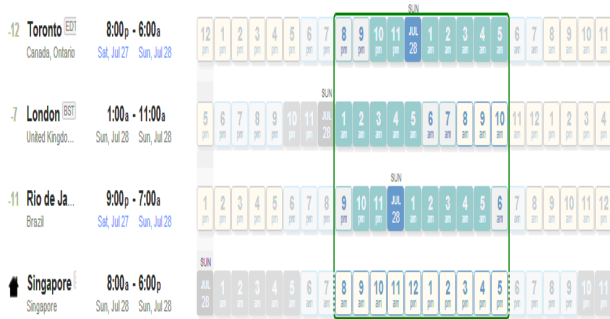

Fig. 4. Working hours in Singapore and how it overlaps with the rest [1]

There is an additional cost benefit to operate services from this region, but that topic is left out for future extension of this model. Another important observation is that the Asia (Singapore) region overlaps with three hours of work within the Europe region (London). After looking at the four regions with four different time zones, it is obvious that the main two regions that will cover twenty hours of support a day are North America (Toronto) and Asia (Singapore) in this model. The requirement for Latin America support is minimal in our model since its working hours are shared with at least one other region. In this example, Europe (London) can provide two additional hours of support or the 6th and 7th hour of the day. However, this situation leaves two hours of “no support” - the 18th and 19th hour of the day. For simplicity reasons, overtime working hours, on-call support and daylight saving time adjustments are not included in this model. Thus far, it is evident that a software organization should allocate a significant portion of their tier 1 support resources in North America and Asia. We randomly chose that 45% of the resource team should reside in North America, 45% in Asia, 8% in Europe, and 2% in Latin America for our model. The tier 2 support team (developer tier) belongs to the North American region and is available only from 8 am – 6 pm EST. In this paper, we created four work shifts for the model, namely a North American, Latin American, Asian and European work shift, as shown in Fig. 5. Specifically, the shifts occur between 8 am – 6pm, 7 am – 5pm, 8 pm – 6 am, and 3 am – 1 pm EST. With this structure, support is not available for two hours a day between 6 pm and 8 pm EST. Though support will not be available for those 2 hours, since users may try to contact the help desk during those hours, a fake shift called “No support shift” was created to cover those two hours. Software users are distributed among the four shifts and the “no support shift.”

Fig. 5. Shifts used for the model and hours covered by each shift

At random, 15% of the company employees are placed in tier 2, consisting of software developers working the North American shift. Additionally, 20% of the employees sit at help desks for tier 1 support distributed among the available regions. The rest of the 65% of employees available in the company will be considered the end-users of the software. Tier 1 help desk helps these users with software usability, training and frequently asked questions. Unresolved issues are escalated to “Tier 2 Queue” for the developers to assist further, and these developers are available only during the North American shift. This can be depicted in Fig.6, where the requests are made by “users” at the “Tier 1 Queue” and served by the help desk at tier 1, the group of people working from four different regions on different shifts.

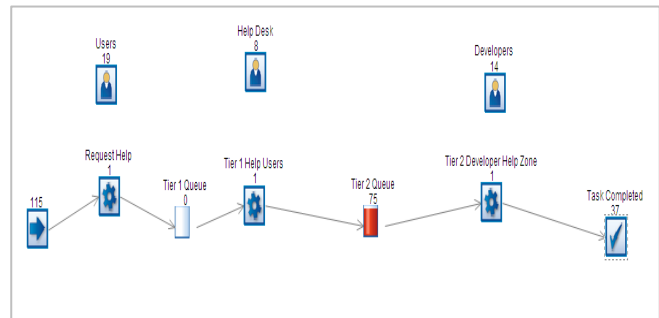

Fig. 6. Base model of software support in Simu8

If the tier 1 help desk can resolve most usability issues, tier 2 developers should encounter only software bugs or feature requests. Hence, only a comparatively smaller portion of the requests should go to tier 2 in an ideal world with stable software. Introducing some exceptions, such as routing only a percentage of the requests to the “Tier 2 queue”, makes this model more interesting. The model can be simulated with varying numbers for the percentages to test scenarios that closely match real-world situations, as shown in Fig.7.

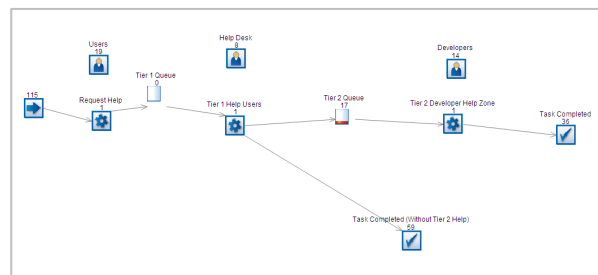

Fig. 7. Software support model in Simu8 with tier 1 and tier 2 layers

The layout of the rest of the company employees and software users is left out purposefully since the focus is on tier 1 and tier 2 support teams. Assumptions are made that they are equally distributed over the available regions. The complete process that this model follows is described in Fig.8. A more complex version of the model is shown in Fig.9, where two additional termination points are added should the users leave the queue in the case of a longer wait. Our base model can be extended to include the extra termination points where users leave the system after a certain amount of waiting time in the queue. A concept model is shown in Fig.10. To have a better representation of how resources are distributed and utilized over the four regions, extra nodes are created.

IV. VALIDATION AND VERIFICATION

Different percentages of requests completed without tier 2 help were implemented to validate this model. As expected, as more requests need “tier 2 support”, there is a longer waiting time as the tier 2 queue becomes busy. If the overall time to process each request at tier 2 is improved, fewer items will be waiting in the tier 2 queue. Service time at the help desk for each request is set to 20 minutes, and at the developer tier, it is set to 60 minutes - assuming it takes more time to resolve an escalated software issue. This processing time can have a significant impact on the overall model. It was also assumed that a user makes a request every 15 minutes on average. If users make requests more frequently, tier 1 and tier 2 queues start to experience hold-ups, as shown in Fig.11. Thus, if the service time at tier 1 is less than the inter-arrival time, then the tier 1 queue is less busy.

V. PRODUCTION RUNS WITH SIMUL8

First, the model was run on a company with 100 employees. Specifically, 65 users work in different time zones (different shifts for this case), 15 developers work in tier 2, and 20 people work at the help desk to provide tier 1 support. Tier 1 support is divided into four shifts to mimic working under different time zones. Nine resources are allocated to each North American and Asian shift, two resources working at a European shift and no one on the Latin American shift. A help desk call is made every 15 minutes on average, and each call servicing time is 20 minutes on average. 70% of the requests are resolved at this tier, and the rest of the 30% are escalated to the developer tier, where it takes 60 minutes on average to service each request. In this model, the clock is set to run for seven days a week around the clock and for an entire week’s duration. The result is shown in Fig.12. The developer tier queue is larger after running this model for a week (Fig.13). Further, although only 30% of the requests are going to tier 2, it takes significantly longer to resolve tier 2 issues since tier 2 is unavailable around the clock. On the other hand, requests resolved at tier 1 via the help desk show a significant improvement compared to the developer tier, as shown in Fig. 14. To see overall improvement, a software company can consider either extending developer help to a different region (so that they are available for more hours) or the company can consider reducing the service time at the tier 2 level. Plotting the queue size against a different percentage of requests routing to Tier 2 gives a clear picture of how it can impact an organization. Later the model is expanded to illustrate apparent differentiation between the regions by introducing

resource and task nodes corresponding to each region, as shown in Fig.15. Running this expanded model in Simul8 shows how the resources are utilized and along which paths. In reality, some users tend to leave the system after a certain time. Our current model can be extended to include these users who can leave when the expiration hits at the queues, as illustrated in Fig.16. After running both models for four weeks in Simul8, a significant improvement is visible in queuing time at the developer tier, and the average time a task spends in the system. Table 1 shows a performance comparison of these two models.

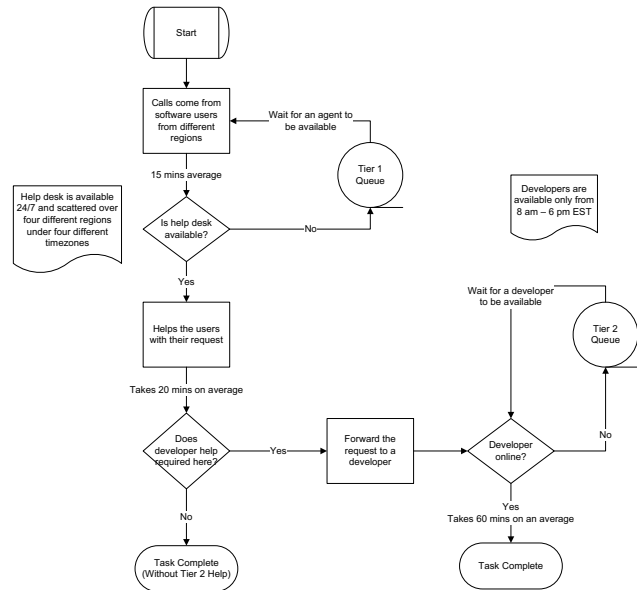

Fig. 8. Flow chart for the Software Support Model

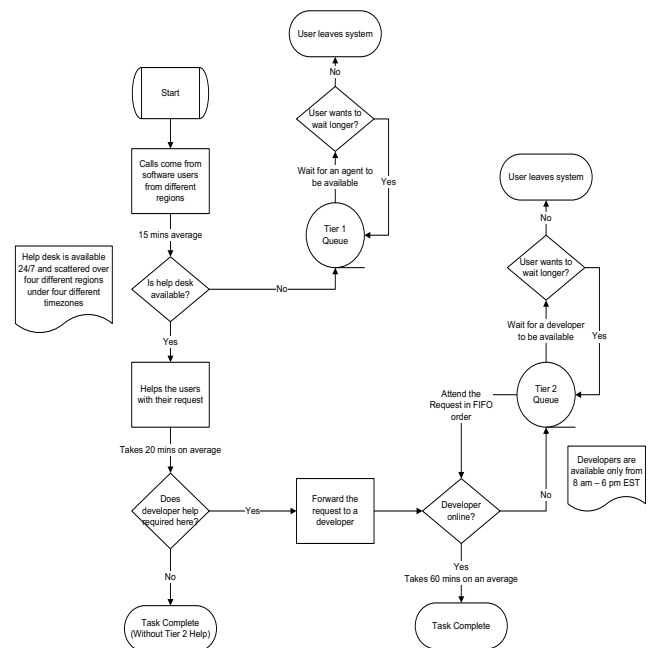

Fig. 9. Flow chart of a software support model where users can leave the queue

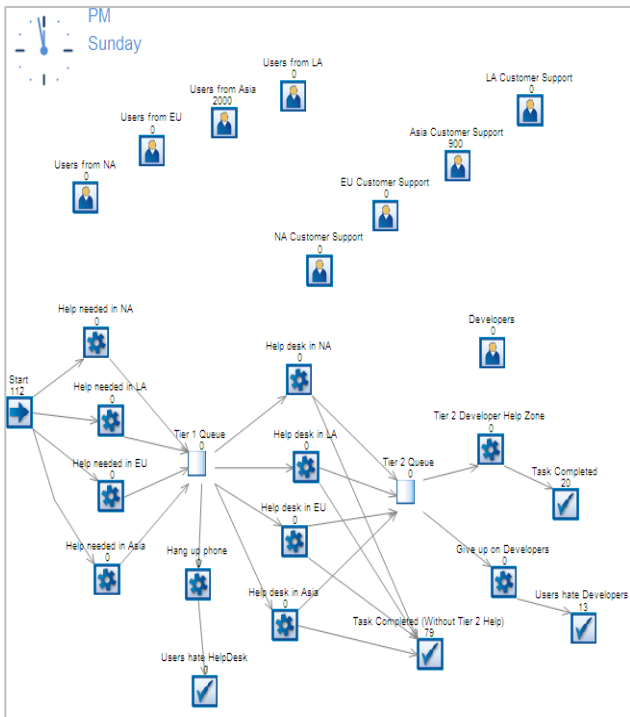

Fig. 10. Support Model with expiration at queues

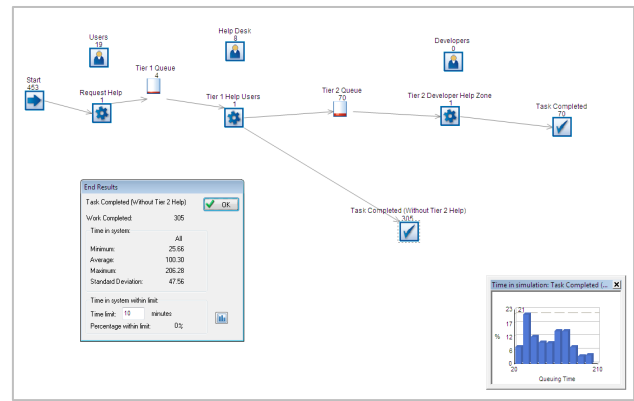

Fig. 13. Tier 1 Queue after a pilot run

Fig. 14. Tier 2 queue is affected by load increase

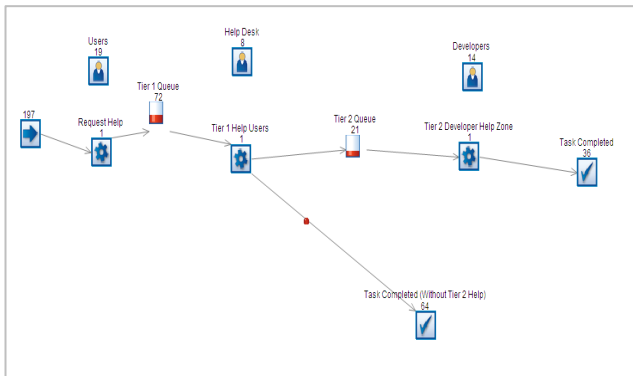

Fig. 11. Pilot run of the model in Simu8

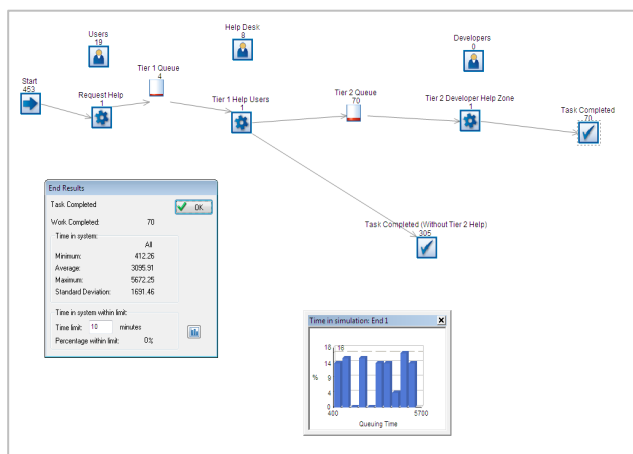

Fig. 12. Tier 2 Queue after Pilot Run

TABLE I. COMPARING THE TWO MODELS

	Model 1	Model 2
	A model with no expiration at queues	A model with expiration at queues
	Users wait until a developer is free to take care of their requests	Users may leave after a certain period of time
Average queuing time at the developer tier	260.63	64.45
Average time in the system at the developer tier	531.47	240.88
Task completed at developer tier	38	19
Average time in the system at the help desk tier	38.36	38.36
Task completed at developer tier	73	73
After running 100 trials average time in the system		
Low 95% range	455.29	222.16
Average result	465.22	223.94
High 95% range	475.22	225.71

VI. CONCLUSION AND FUTURE RESEARCH DIRECTIONS

This paper develops a model that depicts a real-life software organization scenario where software users may require 24/7 support. This model can be further extended to associate cost with each resource and action performed; this can significantly affect how the company employs individuals in different regions and whether the tech support should work at tier 1 or tier 2 level. More software support tiers can be added to the model to add more complexity. The model will be useful as it will provide the

company with an advanced look at the overall efficiency and cost. If the tier 1 resource is more cost-effective than the tier 2 resource, a study can be performed to determine whether training the tier 1 resource team to perform tier 2 functions is a feasible plan. It is important to note that all the queues assumed an infinite capacity and shelf-life in this paper. This situation may be entirely different for many companies in the real world. To conclude, interacting with businesses through many channels can be challenging; however, the future of customer service can be well-planned and structured if a proper model is used to grasp a company's customer service needs ahead of time.

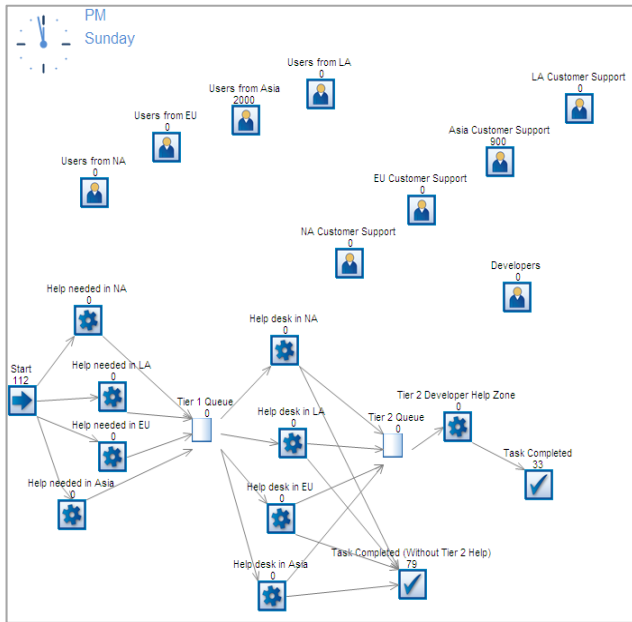

Fig. 15. The expanded model

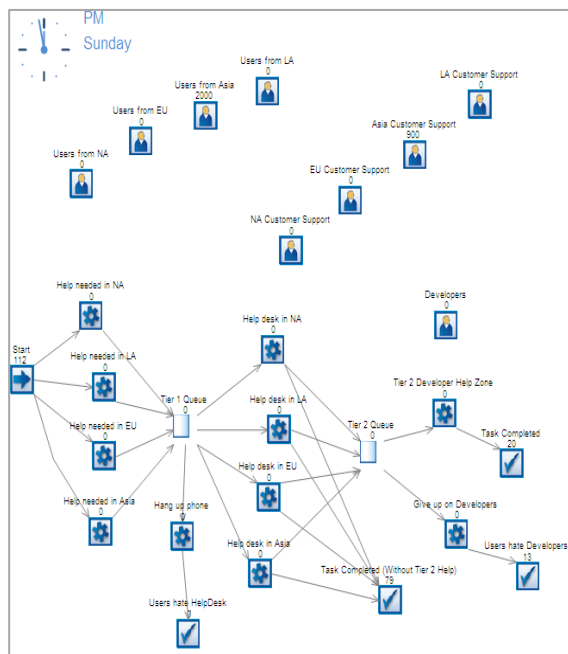

Fig. 16. Extended model with expiration at queues

Combining Ai-driven methods using machine learning-based [12]-[14], supervised learning [15][16], and deep learning [17]-[20] with DES to increase automation and accuracy is one of the main future extensions of this research.

Intelligent Feature Selection on Multivariate Dataset using Advanced Data Profiling

¹ **Abstract**—The differential diagnosis of diseases which share similar clinical features is a real and difficult problem in medicine. This paper demonstrates the use of data mining (DM) techniques to augment standard data profiling methods and establishes an efficient approach for an intelligent feature selection method for disease that share similar features. The results from experiments returned show that by using DM techniques to select features as an additional layer on top of data profiling, there is considerable improvement in the performance of the prediction model built to predict a disease such as “Psoriasis”. A brief comparison between features selected by existing mining tools such as Weka and the proposed approach with respect to predictive accuracy is recorded in this paper. The proposed algorithm works as a promising tool for assisting diagnosis of disease like erythemato-squamous diseases, where the symptoms are overlapping. By combining data cleansing and knowledge discovery techniques, the algorithm aims to be “agnostic” and can be used on a wide variety of data standards with variable data quality.

I. INTRODUCTION

Machine learning models are built to capture relationships in an n-dataset (dataset of size n) between its n-1 features and the (nth) target feature in the dataset. Since such models are highly data-driven, their accuracy relies on how “good” the data is. “Goodness” of any dataset can be determined by understanding the data and preparing it so that it can be deemed “good”. Typically, repositories such as Data Lakes [15] store data in its raw form, which is eventually (pre)processed before it is used in a data mining model. To understand any given data in a dataset requires gathering information about that data, commonly known as metadata. Type of metadata depends on the application for which the data mining model is being designed. As an example, let us consider an application that requires educational data, such as student information, the courses they have completed and grades achieved in these courses. Metadata in this example can be as simple as the student’s name and age stored in its raw form, or it could require some calculation such as average age of students in this dataset. If described and managed well by big data repositories such as data lakes, such metadata can be exploited by analysts to discover underlying relationships between different features in a dataset, and thereby allow data mining models to be better informed about the dataset. Data profiling refers to this structured activity of creating small but informative summaries of a database [8]. Data profiling uses scientific methods to

explore, understand and collect statistics on raw data of a given dataset for detecting statistical distributions and structural patterns.

In a typical real-world scenario, data is integrated from various different sources, and this makes it challenging to provide consistent, clean and accurate data for machine learning models. Data profiling can be used as a pre-processing step in the process of data mining to evaluate datasets for consistency, uniqueness and quality of data. It is a well known fact that data mining models spend 70% of their time in the pre-processing step which clearly needs to be improved [15]. This paper proposes a data agnostic algorithm for data profiling. In this algorithm, a full understanding of the entire data set is not required. The algorithm uses data mining techniques to understand the data (we call it as intelligent data profiling) and use that to select features that could prove to have a higher impact on the accuracy of the final model that is being built. One may argue that the high cost of computational complexity of profiling large datasets may deter data enthusiasts from using it. But this can be overcome by leveraging massively parallel clusters and will not be addressed in this project. Our research aims to build an intelligent data profiling algorithm that evaluates and analyzes different attributes or features in the dataset, with an overall objective of selecting those features that are of good quality and that improve the accuracy of the predictive model built using these features.

This paper is organized in the following way: Section II explains the proposed methodology. Sections III illustrates the evaluation of the proposed algorithm. A literature review of the related work and their limitations is discussed in section IV. Section V presents the conclusions and proposes future work.

II. PROPOSED METHODOLOGY

This section presents the dataset used and proposed methodology for intelligent data profiling and feature selection.

A. The Dataset

The dataset used in this research is on dermatology and is taken from an open-source repository [4]. It includes 34 clinical and histopathological features that have been transformed in a variety of ways to suit this research.

¹978-1-6654-8684-2/22/\$31.00 ©2022 IEEE

1) *Rationale for using the dataset:* Diagnosing skin diseases such as 'Psoriasis' and 'lichen planus' is a real problem in dermatology [5]. Firstly, they all share the clinical features with very little differences. Secondly, there are too many features, some of them do not have enough values or have values that are not meaningful. Some diseases have overlapping features from another disease at the beginning stage and may have the characteristic features at the subsequent stages. In terms of data, the significance of the presence or absence of a feature in the dataset makes the analysis challenging. For example, given the features, it is difficult to differentiate between 'Psoriasis' or 'Lichen Planus' as they have overlapping features (for example, itching is a common feature in both). The proposed method intelligently selects only those features that have a significant impact on the accuracy of the predictive model that predicts the disease.

2) *Notation used :*

1) The following notation is used:

D = dataset

2) Each instance n of D is represented as a triplet:

$$\forall_1^n i, (ca_i, ha_i, ta_i)$$

where ca represents clinical attributes, ha represents histopathological attributes and ta represents the target attribute. $|x|$ indicates the cardinality or number of instances of x

3) D^T – dataset after transformation of attributes

4) $D_{profiled}^T$ - dataset after data profiling of the attributes

5) $D_{reduced}^T$ - optimal set of attributes used for prediction

B. *Transformation of selected features in dataset D*

In general, preprocessing is used to transform raw input data into appropriate formats for subsequent mining [14]. Real-world data is often inconsistent, has missing values and may have data that has errors. Data preprocessing is a technique that is used to resolve such issues.

The transformations on different attributes of D and the rationale for doing so are listed below.

1. The target attribute (ta) in the original dataset [4] has 6 classes. For simplicity, we transform ta to a binary class code problem, i.e. to 2 classes. We aim to predict if a person with several given symptoms (represented by a vector of clinical and histopathological attributes) has psoriasis (class code = 1) or not (class code = 2).

2. Attribute age is a clinical attribute (ca) that is continuous. In order to see the impact of age categories on the outcome (i.e. presence of psoriasis), we chose to discretize age into 5 different bins. This decision was a result of a few experiments with attribute age. Binning is a method to group a number of continuous values into a smaller number of "bins". This research creates bins using equal-width unsupervised discretization method (except for the last bin that is of a larger size than others) [10]. The bins created using this algorithm and their distribution with the target attribute are as follows:

Bin	Interval
1	[< 12.5]
2	[12.5 - 25)
3	[25 - 37.5)
4	[27.5 - 50)
5	[>= 50]

The third bin that caters to the age group 25 - 37.5 has the maximum count of patients among all bins, whereas age group less than 12.5 has the least. The graph in figure 1 shows the distribution of all age groups.

Figure 1. Discretization of Age into bins

3. All other clinical (ca) and histopathological (ha) attributes in the original dataset D can have any of the four values (0, 1, 2 or 3, where 0 indicates the absence of a symptom, 1, 2, 3 indicate the intensity of the symptom present, with 3 representing the highest intensity and 1 the lowest). All these attributes can be categorized as asymmetric attributes.

An asymmetric attribute is defined as an attribute in which the presence of one of the values (e.g. 1) is regarded as more significant than the other (e.g. 0), as opposed to a symmetric attribute in which the value 1 (or higher indicating presence of the attribute) is considered equally significant as its absence (0) [14]. For example, erythema in D is taken to be an asymmetric attribute in this research, where a value of 1 or higher indicates the presence of that symptom and 0 indicates its absence. In an asymmetric attribute, a 1-1 match of erythema in two rows is significant, whereas a 0-0 match has no significance (since 0 implies that the symptom is not present) and is ignored in the proposed method. On the contrary, an example of a symmetric attribute is gender, where 1 represents female and 0 represents male, then a 1-1 match (indicating a female-female match) is as significant as a 0-0 match (indicating a male-male match).

After the above transformation, our dataset now has:

- 11 clinical attributes: asymmetric
- 22 histopathological attributes: asymmetric
- 1 family income: binary symmetric attribute
- 4 binary asymmetric attributes: unique bin for age category

It is worth mentioning here that id numbers of patients are removed from the database in the original dataset D.

C. The proposed algorithm - Predicting Using Intelligent Feature Selection (PIFS)

Algorithm 1 lists the core steps of the proposed algorithm called PIFS (Predicting using Intelligent Feature Selection). Step 1 transforms the original dataset D to D^T . Section B defines the transformation on some of the attributes such as age and the target attribute (ta) and the rationale behind those transformations.

Step 2 performs the data profiling step to convert D^T to $D^T_{profiled}$. We did single-column profiling tasks in terms of the number of rows and uniqueness of the values [1]. Those features or columns that have 80% or more values as 0 (0 indicates absence of that symptom) were eliminated and not included in the new set $D^T_{profiled}$. At the end, the attributes selected for the next step were reduced to a new dataset ($D^T_{reduced}$).

Dataset $D^T_{profiled}$ is certainly more informed than D^T , however, many of its attributes still have a large number of zero values that indicate the absence of a symptom. In order to make our dataset more informed, this research runs an intelligent algorithm that is based on the distribution of different categorical values (0, 1, 2, 3) in each ca or ha attribute in $D^T_{profiled}$. Step 3 of PIFS (Algorithm 1) illustrates its details. Thresholds 1 and 2, selected by combining expert opinion with experiments, are given below. Here, \wedge represents AND; \vee represents the OR symbol.

$$\begin{aligned}
 &threshold_1 : |zeros| \geq 250 \\
 &threshold_2 : 150 < |zeros| < 250 \wedge \\
 &(|ones| \vee |twos| \vee |threes| > 50)
 \end{aligned}$$

These thresholds are determined by the attributes in the current dataset and by the different categorical values that these attributes can have. Figure 2 shows two attributes that do not meet these threshold values and therefore are not selected by PIFS. Figures 3 and 4 illustrate distribution for four attributes that were selected by the proposed algorithm. As can be seen, the number of zeros in both Erythema and Scaling (Figure 3) is negligible. Similarly, figure 3 shows two attributes that were filtered out by our algorithm since they do not meet the two thresholds.

Step 4 creates a predictive model using k-nearest neighbor algorithm to predict the target (psoriasis or not) given a vector from $D^T_{reduced}$. This research chose to use k-nearest-neighbor due to its simplicity. Its results were compared to decision tree model as well (as shown in the experimental section).

Figure 2. attributes not selected by PIFS

Figure 3. attributes selected by PIFS

Figure 4. additional attributes selected by PIFS

K-nearest-neighbor (k-nn) algorithm [14] typically takes 4 inputs in order to predict a target attribute: an integer k (k=number of neighbors), a set of training samples whose target attribute y is known, a test vector t and a similarity or distance function. It then predicts test sample of class label t by performing the following steps :

- 1) calculate similarity between a test vector t and all training samples using the chosen similarity function (as explained below)
- 2) sort these similarity values and pick the top k samples - these are the k nearest neighbors of test sample t
- 3) Use the values of ta of each of the k nearest neighbors of t to predict a value for t. If the total number of neighbors that have a 'Yes' as its target attribute is greater than the total number of neighbors that have a 'No', assign 'Yes' as the class label of t; otherwise assign a 'No'.

Jaccard's Coefficient (JC) works best with asymmetric attributes [14] and therefore is more applicable to this research. Jaccard's Coefficient (JC) between two vectors x and y is

measured as

$$JC(x, y) = \frac{f_{11}}{f_{11} + f_{10} + f_{01}} \quad (1)$$

where f_{11} is the frequency of 1-1 match in vectors x and y , f_{01} is the frequency of occurrence of 0 and 1 in x and y (non-matching pair) and f_{10} is the frequency of occurrence of 1 and 0 in x and y (non-matching pair). For example, if $x = [1, 0, 0, 1]$ and $y = [1, 0, 1, 0]$, then $JC(x, y) = 1/3$. Since all the attributes in D are categorical and asymmetric, the similarity function that we choose to use in the proposed algorithm PIFS is Jaccard's coefficient of similarity.

Algorithm 1: The proposed algorithm PIFS

1. Preprocess and prepare attributes in the original dataset D (call it D^T) - as explained in section 2.2
2. Perform SCP (single-column profiling) data profiling algorithm on D^T to get a new set of attributes (call it $D_{profiled}^T$) - as explained in section 2.3
3. Use an intelligent feature selection method to eliminate those that are (lets call it $D_{reduced}^T$) - as explained in section 2.3

```

for each attribute  $i$  in  $D_{profiled}^T$  do
    find the distribution of its different categories
    if  $|zeros| < threshold_1$  then
        Add  $i$  to  $D_{reduced}^T$ 
    else
        if  $|two| > threshold_2$  OR  $|three| > threshold_2$ : then
            Add  $i$  to  $D_{reduced}^T$ 
        end
    end
end

```

4. Create a predictive model to predict the target attribute (presence or absence of psoriasis) - as explained in section 2.3
 - Divide data into 2 subsets using an 80-20 split: training (80% - $D_{reduced}^{Training}$) and test (20% - $D_{reduced}^{Test}$).
 - Training dataset is used to build the model, whereas test is used to test the model.
 - Build a model by applying a prediction algorithm such as k-nearest-neighbors on the training dataset $D_{reduced}^{Training}$.
 - Apply the model to each vector in the test dataset $D_{reduced}^{Test}$ to predict its ta values.

	Features selected by Weka	Number of zeros
1	Erythema	4
2	Itching	116
3	Scaling	8
4	Follicular-Papules	325
5	PNL-filtrate	229
6	Fibrosis of the papillary dermis	308
7	Clubbing of the rete ridges	248
8	Thinning of the supra-papillary epidermis	249
9	Follicular horn plug	336
10	Perifollicular parakeratosis	337

Table I
FEATURES SELECTED BY WEKA

	Features selected by PIFS	Number of zeros
1	Erythema	4
2	Itching	116
3	Scaling	8
4	Definite Borders	55
5	Exytosis	117
6	Acanthosis	9
7	Parakeratosis	85
8	Inflammatory mononuclear infiltrate	9
9	Spongiosis	195
10	Age	Categorical

Table II
FEATURES SELECTED BY PIFS

III. EVALUATION OF PIFS

The proposed algorithm is evaluated by the following criteria: (1) feature selection (steps 1, 2 and 3 of PIFS) (2) performance of the prediction algorithm (step 4 of PIFS) using measures such as accuracy, recall and fscore [11].

A. Feature selection

Intelligent feature selection is a core step of PIFS, as described in section 2. The selected features are compared with features selected by Weka [16]. Weka is a collection of machine learning algorithms for data mining tasks such as data preparation, feature selection, prediction and clustering.

The features (also referred to as attributes in this paper) selected by Weka using its feature selection algorithm (cfs-SubsetEval + BestFirst) and the number of zeros in each of the selected feature is shown in table I. Note that zeros in this dataset indicate the absence of a feature (or a symptom) of the target disease being predicted (e.g., Psoriasis). All features other than Erythema and Scaling have a very high number of zeros. This implies that Weka is not able to accurately distinguish between the features as they are extremely similar and overlapping – this finding concurs with the claim made by the creators of the dermatology dataset D[4]. Attributes selected by PIFS are shown in table II. The selected features in this table have less number of zeros (0 indicates absence of symptoms) than the features selected by Weka.

B. Performance measurement:

Accuracy measures the ability of the model to match the actual value of the target attribute with its predicted one (e.g.

"Yes" predicted as "Yes"). Accuracy alone is not always a deterministic measure, especially when dealing with target attribute values that are imbalanced or uncommon. For example, let's assume that in a dataset with 100 samples, there are 10 people with target attribute = "Yes" and 90 with a target attribute = "No". Also assume that the model predicts 1 out of 10 people correctly as "Yes", and 90 out of 90 as "No", then the accuracy of the model according to its definition (equation 2) will be calculated as high as 91%. However, this result is misleading as the model is not at all accurate in predicting one of the target attribute values (in this case "Yes"). Other measures that are used to evaluate predictive models are precision and recall. Most models achieve a trade-off between precision and recall, since it is very challenging to keep both the measures high. F-score is a combined measure that assesses this trade-off between precision and recall. Figures 6 and 7 show high values of accuracy and fscore for the proposed model.

$$accuracy = \frac{ActualTrueValuesPredictedCorrectly}{NumberOfPredictions} \quad (2)$$

$$precision = \frac{ActualTrueValuesPredictedCorrectly}{PredictedTrueValues} \quad (3)$$

$$recall = \frac{ActualTrueValuesPredictedCorrectly}{ActualTrueValues} \quad (4)$$

$$f\ score = \frac{2}{\frac{1}{r} + \frac{1}{p}} \quad (5)$$

Performance of PIFS is compared with the models created using Weka. Weka gives over 98% accuracy with classification models such as Naïve Bayes, iBK and J48 (decision tree) using the selected attributes shown in table I. Most likely, this is because weka is unable to distinguish between the presence or absence of a feature (symptom). We also compared the accuracy of PIFS using selected features and all 34 features in the original dataset D. PIFS accuracy with the selected features is as high as 92%, as compared to 60% when all features are used, as shown in figure 5, asserting that PIFS selects its features intelligently. Figure 5 also shows that the accuracy is highest at k = 7 with PIFS features.

IV. RELATED WORKS

In this section, existing work on data profiling and their limitations are discussed. We first describe the different applications of data profiling and thereafter describe the recent works done to cater to these applications. Commonly, data profiling is the set of actions required to determine metadata about a given dataset. Determining metadata requires computation on rows of the given dataset (e.g. finding rows that have missing values such as identifiers) or more commonly on columns in the dataset (single or multiple). In a survey on data

Figure 5. Accuracy of PIFS using intelligent features

Figure 6. Accuracy of kNN model

Figure 7. Fscore of kNN model

profiling [1], the authors classify data profiling tasks as single-column and multi-column profiling, depending on the use case of the task. A traditional application of profiling is in data exploration. Most times, database experts including researchers are faced with a collection of data with not much information about the data due to the proliferation of data generated by

machines. Two main challenges in data exploration are as follows: (1) to assume that the data to be explored is in a well-structured format [12] and (2) to use manual methods such as data gazing to explore data. Data gazing [3], involves experts manually skimming through the dataset to understand its characteristics. In order to do this in an automated way, experts need to know databases well, so that they can run SQL queries to get better insight of the data. But this poses an additional constraint that explorers always have to be database experts [7]. Gathering statistics about the data (typically called as metadata in DBMS) is a common task done by DBMS. Metadata could be on single columns (e.g. number of unique values) or on multiple columns (e.g. find pairs or groups of columns that can be used to optimize queries by DBMS). Such metadata is also useful in doing reverse database engineering (e.g. creating ER models from an existing dataset) [6][1]. The most common application of data profiling is data integration, where data from different sources and with possible different formats are integrated into a single source. When performing integration, columns or features of two schema from different sources are compared to find the matching ones [13]. Data cleansing is considered as an essential step in the process of knowledge discovery and data mining and the need to collect insight into data (using data profiling techniques) is inevitable [9]. Besides these applications, data profiling is extremely useful in Big Data analytics [2]. Operations such as storing and fetching big data are much more expensive than traditional structured systems. Since the data here is typically huge and heterogeneous, gaining an insight into the data and cleaning it before using it to store or query gives some hope to big data researchers [1]. Most of the methods of data profiling listed above follow the traditional cycle of extracting metadata and then using it towards an application.

The methods described above fail to address the volume and heterogeneity of datasets today. If traditional data profiling methods are followed, it would take days to achieve any significant information about the data. To keep up with these challenges, keeping in mind the computational cost of profiling is covered, this paper proposes a progressive algorithm that blends the traditional methods with state-of-the-art data mining methods (particularly supervised mining) to extract metadata. The proposed method is extensible and scalable and can be applied to very large datasets to generate results in a timely manner.

V. CONCLUSION AND FUTURE WORK

The importance of data profiling as a pre-processing step of machine learning models is well known. In this paper, we demonstrate that layering supervised data mining techniques to data profiling, thereby building intelligence in the feature selection process, results in higher accuracy of prediction of differential diagnosis of diseases where there are several overlapping features. The intelligent feature selection algorithm PIFS selects features from a dataset based on the data and its

distribution. No prior knowledge of the dataset is needed. The algorithm safely ignores “noisy data” and selects an optimal and reduced set of features that yields a highly accurate predictive model.

As future work, we plan to test and train the algorithm to achieve better accuracy for a variety of multivariate datasets where differential diagnosis of disease pose a challenge due to overlapping features. The proposed algorithm can also be extended to multiple classes in order to discriminate between other diseases.

Abstract—Capacitive resistivity subsurface imaging of roads operating at very low frequency is susceptible to antenna characteristic capacitance dynamics that may cause unwanted signal reflection, coupling, and unfavorable effect on reception sensitivity. Antennas are conventionally modeled using a complex and repetitive default mathematical method that is prone to human error and discrete results. To address this emerging challenge, this study has developed a new technique for plate-wire antenna capacitance optimization through equatorial dipole-dipole antenna geometry modeling using genetic programming (GP) integrated with metaheuristic methods, namely Archimedes optimization algorithm (AOA), Lichtenberg algorithm (LA), and Henry gas solubility optimization (HGSO). GP was used to construct the antenna capacitance fitness function based on 241 combinations of wire antenna radius and elevation, and dipole plate elevation, length, width, and thickness measurements. Minimization of antenna capacitance (approaching 1 nF) to achieve quasi-static condition was performed using GP-AOA, GP-LA, and GP-HGSO. The 3 metaheuristic-based antennas were 3D-modeled using Altair Feko and compared from the default antenna's electrical features. It was found that even with the smallest dipole geometry, hybrid GP-LA antenna model exhibited the most practical outputs at 5 kHz with correct directional propagation based on its radiation pattern, a realistic receiver voltage of -8.86 dBV which is close to the default model, and a high-power efficiency of 99.925%. While hybrid GP-AOA and GP-HGSO resulted in indirect coupled transceiver systems with unsuitable antenna characteristic capacitance inducing anomalous receiver voltages. The experimental results prove the validity of the developed technique for more accurate determination of optimal antenna geometry.

Keywords—antenna geometry modeling, Archimedes optimization, Henry gas solubility optimization, Lichtenberg optimization, subsurface imaging

I. INTRODUCTION

One of the most popular geophysical imaging techniques used in a broad range of applications is subsurface imaging [1]. It is a non-destructive imaging and evaluation tool based on transmission and reception of low spectral electromagnetic

(EM) waves [2]. This working concept is proven to be very effective in studying the electrical properties of soil and is broadly used in a variety of applications, including surveying underground infrastructures such as cables and pipes, land mines, road inspections, and archaeological and geological studies. [2-3]. Subsurface mapping techniques such as electrical resistivity tomography, use of ground-penetrating radar (GPR), accelerographs, and magnetic techniques can contribute valuable data on urban engineering and environmental sites such as industrial lands, runways, and paved roads [3]. However, these methods may intercept other active signals when utilized in urban areas because these typically operate from high frequency up to ultra-high frequency spectrum. With regards to the efficiency of data acquisition and practical aspects, these approaches still require optimization of the antenna geometry [3].

The quasi-static condition in subsurface imaging is the irreversible effect that is materialized when the frequency of operation from extremely low (ELF) to very low frequency causes dynamic effects to become negligible [3]. In other words, the induction number becomes almost zero and the electrostatic geometric factor reaches one [3]. This is a condition wherein the transmitting and receiving antenna or sensors are fully capacitively coupled to the ground but still can map the electromagnetic skin depth without any change in the signal waveform. The operating frequency, geometric conditions, and ground resistivity or conductivity are factors that affect the quasi-static condition in capacitive coupling to the ground surface [3]. However, only the geometric condition of the antenna can be modified and optimized to avoid the buildup of parasitic capacitance causing matrix residual current or leakage current, ringing of the transmitter terminal, and an increase in the reflected power on the antenna transmission line [3].

Most of the antennas used in industry have no analytical formulas for parameter assessment and optimization [4]. To optimize and simulate such antennas, it is essential to utilize electrostatics modeling software such as using XFDTD antenna design software which is also widely used in the field

of engineering [4]. For antenna effects such as antenna response mismatch and coupling between transmit and receive antennas, near-field calibration can be applied to GPR using the Higher-Order Basic Integral Equation Solver (HOBBIES) EM simulation software or incorporated into LINUX software. The amount of time it takes to complete a task has been reduced, and the level of stability has improved [5-6]. To achieve optimal conditions for the activated antenna pair, the signal type and dielectric properties of the embedded object are analyzed as independent parameters using the Subsurface Imaging (SSI) algorithm and the Finite-difference Time Domain (FDTD)-based virtual tool GrGPR. Comparatively, dipole linear antenna array models associated with towing system can be improved through CST Microwave Studio Simulation Software while optimization in slot antenna geometry is devised by folding the ground of the slot antenna along the slot length to enhance the gain and lessen the backward radiation using Agilent Technologies E8362B vector network analyzer [8-9]. Antennas with small gaps in topology and complex design geometry are becoming progressively prevalent in research and existing commercial equipment, which is believed to be uncertain to use with generators of high voltages [4]. The most recent antenna geometry optimization related to capacitive resistivity imaging uses capacitive dipole [3]. Properties of the antenna were studied and optimized by modeling the capacitance of their architectural parts [3]. This technique has used the modeling of sensor capacitances to expose that the idea of point poles claimed withinside the quasi-static system of capacitive resistivity has a practical understanding withinside the form of plate-wire sensors given that the plate dimensions are limited compared with its dipole length [3]. The most suitable geometry for capacitance resistivity measurements is the use of a dipole-dipole array and data accumulation is accomplished using plate-wire combinations equatorial geometry arrangement [3]. Genetic algorithm has been mainly used also for optimizing antenna geometry based on antenna bandwidth and sensitivity [10], properties of electromagnetic poles [11], S_{11} , and gain parameters [12] that are all extracted from another simulation software. Hence, these optimization techniques are believed to be more effective and efficient through the integration of computational intelligence methods.

Computational intelligence (CI) has offered several approaches for design optimization used for subsurface imaging through population-based metaheuristic algorithms [10-12]. Various applications of Archimedes Optimization Algorithm (AOA) were to attain the best performance of a wind energy generation system, to identify the optimal model of proton exchange membrane fuel cell (PEMFC) stacks based on an improved version of the Deep Belief Network (DBN) and for improving the performance of feedforward neural networks (FFNN) [13-15]. The Lichtenberg algorithm (LA) is shown to be a powerful tool for the identification of damage in mechanical structures constructed by composite materials, providing a more exact prediction that can be useful for modeling an aluminum alloy 2025 T6 metal matrix composite reinforced with red mud [16-18]. Moreover, Henry gas solubility optimization (HGSO) was employed in the field of the automotive industry wherein it was recorded that it can

design better optimal components as well as in obtaining the best parameters in terminal voltage control of a generator in an automatic voltage regulator (AVR) system utilizing a fractional-order proportional-integral-derivative (FOPID) controller [19-21]. Given some of their applications, AOA, LO, and HGSO are said to be high-performance optimization tools that deliver superior and competitive results when solving challenging engineering optimization problems compared to other existing solving algorithms [22-24]. Thus, these methods are proposed in this study to enhance the characteristic capacitance of a single-pair equatorial dipole-dipole subsurface imaging antenna through geometry modeling. The default mathematical method optimizes the antenna results in a prolonged approach as it requires the designer to perform computation, computer-aided designing, reiterated simulations, and extraction of simulated data [10-12].

Despite the advances in antenna geometry optimization techniques for subsurface imaging, other properties of the antenna are still can be optimized by modeling the plate-wire capacitance of the antenna. To work on this emerging challenge, this study has developed a new capacitance model for optimizing the geometry of a single pair equatorial dipole-dipole antenna for very low frequency capacitive coupling to the ground using genetic programming (GP) integrated with metaheuristic optimization algorithms, namely Archimedes, Lichtenberg, and Henry gas solubility optimizers. This is vital to keep the antenna in quasi-static condition for subsurface imaging based on minimum capacitance (approaching 1 nF) to successfully transmit adequate electrical current into the ground. The suitability of AOA, LA, and HGSO was explored in optimizing the antenna geometry parameters, namely elevation of wire segment, radius of wire antenna conductor, dipole plate elevation from the ground, width, length, and thickness of plate that have a direct impact on the plate-wire capacitance of the antenna. The output of this study is an equatorial dipole-dipole antenna with a minimized capacitance that can operate at 5 kHz having higher efficiency than the default model. This study contributes to the: (1) development and application of hybrid GP-AOA, GP-LA, and GP-HGSO in minimizing the capacitance of an antenna for underground imaging in a quasi-static condition; (2) innovation of an efficient technique for faster and more accurate determination of optimal antenna geometry avoiding long mathematical computation; and (3) quantifying the correlations of antenna geometry and its characteristic capacitance.

II. MATERIALS AND METHODS

This study includes four major phases: (1) modeling of single-pair equatorial dipole-dipole antenna geometry using the standard mathematical technique, (2) application of genetic programming to develop the capacitance model, (3) minimization of antenna capacitance through metaheuristic algorithms, (4) remodeling of antenna geometry based on optimized capacitance using industry-standard software, and (5) electrical parameter comparison and statistical evaluation (Fig. 1). Evaluation of the default and proposed CI-based capacitance models are one of the highlights of this work.

Fig. 1. Developmental framework for the optimization of subsurface imaging antenna capacitance through geometry modeling using Archimedes, Lichtenberg, and Henry Gas Solubility metaheuristics

A. Single-pair Equatorial Dipole-dipole Antenna Geometry Modeling

A 5 kHz single-pair equatorial dipole-dipole antenna was 3D modeled in Altair Feko software (Altair, Singapore) based on the standard mathematical approach in determining the radius of the wire antenna segment (a , m), wire antenna elevation (h_w , m), dipole plate elevation from the ground (h_p , m), dipole length (l), dipole width (w , m), and dipole thickness (t , m) (Fig. 2). These antenna geometries are computed to comply with the quasi-static condition in which the geometric factor (K_{eq} , unitless) is approaching 1 (1) with the dipole spacing (r , m) set to 1 m. The target capacitance for this antenna configuration was made close to 1 nF by computing the wire antenna segment (C_w , F) (2) and dipole plate (C_p , F) (3) capacitances combined making a total wire-plate capacitance of $0.5(C_w + C_p)$ with ϵ_o as the free space permittivity of 8.854 pF/m, ϵ_r as the permittivity of air equivalent to 1.001, and d as the distance of the center of wire to the ground that is maintained at 0.209 m. This is to reduce stray parasitics that could affect the reception sensitivity and may drive signal reflection. The dipole spacing (r , m) from the transmitter to the receiver was maintained at 1 m to achieve the ideal induction number (B , unitless) which is approaching 0.

$$K_{eq} = \frac{\frac{1}{\sqrt{r^2+4h_p^2}} \frac{1}{\sqrt{r^2+l^2+4h_p^2}}}{\frac{1}{r} \frac{1}{\sqrt{r^2+l^2}}} \quad (1)$$

$$C_w = \frac{2\pi\epsilon_o\epsilon_r}{\text{acosh}\left(\frac{d}{a}\right)} \quad (2)$$

$$C_p = \epsilon_o\epsilon_r \left[1.15 \frac{wl}{h_p} + 1.4 \left(\frac{t}{h_p}\right)^{0.222} (2w + 2l) + 4.1 \left(\frac{t}{h_p}\right)^{0.722} h_p \right] \quad (3)$$

B. Antenna Capacitance Model Development Using Genetic Programming

Genetic programming (GP) is an evolutionary algorithm that is a hybrid of genetic algorithm and regression tree [25]. In this study, a multigene symbolic regression GP was employed through MATLAB GPTIPsv2 tool to construct the capacitance fitness function as a function of a , h_w , h_p , l , w , and t . A dataset of 241 rows generated by series of 241 computations of different combinations of antenna geometries has been used as input to GP following a stratified sampling scheme of 56% of the dataset volume is set for training the

model, 24% for validation, and 20% for testing. GP starts with initializing 100 random antenna capacitance chromosomes

Fig. 2. 3D schematic of an equatorial dipole-dipole antenna for subsurface imaging operating at 5 kHz where a is the radius of the wire antenna, h_w is the wire antenna elevation, h_p is the dipole plate elevation from the ground, and l , w , and t are the length, width, and thickness of the dipole plate.

and then evaluates the fitness value of the chromosomes (Fig. 3). Next, symbolic regression was performed using mathematical functions with a maximum of 10 genes, and a maximum tree depth of 5. It is followed by selecting 3 capacitance chromosomes through a tournament with a size of 50, 0.1 elite fraction, and enabled lexicographic selection pressure. The fittest (minimum) capacitance chromosomes make the new generation and undergo crossover and mutation with a rate of 0.84 and 0.14, respectively, with an evolutionary rate covariation probability of 0.1. After 100 elapsed generations, GP converged resulting in a capacitance mathematical topology without dipole thickness as non-significant features are neglected in the tournament selection (4). This fitness expression was used for metaheuristic modeling of antenna geometry.

$$C = f(a, h_w, h_p, l, w) \quad (4)$$

C. Antenna Capacitance Optimization Using Metaheuristic Algorithms

In this study, three metaheuristic algorithms, Archimedes optimization algorithm (AOA), Lichtenberg algorithm (LA), and Henry gas solubility optimization (HGSO) were explored in optimizing the antenna capacitance through geometry modeling based on the GP-constructed fitness function (4) (Fig. 3). Inspired by the law of buoyancy, Archimedes optimization algorithm uses the population of solutions as the objects immersed in fluid considering the parameters density, volume, and acceleration to attain neutrally buoyant objects and identify the object with the best fitness score. Part of the iterative process is to update each object's acceleration using (5) to get the new positions when the transfer function operator (TF) ≤ 0.5 , where acc_i^{t+1} is the acceleration of object i for iteration $t+1$, den_{best} , vol_{best} and acc_{best} are the best recorded object's density, volume and acceleration, respectively, while den_i^{t+1} and vol_i^{t+1} are the density and volume of object i for iteration $t+1$, respectively. [23]. Here, the object number was set to 5 representing the antenna

parameters in the fitness function and the four ranges of normalization were set to 2, 6, 0.9, and 0.1.

$$acc_i^{t+1} = \frac{den_{best} + vol_{best} + acc_{best}}{den_i^{t+1} \times vol_i^{t+1}} \quad (5)$$

Lichtenberg algorithm is based on a natural phenomenon of intra-cloud lightning where Lichtenberg figures (LF) are bitmapped in a multi-dimensional space and the particles are the candidate solutions that will be clustered according to the Diffusion Limited Aggregation theory which considers the creation radius (R_c) and stickiness coefficient (S) that influence the fractal dimension (D) (6), and density, respectively, where $N_{cluster}$ and $R_{cluster}$ are the numbers of particles and the average radius of a cluster, respectively. [22]. In this study, LA was configured with 100 population size, $1e^6$ particles for 5D search space, stick probability of 1, creation radius of 150, and refinement of 0.2 (Fig. 3).

$$D = \ln(N_{cluster}) / \ln(R_{cluster}) \quad (6)$$

Henry gas solubility optimization algorithm treats the population of solutions as gases which will be clustered by gas

type based on Henry's constant value that is necessary to obtain the new solubility in (7) where $S_{i,j}(t)$ and $P_{i,j}(t)$ corresponds to the solubility and partial pressure of gas i in cluster j during iteration t , $H_j(t+1)$ is the new Henry's coefficient of cluster j for iteration ($t+1$) and K is a constant, and position of each gas. The equilibrium state of each gas determines the best gas for each cluster where the optimal gas is chosen [24]. In this study, HGSO was configured with 100 initial gases, 5 gas types, and 2 worst gas clusters (Fig. 3).

$$S_{i,j}(t) = K \times H_j(t+1) \times P_{i,j}(t) \quad (7)$$

For AOA, LA, and HGSO, the geometric parameter boundaries were set to [0.0004, 0.2008], [1.91e⁻¹⁷, 0.5524], [0.003, 0.007], [0.1, 0.5], and [2e⁻⁵, 0.002] for a , h_w , h_p , l , and w , respectively. The three algorithms converged after 80 generations and provided the global best solution for minimized antenna capacitance with specific antenna geometry parameter values.

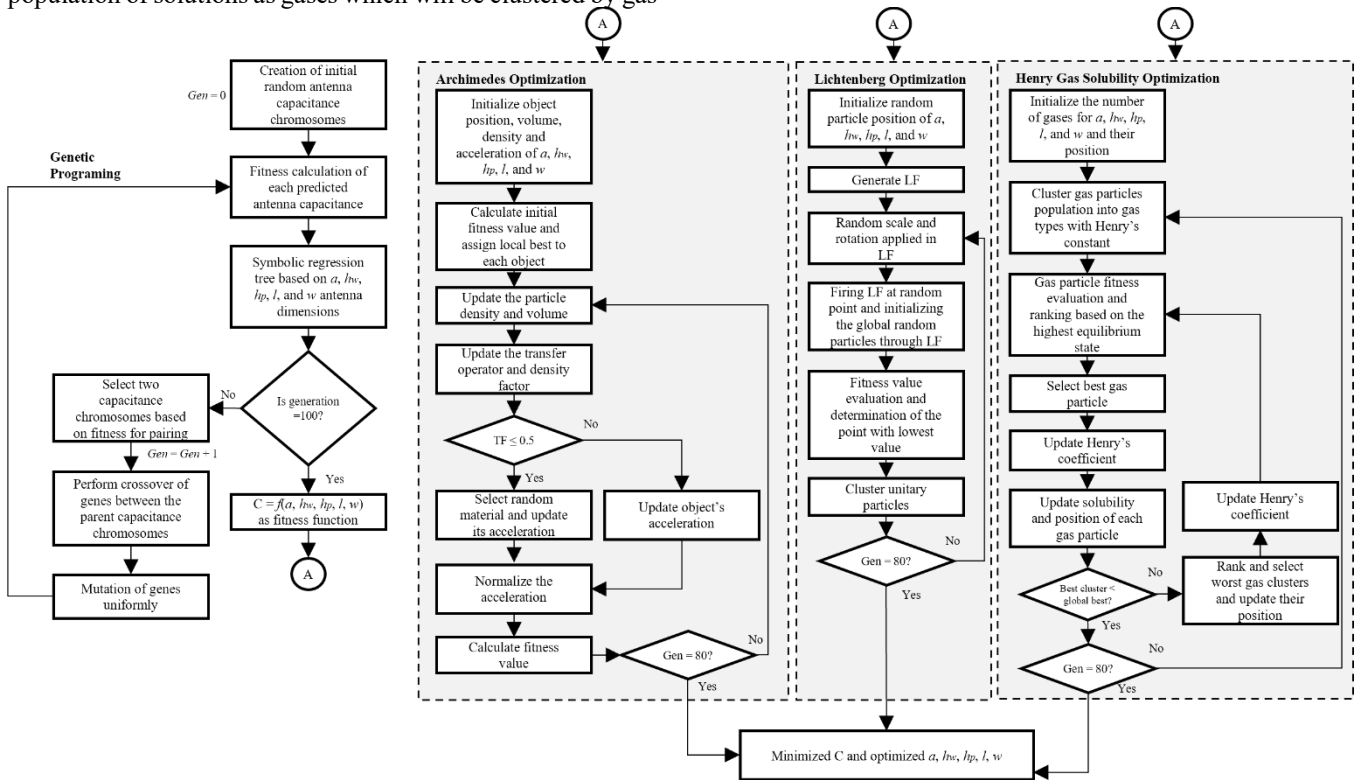

Fig. 3. Proposed hybrid multigene symbolic regression genetic programming and Archimedes, Lichtenberg, and Henry Gas Solubility optimizer framework in minimizing the value of antenna capacitance approaching 1 nF and determining the exact global best combination of the antenna geometry (radius of coaxial cable (a), antenna wire segment elevation (h_w), dipole plate elevation (h_p), and dipole plate (l) and width (w)).

D. Remodeling of Antenna Geometry Based on Optimized Capacitance Model

After a series of explorations and exploitations of AOA, LA, and HGSO, there were 3 new sets of a , h_w , h_p , l , and w of antenna geometry that influence the antenna capacitance. By using Altair Feko software, 3 3D antenna models were

designed with the following additional mechanical configurations: 1 m dipole spacing, graphite as the enclosure material, 0.003 mm enclosure thickness and 0.001 m dipole plate thickness. For the electronic configurations, antennas were simulated with 1kV and 10 W transmitter voltage and emitted power at 5 kHz operation, 5 MΩ receiver resistance. For the environment configuration, the ground plane was set

to planar multilayer substrate with soil resistivity of 3 units and the circuit box dimension to 0.2 m x 0.2 m x 0.2 m. Radiation pattern, electric and magnetic fields, voltage, and power efficiency at the receiver antenna were extracted and graphed using the same tool for the default antenna model (mathematical), GP-AOA, GP-LA, and GP-HGSO antennas. These electronic measurements served as the bases for evaluating which among the developed antenna models is the most recommended for 5 kHz subsurface imaging of roads.

E. Statistical Analysis

Pearson’s correlation analysis with $\alpha \leq 0.05$ was performed using Minitab (Minitab LLC) and surface graphs were constructed to show dynamic relationships among antenna geometry parameters and capacitance.

III. RESULTS AND DISCUSSION

A. Dynamic Relationships of Antenna Geometry and Capacitance

For all the developed antenna models, the total wire-plate antenna capacitance has a strong positive correlation to dipole plate length ($R = 0.907$) and a strong inverse correlation with plate elevation above ground ($R = -0.851$). As antenna wire segment and dipole plate width increase in size, antenna capacitance also increases moderately. On the other hand, the wire antenna’s radius weakly and inversely influences capacitance. Interestingly, if the plate elevation was increased greater than 0.006 m and the antenna wire elevation is below 0.175 m, capacitance approaches minimum (< 40 pF), and maximum capacitance of 100 pF was characterized when plate elevation is 0.006 m and wire elevation is 0.175 m (Fig. 4a). Another finding is that the antenna capacitance is almost constant given that dipole plate width ranges from 0.2 to 0.4 m and the antenna wire radius ranges from 0.02 to 0.03 m (Fig. 4b). It was also analyzed that there is a capacitance trough for the combination of dipole width below 0.2 m and antenna wire radius greater than 0.02 m. Hence, this exact issue in antenna modeling demands the potential of computational intelligence through metaheuristic optimizations.

B. Minimized Capacitance as a Requirement for Quasi-static Condition

By completing the 100 generations of 7-gene GP, it resulted in an antenna capacitance model (8) that considers the issue of non-linearity of antenna geometry. This sensitive GP-based antenna capacitance model is acceptable in this application as it scored a testing accuracy of 82.764% with negligible RMSE of $1.1049e^{-11}$ and MAE of $4.8668e^{-12}$. It was used as the fitness function for all metaheuristic optimizations.

$$C = 2.07e^{-11}h_w - 2.07e^{-11}a + 3.14e^{-10}l + 3.14e^{-10}w - 1.09e^{-10}\log(h_p) - 4.05e^{-13}\log(h_w)^3 + 1.06e^{-8}a^3 - 6.73e^{-10} \quad (8)$$

After 80 generations, GP-AOA, GP-LA, and GP-HGSO converged (Fig. 5) and provided their individual global best solution pertaining to the optimum combination of antenna’s a , h_w , h_p , l , and w for minimized capacitance (Table 1). The fitness curves in Fig. 5 show that only GP-LA and GP-HGSO capacitance models have exhibited substantial exploration and exploitation (marked with red vertical line) (Fig. 5). GP-LA

explored in advanced the 5D search space, thus, locating the cluster of particles in a constraint region as early as the 14th iteration and deliberately exploited to having a minimum capacitance of 63.5321 pF (Table 1). GP-HGSO finished its

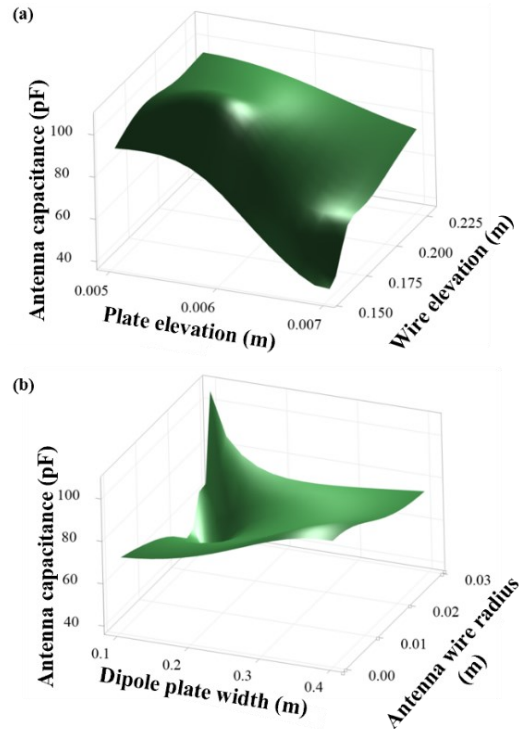

Fig. 4. Dynamics relationship of the capacitance of single-pair equatorial dipole-dipole antenna for 5 kHz operation with references to (a) plate and wire elevations and (b) dipole plate width and radius of antenna wire.

Fig. 5. Fitness curves of the developed capacitance model as optimized using Archimedes, Lichtenberg, and Henry Gas Solubility metaheuristics with a maximum generation of 80. The red vertical lines show the starting point of the exploitation stage for convergence.

exploration at a later iteration than GP-LA and has exploited at a minimum capacitance of 106.5584 pF (Table 1). On the other hand, GP-AOA did not exhibit any exploitation even if the iteration has been extended to 1000. It suggests that GP-AOA neither had a premature convergence nor converged properly even if the resulting capacitance turned to 40.103 pF (Table 1). As compared with the default model, the developed metaheuristic models’ optimum capacitances are just below

and above its value signifying that these hybrid models are acceptable. Likewise, these findings show that the extracted antenna geometry by GP-AOA, GP-LA, and GP-HGSO are within a realistic range (Table 1).

TABLE I. SUMMARY OF ANTENNA GEOMETRY CONFIGURATIONS AS RESULTS OF DEFAULT MODEL AND PROPOSED METAHEURISTIC ALGORITHMS AND THE CORRESPONDING ANTENNA CAPACITANCE (DIPOLE PLATE = 0.001 M)

Antenna Model	a (m)	h _w (m)	h _p (m)	l (m)	w (m)	C (pF)
Default	0.7813e ⁻³	0.2286	0.005	0.4000	0.4000	94.6080
GP-AOA	0.0227	0.1549	0.0069	0.1474	0.1233	40.1031
GP-LA	0.0277	0.1762	0.0070	0.1001	0.1012	63.5321
GP-HGSO	0.0292	0.1800	0.0056	0.5655	0.1000	106.5584

This study conforms to the trend of hybridization of multigene genetic programming with other population-based optimization metaheuristics [25-33]. Previous studies in equatorial dipole-dipole antenna optimization have only dealt with applying genetic algorithm to optimize the geometry based on bandwidth and sensitivity [10], properties of electromagnetic poles including S₁₁ and gain parameters [11, 12] that are all extracted from another simulation software. Hence, the proposed approach of employing computational intelligence is an efficient technique for faster and more accurate determination of optimal antenna geometry avoiding long mathematical computation. Here, instead of performing iterative manual computing of quasi-static condition requirements based on altered combinations of antenna geometry, the optimum characteristic capacitance can be determined basically by using the developed fitness function (8) and the intelligent metaheuristic model will optimize the independent parameters.

C. Enhanced Antenna Geometry Yielded through Capacitance Minimization

For an equatorial dipole-dipole antenna operating at a very low frequency (5 kHz) for subsurface imaging, considerably high characteristic capacitance may negatively influence the directivity of the antenna and produce reactance that will make the antenna resistive causing it not to emit the signal properly. The antenna geometries generated using the default technique, GP-AOA, GP-LA, and GP-HGSO were modeled resulting in radiation spectrums (Figs. 6a to 6d). Note that the dipole length and width are significantly varied in each model causing diverse radiation patterns (Figs. 6a to 6d). It is noticeable that even with the small dipole geometry of the GP-LA antenna, there is no signal reflection and there is directional emission (Fig. 6c).

Because the length recommended by GP-HGSO is 564.935% longer than the GP-LA, the dipole spacing between the transmitter and receiver becomes significantly closer causing widened electric field and magnetic field at the receiver (Figs. 6e to 6f). This instance is probably because of direct coupling due to close proximity. The electric and magnetic fields exhibited by the receiver of GP-LA antenna

mimic the detection of an object as they are condensed in specific proximity (Figs. 6e to 6f). One of the strong bases for evaluating which among these antenna models is the most recommended for subsurface imaging application is the receiver voltage in which the GP-LA records a -8.86 dBV (0.361 V) which is realistic and close to what the default model (standard) records that is -22.5 dBV (0.075 V) (Fig. 6g). This is supported by previous studies that when the transmitted signal is rated above 1 kV operating at very low to high frequency, the receiver voltage signal should just be around microvolt to 2 V [5, 7, 8, 12]. The pronounced receiver voltage values of GP-AOA and GP-HGSO, 38.459 V and 8.913 V respectively, are mainly because of indirect coupling of transmitter and receiver dipoles and unsuitable antenna characteristic capacitance. Moreover, in the case of power efficiency, all models got a high rating with a lowest of 98.658% (default model) and a highest of 99.953% (GP-HGSO) (Fig. 6h). This is to emphasize that GP-HGSO got a high power efficiency rating because of its coupling issue whereas the GP-LA antenna given its practical receiver voltage value, exhibited a 99.925% power efficiency considering this model as the most recommended antenna for VLF subsurface imaging. In subsurface imaging of utilities in urban roads, the characteristics exhibited by GP-HGSO antenna are not recommended as very shallow or probably no utilities will be mapped out, while GP-LA is highly recommended as there is correct directional propagation that is penetrating through the ground and the receiver is sensitive enough to detect the reflected signal at the same phase of the transmitted current. To sum it up, an equatorial dipole-dipole antenna does not require a high voltage reading at the receiver end, instead, it demands sensitivity and proper coupling through manifesting quasi-static condition. And quasi-static condition extendedly requires minimal characteristic capacitance close to 1 nF. This study has established an understanding that the capacitance of 63.532 pF is enough to provide high efficiency and sensitive receiver antenna. This study is limited in thorough experimentation and analysis of the possible impact of different transmitter voltage levels, which could be a good recommendation for future studies.

IV. CONCLUSION

This study proposed a new technique for optimizing the capacitance of an equatorial dipole-dipole antenna operating at a very low frequency for subsurface imaging of utilities embedded beneath the road through the integration of computational intelligence. Combining 7-gene genetic programming (GP) with Archimedes optimization algorithm (AOA), Lichtenberg algorithm (LA), and Henry gas solubility optimization (HGSO) resulted in varied antenna geometries and electrical characteristics. With this, 4 antenna models were developed, namely the default mathematical antenna model, GP-AOA, GP-LA, and GP-HGSO from which the GP-LA exhibited the most practical geometry, realistic sensitivity, and efficient power system. Antenna geometry and signal coupling present in GP-AOA and GP-HGSO negatively influences the electric and magnetic fields and received voltage signal. Dipole length and elevation greatly affect the characteristic capacitance of the antenna. Lastly, this study innovated an efficient technique for faster and more accurate

determination of optimal antenna geometry avoiding long mathematical computation as proven by the GP-LA antenna model. For future studies, variation of transmitted signal

electrical parameters including voltage, frequency, and signal waveform may be done to further improve the antenna model.

Abstract — This work outlines an adaptive non-linear model-based PI like control scheme for the spherical tank level system. The efficiency of the model-based PI like control law is implemented by conducting simulation studies on the spherical tank system. The servo compliance with above said control problem exhibit satisfactory performances. Simultaneously, model state(s) and the influential model parameter(s) were estimated using unscented Kalman filter algorithm and the updated state values of the process model were employed to derive the control strategy. From the effective analysis, it has been observed that the model-based PI like control scheme utilizing non-linear Kalman filter strategy offers better performance over the traditional non-linear model-based PI like controller.

Keywords — Spherical tank, Non-linear model based PI like control, Derivative free Kalman filter, Parameter estimation.

1. INTRODUCTION

Adaptive control schemes like Gain-scheduling (GS), Self-tune-control (STR) and Model-reference-adaptive-control (MRAC) are the well-recognized strategies to control different plants, in which parameter(s) value changes with time. The plethora of designing technique based on closed-loop control performance and robustness criteria are currently available to design the above mentioned adaptive control schemes (Astrom and Wittenmark, 2011).

Literature survey reveals that the following control schemes have been already designed and implemented on the variable area tank systems (e.g. conical or spherical tank): gain scheduled adaptive controller (Astrom and Wittenmark, 1995; Anandanatarajan et al. 2006 and Greg McMillan, 2010). Robust STR (Tan et al. 2001), fuzzy logic controller (Sakthivel et al. 2008), optimal controller using dynamic programming (Bhuvanewari, 2009) and neural network based adaptive control scheme (Bhadra et al 2019, Panda and Panda 2018). To the best of our knowledge, adaptive non-linear model-based PI like control law for controlling liquid level in the spherical tank system has not been reported in the literature.

An optimization-based solution technique would necessarily be devoted to enhance controller performance and is therefore highly desirable. Designing prediction-based control algorithm relies under optimal trade-offs between objective derived on the basis of performances indices and the computational complexity (J.E.G. Refsnes, 2007). Since,

‘controller-observer’ type of combined logic fairly deals with intrinsic robust features in a straightforward manner (Wang et al. 2014) To construct a stable estimator for the continuous-time dynamical system, Kalman filter (KF) would be well suited with/without presence of the plant uncertainty (Subbotina & Tokmantsev, 2014).

Motivated by the increasing need to develop state-of-art ‘direct way of NMBC’ and ‘prediction logic-based’ control implementation for both SISO/MIMO types of processes, a newly developed control strategies were illustrated, taking into account effectiveness, easily deployable, reliability and robustness. Due to difficulties of obtaining measured values of the process parameter(s) from the real plants in several scenarios, an online estimation technique would necessary be exploited to synthesize the estimated parameter(s) value (Liu et al. 2014, Morari and Lee, 1999). The proposed attempt leads to a control framework, where predicted values of the effective model parameters (using non-linear KF approaches) were taking into consideration and the values of the model state(s) and the controller gain were derived implicitly by predicted values of the process parameter(s). Finally, the predicted and the corrected part of the manipulated variable have been determined.

The remainder of this article is given as: A detailed of the literatures and the motivational section was offered in section 1. Section 2 deals with process description of the spherical tank system. The control strategy has been described in section 3. Simulation based realistic results are reported in section 4, Section 5 concludes with an effective analysis.

2. PROCESS DESCRIPTION

The processes considered for the simulation study are spherical tank level process. The first principle equation for the spherical area tank system considered for the simulation study is given below:

$$A(h) \frac{dh}{dt} = F_{in} - F_{out} \quad (1)$$

Here, $A(h)$ indicate area of the tank. (F_{in} or q) and F_{out} signifies inflow and outflow rate of the tank respectively. h is the liquid level. The relationship exhibits between outlet rate (F_{out} or q_{out}) and the liquid height (h) in this tank is mentioned below:

$$F_{out} = c_v \sqrt{2gh} \tag{2}$$

Here, c_v specifies valve co-efficient. Note that, area of the variable tank varies with respect to liquid height in this tank. The area of the tank is computed using the below equation:

$$A(h) = \pi [2rh - h^2] \tag{3}$$

Here, r indicates maximum radius of the tank. Maximum radius and height are chosen as 30 cm and 60 cm respectively. The schematic diagram of the spherical tank process is presented in figure1. Disturbance can be introduced either through changing of downstream valve or adding liquid through q_0 .

Figure1: Schematic diagram of spherical tank system

3. PROPOSED ADAPTIVE NON-LINEAR MODEL-BASED PI LIKE CONTROLLER

This work, introduces a non-linear model-based PI like controller to control the liquid-level in the spherical tank system. The control algorithm is formulated as:

$$F_{in}(i) = \alpha * \theta_{k_c}(i) [h_{sp}(i) - h(i)] + \theta_{bias}(i) \tag{4}$$

$$\theta_{k_c}(i) = \theta_{bias}(i) / \hat{h}(i|i-1) \tag{5}$$

Here, h_{sp} indicates set-point. $\hat{h}(i|i-1)$ is the one step ahead predicted height. Controller gain (θ_{k_c}), bias (θ_{bias}) and (α)

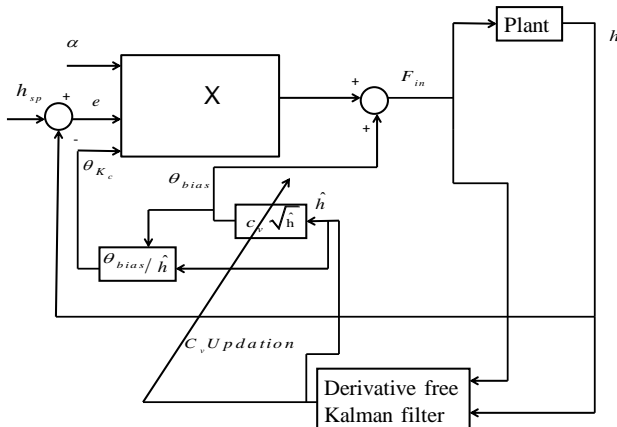

Figure2: Schematic diagram of the developed adaptive non-linear model-based PI like controller.

specifies parameters of the developed control methodology. The pictorial representation of the said control law is presented in figure2. The system equations with model parameters are as follows:

$$\hat{\theta}(i) = \hat{\theta}(i-1) + w(i-1) \tag{6}$$

$$\hat{\theta}(i) = [c_v] \tag{7}$$

$$h(i) = F[h(i-1), F_{in}(i-1), \hat{\theta}(i-1)] + v(i) \tag{8}$$

'h' represents measured output of the plant. 'w' and 'v' are zero mean, independent, Gaussian process noise and measurement noise respectively. 'Q', 'R' signifies noise covariance matrix of the process and measurement noise respectively. The predicted model parameter estimates can be computed as

$$\hat{\theta}(i|i-1) = \hat{\theta}(i-1|i-1) \tag{9}$$

The co-variance matrix with estimated errors in the predicted model parameter estimates are determined as:

$$P_{\theta}(i|i-1) = P_{\theta}(i-1|i-1) + Q \tag{10}$$

Here, the set of (2L+1) sigma-points with the associated weights $w(k)$ are chosen symmetrically about $\hat{\theta}(i|i-1)$ as:

$$\theta_s = [\hat{\theta}(i|i-1), \hat{\theta}(i|i-1) + \sqrt{(L+\kappa)P_{\theta}(i|i-1)}, \hat{\theta}(i|i-1) - \sqrt{(L+\kappa)P_{\theta}(i|i-1)}] \tag{11}$$

Since, measurement-prediction ($\hat{h}(i|i-1)$), computation-of-innovation ($e_{i|i-1}$) and covariance-matrix with innovation ($P_{ee}(i)$) and the cross-covariance-matrix between the predicted parameter estimate errors and innovation ($P_{\theta_e}(i)$) are computed as:

$$\hat{h}^i(i|i-1) = F(h(i-1), F_{in}(i-1), \theta^i(i|i-1)) \tag{12}$$

$$\hat{h}(i|i-1) = \sum_{i=0}^{2L} w_i (\hat{h}^i(i|i-1)) \tag{13}$$

$$e_{i|i-1} = \hat{h}(i) - h(i) \tag{14}$$

$$P_{ee}(i) = \sum_{i=0}^{2L} w_i (\hat{h}^i(i|i-1) - h_r(i|i-1))(\hat{h}^i(i|i-1) - h_r(i|i-1))^T + R \tag{15}$$

$$P_{\theta_e}(i) = \sum_{i=0}^{2L} w_i (\hat{\theta}_s^k(i|i-1) - \hat{\theta}(i|i-1))(\hat{h}^i(i|i-1) - h_r(i|i-1))^T \tag{16}$$

Where, $w_0 = \kappa / (L + \kappa)$ and $w_i = 1 / (2(L + \kappa))$. Here, κ is a tuning parameter. The Kalman-gain is derived as:

$$K = P_{\theta_e} (P_{ee}^{-1}) \tag{17}$$

The updated values of the model-parameter estimates are determined using following relation:

$$\hat{\theta}(i|i) = \hat{\theta}(i|i-1) + K e_{i|i-1} \tag{18}$$

The covariance-matrix of the estimated-errors with updated model-parameter estimation is derived by:

$$P_{\theta}(i|i) = P_{\theta}(i-1|i-1) - K P_{ee} K^T \tag{19}$$

In case of non-linear model based PI like controller, the control logic can be derived using Equation (4-5).

4. RESULTS AND DISCUSSION

1) Open loop study:

To identify the open-loop responses of the spherical-tank system, combination of positive and negative steps in the controller output were introduced. Figure 3(a) shows the step wise variation in the manipulated variable (f_{in}). The changes in the process variable (h) is depicted in figure 3(b).

Figure3. Open-loop assessment of the spherical-tank level system: (a) change in manipulated variable, (b) process variable.

2) Servo-Regulatory response of spherical tank system with non-linear model based PI like controller:

To identify the servo performance and disturbance attenuation capability with non-linear model-based PI like control scheme, stepwise variation in the downstream valve co-efficient as reported in figure 4(c) was propounded. The servo-regulatory response of the spherical-tank level system with non-linear model-based PI like controller is portrayed in figure 4(a). From figure 3(a), it can be observed that the non-linear model-based PI like control method is capable of rejecting disturbances and also able to track the predetermined set value. Evolution of manipulated variable is depicted in figure 4(b). From the simulation study; we can conclude that the disturbance response of the proposed PI like control technique is found to be very sluggish in nature.

Figure4. Servo-regulatory compliance of the spherical-tank level process with non-linear model-based PI like controller (a) process variable, (b) manipulated variable, (c) variation in downstream valve co-efficient (PV: process variable).

3) Servo-regulatory compliance of the spherical-tank level process with proposed adaptive non-linear model-based PI like controller using UKF:

To identify the servo performance and disturbance elimination ability of the proposed adaptive non-linear model-based PI like controller, stepwise variations with downstream valve co-efficient as depicted in figure 5(c) was propounded. Table1 provides values associated with Kalman filter-based parameter estimation technique. The servo-regulatory

Table1. Filter specifications associated with EKF/EnKF/UKF based parameter estimation schemes employing on spherical tank system

Parameter	Value
Measurement noise covariance (R)	1e-8
Process noise covariance (Q)	1e-8
α_1, β and κ	1, 0 and 0
Initialization of parameter (b_0) i.e., $\hat{\Theta}(0 0)$	0.5
Initial error covariance $P(0 0)$	0.25

performance of the spherical-tank level system with adaptive non-linear model-based PI like controller utilizing UKF is presented in figure 5(a). From figure 5(a), it can be concluded that the proposed control law is capable of rejecting disturbances and also able to track the desired level. However, the controller preserves sluggish responses while attenuating disturbances. The variation in manipulated variable is depicted in figure 5(b). From the simulation study; we can conclude that the disturbance response of the non-linear model-based PI like control method is found to be satisfactory. Figure 5(c) and 5(d) shows evolution of the true and estimated value of the downstream valve co-efficient respectively.

Figure5. Servo-Regulatory compliance of the spherical-tank level process with proposed adaptive non-linear model-based PI like controller (a) process variable, (b) manipulated variable, (c) evolution of downstream valve position, (d) estimated c_v .

3) Performance assessment of different controllers:

In order to assess qualitative performances with different level of control actions like servo-regulatory compliance, a performance-based chart like computation time (CT, Table 2), MSE (see Table 3)) were provided. Table 2 shows that proposed adaptive non-linear model based PI like controller using UKF strategy performs better over non-linear model based PI like control approach. As lesser MSE value resulted faster convergence and better accuracy, hence it can be embodied that newly developed control strategy provides faster set point tracking capabilities compared to the traditional model based PI control approach.

Table2. CT per sampling instant with different control schemes on spherical tank system.

Control scheme	Servo-Regulatory (F_{in})
Proposed scheme	1e-02 – 2.5
non-linear model based PI like controller	1e-02 – 2.9

Table3. MSE chart for different control schemes on spherical tank system.

Control scheme	Servo-regulatory
Proposed	5.0217e-05
non-linear model based PI like controller	8.6294e-05

5. CONCLUSION

In this paper, we have successfully designed and implemented an adaptive non-linear model-based PI like control algorithm. From the extensive study on the simulated models of the spherical tank level system, it can be inferred that the servo-regulatory performances of the proposed adaptive non-linear model-based PI like control strategy preserved satisfactory results compared to the traditional non-linear model-based PI like control framework. Further work is in progress to validate the proposed adaptive control algorithm on the experimental spherical tank test rigs available at the process control lab in the Department of Electronics & Communication Engineering, Institute of Engineering and Management, Kolkata.

A Novel Multifaceted Deep Learning-Based Mobile Application for Accurate and Efficient Waste Classification and Increased Composting Engagement in Communities

Samyak Shrimali
Jesuit High School
Portland, Oregon, USA
samyak.shrimali12@gmail.com

Abstract— Solid food waste is slowly accumulating around the world in landfills. This waste is hazardous to human health and our environment when it decomposes as it leads to widespread release of greenhouse gasses such as CO₂ and methane. Composting household waste actively can put wasted food to good use by creating arable soil and help mitigate the waste crisis that causes climate change. But currently, the general public finds it hard to manage and classify exactly what item is compostable and non-compostable. Furthermore, there is lack of motivation, incentive, and community support for composting waste actively. This paper proposes CompostAI, a novel deep learning-based mobile application targeted to make community participation in composting easy and socially engaging. This application uses a Xception convolutional neural network (CNN) model to classify waste into seven categories: compost, paper, cardboard, glass, metal, trash, plastic. The Xception model demonstrated optimal performance as it had the highest accuracy of 78.43% and F1 score of 81.22 out of the six CNN model trained, validated, and tested. CompostAI also has supplemental features that include allowing users to announce local sustainability events, find nearby composting centers, and learn new sustainable living techniques. CompostAI successfully makes community participation in composting easy and socially engaging, increasing composting rates and mitigating the detrimental waste crisis that leads to climate change.

Keywords—Artificial Intelligence, Convolutional Neural Networks, Waste Classification, Image Classification, Societal Computing

I. INTRODUCTION AND LITERATURE REVIEW

In the United States of America, more than 80 billion pounds of food waste is generated each year and more than 87% of this waste ends up in landfills. This leads to the release of over 3.3 billion metric tons of carbon dioxide [1]. Furthermore, this waste decomposes and releases methane into our atmosphere which has 21 times more warming potential than carbon dioxide [2]. This waste crisis is a prominent catalyst of climate change and can be easily mitigated if the general public composts their household waste actively. Composting can help divert food waste from landfills and help mitigate climate

change, while fostering environmental and economic benefits [3].

The primary reasons the general public does not compost is because of the hurdle of distinguishing between compostable/non-compostable material and lack of motivation, incentive, and community support. It is hard for people to read and understand often incomplete signs and boards near waste bins which cover only a few examples of the compostable/non-compostable material. Current practices for the general public to distinguish between compostable and non-compostable material are based upon significant research and support from the world wide web and local composting centers, this is a very labor some, manual, and error-prone process [4]. The general public is in dire need of an easy-to-use tool that can efficiently and accurately distinguish between compostable and non-compostable materials and also motivate them to compost regularly

A few researchers have approached the problem of waste classification using CNN image recognition models. Thung et al. designed TrashNet to classify waste into five classes of recycle and waste. Their model did not achieve a high accuracy; their accuracy was 63% showcasing high prediction error [5]. Researchers from the Indian Institute of Technology designed SpotGarbage uses GarbNet, a custom CNN, to identify garbage on streets. Instead of classifying waste into specific sectors, GarbNet just identified the presence of waste [6]. Both, TrashNet and GarbNet do not classify compostable material or food waste but are examples of potential of CNNs for waste classification applications.

Researchers like Salimi et al. and Gupta et al., have approached this problem in novel way by designing a smart disposal bin which uses several expensive industrial-grade sensors and hardware to classify waste as trash or plastic, but it is ineffective for large scale implementation around the globe [7] [8].

Smartphones have not been previously considered for this application but can be as since they provide high resolution displays, efficient computing power, and a built-in set of accessories (ex. cameras, speakers, etc.). They are also widely accessible, as of 2022, there are over 6.6

billion smartphone users around the world, and this number is projected to keep increasing [9]. The combined factors of widespread smartphone usage, access to high-definition cameras and computing processors in mobile devices lead to a situation where waste classification based on automated image recognition, if technically feasible, can be made available at an unprecedented scale and work to help mitigate climate change.

II. SOLUTION AND METHODOLOGY

This paper presents CompostAI, a novel deep learning-based mobile application targeted to make community participation in composting easy and socially engaging. This application will use state of the art convolutional neural network (CNN) and image classification techniques to identify an object into seven compostable (compost, paper, cardboard) and non-compostable (glass, metal, trash, plastic) classes. It will provide users with a platform to announce local sustainability events, find nearby composting centers, and learn new sustainable living techniques (such as self-composting, planting trees, etc.).

The development of this application was split into multiple phases. In phase one, an efficient and accurate deep-learning model was designed through a comparative analysis of several state-of-the-art convolution neural networks. To find and develop an optimal model, first, an image dataset was obtained and pre-processed. This dataset was acquired from the UC Santa Cruz data repository and consisted of 2,678 images referring to seven classes: compost, paper, cardboard, glass, metal, trash, plastic [10]. The goal was to determine the proper waste class for an item from an image and then classify the item as compostable/non-compostable.

Fig. 1. Example images of a compostable and non-compostable items from the UC Santa Cruz waste dataset [10]

The images were originally 400x300 pixels and using the IMREAD and IMRESIZE functions of the OpenCV python library, they were resized to 224x224 pixels for the CNNs. The dataset was split into a ratio of 80%:15%:5% for training, validation, and testing, respectively.

Fig. 2. Visual representation of the dataset split and number of images in each class

After the image dataset was ready, six different CNNs were designed to explore which led to efficient and accurate waste classification. Each CNN was based on a unique model architecture and varied in size. The CNNs used for the comparative analysis were: Xception, VGG-19, InceptionV3, InceptionResNetV2, MobileNetV2, NASNetMobile [11]. These are considered six of the most accurate, size-efficient, and effective model architectures for vision tools and multiclass classification problems. All these CNNs were initialized with the ImageNet dataset and used pretrained weights [11].

Model Comparison							
Model	Size (MB)	Top-1 Accuracy	Top-5 Accuracy	Parameters	Depth	Time (ms) per inference step (CPU)	Time (ms) per inference step (GPU)
Xception	88	0.79	0.945	22.9M	81	109.4	8.1
VGG-19	549	0.713	0.9	143.7M	19	84.8	4.4
InceptionV3	92	0.779	0.937	23.9M	189	42.2	6.9
InceptionResNetV2	215	0.803	0.953	55.9M	449	130.2	10
MobileNetV2	14	0.713	0.901	3.5M	105	25.9	3.8
NASNetMobile	23	0.744	0.919	5.3M	389	27	6.7

Fig. 3. Comparison chart of the six CNNs considered for a comparative analysis [11]

The models used convolutional layers to extract specific features from the images for identification, max polling layers to down sample the size of the training/validation data, flatten layers to shorten the dimensions of the input, and dense layers to align feature-based predictions to certain categories. To ensure that the models did not pick up the noise between images, additionally to their architectures, dropout and regularization layers were added to monitor their speed of learning and restrict them from overfitting on the dataset.

Through the usage of the OpenCV library, due to the fairly limited dataset size, images were augmented during the training process. Each image was rotated an angle of 0, 45, 90, 180, and 270 degrees, reflected across the x/y axis, cropped, and blurred [12]. This ensured that the model would be able to extract features for a number of different scenarios and improve its downstream performance.

Xception [13] had the highest classification accuracy of 78.4% out of the five other CNNs trained, validated, and tested in this process, therefore, it was chosen as the most optimal model for CompostAI's mobile application.

In phase two, the Xception model was converted from a h5 file to a tflite file for usage on mobile devices using the TensorFlow Lite library. This tflite model was then deployed onto the Android Studio developing environment where it was integrated to make a camera-based classification algorithm.

CompostAI is multifaceted and consists of a number of unique features for its users. In phase three, its internal features and user interface were developed. CompostAI's main feature is that it allows users to scan an item and determine if it is compost, paper, cardboard, glass, metal, trash, or plastic, and compostable/non-compostable using the Xception CNN model. CompostAI's supplemental features include allowing users to announce local sustainability events, find nearby composting centers, and learn new sustainable living techniques. Figure 4 shows images of CompostAI's user interface and its various application features

Fig. 4. Screenshots from CompostAI's mobile application user-interface

III. RESULTS

CompostAI has been through multi-level testing and data analysis. In the initial CNN comparative analysis stage, six different CNNs were designed, trained, validated, and tested. The Xception model was chosen as the most optimal model for CompostAI's waste classification feature as it had the highest classification accuracy of 78.43% and F1 score of 81.22.

Fig. 5. Comparison of each CNNs validation accuracy and validation loss

In addition to validation accuracy and loss, precision, recall, and F1 score were also used to evaluate each CNN

model. Figure 6 shows the different evaluation metric values considered to determine the most optimal CNN.

A. *Precision*: True positive predictions divided by the total number of positive predictions, helps indicate the quality of a positive prediction made by the CNN model.

$$Precision = \frac{TP}{TP + FP}$$

B. *Recall*: True positive predictions divided by the number of true positive predictions and false negative predictions, helps indicate the quality of the CNN in identifying true positives.

$$Recall = \frac{TP}{TP + FN}$$

C. *F1 Score*: Harmonic mean of Precision and Recall, helps indicate the tradeoff between the CNN model's quality in making positive predictions and in identifying true positive

$$F1\ Score = 2 \cdot \frac{Precision \cdot Recall}{Precision + Recall}$$

Convolutional Neural Network - Evaluation Metrics					
Model Architecture	Validation Accuracy	Validation Loss	Precision	Recall	F1 Score
InceptionV3	77.91	1.126	75.23	78.32	77.21
Xception	78.43	0.807	79.92	81.75	81.22
MobileNetV2	66.1	1.178	64.63	67.32	66.83
VGG19	61.02	1.205	60.23	62.74	61.62
NASNetMobile	75.23	0.971	74.86	75.93	75.78
InceptionResNetV2	72.18	1.072	74.28	70.59	73.12

Fig. 6. Evaluation metrics used to determine the most optimal CNN for waste classification

After the Xception model was integrated with CompostAI and the application's user interface and internal algorithms were developed, real-time testing was conducted to further validate CompostAI's waste classification feature. 45 unique items were brought for diagnosis and CompostAI could predict that 41 of them were compostable/non-compostable correctly.

Fig. 7. Normalized confusion matrix of the results from the 45 real-time waste classifications

CompostAI was also presented to 25+ field experts at local composting centers and as a whole, they stated CompostAI significantly aids the general public in waste classification and will ensure they will compost regularly. They also stated that it has the ability to immensely mitigate the waste crisis and climate change.

IV. CONCLUSION

This paper presented CompostAI, a smart solution to make community participation in composting easy and socially engaging to all-in-all increase composting rates and mitigate the detrimental waste crisis that leads to climate change. In conclusion, through comprehensive testing, analysis of results, and expert feedback, CompostAI was a success. The waste classification feature can accurately and efficiently differentiate between more than 30 common compostable and non-compostable items. It is based on an effective and thoroughly trained, tested, and validated neural network that was designed through a comparative analysis of six different convolutional neural networks, each based on a unique model architecture. The chosen Xception model has a high classification accuracy of 78.43% and F1 score of 81.22 and works extremely well as validated with real-time testing. CompostAI's mobile application is thorough and comprehensive, it enables users with composting resources, provides community connection for sustainable choices, and allows users to educate themselves on environmental topics in a simple manner. CompostAI mitigates all the problems with current solutions and creates direct positive human impact.

Future plans for CompostAI include partnering with governments and other nonprofit organizations to enable a rewarding system that reward users for their composting contributions with monetary prizes and create a self-sustaining cycle.

ACKNOWLEDGEMENT

The author would like to thank his family, teachers, and mentors for their invaluable support during his research journey. He would also like to thank the various industry experts who were able to provide him with valuable feedback on his work during the testing and validation phase.

Abstract—The severe accident that occurred in 2011 brought a significant concern to the world, especially in nuclear reactor technology, one of which is decommissioning. Given the radioactive contamination, the decommissioning process requires extensive information, including the knowledge of the chemical composition of the liquid inside the reactor post-accident. The harsh environment limits the choice of technology. The observation must be done using a remote technique. This work discusses the development of a remote elemental analysis technique to visualize as well as analyze the chemical composition of the liquid inside the reactor, using ultrasound technique, namely sonoluminescence. Spectral analysis of alkali metal and alkaline earth solutions (such as NaCl, SrCl₂, and CaCl₂) was conducted to confirm the feasibility of remote elemental analysis using sonoluminescence. The optical system using fiber optic and spectral analysis methods enables remote analysis. The simultaneous confirmation using a camera and developed image analysis algorithm based on the HSV method was conducted to confirm the presence of sonoluminescence.

Keywords—Remote analysis, sonoluminescence, ultrasound, spectrum analysis

I. INTRODUCTION

Post-Fukushima Nuclear Power Station accident in 2011, more attention was put on the post-accident treatment: removing spent fuel, identifying and retrieving fuel debris, and treating contaminated water [1]. Over the past 11 years, researchers have proposed and developed various methods such as radioactive level analysis [2], detection of fuel debris [3], and inspection using a robot with a video camera [4]. This has successfully removed the spent fuel from unit 4 in December 2014 and from unit 3 in February 2021 [5,6]. However, the retrieval of fuel debris and the treatment of contaminated water are still undergoing the process [7]. Some elemental analysis systems were proposed to enhance the efficiency of the process [8]. The elemental analysis system is required to have high radiation durability. The existing elemental analysis devices are mainly huge and have low radiation durability [8]. Therefore, the development of remote elemental analysis using the well-known ultrasound phenomena, Sonoluminescence (SL), is proposed to tackle the harsh conditions inside the reactor. The idea is to attach the ultrasound sensor to the robot with fiber optic light

transmission, enabling remote analysis. A combination of robot and ultrasound technology to perform the remote analysis has been developed [9, 10]

While the study of SL has been widely known among ultrasound researchers, the development of remote elemental analysis serves particular challenges. The basic principle of SL elemental analysis is that a high-intensity ultrasonic wave produces cavitation bubbles that repeatedly grow and are adiabatically compressed in an argon saturated solution, hence the plasma production. The plasma production then induced ionization reactions and photon emission. The photon emitted a particular wavelength for each element. [11, 12]

The development of the purpose as mentioned above requires careful measures in every step. Knowing the nature of SL requires saturated argon gas [13] and an appropriate optical system to analyze the light emission remotely. The conceptual design of remote elemental analysis using SL is shown in Figure 1.

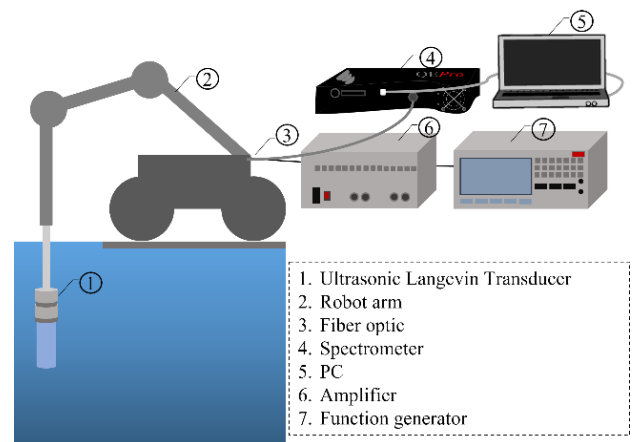

Fig. 1. Conceptual design of remote elemental analysis using SL

The designing process of the remote elemental analysis was divided into four stages: The fundamental study using a commercial bath-type ultrasound transducer, in which the

specific light emission for each element was confirmed and the operating parameter was obtained [14]; the initial steps of remote analysis performed using Langevin transducer, which allows the analysis using a smaller probe, hence, enable the remote sonication [15]; the operation of SL under a flowing solution, to confirm the feasibility on the actual application; finally, the light transmission analysis using the optical system and fiber optics. While the first three steps have been successfully carried out, the last step is still underway.

In this present work, the preliminary results of the development of a remote light analysis system using fiber optic and the spectrometer, including a confirmation using an additional method, are presented.

II. EXPERIMENTAL METHOD

A. Material

Figure 2 shows the schematic of the experimental apparatus used in this work. The experimental apparatus consists of 2 main parts: ultrasound generation and optical analysis systems. The former consists of an ultrasound transducer unit, an ultrasound controller with three operating frequencies (26 kHz, 78 kHz, and 130 kHz), and a power range around 0-50 W (commercial product by KAIJO, QUAVA mini QR-001), sample container.

As of the latter, the SL spectrum analysis system was performed based on a standard OES spectrum analysis principle to analyze the chemical components of the sample. A focusing optic is a convex lens with a diameter of $\varnothing 75$ mm (Thorlabs, Inc.) and $\varnothing 50$ mm (Thorlabs, Inc.), a multimode optical fiber bundle (bundle of seven core fibers with a total light-receiving area of 14 mm^2), and a Czerny-Turner spectrometer (Ocean Insight – QEPRO HC-1 with wavelength range 200-950 nm, grating 600-1200 lines/mm, slit $10 \mu\text{m}$, FWHM $1.6 \mu\text{m}$) were used.

The samples used in the experiment are strontium chloride hexahydrate $\text{SrCl}_2 \cdot 6\text{H}_2\text{O}$ (FUJIFILM Wako Pure Chemical Corp, guaranteed reagent grade, assay 99.0 %), calcium chloride dihydrate $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$ (FUJIFILM Wako Pure Chemical Corp., guaranteed reagent grade, assay 99.0%), and sodium chloride NaCl (FUJIFILM Wako Pure Chemical Corp., guaranteed reagent grade, assay 99.5%), The purified water (ion-exchanged water) was used for the preparation of each sample. Solutions were filled into a 100 ml cylinder container made of PET material. The glycerol (KENEI Pharmaceutical Co., Ltd., type P) was used as an acoustic coupling

B. Data Acquisition Method

Our previous work has thoroughly explained a complete explanation of this method [14, 15]. A brief description of procedures is as follows. The aqueous solution with a certain concentration was prepared 1 hour before the experiment in the 100 ml solution container. The argon injection was done using Takeda Rika Kogyo Co., Ltd., argon 99,99% to attain argon saturated condition. In this process, argon acts as a cavitation agent. The gas flow rate was measured with an airflow meter (Tokyo Kaisei Co., LTD). The saturating solution was placed inside the sono-reactor container for ultrasound sonication.

In the spectrum analysis method, the analysis was performed based on a standard OES spectrum analysis principle to analyze the chemical components of the sample.

Fig. 2. Schematic of the experimental setup

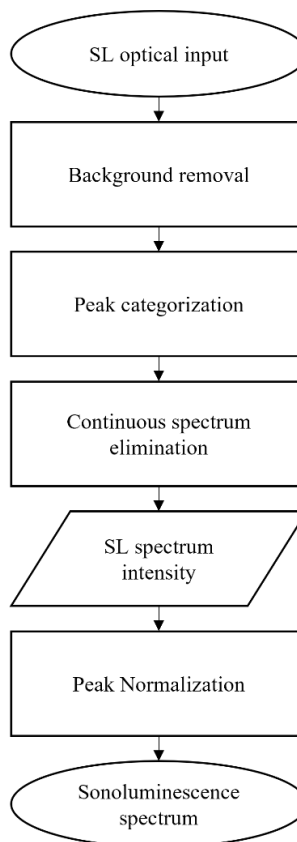

Fig. 3. flowchart of SL spectrum analysis method

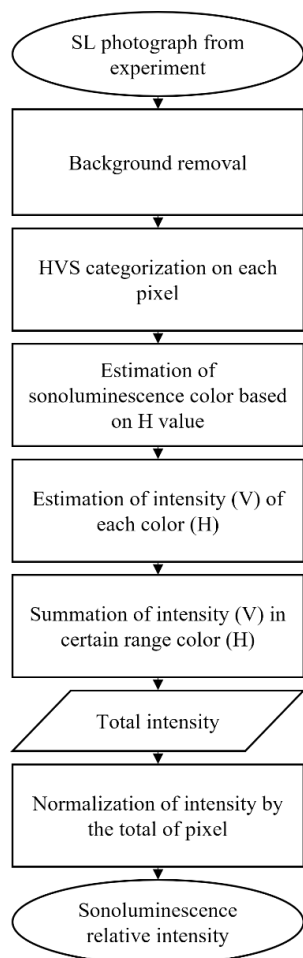

Fig. 4. Flowchart of HSV image analysis method

Once the sono reactor was operated and the SL emitted, the SL emission was then collected through a focusing optic; a convex lens with a diameter of 75 and 50 mm was used to focus the light emission to the fiber optic surface. The fiber optic then delivers the intensified light to the spectrometer. The spectrometer's integration time was set to 3s with 100 average per acquisition. The acquisition was started by measuring the background light without the SL operation, and then the value was used to correct the obtained spectrum. Finally, the background-corrected spectrum was obtained. Further data analysis methods will be explained in the following sub-section.

Moreover, to simultaneously confirm the existence of SL, a still camera (Nikon, D850) with an exposure time of 30 sec was used. A photograph of SL was taken from the side of the reactor.

C. Data Analysis Method

Although the background spectrum was used to eliminate the surrounding light and capture the actual signal during the experiment, unintended spectrum broadening was obtained from the water hydrolysis and argon reaction. Therefore, a data analysis method was developed to isolate the intended peaks. Finally, the data was presented in normalized value for each

acquisition to its own highest peak. The flowchart of the SL spectrum analysis method is shown in Figure 3

An HSV-based image analysis method was developed on MATLAB to analyze the photograph from the experiment. The analysis was done pixel by pixel on the photograph. On every pixel, the analysis was based on three characteristics, hue (H), saturation (S), and value (V). Essentially, hue shows the color distribution, saturation measures the degree of greyness, and value shows the intensity of the color. The analysis of each pixel was focused on the H and V, which correspond to color and intensity, respectively. The total of V for each pixel in *i* or *j* direction represents the intensity as shown in equation (1). The normalization of the results gives the value of relative intensity. The flowchart of image processing using the HSV method is shown in Figure 4.

$$I = \sum_i \sum_j V_{i,j} \quad (1)$$

The analysis of intensity and color from the raw data obtained from the still camera provides a resolution of around 3621x1846 pixels. In addition, using HSV-based color identification, 3% uncertainty of SL intensity can be found from this data acquisition method.

III. RESULT AND DISCUSSION

A. Remote spectrum analysis

The feasibility test on remote spectrum analysis using SL was conducted. The SL generated using the ultrasound equipment was focused using two convex lenses with 75- and 50-mm diameters. The double convex lenses were used to decrease the measurement focal length while maximizing the light intensity. The focused light is then directed to the fiber optic surface to be analyzed using the spectrometer. The existence of double convex lenses increases the visibility of SL by roughly 60%.

The spectra of SL from argon gas-saturated strontium, sodium, and calcium were studied in this paper. The spectra were investigated around 200-1000 nm. The spectrum was corrected using a background and continuum spectrum removal. However, the argon influence on the solution was assumed to be negligible.

Figure 5 shows the strontium, sodium, and calcium spectrum taken under 3s integration time with 100 averaging per acquisition. The integration time was selected after studying SL peaks' behavior on every iteration.

Figure 5 (a) shows the 407 and 421 nm strontium peaks. At the same time, Figures 5 (b) and (c) show the peaks of sodium (589 nm) and calcium (393 and 396 nm), respectively. These results aligned with the line spectrum database of NIST [16]. Some broadening was still observed in the case of calcium, even after the broadening removal. This is presumed to be caused by the resolution of the spectrometer. This is expected since the gratings chosen in this experiment were relatively lower in resolution. Also, some background noises were observed due to the long integration time of the experiment. However, it is

insignificant to the desired wavelength. These results demonstrate the feasibility of developing a remote elemental analysis system using SL.

The analysis of multi-element in the aqueous solution is shown in Figure 6. The figure shows a peak of Na and Ca observed under ultrasonic irradiation normalized to the Na peaks in a single element condition. It can be seen that the presence of mixed solution damped the intensity of the detected peaks compared to single element analysis. This is expected due to the possible quenching phenomenon [17]. Also, a spectrum broadening was observed in the mix condition. This is presumed due to the water hydrolysis that occurred. However, a broadening observed in the single element of Ca did not exist in the multi-element case. The real reason for this behavior is not yet observed.

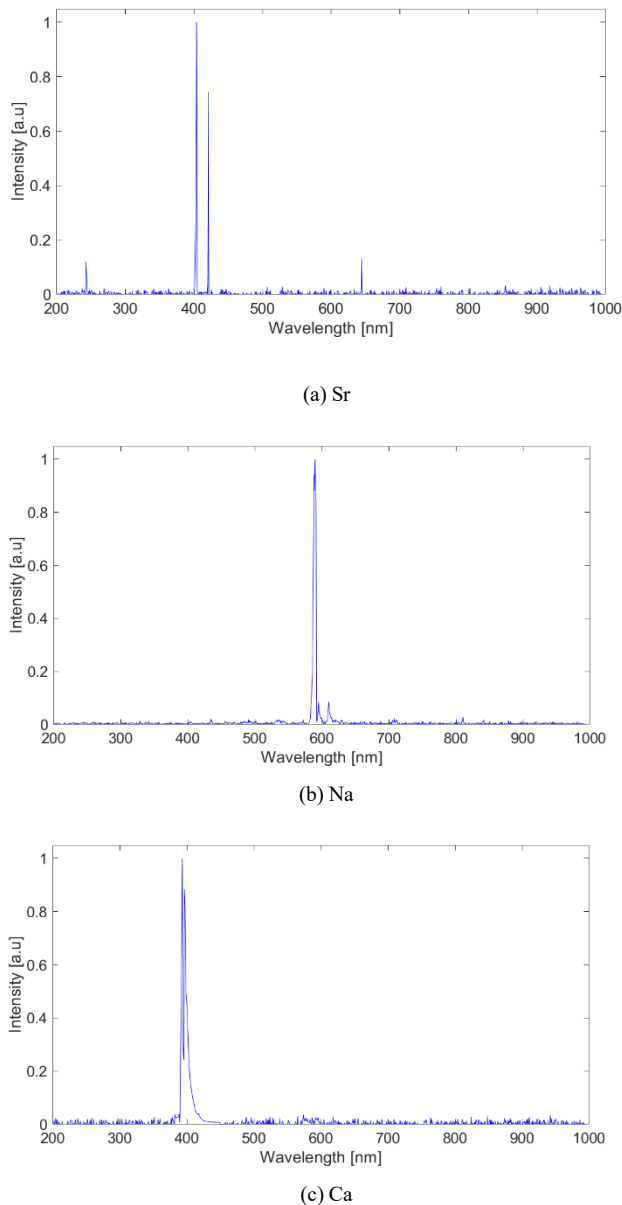

Fig. 5. SL spectrum of various elements

Fig. 6. SL spectrum of mixed elements

Furthermore, the mixed situation and the presence of other solid particles are expected in the actual situation. With this, a test on the presence of solid particles was conducted, and the result indicates the SL intensity was not highly affected by the presence of solid particles. Also, a filtering treatment to remove solid particles could be used as an alternative.

As for the limit of detection, a calibration curve to calculate the limit of detection has been conducted. The result demonstrates that SL intensity was proportional to the concentration of the analyzed element. The lowest element concentration that could be detected in a sufficient number intensity is in order of hundreds of ppm using the current setup and parameters. A possible increase in the detection limit could be obtained using a continuous injection of ionization agents into the solution over the measurement time. The limit of detection for each element varies and depends on several factors such as the temperature of the solution, metal boiling point, ionization energy, and excitation energy of the corresponding elements. Previous studies showed that higher ultrasound power was required to obtain the maximum possible SL intensity for elements with higher ionization energies [18].

B. SL visualization of various elements

A simultaneous observation using a still camera was conducted to confirm the visualization of SL emission. A 30s exposure time photograph of various elements taken in a dark environment is presented in Figure 7. The results show different colors of each component and demonstrate a pattern showing the high and low-intensity area resulting from the ultrasound interaction in the liquid.

Furthermore, the HSV analysis performed on the obtained photograph determines the photograph's color distribution. The use of HSV for image analysis, especially in image segmentation and histogram, has been widely used [19]. The color distribution is on a 360 degrees rotation basis. The advantage of HSV compared to other color schemes is that it has only one dimension of color (H). Roughly, the color is categorized as follows: 0-90 shades of red to yellow, 90-180 for shades of green, 180-270 for blue, 270-360 pink to red.

Fig. 7. SL of various element

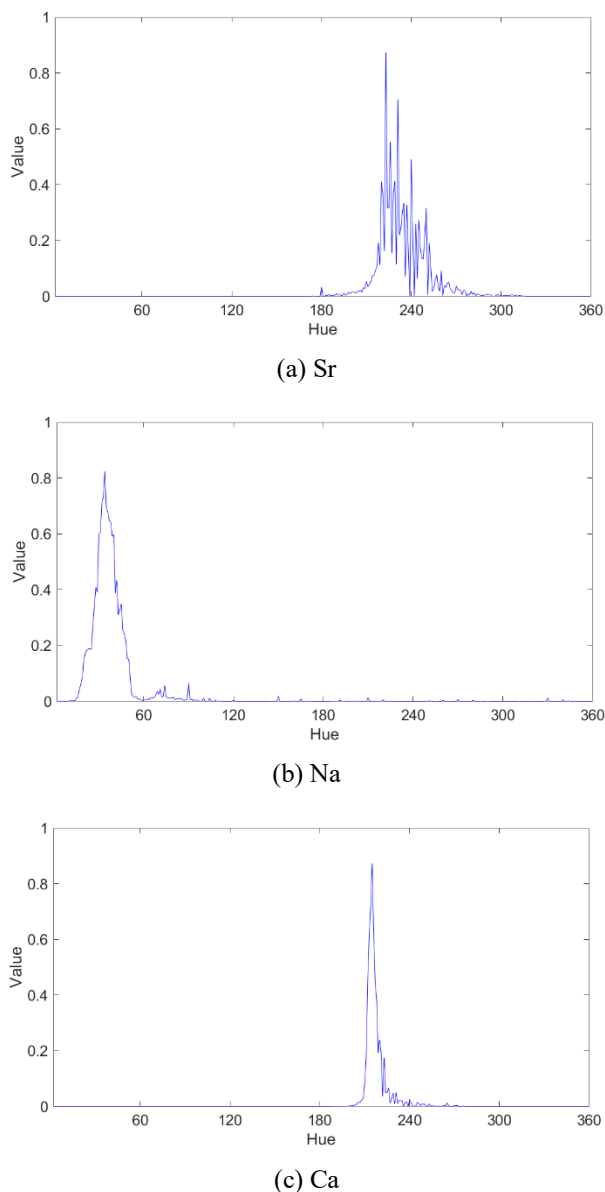

Fig. 8. HSV analysis results of various elements

The algorithm has been tested to various test images before the analysis. The results indicate that the obtained intensity tends to be narrow with the increase in pixel number. This is expected due to the convergence of the data with the increase in pixel number.

The HSV analysis results on strontium, sodium, and calcium are demonstrated in Figure 8. The results match the visual observation of the photograph.

In these results, a broadening peak was observed. Mainly, the one from strontium was the most noticeable, which is expected due to the broad distribution of the color. Nevertheless, these results support the reliability of the results obtained using spectrometers. Hence the feasibility of developing a remote elemental analysis system using SL.

IV. CONCLUSION

The feasibility test on remote spectrum analysis using SL was conducted. Strontium, sodium, and calcium in an aqueous solution were used as a sample in the experiment. The optical arrangement enables the remote spectrum analysis using fiber optic and spectral analysis. A simultaneous observation using a still camera was conducted to confirm the visualization of SL emission. The results obtained in this experiment demonstrate the ability to perform remote elemental analysis using SL.

Abstract— A bond graph modelling of a Photovoltaic system is presented in this study. A Photovoltaic system's four main components are Photovoltaic generator, DC-DC converter, battery, and DC-AC inverter. This study shows the bond graph models of the aforementioned part. A five-parameters PV generator is chosen based on high accuracy and illustrating of the effects of temperature and solar irradiation. To develop a link with reality, the bond graph model is created using the specs of the CS1U-400 Canadian solar module. The effects of different duty cycles have been examined using a bond graph model of a synchronous Boost converter and a synchronous Cuk converter. For a Lead Acid Battery, a novel bond graph model was developed. This model investigates the impacts of temperature and current in charging and discharging scenarios. Finally, a 3-phase inverter bond graph is designed to connect the PV system to the grid. The 20-Sim software is used to simulate the developed models, and the results are discussed.

Keywords—Dynamic modeling, Bond Graph, Photovoltaic System, Renewable Energy System

I. INTRODUCTION

The photovoltaic (PV) power industry is quickly expanding, notably in the field of distributed generation, due to growing interest in renewable energy supplies. As a result, designers require a versatile and trustworthy tool to precisely anticipate the electrical power generated by PV arrays of varied sizes [1]. The difficulty of predicting energy output from a PV cell system is particularly difficult since the electrical current yield is highly dependent on weather and environmental conditions, particularly temperature and global irradiance [2], hence the use of batteries for photovoltaic solar power. The main purpose of using batteries is storing extra energy in sunny days and supply load during night and cloudy days, also stabilizing and regulating voltage and frequency to increase the reliability of system. Moreover, some electrical circuits are needed to achieve this purpose of producing reliable electricity using solar energy and supplying load and connecting to grid. Following parts are essentials of a Photovoltaic System (PV system), Figure 1:

- Solar Panel
- Energy Storage System (ESS)
- DC-DC Converter
- DC-AC Inverter

A photovoltaic system can be modelled in a variety of ways. Semiconductor physics may be used to model a photovoltaic cell at a high level, encompassing phenomena like charge

carrier density, mobility, and recombination in the charge space [3].

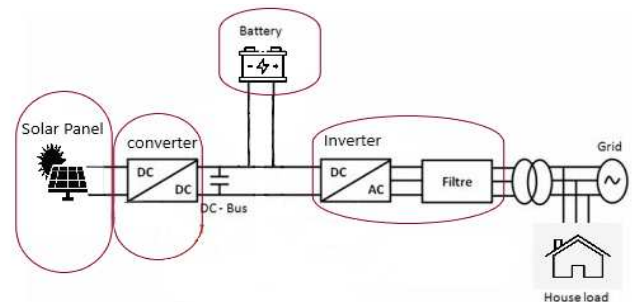

Figure 1. Four essential parts of a PV system

Analytical methodologies are difficult to use for this type of modelling, hence numeric processing is required to run simulations. It means that a lot of computational power is required. Researchers working on novel solar cells, on the other hand, will find such modelling valuable and required. However, such extensive modelling is not necessary for engineers interested in solar cell applications. Among the analytical approaches for computing parameters, the one described in [4] allows for the computation of five parameters using data from the datasheet of the module under investigation. This method is appealing since it does not need any prior testing or measurements. This work used the four-parameter equivalent of one diode with a series resistor [5]. The parameters are calculated analytically, using a technique described in [6]. Other approaches need iterative procedures, thus explicit expressions are employed instead. Because of the five controlling variables, this model[7] is commonly referred to as a "five-parameter model." Its comparable circuit consists of a photovoltaic current source I_{ph} in series with a light-sensitive diode (D) and a shunt resistance (R_p) expressing a leakage current, as well as a series resistance (R_s) indicating internal resistance to current flow. This circuit may be used for a single cell, a module made up of numerous cells, or an array made up of multiple modules [8]. The PV cell's electrical equivalent circuit may also be used to calculate the mathematical equation for PV modules/generators. Internal parameters, voltages, and currents will be a function of the number of cells, modules, and their combination in series and/or parallel, depending on the application [9].

Variable structure systems include switched mode power converters (SMPCs). The structure of the system's dynamical components is determined by the power switch's instantaneous positions. In the literature on mathematical

modelling of SMPCs, several analytical and graphical techniques have been developed. Large signal discrete time models for computer simulation and continuous time models for physical understanding have been presented as analytical approaches [10]. The switching dc-dc converters aid in increasing the voltage from a low voltage source, smoothing the path to a synchronized DC output voltage that would otherwise need a large number of battery voltage sources [11]. Generally, dc-dc converters are used to boost the output of renewable energy systems. High step-up output voltage gain, low input current and low current ripples, high output voltage and low voltage ripples, and improved efficiency are all required for dc-dc converters [12]. The most common DC-DC converters are Buck converter, Boost converter, Buck-Boost converter, Cuk converter, Zeta converter, and Sepic converter, which the most used ones in PV systems are Boost converter, Buck-Boost converter, and Cuk converter.

For all types of power electronics systems, including solar systems, power supply dependability and power quality have become critical challenges. When connecting a solar system to the utility, the PV system must fulfil the harmonic standard as well as the active power supply requirements. Because PV generates DC voltage, an inverter is required to convert the DC electricity to AC before connecting it to the grid. Grid is an infinite-capacity voltage source. The inverter's output voltage and frequency should match the grid's frequency and voltage.

II. INTRODUCTION TO BOND GRAPH

The bond graph is a framework for dynamic modelling. Paynter [13] presented it first, then Karnopp and Rosenberg expanded on it subsequently. This formalism allows the power transfers between the many subsystems of a physical system to be visually depicted in a coherent manner [14]. A bond graph is a multidisciplinary tool for modelling complicated systems that employs a unified methodology [15]. A bond graph model is a graph $G(S, A)$ in which the nodes S represent physical components, subsystems, and other fundamental elements like junctions, and the arcs A reflect power exchanges between the nodes S . A half-arrow carrying two conjugate variables named effort (e) and flow (f) represents this power exchange. The instantaneous power exchanged between two nodes S is represented by the product of these variables. A half arrow represents the transfer of power. Each physical domain studied has its own effort and flow variables [16]. The bond graph formalism is based on the power conservation and energy continuity principles. Energy cannot be generated or destroyed within a system; it can only be stored, dispersed, altered, or exchanged with the outside. As a result, the bond graph formalism only has a few parts. The element R allows for the representation of energy dissipation, whether it is reversible or irreversible. The factors C and I make it feasible to represent different energy storage forms. The transformation components TF and GY allow for the representation of energy transformation and/or movement from one physical domain to another. It is feasible to simulate the conditions of the system with which the latter would carry out the energy exchanges using the source elements of effort Se and flow Sf , which may be assimilated to limitless sources [17]. The junction elements, which are utilized to link components with the same effort (junction

"0") or the same flow (junction "1"), are added to these diverse elements. The idea of causality, which controls the interactions between components at the level of efforts and flows, is one of the most significant structural aspects of bond graph formalism. Indeed, the cause-effect linkages may be derived directly from the system's graphical representation [18].

In Electrical Engineering, the bond graph approach is also beneficial. Designers will be able to create a variety of dynamic systems with appropriate features using this method. All forms of electrical components and parasitic phenomena can be described by specifying linear and/or non-linear R , I , C , TF , and GY components. As a result, creating accurate and realistic dynamic models of various circuits and topologies will no longer be an issue.

III. LITRATURE REVIEW

Many electrical models have been presented to simulate PV cells working under various situations [19,21]. The number of parameters to be identified determines the model's complexity. Each model is simply an upgrade on the ideal model, which includes a current source to represent the incident solar power and a diode to represent the P-N junction. Additional features can be included to improve the description of the PV cell's performance in different operating modes. The most common model is the one-diode model. Because of its simplicity and accuracy in power generating mode, it is employed for PV cells and PV modules. The Bishop model, which represents the performance of a PV cell under reverse polarization, is a result of the development of the one-diode model. The two-diode model improves on the one-diode model by accounting for resistive losses and recombination processes in the circuit's different electrical components. Since this model is unable to express the PV voltage as an explicit function of the current, it must be solved iteratively or by using the Lambert-W function. As a result, high precision comes at the expense of a complicated formalization of the issues and a high computational cost. In [21], a dynamic battery model is provided that accounts for temperature variations and may be implemented into electric vehicle simulation for computer simulation testing purposes; However, there is no consideration of battery behavior in charging and discharging situations. In [22], the study presents a bond graph technique to model switched mode power converters such as, H-bridge inverter, Boost converter, and Cuk converter. The notion of switched power junctions is used to simulate the switching phenomena. The bond graph modelling of switching power converters is discussed in order to achieve the big signal averaged, steady-state, and tiny signal AC models. [23] proposes a bond graph model of a photovoltaic construction consisting of a solar generator, a Maximum Power Point Tracking converter, and a three-phase inverter powering an asynchronous motor-pump. The system responses were significantly enhanced after a vectorial control study of the closed loop system.

In this paper, a bond graph model of a photovoltaic-battery system is presented, which includes a five-parameter PV cell, a Boost converter, a Cuk converter, a lead acid battery, and a

three-phase inverter. The solar cell and power switches were constructed using datasheet parameters.

This paper structure includes six sections. Section I gives an overview of the concept of PV system and four essential parts. In section II, a brief introduction of bond graph modeling is proposed. A review of some recent related research is presented in section III. Section IV illustrates the bond graph models of mentioned parts of a PV system and discusses the equations and dominant parameters of each part. In section V, the simulation results are discussed. And in the last section a brief conclusion is presented.

IV. SYSTEM MODELING

A. Bond graph model of the PV generator

A model with five parameters is picked up for this work. This model includes a current source that provides a current I_{ph} proportional to the illumination, a diode for the cell's polarization phenomenon through which the current I_d flows, and a series resistor R_s and a parallel R_p for the losses, Fig. 2.

The five parameters of this model are extracted using numerical iterative approaches such as the Levenberg-Marquardt algorithm. Analytical approaches [24,25] can also be utilized to solve the implicit nonlinear equation that reflects the five-parameter model.

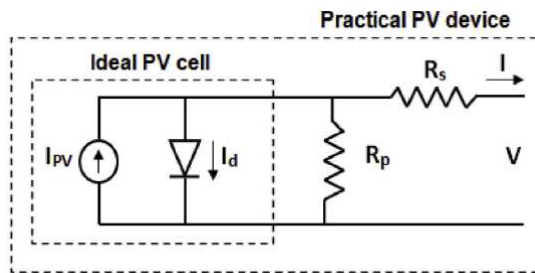

Figure 2. 5-parameter Practical PV cell model

Equation (1) and (2) illustrate the internal PV cell produced current and diode current, respectively:

$$I_{ph} = n_p(I_{sc} + K_i(T - T_r))(S_i/100) \tag{1}$$

$$K_i = I_{sc}I_{sc} \tag{2}$$

$$I_d = n_p I_{sat} \left(\exp\left(\frac{qV}{AKTn_s}\right) \right) \tag{3}$$

which I_d , R_s , R_p , I_{ph} , n_p , n_s , I_{sc} , I_{sc} , I_{sat} , T , T_r , q , A , K , and S_i are output current, diode current, series resistor, parallel resistor, Photo Current, number of cells connected in parallel, number of cells connected in series, short circuit current coefficient, short circuit current, saturation current, temperature, temperature reference, electron charge, ideality factor, Boltzmann constant, and Solar illumination (Irradiation), respectively.

Following equation shows the output current of the PV cell, based on electrical circuit:

$$I = I_{ph} - I_d - \left(\frac{V + I R_s}{R_p} \right) \tag{4}$$

The equation (4) represents the modified diode shield voltage as the temperature changes, where k_v is the temperature coefficient of open circuit voltage:

$$V_t = K_v(T - T_r) \tag{5}$$

$$K_v = C_t V_{oc} \tag{6}$$

which V_t , K_v , T , T_r , C_t , and V_{oc} are, respectively, modified diode shield voltage, temperature coefficient of open circuit voltage, temperature, temperature reference, temperature coefficient, and open circuit voltage.

The I-V characteristic of this module is represented by the following equation:

$$I(1 + R_s/R_p) = -n_p I_{sat} \left\{ \exp\left(\frac{q}{AKTn_s}\right) \left(\frac{V}{n_s} + IR_s\right) - 1 \right\} + n_p I_{ph} - \frac{V - n_s}{R_p} \tag{7}$$

The CS1U-400 Canadian solar module is utilized to simulate in this investigation. Table 1 lists the CS1U-400 specs that were used in this investigation.

The bond graph model of the PV cell has been illustrated in Figure 3.

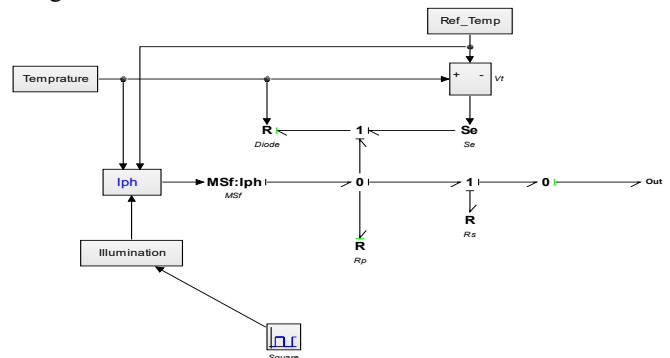

Figure 3. Bond graph model of PV generator

The aforementioned model, Figure 3, contains the implementation of three equations, with the one that calculates the photocurrent based on two factors, sun irradiation and temperature, being the most important, equation (7). The external I_{ph} block includes these parameters, allowing users to create C code and link it to SYMBOLS. To generate an I_{ph} current, equation (1) is expressed as a "Iph.dll block" in C code.

The photovoltaic generator is connected to DC bus through a step-up DC-DC converter.

B. Bond graph model of the DC-DC converters

To increase the DC voltage to standard level, stabilizing the transferred power, and providing the Maximum Power Point Tracking option, using a step-up converter is necessary. In this work, two most popular switch mode converters,

figure 4, which are synchronous Boost converter and synchronous Cuk converter, have been modeled in 20-Sim software, Figure 6. In designing these converters, IRF150 characteristics as the power switch has been used, Figure 5.

Following equations illustrate design characteristics of Boost Converter[26]:

$$\frac{V_{out}}{V_{in}} = \frac{1}{1-D} \tag{8}$$

$$\frac{I_{out}}{I_{in}} = 1 - D \tag{9}$$

$$L = \frac{V_{out}D}{\Delta i_L f} \tag{10}$$

$$C_o = \frac{D}{R(\Delta V_{out}/V_{in})f} \tag{11}$$

frequency. Also design characteristic of Cuk converter have been shown below[26]:

$$\frac{V_{out}}{V_{in}} = -\frac{D}{1-D} \tag{12}$$

$$\frac{I_{out}}{I_{in}} = -\frac{1-D}{D} \tag{13}$$

$$L_1 = \frac{V_{out}D}{\Delta i_{L1}f} \tag{14}$$

$$L_2 = \frac{V_{out}D}{\Delta i_{L2}f} \tag{15}$$

$$C_o = \frac{D}{R(\Delta V_{out}/V_{in})f} \tag{16}$$

$$C_1 = \frac{D}{R(\Delta V_{C1}/V_{out})f} \tag{17}$$

which $L_1, L_2, \Delta i_{L1}, \Delta i_{L2}, C_o, C_1,$ and ΔV_{C1} are, respectively, input inductor, output inductor, input inductor current ripple, output inductor current ripple, output capacitor, series capacitor, and series capacitor voltage ripple.

C. Bond graph model of the Lead Acid battery

There are some parameters which play significant roles in lead acid battery performance, such as temperature, State of Charge (SOC), charging current, and discharging current. A model which can predict the battery behavior in different values of mentioned parameters correctly, is a desirable model. Figure 7 shows the battery equivalent model which is the best option to satisfy aforementioned criteria. In this work, Battery is “T-105 with Bayonet Cap” specifications have been used to design bond graph model.

Any change in solar irradiation and temperature will have direct impact on PV generator performance.

By running the Boost converter in a situation where PV panel is on nominal situation, the results of the converter output will be shown in Figure 11. In case of changing duty cycle, the output voltage and output current will change, based on (8) & (9). Switching frequency of both converters are 50 KHz.

Charging and discharging of the battery has been shown in Figure 12. In Figure 12 and 13, the outputs of a single Lead Acid battery is shown at 25 and -10 degrees, respectively. Therefore, in lower temperature the battery capacity decreases and with same currents in lower temperature it discharges and charges faster. But, in order to add the ESS to the PV system, the output voltage must be equal to the DC bus voltage. By putting number of batteries in series this purpose will be achieved. Based on the design, the ESS can be put in lower DC voltage (PV output) or high DC voltage (converter output). In most cases the energy storage system will be at high DC voltage part. In this work also, because of next works in future and further developments, it is connected to high DC voltage. Therefore, by putting 25 single batteries in series, it will possible to attach them to DC bus.

(a) D=0.75.

(b) D=0.6.

Figure 11. Boost converter waveforms. (a) D=0.75. (b) D=0.6.

As mentioned before, to connect the PV system to grid, an inverter is needed. In North America, the standard voltage is 120 v and 60 Hz. To achieve this purpose and based on (24), DC voltage must be 150V, also switching frequency has to be 60 Hz. The results of simulation of the 3-phase inverter with mentioned situation have been shown in Figure 14.

VI. CONCLUSION

A bond graph modelling of a PV system is provided in this paper. PV generator, DC-DC converter, Battery, and DC-AC inverter are the four fundamental components of a PV system that have been modelled in this article. Because being more accurate and showing the effects of temperature and solar irradiation more precisely, a five-parameters PV generator is chosen. The specifications of the CSIU-400 Canadian solar module are utilized to create the bond graph model in order to make a connection with reality. Bond graph model of a synchronous Boost converter and a synchronous Cuk converter, as two of the most popular candidates of PV applications, are designed and the effects of different duty cycles have been studied. A new bond graph model for a Lead Acid Battery was created. The effects of output current and temperature in charging and discharging scenarios are investigated in this model. Finally, to link the PV system to the grid, a 3-phase inverter bond graph is designed.

Abstract—This paper investigates the system sizing, schema, modeling, and simulation of a 500 MW, grid-connected PV farm at a site close to the Churchill Falls Airport in Labrador. The objective is to understand the PV farm's technical and economic feasibility. The system is sized manually and with the help of PVWatts. The outputs from this calculation and PVWatts are used to select system components, such as solar panels and MPPT inverters. The plant is divided into four blocks of 125 MW each for ease of maintenance, control, and redundancy for planned and unplanned outages. Pooling transformers, high voltage switchgear, grid transformers, and the export transmission line are sized accordingly. System performance is analyzed using NREL's System Advisor Model (SAM) software. The grid-connected PV system, with the inverter, is modeled in Simulink (MATLAB) for dynamic simulations. Protection and control scenarios are also modeled in Simulink. The system's output parameters are then analyzed to understand power output and stability. Finally, recommendations on feasibility and further work are discussed.

Keywords—*photovoltaics, solar farm, MPPT, protection, control, grid, Simulink, MATLAB, SAM, PVWatts.*

I. INTRODUCTION

Presently, there is no large PV installation in Labrador, NL. The population of Labrador is more than 30,000. Electricity is mainly supplied from large hydropower plants. Remote communities are powered by diesel generators. Labrador has a large area that could be utilized for large-scale solar power generation. This paper presents the feasibility of a 500 MW solar power generation in Labrador. Large-scale solar power generation will help decrease greenhouse gas emissions. Capacity addition near the high voltage grid will help improve the utilization of transmission infrastructure and electricity export to inter-provincial and international markets.

This report includes an investigation of other literature on the implementation of grid-connected PV farms; an examination of the details of implementing a grid-connected PV farm at a location close to the Churchill Falls Airport in Labrador, Eastern Canada; modeling and dynamic simulations of the project in Simulink; and control and protection design. The report describes site selection, selection of the main components, system

sizing calculations, and the overall schematic. Modeling and simulation are performed using various software tools to derive the annual and monthly DC/AC energy production, system losses, and system behavior in varying conditions. This report aims to understand the technical and economic feasibility of a large-scale PV farm in Labrador, an area with low average solar irradiation.

II. LITERATURE REVIEW

A previous study was done to design a 50 MW utility-scale Solar PV farm in India [1]. The study objective was to design the complete power system, from PV panels to the overhead transmission line connection, to deliver the power to the 132 kV utility grid. The ratings selected for the PV panels and the string inverter were 330 Wp and 160 kW, respectively. The power plant was divided into eight blocks of 6.25 MW each. Within a block, a number of inverters were paralleled to feed an 800 V LT Panel. This power was stepped-up through a three-winding, inverter-duty transformer rated as 33 kV/0.8 kV/0.8 kV, Dy11y11, 5/6.25 MVA. The 33 kV output from each block was connected to a main 33 kV switchgear through a number of incomers. A single outgoing feeder of the 33 kV switchgear was connected to a 132 kV/33 kV, YNyn0, 32/40/50 MVA pooling substation transformer. The output of the pooling substation transformer was connected to the utility grid through an overhead link [1]. PV farm layouts, cable route layouts, transformer yard layouts, 800 V, 33 kV, and 132 kV Single Line Diagrams were prepared as the output of the study project [1]. PV Syst software was used for simulation in this project. Based on the selected configuration and with 45% overloading capacity of inverters, the total number of panels was calculated as 6864. The total land requirement for the project was estimated at 250 acres [1].

In their paper 'Design and Simulation of a 10 MW Photovoltaic Power Plant using MATLAB and Simulink', the authors describe the components of a PV farm power generation system [2] consisting of:

- (1) an array of PV panels grouped in series or parallel to achieve maximum power output
- (2) a DC-DC boost converter, used as a load regulator and to convert PV array output voltage to a voltage suitable for the inverter

- (3) a three-phase DC-AC converter to convert from DC to AC and to supply this electrical energy to the three phase grid, a three-phase step-up transformer to convert the low voltage output of the inverter to the voltage rating of the grid, and
- (4) a PV power generation system controller containing the Maximum Power Point Tracking (MPPT) controller for the DC-DC boost converter and inverter controller [2].

To design the PV array, they considered several manufacturers of PV cells, including Mitsubishi, Sharp, Sanyo, BP Solar, and Suntech. They selected Sanyo’s HIP-225HDE1 PV module with a maximum power rating of 225 Wp to fit PV array design requirements [2]. The authors used the Simulink module in MATLAB to simulate the system. The PV field was built in software using elements from the SimPowerSystems library. The Simulink model included

- (1) the Signal Builder Tool to build solar radiation and panel temperature signals to test the system under different conditions,
- (2) the PV farm with PV cells,
- (3) the DC-DC converter, along with the MPPT control system,
- (4) the three-phase inverter with its dedicated control system,
- (5) the step-up transformer to connect the inverter to the grid and the grid into which energy is transferred.

To simulate real-world conditions, the authors adjusted parameters such as solar irradiance and PV cell temperature to understand their corresponding effect on the PV array’s output power and voltage [2].

Keiichi K. et al. mentioned in [5] that the initial cost for a very large-scale PV plant is 1-3 MUSD/MW, with OPEX of 1% of the initial cost. The Levelized cost of energy (LCOE) for utility-scale PV generation globally is estimated at approximately 0.15 USD/kWh, 0.10 USD/kWh, and 0.05 USD/kWh for the higher initial cost case (3 MUSD/MW), middle case (2 MUSD/MW) and lower case (1 MUSD/MW), respectively. However, there are some differences depending on regional conditions.

III. SITE SELECTION

The site selection was based on various criteria such as solar irradiance, terrain, vicinity to the high voltage transmission line for power evacuation, and vicinity to means of transport. The selected location has the following characteristics and advantages. (1) Solar irradiation of 3.5 kWh/m²/day, (2) vicinity to high voltage grid for power evacuation with the option to connect to 230 kV, 138 kV, and 69 kV grids, (3) vicinity to means of transport viz. Trans-Labrador Highway 500 and the Churchill Falls Airport, (4) the selected site has a flat terrain, and (5) the Churchill Falls community and the Churchill Falls Hydro-Electric Substation are nearby, which can prove

advantageous for personnel management during project phases of construction, operation, and maintenance.

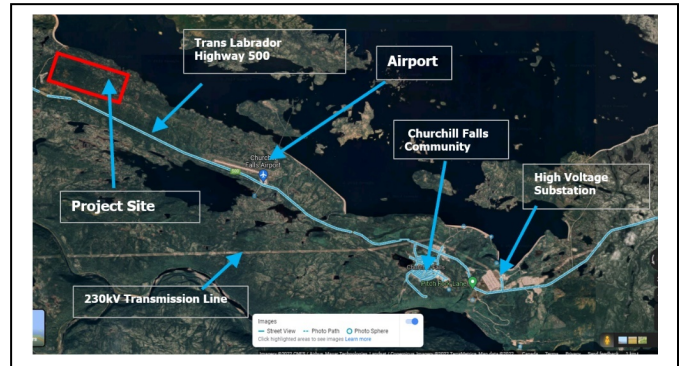

Fig. 1. 500 MW PV Farm Site Selection

IV. SYSTEM COMPONENTS

A. System Components

The following are the main components of the system. (1) photovoltaic modules, (2) DC combiner boxes, (3) inverters, (4) step-up pooling transformers, (5) pooling switchgears and (6) step-up grid transformers.

B. PV Module Selection

Based on utilization in previous utility-scale solar power plants and high-efficiency criteria, the Canadian Solar CS6U-340M PV module is selected. The module has a 17.49% efficiency with a rated output power of 340 W, open-circuit voltage of 37.9V, and a short circuit current of 9.48A.

C. Inverter Selection

Based on utilization in previous utility-scale solar projects, high power rating, and high efficiency, the ABB PVS980 2000 kVA-K inverter is selected. The inverter has a rated output power of 2000 kVA, output voltage of 660 V, maximum DC input power of 3200 W, maximum DC input voltage of 1500 V and MPPT voltage range between 935-1500 V at 35°C.

V. SYSTEM SIZING AND CALCULATION

A. PVWatts Calculation

After site selection, the preliminary kWh energy output from the proposed site was calculated using PVWatts, an online tool developed by National Renewable Energy Laboratory (NREL). The output results are shown in the table below.

TABLE I. PVWATTS CALCULATION RESULT

Property	Unit	Value
Land Requirement	km ²	3.3
Energy Output	kWh/yr	596078656
Average Annular Radiation	kW/m ² /day	4
Energy Value	\$	74629010
Capacity Factor	%	13.6

B. System Structure

The overall plant is divided into four blocks, with all blocks having an identical arrangement for ease of operation, maintenance, and control. The power system of each block starts from an individual PV module and ends at the 230 kV terminals of its grid transformer. To get the desired DC voltage per the inverter specification, 32 no. of PV modules are connected in series to form a string. Further, 288 strings are connected in parallel to supply input DC power to a single inverter. The scheme is designed such that each string voltage (operating and open circuit) shall be below the rated maximum input voltages allowed at the input of the inverter.

Also, the total input power of parallel strings shall be below the specified limit by the inverter vendor. Since the inverter can take only 24 DC inputs, the intermediate DC Combiner Boxes (DCBs) shall be installed between PV module strings and the inverters. Each DCB takes DC power from 12 strings and combines it in the form of a single DC output for further connection to the DC side of the inverter.

C. Power Evacuation

Due to the vicinity of the Churchill Falls Generating Station and its substation, there are three voltage-level options available for power evacuation: 230 kV, 138 kV, and 69 kV. Considering the criteria of shortest distance and low ampacity requirement, the existing 230 kV overhead transmission line is chosen for power evacuation. The direct length from the project site to the 230 kV transmission line is approx. 5 km as measured on google maps. Each block is designed to export power individually to the existing transmission grid. AC power output from the inverter is available at 60 Hz, 660 V level, which is connected to the low voltage primary side of the pooling transformers. There are twenty pooling transformers per block, each accepting power from two inverters. Pooling transformers are inverter-rated, three winding, 660 V/660 V/35 kV, DY5Y5, 7.5 MVA step-up transformers. Output from all 20 pooling transformers is combined at a 35 kV, 3-phase, 3-wire, gas-insulated, pooling switchgear. A single feeder from each 35 kV pooling switchgear feeds the power to the 35 kV / 230 kV, YNyn0, 125 MVA, step-up grid transformer. In each block, there is one pooling switchgear and a grid transformer (totaling 4). Finally, the 230 kV side of the grid transformers is connected to the existing transmission grid through a new 230 kV transmission link and air-insulated gantry structure. This link comprises of 3-wire, 4-circuit overhead transmission link (1-circuit per grid transformer).

D. System Schematic

The following figures show the schematic of the DC combiner box and the four system blocks that make up the 500 MW PV capacity.

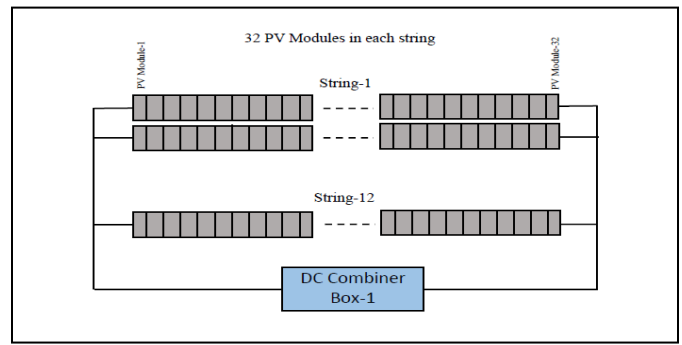

Fig. 2. Schematic of each DC combiner box

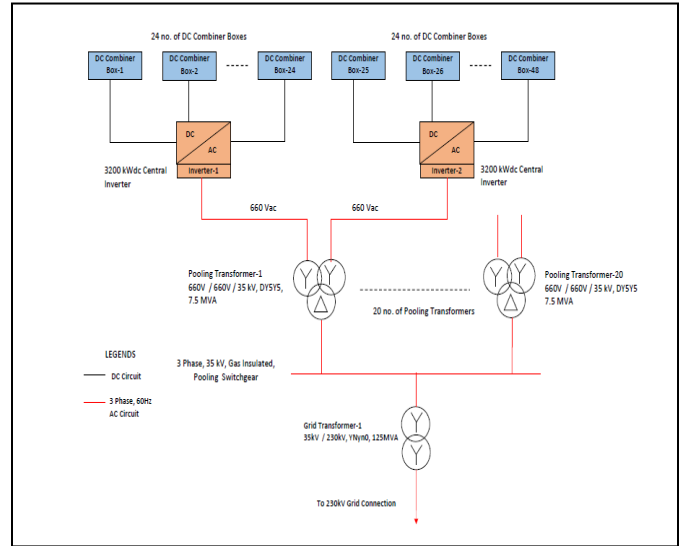

Fig. 3. Scheme diagram of each block

VI. SYSTEM ADVISOR MODEL ANALYSIS

The modeling and simulation were done in System Advisor Model (SAM), a free techno-economic program model that enables individuals in the renewable energy business such as policy analysts, researchers, project managers, engineers, and technology developers to make better decisions. SAM can simulate a wide range of renewable energy systems, including photovoltaic systems, battery storage, industrial process heat from parabolic, marine energy wave systems, wind power, solar water heating, geothermal power generation, fuel cells, biomass combustion, and high concentration photovoltaic systems. The system designed is located near the Churchill Falls Airport, and the resources were downloaded in the SAM software from National Solar Radiation Database (NSRDB), as shown below [3].

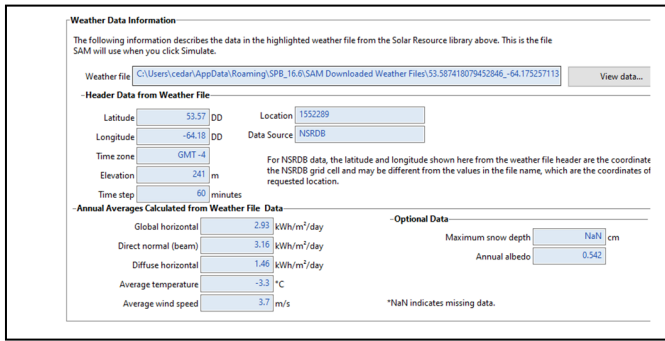

Fig. 4. Selected site's weather data in SAM UI

A. PV Module Analysis

The PV solar panel model used is Canadian Solar Max Power CS6U-340M with an output rated power of 340 Watts and 17.485% efficiency, while in the SAM software, the output power was calculated to be 339.963 Watts. The model was not available in the software library; hence it was manually entered.

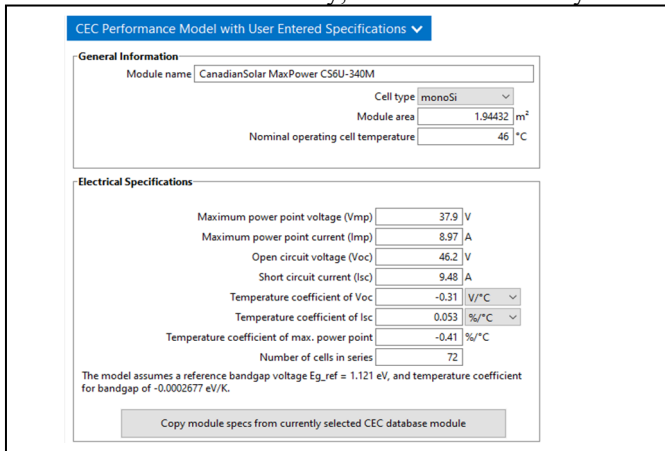

Fig. 5. CS6U-340M module specifications in the SAM UI

B. Inverter Analysis

The inverter model used is ABB's PVS980-58-2000 kVA-K. The model wasn't available in the library of the software, so it was manually entered.

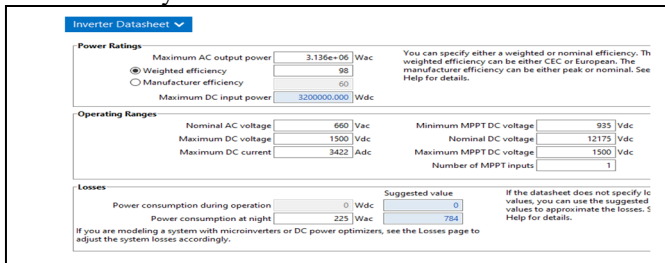

Fig. 6. PVS980-58-2000 kVA-K inverter specifications in the SAM UI

C. System Design

The system design uses the following parameters.

TABLE II. SYSTEM PARAMETERS

Property	Value
Number of inverters	250
Nameplate DC capacity	499,935.989 kW
Total AC capacity	784,000 kW
Total inverter DC capacity	800,000 kW
Number of Modules (PV)	1,470,560
Number of strings	45,955

Several losses are taken into consideration.

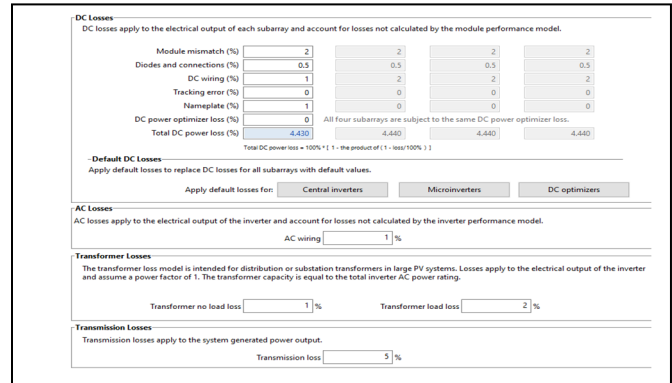

Fig. 7. System losses entered in SAM UI

D. Analysis Results

Results from running the system simulation in SAM are shown below.

Fig. 8. Annual DC energy production

As expected, DC energy production is higher during the spring and summer months, where days are longer, and lower where winter days are shorter. The annual AC energy production and average hourly energy production charts are shown below.

Fig. 9. Annual AC energy production

Fig. 10. Energy production averaged hourly over the year.

VII. SYSTEM DYNAMIC SIMULATION

The objective of the dynamic simulation is to simulate PV array output under the MPPT regime and plot the output characteristics on a time scale. The PV output voltage needs to be controlled to get the maximum power at any given irradiance. Also, since the power output from the PV arrays is DC, it needs to be converted and filtered to get 60 Hz AC for the purpose of exporting to the grid. These two functionalities are executed through DC-DC converters and DC-AC inverters, respectively. For this study, central inverter topology is considered, wherein the number of PV strings is paralleled as the input to an inverter.

Fig. 11. Central inverter topology

As per the ABB datasheet, each inverter has one MPPT. For dynamic simulation purposes, DC Combiner Box level PV array size is considered, i.e., 12 strings with 32 modules in each string. The selected PV module (Canadian Solar, CS6U-340M) is readily available in the Simulink library. The irradiance is

considered as variable between 600 W/m² and 250 W/m², whereas the temperature was kept constant at -4.57 °C (the yearly average temperature at the project location), respectively. PV array output is connected to a DC-DC boost converter. Boost converter output voltage is stabilized to 1200 V by selecting the value of Vnom_dc as 1200 V in the VSC controller block. This is based on the mean value of the allowed input range for ABB inverter (935 to 1500 V DC).

The MPPT algorithm in the Simulink model is of Incremental Conductance type. DC output from boost converter is converted to AC through a DC-AC, 3 phase inverter and further stepped up by a Ygd11, 660 V/35 kV transformer. To match with PV array size modeled in Simulink, the transformer rating is selected as 3500 kVA for this simulation. The inverter output filter capacitance rating is 10% of the transformer rating, i.e., 350 kVAR. A swing bus with ratings of 235 kV, 2500 MVA is modeled along with a 30 MW, 2 MVar local load to represent the grid. The simulation was run for a period of 2.5 sec. The voltage, current, and power plots are included below.

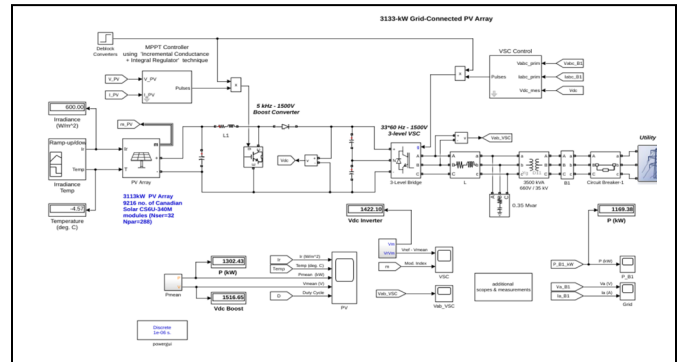

Fig. 12. MATLAB Simulink model

Fig. 13. Variation in solar irradiance

Fig. 14. Power output on 35 kV side of Pooling Transformer

Fig. 15. Voltage output on 35 kV side of Pooling Transformer

Fig. 16. Current output at the 35 kV side of Pooling Transformer

Fig. 17. Inverter output voltage waveform

As the result of the simulation, the PV array output is stabilized at 1945 kW, at 1.7 sec., with the input of 600 W/m² irradiance and -4.57°C temperature. The generated PV array voltage (V_{mean}) stabilized at 1210 V. The boost converter stabilizes the voltage to 1200 V, which is less than the maximum allowed voltage limit of 1500 V DC at ABBs PVS980 inverter incoming side. The 0.35 MVar capacitor is used at the output port of the inverter to remove the harmonics. The power exported on the 35 kV side of the pooling transformer is 1914 kW at the end of the 2.5-sec simulation duration.

TABLE III. SIMULATION RESULTS

Parameter	Result
PV capacity connected	3133 kW
Solar power generated	1945 kW
Power exported	1886 kW
PV voltage output	1210 V DC
Inverter output voltage	683V RMS ac
Voltage output for export	16.38 kV (RMS ac)

Parameter	Result
Overall simulation efficiency	60.5%

VIII. SYTEM PROTECTION AND CONTROL

The objective of this section is to describe protection and control requirements during variations in inputs or in the grid conditions. Earlier configuration of grid is retained, which includes a swing bus of 235 kV, 2500 MVA_{sc}, and a local load at Churchill Falls substation of rating 235 kV, 30 MW, 2 MVar.

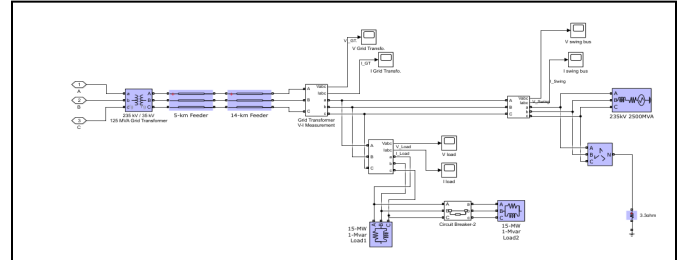

Fig. 18. Simulink model of utility grid and local load

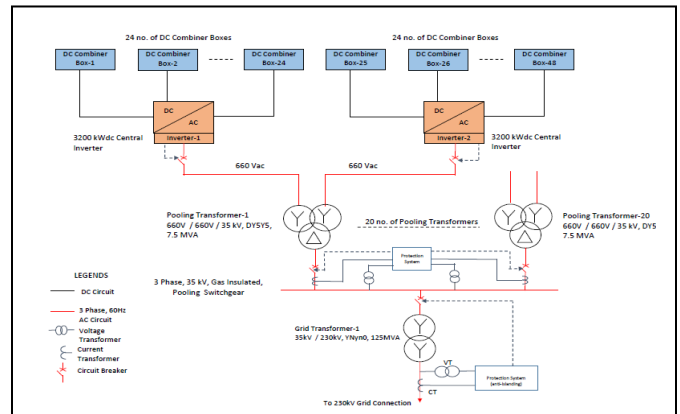

Fig. 19. Scheme diagram with protection and control system

The following cases are simulated – (1) variation in load, (2) grid islanding, and (3) variation in capacitance.

A. Variation in Load

For this simulation, the case load is split into two equal blocks, each of 15 MW, 1 MVar. One of the loads is switched off at 1 sec by opening the Circuit Breaker-2. The simulation is run for 2.5 sec. Irradiance and temperature are kept constant at 600 W/m² and -4.57°C, respectively.

Fig. 20. Local-load current profile

Fig. 21. Voltage (phase to phase) and current at 35 kV side of pooling transformer

Fig. 22. 235 kV Transmission Line voltage (ph-ph)

Fig. 23. Transmission Line current, on 235 kV side of Grid Transformer

Fig. 24. Transmission line current, on the swing bus side

It is observed that 50% load loss does not affect the load shared (i.e., current) by the PV plant. However, the current profile measured at the swing bus side (I_{Swing}) drops to half the value. This denotes that, since the rated capacity considered

for the PV system (3133 kW) and the Grid Transformer (125 MVA) are much weaker than the swing bus, the majority of load current is supplied by the swing bus. Also, even during loss of 50% of the load, the voltage of the transmission line is held stable by the swing bus at close to nominal capacity, i.e., 235 kV ph-ph. (Note- Current value from swing bus is higher than load bus as swing bus also supplies the charging currents for transmission lines and the grid transformer. In this case, since the voltage and current at the output of the PV system (i.e., on the 35 kV side of pooling transformer) are stable and within range, the protection system does not need to operate or isolate the PV system.

B. Grid Islanding

In the islanding scenario, the grid is lost completely on the occurrence of some major disturbances on the grid or unexpected opening of the connecting circuit breaker. To simulate this case, Circuit Breaker-1 on the 35 kV side of the pooling transformer is made open at 1 sec. This results in the isolation of the grid while the PV system is still generating power.

Fig. 25. Voltage and current on 35 kV side of pooling transformer

Around 0.5 sec, the PV system output current stabilizes with an RMS value of 85.59A between 0 to 1 sec. However, on the occurrence of grid loss at 1 sec., the PV system current output goes down to zero. On the other hand, voltage is held stable at 34.97 kV from 0 sec to 1 sec. After 1 sec., at the grid loss instant, overvoltage scenario occurs with the major rise from 2.25 sec. onwards. Generally, power system equipment is suitable for 10% overvoltage in normal running conditions. As observed from graphs, grid islanding poses a major overvoltage abnormality. Near the end of the simulation cycle, values as high as 235 kV can be seen on 35 kV rated secondary of the pooling transformer. To avoid this scenario, fast-acting, anti-islanding protection is necessary. Protection relays on the PV system side shall get inputs from transmission line voltage and current transformer to monitor the healthiness of the grid. On the occurrence of loss of grid or grid-fault, the protection system should act instantaneously to shut down the generation. Solar power plants shall be isolated to avoid supplying power to the faulty grid and thereby safeguarded from major insulation failures.

C. Variation in Capacitance

The output filter capacitance of the inverter is reduced to 0.15 MVAR from the normal value of 0.35 MVAR.

Fig. 26. Voltage and current on 35kV side of pooling transformer

Since no significant excursions were observed from normal voltage and current values, a protection system is not required to operate in reduced capacitance of the inverter filter. However, reduced capacitance may give rise to current harmonics.

IX. RESULTS AND DISCUSSION

This research investigated the system sizing, schema, modeling, and simulation of a 500 MW, grid-connected PV farm at a site close to the Churchill Falls Airport in Labrador to understand the PV farm's technical and economic feasibility. The system was sized using manual calculations and the PVWatts. A solar PV module and an MPPT inverter were selected using this information. The overall plant was divided into four blocks of 125 MW each for ease of maintenance, control, and redundancy in case of planned and unplanned outages. Pooling transformers, high voltage switchgear, grid transformers, and the export transmission line was sized accordingly. System performance was analyzed using System Advisor Model. A grid-connected PV system with the inverter was modeled in Simulink, MATLAB for dynamic simulations. The grid was modeled as a swing bus along with a local load.

System output parameters were analyzed for varying conditions.

In Canada, the average installation cost of a PV farm is \$1.25/Watt [4]. For this 500 MW system, the installation cost would be approximately \$625 million, with additional operational and maintenance costs over the system's lifespan. The land area requirement for this system, coming up to nearly 3.33 sq. km, is quite large. Our observation is that utility-scale PV plants are more practical in provinces with higher average annual solar irradiance, like Ontario and Alberta. Future technological improvements in PV cell efficiency could make this installation more practical in areas with lower average annual solar irradiance, such as in Labrador.

Future work in this project will include tuning the inverter output filters to reduce THD (total harmonic distortions), performing a detailed sizing of other equipment such as DC & AC cables, transmission lines; plant layout design; and detailed cost analysis of the solar power plant.

Abstract—This paper presents a novel optimal control algorithm for coordinated force and motion control of multi rover robotics system with mecanum wheels while manipulating a common payload. Such a system with kinematical rolling conditions lead to non-holonomic constraints. The proposed control algorithm focuses on the minimization of joint torques, the rover-mecanum wheel moments as well as the contact force / moments made with the payload. A quadratic cost function in terms of the joint torques, the wheel moments and the contact forces and moments are minimized to overcome the so called joint torque saturation problem commonly seen while manipulating a common payload and also to provide an optimum solution for such an underdetermined system with non-holonomic constraints. Furthermore, the proposed control algorithm provides an on-line trajectory generation capability while manipulating a common payload for both the rovers and the arms simultaneously. The computer simulation results show that the control algorithm works efficiently and the minimum joint torques, and the contact forces and moments can be obtained while the end-effectors are manipulating and tracking a desired payload trajectory.

Keywords— *optimal control, coordinated motion and force control, multi rover system, mecanum wheels*

I. INTRODUCTION

There has been a considerable amount of interest in mobile rovers working in complex environments including space, mining and construction and military.

Initial technological challenges included mechanical design, especially related to the mechanics of locomotion, collision free trajectory generation, dynamic control of rover and mounted robotics manipulators.

Necsulescu et al [1] and [2] studied free and contact motion for rovers and developed impedance control techniques for real-time collision free motion generation as well as force control.

Control of mobile rovers subject to nonholonomic constraints were demonstrated using Differential Wheeled Mobile Robots (DWMR) in [3] and [4]. These nonholonomic constraints are often experienced when the kinematic constraints cannot be written in terms of time derivatives of some functions of the generalized coordinates.

The control of a mechanical system with nonholonomic constraints has been studied extensively and quite often,

kinematic control is designed ignoring the dynamics of the system [5]. It has been illustrated in [6] that a mechanical system with nonholonomic constraints can still be controlled despite the structure of the nonholonomic constraints. It was also demonstrated that a nonholonomic system cannot be stabilized to a single equilibrium point by a smooth time-invariant feedback [7].

Control of Multiple Robot Manipulators with Optimal Force Distribution was demonstrated in Kalaycioglu [8]. However, this study did not include rovers and was limited to two cooperating arms.

Recently, mechanics of wheeled locomotion drew considerable amounts of attention [9] – [14]. Several studies focused on the kinematics and dynamics modeling of the mecanum wheel, a special type of omnidirectional wheel [15] – [20].

Although, there is a compilation of extensive research studies, publications, and system development in the areas of single rover trajectory control, motion control of the arm, etc., the research is still at its infancy when it comes to payload sharing multiple rovers and mounted arms, their coordinated real-time collision-free trajectory generations and gross and fine control of the motions while operating a common payload.

The paper is structured into four sections. Section II presents the theoretical formulations, including the kinematics, dynamics model of the compound system which consists of two rovers and two n-degree redundant manipulators and a common payload. An optimal control algorithm is formulated by minimizing joint torques, wheel moments and the contact force/moments, respectively. Simulation results and discussion are presented in Section III and some concluding remarks are provided in Section IV.

II. THEORETICAL FORMULATIONS

A. Description of the System

The system under consideration consists of two identical four-wheeled mobile rovers with mecanum wheels and two n-DOF redundant manipulators which are mounted on these rovers operating a common payload. An example of the system of mobile rovers with two n-degree robots is illustrated in Fig. 1.

Fig. 1. Rover Robotics System Description

The system parameters of the robots and rovers used in the simulations are provided in Table 1. Let the R_{ci} , the position vector and the orientation angle ψ_i define the location of the centre of mass C_i of the rover- i with respect to the inertial coordinate system, X, Y, Z . A set of coordinate axes x_{ci}, y_{ci}, z_{ci} fixed to the center of the rover is obtained from the inertial coordinate system through a rotation around Z -axis with an angle of ψ_i .

The masses of the rover and the wheels are denoted by m_{ci} and m_{wij} while the distances between the centers of wheels along the y_{ci} and x_{ci} -axes are defined by $2a$ and $2b$, respectively.

Each mecanum wheel has a radius of s while the angle of rotation and the angular rate for each wheel are identified as ϕ_{ij} and ω_{ij} respectively, $j=1...4$. As shown in Fig. 1, the mecanum wheels have rollers attached to their outer rims. The angle between the x_{ci} and the axis of rotation of the roller is defined by β_{ij} for each wheel, $j=1...4$ and $i=1,2$ for each rover.

B. Kinematics Model of the System

The velocity of the centre of the wheel, V_{mi} can be calculated by

$$V_{mij} = V_{ci} + \Omega_{ci} \times r_{wij} \tag{1}$$

$$\Omega_{ci} = \dot{\psi}_i e_z \tag{2}$$

where V_{ci} is the velocity of the rover's centre of mass, Ω_{ci} is the angular rate of the rover along the z_{ci} , and e_z is the unit vector along the z_{ci} and finally r_{wij} is the displacement vector measured from the rover's centre of mass to the centre of the wheel.

The velocity of the point P, the centre of the roller can be calculated as

$$V_{pij} = V_{mij} + \omega_{ij} \times \rho \tag{3}$$

where ρ is the displacement vector measured from the centre of the wheel to the centre of the roller, point P.

If there is no slip, V_{pj} can not have a component along the axis of roller rotation $e_{\beta j}$, namely

$$V_{pij} \cdot e_{\beta ij} = 0 \tag{4}$$

where $e_{\beta ij}$ is the unit vector along the axis of the roller rotation. Substituting (3) into (4), carrying out the cross product, one can obtain the following relationship:

$$\begin{aligned} V_{mij} \cdot e_{\beta ij} + (\omega_{ij} \times \rho) \cdot e_{\beta ij} &= 0 \\ (\omega_{ij} \times \rho) &= -\omega_{ij} s e_x \\ V_{mij} \cdot e_{\beta ij} &= s (e_x \cdot e_{\beta ij}) \end{aligned} \tag{5}$$

where e_x is the unit vector along the x_{ci} axis and s is the radius of the wheel.

Also, substituting (1) into (5), one can rewrite the constraint equation as follows:

$$\begin{aligned} V_{ci} \cdot e_{\beta ij} + (\Omega_{ci} \times r_{wij}) \cdot e_{\beta ij} &= \omega_{ij} s (e_x \cdot e_{\beta ij}) \\ V_{ci} \cdot e_{\beta ij} + (r_{wij} \times e_{\beta ij}) \cdot \Omega_{ci} &= \omega_{ij} s \cos(\beta_{ij}) \end{aligned} \tag{6}$$

where β_{ij} is the angle between the unit vectors of e_x and $e_{\beta ij}$

$$\begin{aligned} e_{\beta i1}^T &= [\cos(\beta_{i1}), -\sin(\beta_{i1}), 0] \\ e_{\beta i2}^T &= [\cos(\beta_{i2}), \sin(\beta_{i2}), 0] \\ e_{\beta i3}^T &= [\cos(\beta_{i3}), \sin(\beta_{i3}), 0] \\ e_{\beta i4}^T &= [\cos(\beta_{i4}), -\sin(\beta_{i4}), 0] \\ r_{wi1}^T &= [a, b, 0] \\ r_{wi2}^T &= [a, -b, 0] \\ r_{wi3}^T &= [-a, b, 0] \\ r_{wi4}^T &= [-a, -b, 0] \end{aligned} \tag{7}$$

Substituting (7) into (6) and assigning β_{ij} as $\pi/4$, one can obtain the following equations:

$$V_{ci} = \begin{bmatrix} V_{cxi} \\ V_{cyi} \\ V_{czi} \end{bmatrix} = \begin{bmatrix} s(\omega_{i1} + \omega_{i2})/2 \\ s(\omega_{i3} - \omega_{i1})/2 \\ 0 \end{bmatrix}$$

$$\Omega_{ci} = \begin{bmatrix} \Omega_{cxi} \\ \Omega_{cyi} \\ \Omega_{czi} \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ s(\omega_{i3} - \omega_{i1})/(2(a+b)) \end{bmatrix}$$

$$\omega_4 = \omega_1 + \omega_2 - \omega_3 \quad (8)$$

The rotational transformation from the inertial to the rover body axes is represented by the following rotation matrix:

$$\Psi_z = \begin{bmatrix} \cos\psi & \sin\psi & 0 \\ -\sin\psi & \cos\psi & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad (9)$$

Similarly, each homogeneous transformation matrix T_i^j that transforms the coordinates of a point from frame j to frame i on a robot manipulator is calculated using Denavit-Hartenberg (D-H) convention.

$$T_i^j = \underbrace{A_{i+1}} \underbrace{A_{i+2}} \dots \underbrace{A_{j-1}} A_j \quad i < j$$

$$A_i = \begin{bmatrix} \cos\theta_i & -\sin\theta_i \cos\alpha_i & \sin\theta_i \sin\alpha_i & a_i \cos\theta_i \\ \sin\theta_i & \cos\theta_i \cos\alpha_i & -\cos\theta_i \sin\alpha_i & a_i \sin\theta_i \\ 0 & \sin\alpha_i & \cos\alpha_i & d_i \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (10)$$

where the four quantities $\theta_i, \alpha_i, d_i, a_i$ are parameters of link-i and joint-i and a_i is the length of the link, α_i is the twist, d_i is the offset while θ_i is the joint angle.

The Jacobian matrices and their first-time derivatives between the centre of the rover and a point-k on the robotics manipulator can also be calculated as follows:

$$\begin{pmatrix} \dot{j}_c^k \\ \dot{L}_c^k \end{pmatrix}_L = \begin{bmatrix} e_z & e_1 & \dots & e_5 & e_7 \\ e_z \times r_{ck} & e_1 \times r_{1k} & \dots & e_5 \times r_{5k} & e_7 \times r_{7k} \end{bmatrix} \quad (11)$$

$$\begin{pmatrix} j_c^k \\ L_c^k \end{pmatrix}_L = \begin{bmatrix} e_z & e_1 & \dots & e_7 \\ e_z \times (\Omega_c \times r_{ck}) & e_1 \times (\theta_1 \times r_{1k}) & \dots & e_7 \times (\theta_7 \times r_{7k}) \end{bmatrix} \quad (12)$$

where e_z is the unit vector along Ω_c rover's fixed rotation axis, e_i is the unit vector along the rotation axis of the i^{th} joint and r_{ck}, r_{ik} are the displacement vectors from the centre of rover and i^{th} joint to the point k, respectively.

The angular and linear velocities and accelerations of any point on the first rover arm can be determined by using the Jacobian matrix:

$$\begin{bmatrix} \Omega_k \\ V_k \end{bmatrix}^L = \begin{pmatrix} j_c^k \\ L_c^k \end{pmatrix}_L \begin{bmatrix} \Omega_c \\ V_{cL} \end{bmatrix} + \begin{bmatrix} 0 \\ V_{cL} \end{bmatrix} \quad (13)$$

$$\begin{bmatrix} \dot{\Omega}_k \\ \dot{V}_k \end{bmatrix}^L = \begin{pmatrix} j_c^k \\ L_c^k \end{pmatrix}_L \begin{bmatrix} \dot{\Omega}_c \\ \dot{\theta}_L \end{bmatrix} + \begin{pmatrix} j_c^k \\ L_c^k \end{pmatrix}_L \begin{bmatrix} \Omega_c \\ \theta_L \end{bmatrix} + \begin{bmatrix} 0 \\ V_{cL} \end{bmatrix} \quad (14)$$

where $\dot{\theta}_L^T = [\dot{\theta}_1, \dot{\theta}_2, \dot{\theta}_3, \dots, \dot{\theta}_n]$ is the first rover-arm joint rates, Ω_k and V_k are the (3x1) angular and linear velocity vectors of the k point on the first arm, respectively. Again, the angular and linear velocity of any point of the second arm can also be calculated by simply changing the index from L to R.

C. Dynamics Model of the System

The Lagrangian formulation is employed to obtain the dynamics equations of motions of the robotics system. The total kinetic energy of the system T_t can be calculated by adding both the translational and rotational kinetic energies of the rovers and the robot manipulators.

$$T_t = T_{tra} + T_{rot} \quad (15)$$

The translational and rotational velocities of the centre of mass of the rovers and the robot links are provided in (8) and (14). These expressions are substituted into (15) to obtain the total kinetic energy of the system.

The Lagrangian equations can be written as

$$\frac{d}{dt} \left(\frac{\partial T_t}{\partial \dot{q}_n} \right) - \frac{\partial T_t}{\partial q_n} = Q_n, \quad n = 1, \dots, 2m \quad (16)$$

where q_n are the generalized coordinates as

$q^T = [\phi_{1L}, \phi_{2L}, \phi_{3L}, \phi_{1R}, \phi_{2R}, \phi_{3R}, \theta_{1L}, \dots, \theta_{nL}, \theta_{1R}, \dots, \theta_{nR}]$ and Q_n are the generalized forces and $m = (n+3)$, n is the number of degrees of freedom of the redundant manipulators.

After substituting (15) into (16) and carrying out the differentiation, one can obtain the following equations of motions for the system.

$$\begin{bmatrix} G_{WL} & G_{WLR} & G_{W\theta L} & G_{W\theta R} & \dot{\Omega}_L \\ G_{WLR}^T & G_{WR} & G_{W\theta L} & G_{W\theta R} & \dot{\Omega}_R \\ G_{W\theta L}^T & G_{W\theta L}^T & G_{\theta L} & G_{\theta LR} & \ddot{\theta}_L \\ G_{W\theta R}^T & G_{W\theta R}^T & G_{\theta LR}^T & G_{\theta R} & \ddot{\theta}_R \end{bmatrix} \begin{bmatrix} c_L \\ c_R \\ c_{\theta L} \\ c_{\theta R} \end{bmatrix} + \begin{bmatrix} \dot{\Omega}_L \\ \dot{\Omega}_R \\ \ddot{\theta}_L \\ \ddot{\theta}_R \end{bmatrix} = \begin{bmatrix} M_L \\ M_R \\ \tau_{\theta L} \\ \tau_{\theta R} \end{bmatrix} \quad (17)$$

where \underline{G} , the inertia / mass matrix is a positive definite matrix and, $\dot{\Omega}_L, \dot{\Omega}_R$, are the angular accelerations of the wheels of the two rovers, $\ddot{\theta}_L, \ddot{\theta}_R$ are the joint angular accelerations for the two arms respectively. $c_L, c_R, c_{\theta L}$, and $c_{\theta R}$ are the non-linear terms while M_L, M_R are the wheel control moments for the rovers and $\tau_{\theta L}, \tau_{\theta R}$ are the joint control torques for the arms, respectively.

where $\Omega_L^T = [\omega_{L1}, \omega_{L2}, \omega_{L3}]$ consists of the angular rates of the three wheels of the first rover, similarly Ω_R^T can be written in terms of the second rover's wheel angular rates. The

fourth wheel angular rate is dependent on the first three if there is no slip as shown in (8). The sub-index L is referred to the first and R is to the second rover and robot manipulator, respectively.

D. A Novel Optimal Control Technique

The system consisting of two redundant robot manipulators mounted on two rovers manipulating a common payload is mathematically an underdetermined system due to the redundant number of actuators and sensors available to control the rotational and translational motions of the rovers and the links.

In this section, a new two-stage optimal control technique is developed and demonstrated in a control system block diagram in Fig. 2.

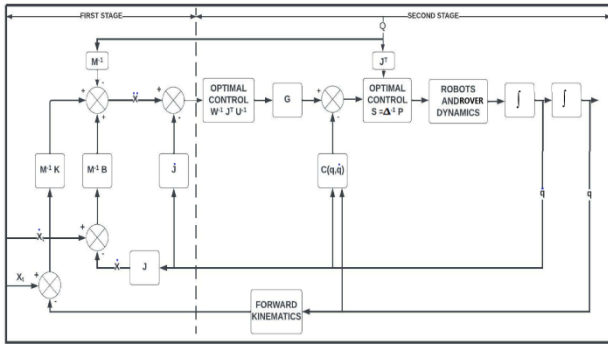

Fig. 2. Two stage optimal control system block diagram

The first stage of the block diagram consists of a well-known impedance control technique which facilitates the generation of the desired trajectories for the two end-effectors for a given trajectory of the payload and is presented in (18).

$$\ddot{X}_i = \underline{M}_i^{-1} \underline{B} \{ \dot{X}_{di} - \ddot{X}_i \} + \underline{M}_i^{-1} \underline{K} \{ \tilde{X}_{di} - \tilde{X}_i \}, \quad i = L, R \tag{18}$$

where, \underline{M}_i , \underline{B} , \underline{K} are 6x6 positive definite impedance matrices and can be selected to meet the requirements of the tracking performance while \tilde{X}_i . (i varies between L and R for each arm) are the desired end-effector trajectories for the two arms and \tilde{X}_{di} are the given trajectories for the arm attachment point on the payload. The matrix selection process will not be discussed here for the sake of brevity.

Equations (13) and (14) can be rewritten by substituting Ω_L and Ω_R and eliminating Ω_C and V_C from the equations.

$$\tilde{X}_L = \begin{bmatrix} \Omega_k \\ V_k \end{bmatrix}^L = \begin{bmatrix} J_c^k \\ \end{bmatrix}_L \begin{bmatrix} \Omega_L \\ \dot{\theta}_L \end{bmatrix} \tag{19}$$

$$\dot{\tilde{X}}_L = \begin{bmatrix} \dot{\Omega}_k \\ \dot{V}_k \end{bmatrix}^L = \begin{bmatrix} J_c^k \\ \end{bmatrix}_L \begin{bmatrix} \dot{\Omega}_L \\ \dot{\theta}_L \end{bmatrix} + \begin{bmatrix} J_c^k \\ \end{bmatrix}_L \begin{bmatrix} \Omega_L \\ \dot{\theta}_L \end{bmatrix} \tag{20}$$

Carrying out the least-square minimization of joint rates, one can solve for the inverse kinematics to obtain Ω_L and $\dot{\theta}_L$ and their time derivatives from (19) and (20).

$$\begin{bmatrix} \Omega_i \\ \dot{\theta}_i \end{bmatrix} = \underline{W}_i^{-1} \left(J_c^k \right)_i^T \underline{U}_i^{-1} \dot{\tilde{X}}_i \tag{21}$$

$$\begin{bmatrix} \dot{\Omega}_i \\ \ddot{\theta}_i \end{bmatrix} = \underline{W}_i^{-1} \left(J_c^k \right)_i^T \underline{U}_i^{-1} \left\{ \ddot{\tilde{X}}_i - \left(J_c^k \right)_i \begin{bmatrix} \Omega_i \\ \dot{\theta}_i \end{bmatrix} \right\} \tag{22}$$

$$\underline{U}_i = \begin{bmatrix} J_c^k \\ \end{bmatrix}_i \underline{W}_i^{-1} \begin{bmatrix} J_c^k \\ \end{bmatrix}_i^T \tag{23}$$

where \underline{W}_i is a (n+3) by (n+3) positive definite weighting matrix. The sub-index i , can be replaced by L for the first rover and its associated arm and R for the second rover-arm, respectively.

Through the application of the inverse dynamics of the system as illustrated in the control block diagram, the joint torques, and the rover-wheels moments then can be calculated accordingly, as shown below

The second stage of the block diagram is original, pragmatic, and based on optimal control techniques. The formulation is presented below.

A cost function C is designed to minimize the joint torques τ_{θ_L} , τ_{θ_R} , the wheel moments M_L and M_R as well as the contact forces and moments \tilde{F}_i and \tilde{N}_i applied by the arms on the common payload

Thus, the cost function, C can be described as:

$$C = \frac{1}{2} \tilde{S}^T \underline{W} \tilde{S} + \tilde{\lambda}^T \tilde{E} \tag{24}$$

\underline{W} is a square (2n+18, 2n+18) positive definite weighting matrix, n is being the total number of joints for each arm while $\tilde{\lambda}$ is the ((2n+12), 1) Lagrangian multiplier and \tilde{E} is the constraints equations vector which is defined by (26).

The \tilde{S} vector consists of the contact forces and moments as well as the wheel moments and joint torques for the two rovers and arms, respectively as shown below:

$$\text{Let } \tilde{Q}_i = \begin{bmatrix} \tilde{N}_i \\ \tilde{F}_i \end{bmatrix}, \text{ then } \tilde{S}^T = [\tilde{Q}_L, \tilde{Q}_R, M_L, M_R, \tau_{\theta_L}, \tau_{\theta_R}] \tag{25}$$

where \vec{F}_i and \vec{N}_i are the contact forces and moments applied by the arm ($i = L$ and R for the first and the second arm respectively) on the common payload, respectively.

The \vec{E} vector can be written as follows:

$$\vec{E} = \begin{bmatrix} \vec{F}_L + \vec{F}_R - m_t \ddot{x}_t \\ \vec{N}_L + \vec{N}_R - d_L \times \vec{F}_L - d_R \times \vec{F}_R - [I_t \Omega_t + \Omega_t \times I_t \Omega_t] \\ G_{WL} & G_{WLR} & G_{W\theta L} & G_{W\theta R} & \dot{\Omega}_L \\ G_{WLR}^T & G_{WR} & G_{W\theta L} & G_{W\theta R} & \dot{\Omega}_R \\ G_{W\theta L}^T & G_{W\theta L}^T & G_{\theta L} & G_{\theta LR} & \ddot{\theta}_L \\ \llbracket G_{W\theta R}^T & G_{W\theta R}^T & G_{\theta LR}^T & G_{\theta R} \rrbracket \llbracket \ddot{\theta}_R \rrbracket \end{bmatrix} - \begin{bmatrix} c_L \\ c_R \\ c_{\theta L} \\ c_{\theta R} \end{bmatrix} - \begin{bmatrix} M_L \\ M_R \\ \tau_{\theta L} \\ \tau_{\theta R} \end{bmatrix} \quad (26)$$

where m_t and \ddot{x}_t are the mass and the translational acceleration of the payload and. $d_i^T = (x_i, y_i, z_i)$ is the displacement vector measured from the arm's attachment point to the centre of mass of the payload, I_t is the inertia matrix of the payload around its centre of mass and $\dot{\Omega}_t$ is the angular rate of the payload.

Minimizing the cost function C with respect to \vec{S} , and $\vec{\lambda}_i$ can be carried out by differentiating C with respect to $\vec{\lambda}_i$ and \vec{S} . One can calculate the minimum norm of joint torques, wheel moments and the end-effectors force and moments exerted on the common payload.

$$\frac{\partial C}{\partial \vec{S}} = \vec{0} \quad (27)$$

and

$$\frac{\partial C}{\partial \vec{\lambda}} = \vec{0} \quad (28)$$

After some algebraic manipulations and eliminating $\vec{\lambda}$ from the equations, one can write the minimum norm of \vec{S} vector which consists of joint torques, wheel moments and the contact force and moment vectors as follows:

$$\vec{S} = \underline{\Delta}^{-1} \vec{P} \quad (29)$$

where $\underline{\Delta}$ is a $((2n + 18), (2n + 18))$ square matrix while n is being the number of joints. $\underline{\Delta}$ and \vec{P} are provided below:

$$\underline{\Delta} = \begin{bmatrix} W_{NL} & \vec{0} & -W_{NR} & \vec{0} & -W_{FL} (J_C^k)_L^T & W_{FR} (J_C^k)_R^T \\ (D_L - D_R)W_{NL} & W_{FL} & \vec{0} & -W_{FR} & -(1 + D_L - D_R) (J_C^k)_L^T & W_{FR} (J_C^k)_R^T \\ \vec{0} & \frac{1}{D_L} & \vec{0} & \frac{1}{D_R} & \vec{0} & \vec{0} \\ \frac{1}{D_L} & -D_L & 1 & D_R & \vec{0} & \vec{0} \\ (J_C^k)_{L1}^T & (J_C^k)_{L2}^T & \vec{0} & \vec{0} & 1 & \vec{0} \\ \vec{0} & \vec{0} & (J_C^k)_{R1}^T & (J_C^k)_{R2}^T & \vec{0} & 1 \end{bmatrix} \quad (30)$$

$$\vec{P} = \begin{bmatrix} \vec{0} \\ \vec{0} \\ \vec{0} \\ \vec{0} \\ m_t \ddot{x}_t \\ [I_t \dot{\Omega}_t + \dot{\Omega}_t \times I_t \dot{\Omega}_t] \\ G_{WL} & G_{WLR} & G_{W\theta L} & G_{W\theta R} & \dot{\Omega}_L \\ G_{WLR}^T & G_{WR} & G_{W\theta L} & G_{W\theta R} & \dot{\Omega}_R \\ G_{W\theta L}^T & G_{W\theta L}^T & G_{\theta L} & G_{\theta LR} & \ddot{\theta}_L \\ \llbracket G_{W\theta R}^T & G_{W\theta R}^T & G_{\theta LR}^T & G_{\theta R} \rrbracket \llbracket \ddot{\theta}_R \rrbracket \end{bmatrix} + \begin{bmatrix} c_L \\ c_R \\ c_{\theta L} \\ c_{\theta R} \end{bmatrix} \quad (31)$$

$$D_i = \begin{bmatrix} 0 & -z_i & y_i \\ z_i & 0 & -x_i \\ -y_i & x_i & 0 \end{bmatrix} \quad (32)$$

where $d_i^T = (x_i, y_i, z_i)$ is the displacement vector measured from the arm's attachment point to the centre of mass of the payload and the matrix D_i is obtained from the components of the displacement vector.

III. RESULTS AND DISCUSSION

The computer simulation results are presented and discussed in this section.

In this simulation, the desired trajectory for the center of mass of the common payload was generated and in turn the trajectories for the two end-effectors were obtained while they were holding a common payload. The impedance control technique as illustrated in the first stage of the control block diagram was employed for the trajectory generation.

The main objective of this simulation was to obtain the minimum norm of the joint torques, the rover wheel moments and the contact forces and moments exerted on the payload by the two arms while tracking a desired end-effector pose.

Table 1 parameters were used for the rovers and the robotics arms in the computer simulations. Two scaled version of the 7 DOF Space Station Remote Manipulators were employed as part of the simulations.

The desired trajectories for translational as well as rotational motions of the payload are plotted with time in Fig. 3.

Fig. 3. Variation of the desired trajectory for payload

The minimum norm of the joint torques, and the contact forces and moments exerted on the payload by the two robot manipulators while carrying a common payload were plotted in Fig. 4a-i below. The minimum norm of joint torques (red lines) are plotted against the joint torques (blue lines) obtained by only minimizing the joint rates by the least square (i.e. only part 1 of the control block diagram is exercised). The comparison of the joint torques clearly demonstrate that the minimization scheme works efficiently.

Fig. 4. Minimum norm of joint torques (first and second arm) and the contact forces and moments

The joint accelerations for each robot are also calculated using (22) and are plotted with time in Fig. 5.

Fig. 5. Variation of joint angular accelerations for the first and second arm

The joint angular rates and angles were obtained by integrating the joint accelerations using (13) and were plotted in Fig. 6.

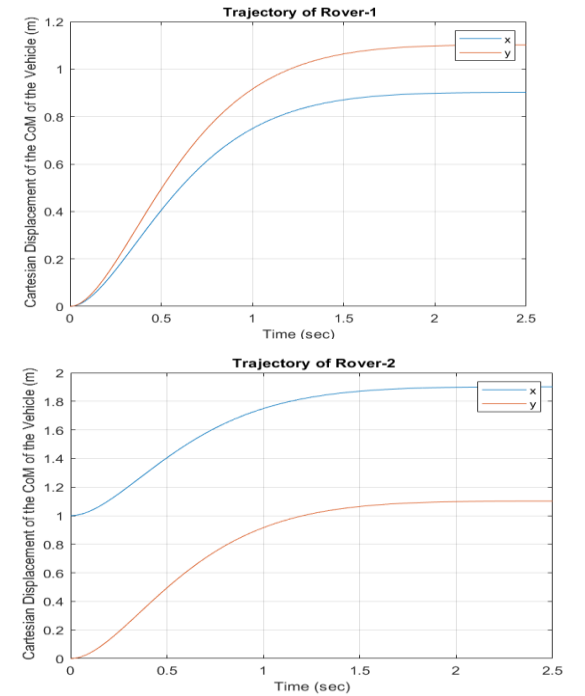

Fig. 6. Variation of joint angular rates and angles for the first and second arm

The trajectories of the centre of mass of the rovers 1 and 2 were also obtained by (22) and (8) and were plotted with time Fig. 7.

Fig. 7. Variation of Rover 1 and 2 positions and orientations with time

The angles of rotation for the rover wheels were also obtained by making use of (22) and were plotted in Fig. 8

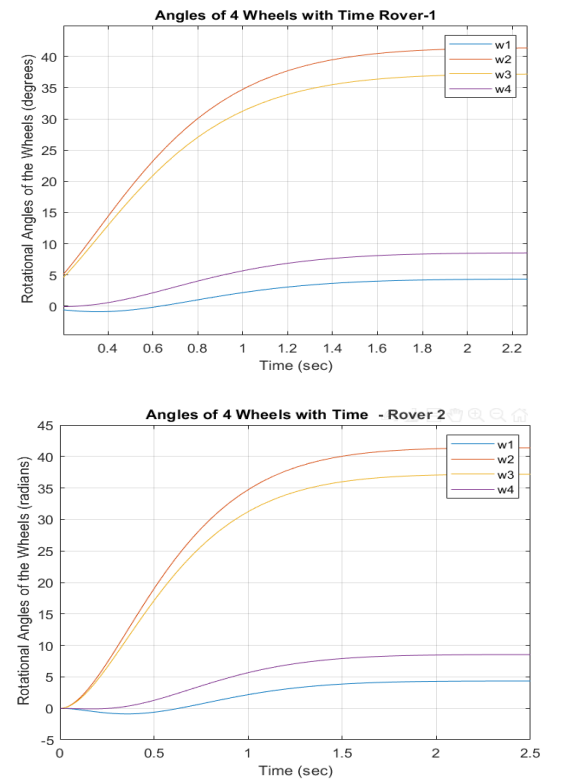

Fig. 8. Variation of angles of rotations for each wheel of rover 1 and 2

IV. CONCLUSION

This paper presented a novel optimal control algorithm for coordinated force and motion control of multi rover robotics system while manipulating a common payload. The proposed control algorithm focused on the minimization of joint torques, rover wheel moments as well as contact force / moments made with the payload. The norm of joint torques, wheel moments and the contact forces and moments were minimized to overcome the joint torque saturation problem commonly seen while

manipulating a common payload and also to provide an optimum solution for an underdetermined system with non-holonomic constraints. Furthermore, the proposed control algorithm provided an on-line trajectory generation capability while manipulating a common payload for both the rovers and the arms simultaneously.

The computer simulation results showed that the proposed control algorithm worked efficiently, and the minimum joint torques, and the contact forces and moments were obtained. Moreover, the optimal solution simultaneously satisfied the non-holonomic constraints while the end-effectors were carrying a common payload and tracking a desired payload trajectory.

Abstract—The paper compiled and structured data to construct a correlation model. The reasons for flight delays and cancellations between 2009 from 2019 are examined, based on the statistical electronic source “Bureau of Transportation Statistics”. The normalized data are calculated from the primary data. Based on the data collected, a primary histogram was constructed (outliers were not checked). In addition, significant and weak influencing factors have been identified for the constructing of a correlation table, this table helps to identify an additional factor influencing a flight delay or cancellation. Based on the data from the table, a new histogram was built and a correlation table was constructed, allowing regression analysis to be started. At the beginning of the regression analysis, regression statistics are used and an analysis of variance is performed, then the regression analysis is performed directly and the results of the regression are summed up. Based on the summed-up results, a histogram was built, which takes into account all the statistics and calculations, showing the predicted number of delays or cancellations of flights and their actual number.

Keywords—Regression analysis, mathematical model, climate, temperature sensation, temperature factors

I. INTRODUCTION

The solution of practical problems by mathematical methods is consistently carried out by formulating the problem (development of a mathematical model), choosing a method for studying the obtained mathematical model, analyzing the obtained mathematical result. The mathematical formulation of the problem is usually presented in the form of geometric images, functions, systems of equations, etc. The description of an object (phenomenon) can be represented using continuous or discrete, deterministic or stochastic and other mathematical forms. The theory of mathematical modeling ensures the identification of the patterns of the flow of various

phenomena of the surrounding world or the operation of systems and devices by their mathematical description and modeling without field tests [1].

Mathematical analysis is widely used in physics, computer science, statistics, engineering, economics, business, finance, medicine, demography and other areas where a mathematical model can be built to solve a problem and its optimal solution needs to be found.

Regression analysis can be used to estimate the degree of relationship between variables and to model future dependencies. In fact, regression methods show how changes in the “independent variables” can be used to fix the change in the “dependent variable”. This model can be used to detect trends and make forecasts. Suppose the company's sales have been growing for two years. By doing a linear analysis of the monthly sales data, the company could predict sales in the coming months. It is with the help of regression analysis that a mathematical model will be formulated showing the ratio of the predicted number of cancellations and delays of flights to the actual ones [2].

Air transport is gaining more and more popularity, more and more people prefer to use air transport to move from one locality to another, as it significantly reduces the travel time and allows you to get to the right place in the shortest possible time. Air transportation is becoming one of the most popular passenger transportation services at the present time, due to the speed, comfort, safety and availability of this type of transportation. This service reaches its maximum values in the field of international mobility, the purpose of which in most cases is tourism. Passenger air transportation is a service for the transportation of the population on an aircraft, provided on various conditions. In the Russian Federation, air transportation services for the population are among the types of activities carried out by civil aviation (in addition to

passenger air transportation, civil aviation carries out activities of a general social nature in the field of medicine, sports and culture, agriculture, etc.). Air transportation of the population is divided into: domestic and international; regular and charter; commercial and non-commercial. Among other things, air transport also has a significant important role in business (business trips, business meetings, etc.). But, despite all the comfort and accessibility, air transport also has a large number of nuances, which are mainly manifested in the loss of time, waiting for a plane that is delayed for one reason or another. It is also not uncommon for flights to be canceled, for example, due to weather conditions or other factors that are almost impossible to fully predict. We will stop on the cancellation factors. We will determine the possible reasons for the cancellation or delay of flights. Of course, one of the main reasons is the weather. Unfortunately, even with modern forecasting capabilities for positive weather conditions, not everything always goes according to plan, and in some cases it is necessary to delay or even cancel a flight due to the threat of a crash, respectively, a threat to the lives of passengers and crew members. Much less often, but still, the reason for canceling a flight can be a transport security check. The reason for the intervention of TB can be a complaint from crew members or directly from the passengers themselves about a suspicious person or object. In this case, the TB can land the plane for a forced check of the passenger, and the flight is delayed accordingly. Extremely rarely, but one of the reasons for the intervention of TB can be a terrorist threat or its prerequisites. Safety intervention is also necessary if there is a violent passenger in the cabin, disturbing the peace of the others or interfering with the work of the crew. A more frequent factor is the delay or cancellation of the flight by the national aviation system, the reason for the intervention may be the unstable political situation in the country that is part of the journey. In this case, a change of route or a flight cancellation may occur. Sometimes the flight can be canceled by the airline itself, the reasons for

this can be very different, often the company does not report the reason for canceling the flight. At present, all these factors have long been known and quite successfully predicted. Next, we will conduct a regression analysis and check which factors stand out from the rest and compare the actual number of events with the predicted ones [3], [4].

II. DATA COLLECTION AND SORTING

Using data taken from the Bureau of Transportation Statistics and other sources, we will compile a table from 2009-2019, in which the main indicators will be the number of delays and the factors affecting them [5]–[8]:

- The number of delays due to bad weather.
- Suppose for 2009 the number of delays was 41865, and for 2019 it is already 46303.
- The number of delays due to security checks.
- Delays for 2009 are 2328, and already for 2019 there were 2642.
- The number of delays due to the national aviation system.
- The number of delays in 2009 was 450,645, but in 2019 the number increased to 439,491.
- The number of delays due to the airline itself.
- Delays in 2009 were 323,743, and already in 2019 they were 387,853
- The number of delays due to other reasons.
- The number of delays in 2009 was 399709, but already in 2019 these delays increased to 512965.

Having collected the necessary data, we enter them into Excel and create a histogram (Figure 1).

Fig. 1. Flight delays for one reason or another to the total number of delayed or canceled flights.

Having made a histogram, we carry out conditional formatting to exclude possible outliers. “Conditional formatting marks indicators with different colors, and if there is an indicator in a particular factor, the color of which is radically different from the rest, this is an outlier [9]. Outliers are values that are very different from the rest, and they are not desirable for use in constructing a regression equation, since the equation will be unstable in use, that is, when new data is added, the old indicators change greatly, which will lead to the function becoming completely different [10].

In this case, no such outliers were found, so it is possible to carry out a correlation analysis, as a result of which we

will get a table where you can see the factors that do not or weakly affect the number of delays.

We determine non-influencing factors according to the following principle, if the factor is close to 1, then it has an influencing value on the main factor, respectively, if it is far from 1, then it is not influencing.

III. BUILDING A CORRELATION TABLE OF LINKS AND WORKING WITH DATA

The correlation coefficient r_{jk} characterizes the relationship between two features x_j and x_k in the case of a linear correlation between them. For any signs and random variables, it is calculated by the formula (1):

$$r_{jk} = \frac{1}{N} \sum_{i=1}^N y_{ij}y_{ik} \quad (1)$$

where y_{ij} and y_{ik} are the normalized features x_j and x_k for the i -th dimension (object). As a result, we obtain the matrix of correlation coefficients R [11].

The matrix is calculated using normalized factors in Excel or Statistica. Also, we cannot use the initial data, so we calculate the normalized factors and use them to build a correlation table [12], [13].

Factors (normalized):

- Number of delays due to Bad weather (0.901).
- Number of delays due to Security Review (0.548).
- Number of delays due to the National Aviation System (0.968).

- Number of delays due to the Airline (0.97).
- Number of delays due to other reasons (0.972).

In our case, the weakly influencing factor was: Security check.

And also, the most influential:

- National aviation system.
- Airline.
- Other reasons.
- Bad weather.

The result of working with data can be seen in the table (Table I)

TABLE I. CORRELATION TABLE

	Y	Factor 1	Factor 2	Factor 3	Factor 4	Factor 5
Y	1	-	-	-	-	-
Factor 1	0.970	1	-	-	-	-
Factor 2	0.968	0.893	1	-	-	-
Factor 3	0.972	0.947	0.912	1	-	-
Factor 4	0.901	0.898	0.909	0.822	1	-
Factor 5	0.548	0.482	0.636	0.417	0.564	1

Looking at the factors, we can calculate one of the unnecessary ones. This is a “Security Check”, this factor has little effect on delays and does not occur very often.

factors that affect the number of delays, we also perform conditional formatting to exclude outliers, in this situation no outliers were found [14].

After calculating unnecessary factors, we discard them and create a new more accurate table with the remaining

Detailed data see in the histogram (Figure 2).

Fig. 2. Number of delays to total delays.

IV. REGRESSION DATA ANALYSIS

After we are convinced of the available data, we can proceed to regression analysis, as a result of which we obtain the following data.

The R-square describes how accurately the constructed model describes the reality of this function, the maximum value of the R-square is 1, that is, 100% correctly describes

reality, the model is considered good if this coefficient is higher than 0.8 [15]; in our case, the R-square is 0.996, which means the quality of the model is real; F-significance is how adequate the resulting equations are, the lower this value, the better [16]. Our value is 0.000004753.

See tables for details (Tables II-IV).

X5	12.82	13.3	0.96	0.38	-21.36	47.01	-21.36	47.01

Further, it will be useful for us to know what is the residual when predicting Y. The residual is the difference between the predicted Y and the real one. For example, in the 1st observation (2009), the predicted Y is 1.33 million, and the real one is 1.323 million, the remainder becomes -

7180, that is, this is the difference between the calculated Y and the real one. The residual reflects how accurately this model calculates delays, the smaller the residual, the more accurately the assembled model considers [17], [18]. Detailed data look at (Figure 4).

Fig. 3. Difference between predicted Y and total delays.

CONCLUSION

Using the method of regression analysis, a mathematical model was obtained, based on which, the authors from a large amount of data (Big Data) identified those that strongly affect the number of delays in the United States. Therefore, after receiving data from a mathematical model, the most influential factor can be determined. This factor includes many factors that are insignificant in their frequency and influence, which did not make sense to consider separately, since only in their totality they represent a significant unit in our study. It is also worth mentioning such factors as the delays of the National Aviation System and the delays of the Airline itself, they quite strongly influence the number of cancellations or flight delays, as well as other reasons for the delay. Other factors have less impact on flights than safety checks are not very frequent and therefore do not have a significant impact on overall statistics. Bad weather is also a fairly strong influence factor, but quite easily predictable, so it does not have much effect on statistics comparing the actual number of cancellations to the predicted one. This work demonstrates the significance of

regression analysis and its advantages. So far, regression analysis is one of the most popular and accurate. The precision of the regression equation is basis of the regression analysis. While all models will have some errors, but understanding these statistics will help determine if this model can be used for analysis purposes or if additional transformations are required [19]. The expected values are calculated based on the regression equation and the values for each independent variable. Ideally, the expected values should correspond to the observed (predicted) values [20]. In our case, these values are extremely close, which is very positive, since the predicted number of flight delays or cancellations almost completely corresponds to the real one, which means that airlines are ready to predict their financial losses in advance and minimize them, as well as create conditions for comfortable waiting for passengers.

Abstract—The article collected and structured data for regression analysis. The reasons for which cork is formed in the city of Krasnoyarsk were considered. Using the collected data, a primary histogram (not tested for emissions) was constructed. The following factors were identified as relevant and weak-influencing factors for the construction of the correlation table, this table helps to identify the superfluous influence on the formation of traffic jams. Taking into account the table, a new histogram was constructed and a correlation table was created, which allows to start regression analysis. At the beginning of the regression analysis regression statistics are used and the variance analysis is carried out, then the regression analysis is made directly and the regression results are summarized. Based on the summing up of the histogram, which takes into account all statistics and calculations, which reflects the predicted number of traffic jams and the real factors influencing the formation of traffic jams.

Keywords— *Regression analysis, mathematical model, climate, temperature factors, traffic jams*

I. INTRODUCTION

Mathematical models as tools allowing to study the complex processes of the real world, including transport infrastructure, without capital costs, are a popular tool for solving many problems in various spheres of the national economy. The development of information technology and computing tools allowed to expand the scope of tasks solved with the help of models [1], [2].

The rapid growth of the urban car fleet has stretched the capacity of the street and road networks. Therefore, the issue of assessing the efficiency of traffic management in a high-load environment has become more acute, especially for large and large cities [3]. When looking for the best strategies for managing In the search for better strategies for traffic management, in making optimal decisions in the design of new transport infrastructure, as well as in the

choice of rational traffic management, it is necessary to make the most effective transport decisions [4].

Regression analysis allows solving two problems. The first problem is based on the choice of independent variables that significantly influence the dependent quantity, and the definition of the form of the regression equation. This problem is solved by analyzing the studied relationship. Formal tools can help here only by some benchmarks. The second task is to evaluate the parameters. It is solved by different statistical methods of data processing and observation. Most often, regression parameters are estimated using the least squares method. The regression analysis uses a random variable as a function, with arguments based on non-random variables [5]. The field of application of regression analysis in the economy is the study of impacts on labor productivity and cost of various factors. Before building a regression model, the topics to be considered should be selected and quantified [6].

The choice of the type of regression dependency is based on the following position: the need to correlate the selected dependency with professional-logical assumptions about the nature and nature of the relationships under study. Regression dependencies often use simple dependencies that do not require complex calculations that can be easily interpreted. The practical application of regression analysis is based on the fact that the linear regression equation clearly expresses the relationship between indicators even when they are more complex and require significant calculations [7]-[9].

One of the key problems of any large city is the increase in the number of cars. For example, in Krasnoyarsk over the past 10 years, there have been almost twice as many cars. However, mass motorization has created traffic jams, which have long become a big problem primarily large cities all

over the world [10], [11]. Megacities work like cork factories. Every day and everywhere, traffic jams lead to huge economic, time, psychological, environmental and other costs that fall on the shoulders of drivers of cars and other vehicles, transport companies, city and national economies, as well as pedestrians and city residents [12]. For example, a significant part of the traffic is made up of various business entities, delivery services, delivery of retail goods. Timely delivery of goods is strategically important, especially for large shopping centers and hypermarkets. This ensures the rhythm of the trading process. Modern cities and megacities need a constant increase in the volume of transport communication, increasing its reliability, safety and quality. This requires an increase in the cost of improving the infrastructure of the transport network, turning it into a flexible, highly manageable logistics system. At the same time, the risk of investments increases significantly if the patterns of development of the transport network and the distribution of the load on its sections are not taken into account. Ignoring these patterns leads to frequent traffic jams, significant overload of individual network nodes, an increase in the accident rate, and environmental damage. To search for effective strategies for managing traffic flows, optimal solutions for designing a road network and organizing traffic, it is necessary to take into account a wide range of traffic flow characteristics, patterns of influence of

external and internal factors on the dynamic characteristics of a mixed traffic flow [13], [14]. The task of any city is to provide the ability to quickly move along the highways of the city, but this is not always possible, since many different factors affect the congestion of the city at a certain moment.

For example, the day of the week or the number of accidents on a certain day, time of day, various road works, broken traffic lights, etc. have a significant impact on city traffic. Using regression analysis, we identified the main factors that affect traffic congestion in the city of Krasnoyarsk and conducted an analysis with which, in the future, it is possible to analyze and improve the road capacity in the city of Krasnoyarsk [15].

II. SELECTION OF FACTORS FOR THE REGRESSION MODEL

We get input factors that affect the number of traffic jams in Krasnoyarsk. The first histogram (Figure 1) shows the factors morning, afternoon, evening, the number of cars, thousand. The second histogram (Figure 2) shows the evening factors, the number of cars in thousand.

The third histogram (Figure 3) shows the factors the number of accidents, faulty traffic lights, the price of gasoline per liter.

Fig. 1. Factors are shown: morning, afternoon.

Fig. 2. Factors are shown: evening, number of cars in thousand.

Fig. 3. Factors are shown: number of accidents, faulty traffic lights, price of gasoline per liter.

As a result, we got 7 factors that may affect traffic jams in the city. The main indicator for us is the number of traffic jams.

The next indicator that possibly affects the population is the time of day, morning, afternoon and evening. The

following are indicators of the number of cars, thousand, the number of faulty traffic lights, the price of gasoline per liter.

III. BUILDING CORRELATION TABLES

In Table I shows the correlation made on the output of the collected statistics.

TABLE I. CORRELATION TABLE OF VARIOUS FACTORS

	Y	X1	X2	X3	X4	X5	X6	X7
Y	1							
X1	0.902	1						
X2	0.407	0.048	1					
X3	0.920	0.758	0.310	1				
X4	0.967	0.847	0.429	0.906	1			
X5	0.978	0.932	0.282	0.9	0.958	1		
X6	0.987	0.883	0.429	0.904	0.974	0.965	1	
X7	0.948	0.804	0.495	0.879	0.969	0.921	0.94	1

In the correlation table (Table I), all values and ranges are from -1 to 1, and the closer the coefficient is to 1 or (-1), the stronger the relationship between the factors. In the resulting table, you can clearly see that each factor affects traffic jams in different ways, some more than some less. The most influential factor is faulty traffic lights (X6), since its indicator of connection with traffic jams is as close as possible to one (0.987) the number of cars thousand. The next most important factor is the number of accidents (X5) (0.978) the next most important factor is the number of cars thousand. (X4) (0.967) the next most important factor is the price of gasoline per 1 liter (X7) (0.930) the next most important factor is evening (X3) (0.920) the next most

important factor is morning (X1) (0.902) the next most important factor is day (X2) (0.407).

Also, if the factors have too weak a connection with the key factor (traffic jams), they must also be excluded, since they will not have any effect in the constructed regression equation, this is a day. In the end, we are left with 6 factors, from which we collect a new table with factors that affect traffic jams for regression analysis.

The second table (Table II) shows statistics with factors after correlation. The third table (Table III) shows the correlation based on the new statistics.

TABLE II. STATISTICS AFTER CORRELATION

Traffic jams	Morning	Evening	Number of cars	Number of accidents	Faulty traffic lights	The price of gasoline per liter
12	5	3	3.648	15	32	46.9
14	4	6	3.784	16	36	47.1
12	3	5	3.62	14	31	47.3
14	4	6	3.754	17	35	47.1
11	2	5	3.543	13	29	46.9
7	1	3	2.356	10	16	46.4
2	0	1	1.254	6	7	45.4
15	7	5	3.876	17	37	47.2

16	8	6	3.947	18	38	47.3
17	8	5	4.143	20	40	47.5
16	7	6	4.023	19	37	47.3
13	6	5	3.698	17	31	47.1
9	2	3	2.785	11	23	46.7
4	0	1	2.267	8	15	46.3
9	4	3	2.696	12	25	46.5
11	4	4	3.542	15	28	46.9
10	5	4	3.312	14	27	46.7
11	5	5	3.475	16	29	46.8
8	3	3	2.621	12	21	46.6
3	0	1	1.543	7	13	45.5

TABLE III. CORRELATION TABLE OF THE RELATIONSHIP OF VARIOUS FACTORS

	Y	X1	X2	X3	X4	X5	X6
Y	1						
X1	0.902	1					
X2	0.92	0.758	1				
X3	0.967	0.847	0.906	1			
X4	0.978	0.932	0.9	0.958	1		
X5	0.987	0.883	0.904	0.974	0.965	1	
X6	0.948	0.804	0.879	0.967	0.921	0.94	1

The most influential factor is the number of faulty traffic lights (X5) as its relationship with traffic jams is as close as possible to one (0.987) the next most important factor is the number of accidents (X4) (0.978) the next most important factor is the number of cars thousand (X3) (0.967) the next most important factor is the price of gasoline per 1 liter (X6) (0.930) the next most important factor is the evening (X2) (0.920) the next most important factor is the morning (X1) (0.902).

Also, if the factors have too strong a relationship with each other, they must also be excluded, since they will not have any effect in the constructed regression equation, the number of accidents. In the end, we are left with 5 factors, from which we collect a new table with factors that affect traffic jams for regression analysis [16], [17].

The fourth table (Table IV) shows the final factors after the final correlation.

TABLE IV. FINAL TABLE BY FACTORS AFTER THE FINAL CORRELATION

Traffic jams	Morning	Evening	Number of cars	Faulty traffic lights	The price of gasoline per liter
12	5	3	3.648	32	46.9
14	4	6	3.784	36	47.1
12	3	5	3.62	31	47.3
14	4	6	3.754	35	47.1
11	2	5	3.543	29	46.9
7	1	3	2.356	16	46.4
2	0	1	1.254	7	45.4
15	7	5	3.876	37	47.2
16	8	6	3.947	38	47.3
17	8	5	4.143	40	47.5
16	7	6	4.023	37	47.3
13	6	5	3.698	31	47.1
9	2	3	2.785	23	46.7
4	0	1	2.267	15	46.3
9	4	3	2.696	25	46.5
11	4	4	3.542	28	46.9
10	5	4	3.312	27	46.7
11	5	5	3.475	29	46.8
8	3	3	2.621	21	46.6
3	0	1	1.543	13	45.5

IV. ANALYSIS OF VARIANCE

As a result of the analysis of variance, we get a table (5-7) in which the key factors for us are R-square, Significance F and all coefficients.

TABLE V. REGRESSION STATISTICS

Regression statistics	
Multiple R	0.99
R-square	0.99
Normalized R-square	0.99
Standard error	0.51
Observations	20

TABLE VI. ANALYSIS OF VARIANCE

	df	SS	MS	F	Significance F
Regression	5	348.54	69.71	266.67	0
Remains	14	3.66	0.26	-	-
Total	19	352.2	-	-	-

TABLE VII. ANALYSIS OF VARIANCE

	The coefficient	is the standard error	t-statistics	P-Value	Lower 95%	Upper 95%	Lower 95%	Upper 95%
Y-intersection	-96.91	38.68	-2.51	0.03	-179.87	-13.95	-179.87	-13.95
Variable X1	0.32	0.1	3.16	0.01	0.1	0.54	0.1	0.54
Variable X2	0.47	0.17	2.73	0.02	0.1	0.84	0.1	0.84
Variable X3	-1.16	0.89	-1.3	0.21	-3.08	0.75	-3.08	0.75
Variable X4	0.29	0.07	4.19	0	0.14	0.43	0.14	0.43
Variable X5	2.15	0.87	2.48	0.03	0.29	4	0.29	4

The R-square describes how accurately the constructed model describes the reality of this function, the maximum value of the R-square is 1, that is, 100% correctly describes the reality, the model is considered good if this coefficient is higher than 0.8; in our case, the R-square is 0.985, which means the quality of the model is close to reality; F-significance is how adequate the resulting equations are, the lower this value, the better, we have this value equal to 2.4656950212146E-12.

The resulting coefficients are the coefficients that are needed to build the regression model function. The function (1) itself looks like [18]-[20]:

$$Y=A_0+A_1*X_1+A_2*X_2+\dots+A_n*X_n \quad (1)$$

where A_n – regression coefficient, X_n – influencing factor, $n \in [0, \dots, i]$, i is number of variables (cases under consideration).

V. RESULTS AND DISCUSSION

Residuals affect the application of the model in real life and possible errors in predicting future data, the larger they are, the higher the probability of error. From the presented data, it can be concluded that the errors can be insignificant (Figure 4).

Fig. 4. Residuals: observation predicted by Y, traffic jams.

The morning factor, when it is changed by 1, the number of traffic jams will change by (0.274) this factor will also greatly affect the price of gasoline per liter (0.934).

CONCLUSION

In the course of the study, on the example of the city of millionaire, the possibility of using regression analysis in everyday life was illustrated and its effectiveness in solving a specific problem was shown - factors that influence the formation of traffic jams in the city of Krasnoyarsk. The regression analysis identified the main factors and the importance of each of them, obtaining an adequate model. The analysis revealed that the most important factor is the "number of cars", which significantly affects the factor "faulty traffic lights". A rather unexpected factor, which is in second place is the "price of gasoline". Also, with the help of regression analysis, little significant factors were found that were excluded from the final model. These were the "day" and the "number of accidents". Thus, with the help of the regression analysis, it is possible to predict and further optimize traffic flows in the city of Krasnoyarsk.

From the large amount of data, we found those that really affect the number of traffic jams getting a high level of the model. The most influential factor is the number of cars when changing it by 1 amount of traffic jams change to (0.685) as well as this factor will strongly affect the faulty traffic lights (0.974) and the price of gasoline per liter (0.954) the second most important factor is the price of gasoline per liter when an increase of 1 number of traffic jams change to (0.480) this factor does not affect other factors as it last in the 3rd place is the factor of the evening when changing it by 1 number of traffic jams change to (0.451) the same factor will strongly affect the number of cars (0.906) and faulty traffic lights (0.904) and the price of gasoline per liter (0.893) 4th place when changing it by 1 number of traffic jams change to (0.313) so this factor will greatly affect the evening (0.920) on the number of cars (0.967) for faulty traffic lights (0.987) per liter of petrol (0.930) 5th place is occupied by faulty traffic lights.

Abstract—This paper examines the theoretical basis for the elaboration of a development strategy for an organization producing household appliances, especially refrigeration equipment. We considered what the strategic management is and what it solves. And also studied the basic principles of strategic management. It has been found that there are two approaches to strategic management that differ in how organizations use their resources. Moreover, during the course of the work, issues related of development the strategic management of the organization were identified. It was found that it is economically beneficial for both the supplier and consumers to carry out domestic assembly of foreign equipment, as this allows manufacturers to significantly reduce customs duties and transportation costs. Thus, in order to develop an organization's development strategy, it is necessary to separate the tools to develop a strategy depending on the place of origin. It has proved necessary to apply a scientific and methodological approach, to identify and analyse the gaps and to develop patterns for selecting strategic alternatives.

Keywords— Costs, development strategy, household appliances, strategic management, theoretical foundations, control automation, optimization parameters process, technological parameters

I. INTRODUCTION

Over the past ten years, the Russian home appliances market has been formed and more clearly structured. In terms of growth rates, it occupies a leading position in the consumer goods market. To date, the household appliances market is already quite saturated, while growth rates are beginning to slow down, competition is becoming fiercer, and the entry of a new player into the market is associated with high risks and capital investments. The situation on the Russian refrigeration equipment market is characterized by

an excess of supply over effective demand, which stimulates increased competition among market players. Both “industrial refrigeration” and “commercial refrigeration” are characterized by oversupply and fierce competition between players. Under the current conditions, it is very difficult for domestic enterprises to compete with foreign manufacturers.

Under these conditions, the issues of developing an effective strategy for the development of an enterprise become relevant.

The efficiency of economic entities is determined by their strategy. Organizations that pay close attention to strategy are more competitive and resilient. The value of competitiveness, which allows the firm to survive in the competition, has recently increased dramatically. All companies in a highly competitive and rapidly changing environment must not only focus on the internal state of affairs in the company, but also develop a long-term strategy that would allow them to keep up with the changes taking place in their environment [1]-[3].

A modern tool for managing the development of an organization in the face of increasing changes in the external environment and the associated uncertainty is the methodology of strategic management.

Strategic management is an activity consisting in choosing the scope and system of actions to achieve the long-term goals of the organization in a constantly changing environment [4]-[6].

This is the area of activity of the top management of the company, whose main responsibility is to determine the preferred directions for the development of the organization, setting fundamental goals, optimal allocation of resources,

using everything that gives the organization a competitive advantage.

Strategic management acts as a process that allows the organization to interact with its environment. At the same time, strategic management is a field of knowledge about techniques, tools, methodology for making strategic decisions and methods for their practical implementation. Strategic management activities are associated with setting the goals and objectives of the organization, as well as maintaining relationships between the organization and the environment, which help it achieve its goals, correspond to its internal capabilities and allow it to remain susceptible to changes in the external environment.

II. MATERIALS AND METHODS

Strategic management solves problems:

- Overcoming the crisis state of the company, which is caused by the discrepancy between its capabilities and the requirements of the environment for occupying a leading position in the market (in the industry) in the future.
- Ensuring viability in any most unexpected situation.
- Creation of conditions for long-term development, taking into account external and internal opportunities.

The main principles of strategic management are:

- The overcoming of the unity of the company and the environment, used in setting the main goals and objectives, creating a program for their implementation.
- Orientation to the realization of the vision of the future, the mission of the company, its global quality goals, the achievement of competitiveness.
- Consideration in the formation and choice of strategies of the characteristics of the markets in which it operates, its strategic potential.

There are two approaches to strategic management: traditional and modern.

The traditional approach assumes that firms use their strengths for a strategic breakthrough in the existing competitive environment of the opportunities that open up before them [7]-[9].

The modern approach is that organizations, by manipulating their resources, form an external environment for themselves, the demands of which they can satisfy with the greatest benefit for themselves. For example, monopolies, by reducing the supply of their products and creating artificial shortages, are able to raise prices and extract excess profits.

In other words, the emphasis is gradually shifting from actions related to preparing for the future to actions aimed at its purposeful formation. At the same time, reliance is placed on personnel, as on the most valuable resource of the company, information systems and constant structural changes.

The subject of strategic management is a strategic process, the stages of which are shown in the Figure 1.

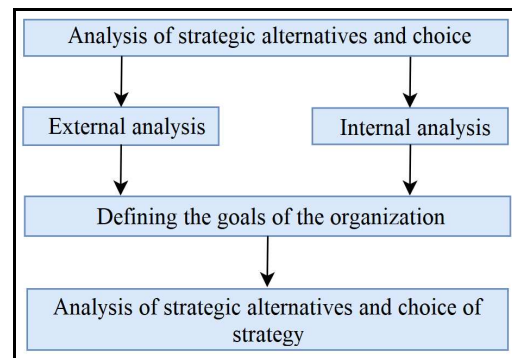

Fig. 1. Stages of the strategic process.

The main features of strategic management are:

- The mission of strategic management is aimed at the survival of the organization in the long term by establishing a dynamic balance with the environment, allowing to solve the problems of persons interested in the activities of the organization.
- The focus of strategic management is looking outside the organization, looking for new competitive opportunities, monitoring and adapting to changes in the environment.
- Strategic management is focused on the long term.
- The basis for building a management system are people, information support systems, the market.
- The personnel of the organization is its foundation, represents its main value and source of its well-being (with operational management, a view of employees as a resource of the organization, strategic management - as performers of individual works and functions).

The criterion for the effectiveness of strategic management is the timeliness and accuracy of the organization's response to new market demands and changes depending on the changing environment.

Strategic management is the management of an organization that relies on human potential as the basis of the organization, orients production activities to consumer needs, responds flexibly and makes timely changes in the organization that meet the challenge from the environment and allow achieving competitive advantages, which together makes it possible for the organization to survive in the long term, while achieving their goals [10]-[12].

III. PROBLEMS OF DEVELOPING THE STRATEGIC MANAGEMENT OF THE ORGANIZATION

Strategic problems are the discrepancy between the current state of the managed object and the set strategic goals.

The definition of strategic problems involves an assessment of the initial state of the managed object (organization), the timely determination of strategically targeted priorities, and then a comparison between them.

It is necessary to distinguish between the strategic problems of the organization and its weaknesses. The latter are determined by comparing the factors of the internal environment with those of competitors. Strategic problems

manifest themselves as a discrepancy between the strategic goals of the current state of the organization.

Modern economic realities (obsolescence of technologies, saturation of demand, rapid obsolescence of products, tougher competition) require a response, primarily to strategic problems.

Management should understand that all sources of production problems are not inside the enterprise, but in the external environment. It is noted that the balance of attention of managers to strategic and operational problems should, ultimately, be determined by the external environment in which the organization operates. If it is favorable, one can focus on operational issues, if the external environment is turbulent and volatile or demand is close to saturation, the focus should be on strategic issues.

An analysis of the activities of enterprises in various industries shows that, despite the abundance of published information and literature, almost no organization can demonstrate a more or less successful example of organizing strategic management.

The main problems of strategic management include the following:

A. The degree of validity of the choice of one or another direction of development

Despite the limited number of goals that an organization usually pursues, there are always alternatives in choosing ways to achieve these goals. The vast majority of well-known solutions in this area come down to a format convenient for reflection and discussion: all kinds of matrices, diagrams. However, they do not give the slightest idea about the real costs and income of the organization, about the value of the organization's business in certain areas.

Of course, the involvement, understanding and motivation of employees at all levels of company management is important, but this does not solve the problems of valuation of the strategies under consideration. And, besides, given the mindset of managers, it is hardly worth hoping for the correct choice of development strategy. Yes, and the economics of enterprises is not at the level to hope to solve problems with the help of conceptual "squares".

B. The problem lies in the one-sided approach to the development and implementation of the strategy

As you know, there are two levels of strategies: corporate strategy and business strategy. Corporate strategy is to determine the development path of the company as a whole.

C. With what product (service) and in what market the organization will work

Business strategy contains the entire set of actions to organize the production of a product or service with which the company has to work on the market. The connection between these two levels is obvious: the better the business strategy is implemented (production flexibility, high manufacturability, low costs, and so on), the more degrees of freedom in adopting a corporate strategy through effective diversification of production, product differentiation, and so on.

The relatively stable economy and the transparency of the activities of Western companies provide an opportunity for an approximate assessment of the quality of the implementation of a business strategy in a number of ways, and therefore the main emphasis is on the implementation of a corporate strategy. A similar approach is used by domestic enterprises. But the specifics of the connection between corporate strategy and business strategy for domestic enterprises is such that the unused, underestimated production potential of an enterprise can often turn all ideas about a seemingly successful corporate strategy adopted.

D. Banal confusion of long-term and strategic planning

The main difference between long-term (sometimes called corporate) and strategic planning lies in the interpretation of the future. The system of long-term planning assumes that the future can be predicted by extrapolation of existing growth trends, changes in the dynamics of the company's financial indicators.

In the system of long-term planning, the indicators to be achieved are, rather, the goal in the strategic management system, this is a guideline. In the first case, in the course of the enterprise's activity, the degree of achievement of the goal is controlled by comparing the actual and planned intermediate indicators. In the second case, it is the same, but each subsequent step is adjusted (through the system of management decisions) according to the results of the previous one, focusing on the final indicators. In the first case, the need to achieve the goal is unambiguous. In the second case, in the process of implementation, the landmarks can be replaced.

Thus, in the system of strategic management there is no assumption that the future must necessarily be better than the past, and it is not believed that the future can be studied by extrapolation.

The process of strategic management assumes that at each time interval alternatives will be selected to achieve the goals with maximum effect.

E. The problem arises at the stage of implementing the strategy

It lies in the "discontinuity" of the strategy along the vertical. Traditionally, the process of developing a strategy involves going through several stages. For example, how do most authors imagine the sequence of developing a strategic plan:

- Development of the mission and goals of the organization, assessment and analysis of the external environment.
- Management survey of strengths and weaknesses.
- Analysis of strategic alternatives, choice.
- Implementation and evaluation of the strategy.

But it would seem that a well-thought-out and understandable development strategy for management fails as soon as it comes to its implementation. And the point is not only that the appropriate functional strategies are poorly formulated and developed. In the vast majority of cases, having received a certain target setting (understandable at a high level), the head of department, manager, production engineer, who is used to dealing with very specific technical, technological parameters, does not understand

how to proceed with its implementation. If during the development of the strategy, tasks were discussed and solved at the level of financial and economic indicators, then the head of production should solve it at the "technical" level: what equipment should be changed first of all? what - in the second? And is it really worth changing?

F. "Instability" of adopted strategic plans

A well-designed strategic development plan falls apart at the first changes in transport tariffs, energy tariffs, violations of the structure of suppliers and their working conditions, and so on, not to mention the rapid assessment of emerging opportunities. To what extent are operational decisions taken in these cases consistent with the adopted development strategy? Or maybe, taking into account the influence of external factors, generally switch to a different strategy? To what extent, under the critical influence of external factors, should the adopted strategy be followed? And if circumstances force us to abandon the adopted strategy, then which one and how should we switch to? The dynamics of business development in modern conditions requires that the answers to these questions be given "yesterday".

G. The problem concerns the organizational side of strategic management

It can be viewed from two points of view: from the point of view of the organizational structure of the company in general and from the point of view of the strategic management unit.

1) *Aspect 1.* At present, new commercial structures are constantly being organized: a certain set of a number of enterprises (sometimes from different industries), united by one control superstructure. At the same time, management is carried out solely on the basis of financial and economic indicators. Naturally, the expediency of the participation of technologists in the management of large companies is being questioned. At first glance, it would seem that the right decision and quite a market one. If one of the enterprises is "fevery", then it must either be sold or tried to "treat" using drastic measures.

But an analysis of trends in the development of business management systems shows that more and more methods are emerging that take into account both financial and non-financial indicators.

When developing a strategy, we must answer a number of questions, namely: how can the market (and external environment) in which the enterprise operates potentially change? How should the company respond to this change? how should the product, its functionality and cost performance change in response to likely market changes? how to change the functional qualities of the product, the production technology, volumes and structure of resource support should change? how should business processes, management system and organizational structure at the enterprise change to ensure an adequate response to the market?

In this case, it is quite obvious that, by switching to managing an organization on the basis of only financial and economic indicators, the owners risk losing sight of one of the key components of the strategic plan - the use of new modern technologies, equipment and equipment. An example is the recent announcement that film cameras will

be discontinued. It is impossible to take into account such a factor when managing a strategy at the level of only financial and economic indicators.

This suggests that, along with financial and economic employees, employees with technical education should also participate in strategic management - specialists who are able to see and foresee (predict) the consequences of the emergence and development of new technologies, machinery, equipment, as well as specialists in the field of business management.

2) *Aspect 2.* Strategic plans are developed and adopted no more than once a year. As a rule, divisions of various levels are engaged in its development to varying degrees. A group of 3 to 5 people is involved in ensuring the development and preparation of the strategic plan. In this case, the final decision is made by the management, the owners of the company. But once the plan is developed, the group remains idle. Of course, one can object: "And control over the implementation of the plan?" For effective control, it is necessary to have a set of certain benchmarks by which you can assess the degree of deviation from the original plan. But monitoring is not enough, it is necessary to quickly find a solution that allows using the current situation with maximum benefit.

IV. RESULTS AND DISCUSSION

Home appliances are an integral part of people's lives. The transition to new business conditions, which in itself became very painful for many enterprises, coincided with an increase in the supply of foreign equipment and a fall in the purchasing power of the population.

To increase the competitiveness of products, it was necessary to modernize production in accordance with modern standards and launch new models, but most enterprises simply did not have the money for this. All this led to a reduction in unprofitable production, to the shutdown of enterprises and the almost complete disappearance of domestic electrical appliances from store shelves.

The devaluation of the ruble that took place had a positive effect: the consumer began to look closely at domestic products, which immediately turned out to be much cheaper than imported ones, and in terms of design and quality they were already close to foreign models. In addition, after the crisis, foreign investors moved to Russia, who decided that under these conditions it would be more profitable to open their production in Russia than to import equipment into the country. Thus, the growth in demand stimulated the growth of production.

We single out the typical features of household appliances [13]-[16]:

- Goods of mass and durable consumption.
- Variety of product brands on the market.
- Promotion of goods through the Internet (Internet sales).
- Modern and multifunctional equipment.
- Variety of built-in home appliances.

In this paper, refrigeration equipment is studied in more detail.

The capacity of the Russian market of commercial refrigeration equipment reaches 210-230 million rubles. Commercial refrigeration equipment occupies a significant segment of the entire refrigeration market and, according to most experts and company representatives, further dynamic development of this sector is expected. This is due to the influence of such a factor as the rapid development of the trade sector, including large retail chains, which accordingly increases the demand for trade equipment by an average of 25% per year. However, at the same time, the lack of specialized enterprises for the production of high-quality components and the generally undeveloped infrastructure of the domestic industry hinder the growth of production volumes and lead to an increase in imports of commercial refrigeration equipment (RTW) from abroad.

Considering the list of THW on the market, it can be classified as follows: freezing and refrigerating display cases, racks (hills, racks), cabinets, chambers, combined display cases, mobile refrigeration units, ice generators and other special equipment. All appliances differ in many ways, including size, price characteristics, manufacturer's brand, and much more [9].

Each category of products, depending on the modifications, is in greater or lesser demand among consumers. For example, according to statistics, the market demand for chest freezers with metal lids is about 18%, for products with straight glass lids - 45%, with curved glass doors - 15%, for chest freezers with inclined glass lids - 22%. As for islands, the situation is as follows: low-temperature islands with a mode from -25 to -18 °C account for about 65% of demand, products with a temperature regime of -25 ... + 8 °C - 25% and about 10% fall on other refrigeration equipment.

Depending on the temperature regime maintained in the refrigerated volume, medium-temperature, low-temperature and combined equipment is distinguished. With regard to refrigeration, the market offers installations with remote or built-in refrigeration, as well as equipment for connecting to central refrigeration. It is on the last point that it is worth dwelling in more detail.

Due to the changing working conditions of modern trade, the active introduction of modern technologies and a significant increase in competition, trade enterprises are faced with such tasks as reducing their own costs and meeting the growing needs of potential buyers. Therefore, many domestic and foreign manufacturers have developed commercial refrigeration equipment for central cooling, which successfully helps to solve the above problems.

Firstly, this equipment can be built in lines of any length with arbitrary bending angles of the lines, which allows designing sales areas according to individual projects and taking into account the specific features of the stores.

Secondly, the remoteness of the refrigeration units in the utility rooms significantly reduces the noise level in the trading floors.

And finally, the life of the central cooling compressors is 2.5 times longer than that of installations with built-in units.

With regard to new developments in this area, it became possible to computer monitor the central refrigeration system with automatic scheduling of temperature changes and monitoring the pressure level in the compressor.

Modern refrigerator factories are, in fact, assembly plants. A high level of mechanization and automation of technological processes, combined with an extensive unification of units and parts, ensures high quality goods at minimal manufacturing costs. Directly at the factories, cabinets, chests and doors are made, which are not economically feasible to transport over long distances. For deliveries over many kilometers, one would have to "carry air", since the cabinets take up a lot of space and weigh little.

There are two main product groups in the market under consideration:

1) *Group "Industrial refrigeration", which includes the following types of equipment:*

a) *Equipment for freezing and storage at low and medium temperatures of food in storage warehouses.*

b) *Equipment for technological conditioning of commercial real estate and production shops.*

c) *Refrigeration equipment to accompany all kinds of production processes.*

The main consumers of such equipment are: warehouses, food processing enterprises, industrial enterprises, commercial real estate objects, breweries and enterprises for the production of soft drinks.

2) *Group "Commercial refrigeration", includes the following types of equipment:*

a) *Commercial refrigeration equipment.*

b) *Refrigerators of small sizes.*

c) *Refrigeration equipment for technological processes in the catering system.*

d) *Commercial district cooling systems.*

The main consumers of this equipment are: shops, supermarkets, food markets, as well as catering establishments and small breweries.

Note that the predominant share of the Russian market is industrial refrigeration equipment - sixty percent, commercial refrigeration equipment accounts for forty percent of the market. The data is presented in Figure 2.

Fig. 2. Structure of the Russian market of refrigeration equipment.

The most cost-effective, both for suppliers of refrigeration equipment and for its consumers, is the

assembly of foreign equipment in Russia. The quality of the Russian assembly is quite satisfactory, at the same time, this allows manufacturers to significantly reduce customs duties and transportation costs, and consumers to purchase equipment at a lower price than imported equipment, in a shorter period of time.

The annual increase in sales of commercial refrigeration equipment is about thirty, thirty-five percent and is provided mainly by the active development of large retail chains.

At the same time, the growth in the production of commercial refrigeration equipment is constrained by the underdeveloped infrastructure of the domestic industry, which leads to an increase in imports.

Describing some of the main trends in demand for refrigeration equipment, it should be noted that the main consumers of refrigeration equipment are chain supermarkets, food plants, breweries and industrial refrigerators.

Thus, the prospects for the development of the refrigeration equipment market in the coming years are directly related to the prospects for the development of medium and large enterprises in the processing industry and trade [17]-[20].

Among the main buyers of units it is worth noting the retail trade, which is one of the fastest growing and profitable segments of the refrigeration equipment market. Today, most of the world's retail formats are represented in Russia - stalls, shopping pavilions "within walking distance", discounters, specialized stores, super- and hypermarkets.

With regard to suppliers, the main types of sales organization can be divided into three categories:

- Realization of equipment directly without intermediaries, which is typical for equipment manufacturers operating in the local market with the simultaneous organization of other promotion channels.
- The most common dealer organization of sales, which assumes that the manufacturer sells products to dealers at special prices with the provision of warranty service and a number of other benefits.
- Representative sales consist in the organization of regional and international representative offices through which goods are sold. Among the main advantages of this type of sales is central management and a single pricing policy.

It should be noted that the current situation in the Russian refrigeration equipment market is characterized by an excess of supply over effective demand, which stimulates increased competition among market players. Both "industrial refrigeration" and "commercial refrigeration" are characterized by an overabundance of supply, fierce competition between players.

CONCLUSION

Under the current conditions, it is very difficult for domestic enterprises to compete with foreign manufacturers. According to experts, only a significantly lower price in relation to imported analogues allows domestic equipment

to remain competitive to some extent, while the quality and level of service are significantly inferior.

Considering the general trend, it can be noted that the domestic industry is developing very rapidly and in record time, the only limitation is the financial capabilities of some enterprises. However, even in such conditions, domestic manufacturers went far ahead, new modifications of commercial refrigeration equipment were introduced to the market, such as Economy class with built-in refrigeration, with a smooth transition to the model range of more elite Business class units with an external cooling system, etc. Also, manufacturers are mastering a variety of related niches and the production of equipment of the "Lux" and "Centroholod" classes.

Thus, sectoral features of the activities of the organization for the production of household appliances were identified when developing a development strategy. These features require the organization of strategy development tools according to the places of occurrence, there is a need to apply a scientific and methodological approach, identify and analyze deviations and draw up a scheme for choosing strategic alternatives. To facilitate the choice of strategic development tools, it is recommended to find an approach to strategic development, and also, if it is appropriate, apply this method to a particular firm.

Abstract—The article considers the role of methods in the organization of management activities. The methods of formation of the organization's development strategy are singled out, how they are applied and the use of methods in the formation of the organization's development strategy is justified. Groups of tools for forming an organization's development strategy, which must be used to assess the factors of an organization's competitiveness, have also been studied, and models for using these tools have been considered. As a result, the factors that determine the competitiveness of the enterprise were identified. It was revealed that the main idea of the market competition comes from the struggle to obtain the greatest benefit through the best efficient use of economic resources with their limitations, and also that the competitiveness of a trading company in a market economy is the connecting part of the management of an economic entity, revealing the rate of efficiency of use of economic resources. economy of economic resources opposite to the efficiency of the use of economic resources by potential competitors. It was concluded that strategic development tools are a scientific and methodological approach related to the choice of the proposed strategic planning tools.

Keywords— Development strategy, company, methods and tools, organization, UML

I. INTRODUCTION

The role of methods in the organization of management activities is no less important than the role of technologies, since with the help of methods we can navigate through numerous strategies, identify, classify and group them, develop typical schemes for searching, selecting and implementing strategies [1]-[4].

In the practice of strategic management, a system of techniques has developed that allows planning the strategic position of an enterprise. These are the so-called strategic management models. They were developed at various enterprises in order to plan their future strategic position aimed at providing competitive advantages.

There are many strategic models that can be used in a wide variety of situations. Many of them cannot be applied

at other enterprises, since they are based on taking into account the specifics of a particular production system. Others, on the contrary, are universal [5]-[8].

II. METHODS FOR FORMING THE ORGANIZATION DEVELOPMENT STRATEGY

To date, the most developed for practical application in the enterprise are such methods of strategic management as:

A. Management Method by Ranking Strategic Objectives

This method consists in early detection of unexpected changes both inside and outside the enterprise and quick response to them.

As part of management using ranking, the following activities are performed [9]-[11]:

- Constant monitoring of trends in the external environment is carried out.
- An analysis of the identified trends in changes in the external environment is carried out and an assessment of the urgency of decision-making is carried out, which are brought to the attention of the top management of the organization.
- The top management and planning and economic service of the enterprise considers the results of the analysis of external and internal trends of the enterprise and, in turn, ranks them into four categories:
 - a. The most urgent and important tasks that require immediate consideration are sent to the study, during which acceptable decisions are developed and adopted by existing parts of the organization.
 - b. Important tasks of medium urgency that can be solved within the next planning period.
 - c. Important but non-urgent tasks that require constant monitoring.

- d. Tasks that are insignificant for the enterprise and do not deserve further consideration.
- The top management of the enterprise controls the decisions made by the company's divisions and evaluates them in terms of possible strategic and tactical consequences..
- Management should continually review and update the list of emerging issues and their prioritization.

From the point of view of practical use, the management method by ranking strategic tasks is a relatively simple system for tracking trends in changes in the external and internal environment of the organization.

B. Weak and Strong Signal Control Method

In the decision-making process in organizations, a large role is given to the stage of problem recognition. Is the firm able to identify the problem based on the available information, evaluate its significance and take appropriate measures to solve it? If "yes", then we are dealing with information of such quantity and quality that we define it as "strong signals". If "no", then the point is the "weakness" of the signals. We could identify many impending problems if we could learn to identify and account for the so-called "weak signals" - early inaccurate signs of upcoming important events [12]-[15].

The basis of the method of strategic management by weak signals is the development of strategies for "weak reactions" (cautious, preliminary) of the company in the external and internal environment.

Technological operations of the method are as follows:

- Establish warning-sensitive surveillance and identify "weak signals".
- Identification of problems and assessment of consequences.
- Development of alternative "weak reactions" and selection of the preferred reaction.
- Establishing possible responses and response dynamics, as well as diagnosing readiness to respond.

The strong signal control method is a very common method. Indeed, situations often arise in firms when individual specialists have been talking about impending threats for a long time, but due to various filters operating in the organization, the decision to react is made only when the situation becomes clear to everyone, including employees of the firm at all levels, consumers, suppliers and important to competitors. And when the decision is made, it turns out that there is no more time.

C. Method of Management in the Conditions of Strategic Surprises

In real life, some problems elude observers, no matter how hard they try to identify them, and turn into strategic surprises. It means that:

- Problem occurs suddenly and unexpectedly.
- It sets new challenges that do not match the past experience of the organization.

- An organization's failure to take adequate countermeasures results in either major financial damage or reduced profit opportunities.
- Countermeasures must be taken urgently, but the organization's normal operating procedures do not allow for this.

In such cases, as a rule, the old strategies are not suitable: the tasks are new, the information that needs to be comprehended is escalating, creating overload for decision makers. An initiative from below in the face of strategic surprises, numbing of a systemic nature, can only aggravate the situation.

The characteristic features of this system are as follows [16]-[18]:

- In times of strategic surprise, an emergency communication network is activated that operates across organizational boundaries, filters information, and quickly communicates it to all parts of the organization.
- During the state of emergency, management responsibilities are redistributed: one group devotes their attention to monitoring and maintaining a healthy morale in the organization, another to carry out normal work with a minimum level of disruption, and a third to take emergency measures.
- A network of task forces is put in place to develop contingency measures:
 - a. Heads and members of operational groups, despite the established channels of intra-organizational relationships, constitute units or groups of strategic action, not planning.
 - b. Communication between the operational teams and the senior management team is built directly.
 - c. A management group belonging to the top management formulates the overall strategy, allocates responsibility among the performers and coordinates management.
 - d. Grassroots task forces carry out work in their areas as part of an overall strategy.

Operational groups and links between them are formed in advance and are tested. To do this, several communication systems for various purposes can be organized in advance: one for solving unexpected sales problems, another for technology, a third for politics, etc. At the same time, operational teams learn to quickly respond to fundamentally new problems by combining precise methods of analysis with a creative approach.

The central objective of the method is to ensure the strategic flexibility of the organization.

D. Method of Management Through the Choice of Strategic Positions

One of the disadvantages of strategic planning is that this type of management does not take into account the capabilities of the company itself to implement certain strategies. As a result, in any case, the company's managers need to check (evaluate) the strategy for feasibility.

Management through the choice of strategic positions is a management in which the planning of the company's strategy is carried out simultaneously with the planning of the capabilities (resources) of the company. This allows us to weed out strategies that are not feasible in advance at an early stage and select those that are most likely to be implemented. In addition, while implementing the company's strategy, along with actions aimed at improving the competitive position of the company, its resource base is also developing. The resource base of the company forms its

functional potential, i.e. the potential of the firm's marketing, manufacturing, R&D, financial services, and general corporate management skills.

III. TOOLS FOR FORMING THE ORGANIZATION DEVELOPMENT STRATEGY

To assess the factors of the company's competitiveness, it is necessary to apply the tools of strategic analysis, which are shown in Figure 1.

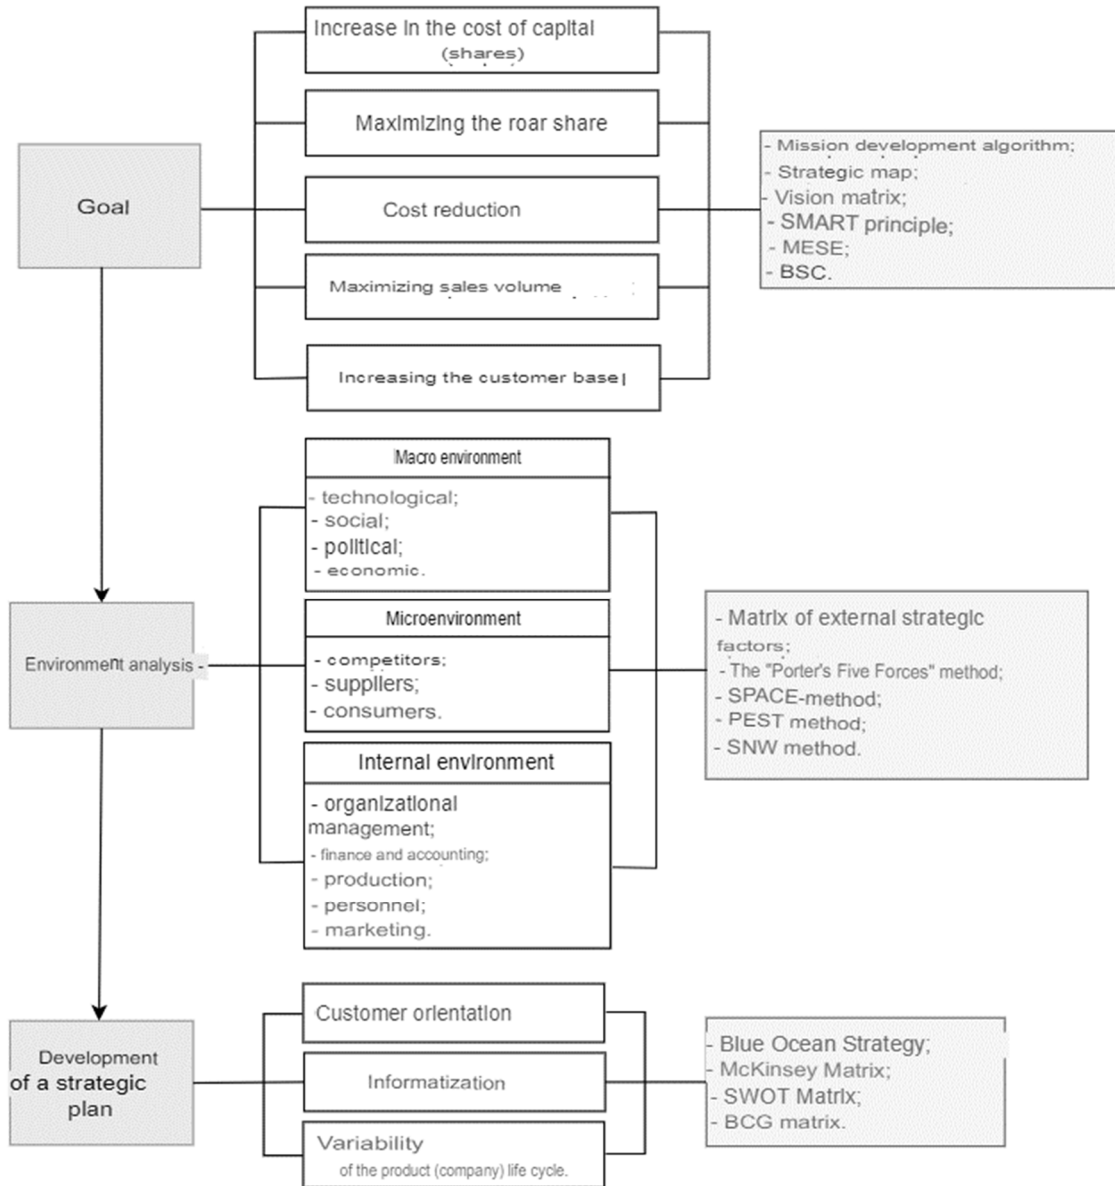

Fig. 1. Strategic Analysis Tools.

Goal setting and decomposition tools: the classic tree of goals, SMART - analysis, and management tools that have recently appeared in management theory: the SLRO paradigm (Socio-Labor Relations-Organization) and the model (methodology) for the development of VPM, based on the paradigms "as is" and "it should be". At the same time, when setting goals, no fundamental changes are required from what has been achieved, the well-known "tree of goals" works. If it is required to set high goals that are unattainable with the current organization, then it is

necessary to set goals for carrying out changes - a model (methodology) for the development of HRP is needed.

A. SMART Analysis

Currently, one of the most common methods for determining the goals of the organization is the SMART technology. Accordingly, the goal should be [19]-[21]:

- Specific.
- Measurable.
- Achievable.

- Realistic.
- Time-Bound.

B. Enterprise paradigm Social and Labor Relations - Organization

A paradigm is a necessary and sufficient clearly structured system of key provisions that determines the formal and informal organization of an enterprise, all its activities, and the results it achieves.

The need to form a paradigm is determined by the fact that the vision of an enterprise is a huge, unlimited array of heterogeneous subjective information. In fact, the paradigm is a structured vision of the enterprise in all major aspects of its activities. The SLRO paradigm has a basis - social and labor relations in the enterprise and its organization (formal and informal) determined by this basis. The practical use of the SLRO enterprise paradigm leads to the resolution of most of the problems of both management consulting and independent organizational change.

C. Model (Methodology) of the Development of HRP

(Vision-Paradigm-Model - 2016) - the most modern model, based on the SLRO paradigm, which allows you to solve both the development of the enterprise as a whole and the problems that arise in the course of its activities.

Model steps:

- Building on the basis of the current vision of the system of necessary and sufficient key provisions that determine the activities of the enterprise - the "as is" paradigm.
- Modeling, strategic analysis and obtaining a system of key provisions that provide the maximum achievable results of the enterprise - the paradigm "as it should be".

At the same time, the goals themselves are defined, the system of personnel motivation to achieve the accepted goals, the joint development of the organizational structure and the main provisions of the enterprise strategy, otherwise it is simply impossible to ensure the setting of maximum, but achievable goals of the enterprise.

- Strategic analysis of the key provisions of the "as is" and "as it should be" paradigms, obtaining a system of changes that need to be carried out in the enterprise in order to set and achieve the highest possible goals.
- Determination of a strategy for implementing the necessary changes necessary to achieve the accepted goals of implementing these changes.

Thus, this model is both a goal setting tool and a strategy development tool. It should be noted that the VPM methodology, including the SLRO paradigm, is effective for all types of development - both the integrated development of an enterprise and the development of individual critical areas: organizational structures, business processes, organizational documentation, remuneration and motivation systems, etc.

D. Tools for Developing Strategy and Strategic Management, Organizational Development in General

The second group includes well-developed and widely used methods and tools for developing a strategy and strategic management, as well as tools for developing an organization (carrying out changes), increasing its potential, transferring it to a new higher level of development, which themselves are still constantly evolving.

Kurt Lewin's (1947) developmental model includes three stages:

- Defrosting.
- Changes.
- Freeze.

At the first stage, the need for changes is recognized and a strategy for their implementation is developed. In the second stage, the changes themselves are carried out. At the third stage, a new organizational culture is formed, making the changes irreversible. These three generalized phases are used by all subsequent development models, but they are so general that they give only the first idea of how to make changes.

Larry Greiner's Model - Model of Successful Organizational Change (1967) includes 6 stages:

- Pressure and arousal.
- Intervention and reorientation.
- Diagnostics and recognition.
- Innovation and commitment.
- Experiment with a new solution and seek improvement.
- Reinforcement and agreement.

Here, the first four stages are the unfreezing stage of the Levin Map, followed by the change and freezing stages.

John Kotter's Development Model (1995) is the latest and best-known organizational development model. It has 8 steps, they are more detailed than Kurt Lewin's, but again they give only a general direction, they do not give specific methods.

- Create an atmosphere of urgency around a big opportunity.
- Formation of a powerful governing coalition.
- Create a vision and strategy for its implementation.
- Sharing the vision.
- Enable others to act on the vision.
- Planning and creating short term wins.
- Consolidate improvements and produce more further changes.
- Institutionalize new approaches.

In this case, the first four to five stages are Kurt Lewin's unfreezing stage, then there are the change and freeze stages.

E. Management Decision Support Tools

The third group includes methods for analyzing the internal and external environment, which allow setting adequate goals for strategic management and determining the need for organizational development: carrying out organizational changes to overcome emerging problems and crises, as well as the implementation of new ideas and opportunities.

a) GAP analysis is used to develop a strategy based on the concept of solving strategic problems. GAP analysis is understood as a set of activities that allow drawing conclusions about the discrepancy between the internal marketing environment and the external environment. Its purpose is to identify those market opportunities that can become effective market advantages for the company..

The essence of this model is to determine the strategies and processes that a firm can use to achieve excellence in customer service. A simple concept, however, turns out to be difficult to apply in practice.

b) PEST analysis (sometimes referred to as STEP) is a marketing tool designed to identify political (Political), economic (Economic), social (Social) and technological (Technological) aspects of the external environment (consumers, competitors, suppliers, political and economic situation and its trends, new product trends) that affect the company's activities.

To carry out a PEST analysis, each specific company must have its own list of key environmental factors that have a significant impact on its business, contain potential threats or new opportunities for the development of the organization.

The results of the PEST analysis make it possible to assess the external economic situation in the sphere of production and commercial activities, to study the market in which the company operates or is going to operate.

c) SNW analysis is an analysis of the strengths and weaknesses of an organization. The internal environment is evaluated by three values:

- *Strength* (strong suit).
- *Neutral* (neutral side).
- *Weakness* (weak side).

As practice has shown, in a situation of strategic analysis of the internal environment of an organization, it is best to fix the average market state for this particular situation as a neutral position.

To successfully analyze the organization's environment, it is necessary to identify threats and opportunities and evaluate them in terms of their importance and degree of influence on the organization's strategy.

Usually SNW-analysis is used for a deeper study of the internal environment of the organization after the SWOT-analysis.

d) SWOT analysis is applied to study the environment. He divides the significant factors of the external and internal environment into four categories:

- *Strength*.

- *Weakness*.
- *Opportunities*.
- *Threats*.

The SWOT methodology involves first identifying strengths and weaknesses, as well as threats and opportunities, and then establishing chains of links between them, which can later be used to formulate the organization's strategy.

e) The ADL matrix (ADL) was developed by the consulting company A. D. Little. Unlike the BCG matrix, this model is based on two variables that reflect the maturity of the sector (the life cycle of the industry) and the position in relation to competitors.

The life cycle phases are as follows:

- Origin.
- Growth acceleration.
- Growth slowdown.
- Maturity.
- Attenuation.

The main theoretical position of the A. D. Little model is that a single type of business of any corporation can be at one of the stages of the life cycle described above, and, therefore, it must be analyzed in accordance with this stage.

The type of business, at the same time, can occupy one of five competitive positions:

- Dominant.
- Strong.
- Favorable.
- Durable.
- Weak.

The combination of two parameters: four stages of the production life cycle and five competitive positions - make up the so-called ADL/LS matrix, which consists of 20 cells.

f) Model (matrix) BCG (*Boston Consulting Group - BCG*). The Boston Matrix is based on the product life cycle model, according to which a product goes through four stages in its development.:

- Entering the market (product "problem").
- Growth (product "star").
- Maturity (goods "cash cow").
- Recession (product "dog").

To assess the competitiveness of certain types of business, two criteria are used:

- Growth rate of the branch market.
- Relative market share.

Thus, the division of business types (individual products) into four different groups is carried out.

Ideally, a balanced nomenclature portfolio of an enterprise should be formed in such a way that the enterprise operates effectively both in the short and long term.

g) The “General Electric”-“McKinsey” Matrix was developed by the McKinsey Consulting Group in conjunction with the General Electric Corporation and is called the “Business Screen”. It includes nine squares, and the analysis in this matrix is carried out according to the following parameters:

- Attractiveness of SZH.
- Position in competition.

The indicator “attractiveness of SZH” is not controlled by the company, i.e. those that one or another economic entity can only fix and focus on them. The indicator “position in competition”, on the contrary, depends on the results of the activities of the business entity itself.

h) “The Five Forces of Competition model” by M. Porter is the most well-known and widely used model for assessing the attractiveness of an industry. Porter's five forces include:

- Threats of substitute products.
- Threats of new players.
- Bargaining power of suppliers.
- Bargaining power of consumers.
- Level of competition.

This model makes it possible to more purposefully assess the competitive situation in the market and, on this basis, to develop such a variant of the long-term strategy of the company, which will ensure its protection from the impact of competitive forces to the greatest extent and at the same time will contribute to the creation of additional competitive advantages.

i) I. Ansoff's model is used to develop strategic alternatives. It allows you to use several strategies at the same time. This model is based on the premise that the most appropriate strategy for strong sales growth can be determined by the decision to sell existing or new products in existing or new markets. I. Ansoff's matrix is intended to describe the possible strategies of an enterprise in a growing market.

On one axis in the matrix, the type of product is considered - old or new, on the other axis - the type of market, also old or new.

The advantages of using planning according to the I. Ansoff matrix are visibility and ease of use. The disadvantages of using planning according to the I. Ansoff matrix are a one-sided focus on growth and restrictions in the context of two characteristics (product - market).

F. Strategy Implementation Tools

The tools for implementing the organization's strategy include the following:

a) Leadership is a belief, a motivation, a culture. Leadership is key to the implementation of the strategy, because it ensures the assimilation of new behaviors that are

necessary for the implementation of the new strategy. Flexibility and openness in the context of globalization are becoming one of the main managerial qualities.

Managers create and maintain a culture that underpins the strategy. Leadership unites employees around a new vision for the future of the company and creates commitment to a new strategy. Culture is a link between the strategy and the results of its implementation, each strategic area of activity has its own structure.

b) Structure is the organizational structure, teams, degree of decentralization, distribution of production capacities. Usually, a new strategy requires adjustment of the organizational structure: positions are added and changed, teams are reorganized, etc. These changes should support the new strategy.

c) Information and control systems are a system of remuneration and incentives, resource allocation, information and technology systems, rules and procedures. These are the main tools for implementing the strategy. Employees are rewarded for implementing new ideas. Additional resources are received by units that make the greatest contribution to the achievement of strategic goals. New information technologies support ongoing changes. Firms seek to meet the individual needs of consumers using the Internet.

d) Human resources are the most valuable asset of an organization, its employees. Recruitment, training and promotion of employees is carried out in the interests of achieving the strategic goals of the company. Implementation of changes causes resistance, to overcome which special programs are formed.

The factors that ensure the competitiveness of a trading company directly depend on the goals of a trading company. This process is interconnected and is directly proportional. In order to strengthen the ability to compete, the firm needs to consolidate its position in the market.

The competitiveness of an enterprise is determined by the following factors:

- Quality of sold products and services.
- Having an effective marketing and sales strategy.
- Qualification level of personnel and management.
- Technological level of production.
- The tax environment in which the trading firm operates.
- Availability of funding sources and their attraction.

There are several ways to increase the level of competitiveness of firms.:

- Regular use of innovations.
- Search for new, higher quality products.
- Release of goods of such quality which would correspond to the state and world standards.
- Sales of goods to those segments of the industry, where the highest requirements for service and quality.

- The use of only high-performance material and raw materials.
- Regular retraining and training of personnel.
- Increasing the monetary interest of personnel and improving the level of working conditions.
- Implementation of marketing research of the industry, in order to fix the needs of consumers.
- Analysis of potential competitors to identify their strengths and weaknesses.
- Keeping contacts with research companies and investing in research and development that affect the level of product quality.
- Application of the most effective marketing research.
- Accounting for personal product superiority over potential competitors.

Using such paths, the firm will be able to increase both personal competitiveness and consolidate monetary stability.

IV. RESULTS AND DISCUSSION

The best way to generate income in a market economy is the sale of goods and the surplus value included in it. At the same time, the creation and sale of goods is carried out by

using economically limited materials. From this it follows that the extraction of income in a market economy is determined by the volume of applicable economic potentials or the ratio of the resulting conclusion and the costs made to obtain them. Thus, the main idea of market competition comes from the struggle to obtain the greatest benefit through the best efficient use of economic resources with their limitations.

The degree of effectiveness of the use of economic resources by a firm correlates with the relativity of the level of development of the expended forces received by the social creation and, as a result, production and other relationships regarding the efficiency of spending resources by potential competitors. Thus, the competitiveness of a trading company in a market economy is the connecting part of the management of an economic entity, which reveals the rate of efficiency in the use of economic resources by the economic economy, which is opposite to the efficiency of the use of economic resources by potential competitors.

The level of competitiveness of an enterprise depends on many factors that can be conditionally grouped; the scheme for presenting factors is presented in Table I.

TABLE I. FACTORS PROVIDING THE STRATEGIC COMPETITIVENESS OF A TRADING COMPANY

	Factors	External	Internal	Relevant	Irrelevant
Competition factors	1. Increase in the cost of capital (shares)	+	-	-	+
	2. Increasing the customer base	+	-	+	-
	3. Maximizing market share	-	+	+	-
	4. Cost reduction	-	+	-	+
	5. Maximizing sales volume	-	+	+	-
Consumer factors	6. Political	+	-	-	+
	7. Economic	+	-	-	+
	8. Social	+	-	+	-
	9. Technological	+	+	+	-
	10. Competitors	+	-	+	-
	11. Suppliers	+	-	-	+

	13. Organizational management	-	+	-	+
	14. Staff	-	+	-	+
	15. Production	-	+	-	+
	16. Marketing	-	+	-	+
	17. Finance and accounting	-	+	-	+
Factors of informatization	18. The level of informatization	-	+	+	-
	19. Variability of the product life cycle, the life cycle of the company	+	+	-	+
	20. Customer orientation	-	+	+	-

CONSLUSION

It is necessary to understand that the problem of increasing the competitiveness of a trading firm is to reduce the bad inclination of the competitive environment, To determine which competitive advantages should be issued and controlled for strategic development planning, as they alone reveal the market position of a trading firm in a competitive environment.

And since there is no common definition of «tools of strategic planning», its object and object, goals and objectives, then, based on what has been considered in the work, it is possible to give the following definition. Tools of

strategic development - a scientific and methodical approach, connected with the choice of the proposed tools of strategic planning.

Abstract— The article considers what should be taken into account for the development of the strategic plan of the organization for the production of household appliances and how to develop scientific and methodical approaches to the strategic development of the organization. In this work developed its own approach to scientific and methodical development of strategic development, which includes all the principles of scientific approach. It was revealed that it is necessary to carry out significant analytical work to identify strengths and weaknesses of the organization. The main stages of strategic management were studied, which were applied on the example of the enterprise producing refrigeration equipment. Accordingly, existing types of development strategies of the organization were reviewed and compared to select a suitable strategy. The chosen strategy was tested in practice and it was concluded that the implementation of the chosen strategy will entail the achievement of most of the strategic objectives of the enterprise.

Keywords— Application, methodology for developing, refrigeration equipment, strategic management

I. INTRODUCTION

In order to develop a strategic plan for the development of the organization for the production of household appliances, it is necessary to take into account and develop scientific and methodological approaches to the strategic development of the organization. However, it is likely that there is a way for each organization to develop a methodological approach. The crux of the methodology is that the household product organization cannot develop such a modality on its own. In addition, the organization's staff may not always appreciate the methodical approach as a basis for developing strategic development.

The sequencing of the choice and application of development tools is often only recommendatory, usable and can be neglected. Different methods are used to assess the impact of different planning tools, as mentioned above. There are a number of measures to implement the strategic plan, but the scientific and methodological approach

provides an opportunity to understand the strategic development model.

In this research work developed its own approach to scientific and methodical development of strategic development. It incorporates all the principles of the scientific approach, however, contains only those functions and principles that are necessary for the organization of the production of household products.

The process of developing a strategy based on the definition of vision, mission and purpose is to define the very characteristics of the organization in the future; to conceptualize the developer to the state of the organization that corresponds to those characteristics, projection of the state to the real environment in order to determine actions leading to an ideal result. However, once the vision, mission and objectives have been formulated, it is premature to proceed to the development of the strategy. The strategy cannot be detached from the organization and its reality. Therefore, significant analytical work is needed to identify strengths and weaknesses of the organization, opportunities and threats posed by the external environment, to investigate the problem field and to analyse the strategy of the organization.

II. METHODS AND MATERIALS

The main stages of strategic management are:

- Analysis of the environment.
- Defining the mission and goals of the organization.
- Formation and choice of strategy.
- Implementation of the strategy.
- Evaluation and control of the implementation of the strategy.

The company selected as an example produces household refrigerators, freezers, commercial refrigeration equipment, and medical equipment.

For functioning, the management of the organization needs to plan its activities and develop a methodology for the development of the organization, taking into account the tools. To apply the most appropriate strategy, the firm needs to consider all existing strategies, and finally implement the chosen strategy into the organizational structure.

III. DEVELOPMENT OF LONG-TERM AND SHORT-TERM OBJECTIVES OF THE ORGANIZATION

Long-term goals of the organization are determined for 10-30 years or more, short-term goals for 3-5 years. Sometimes organizations do not distribute goals into short-term and long-term goals, but form the highest-level goals, called strategic ones.

To adopt any of the existing strategies, the enterprise must be considered in terms of assessing factor advantages. In Table I, one can trace the implementation of the strategic development methodology on the example of an enterprise producing refrigeration equipment.

TABLE I. APPROBATION OF THE METHODOLOGY ON THE EXAMPLE OF AN ENTERPRISE PRODUCING REFRIGERATION EQUIPMENT

Factor	Specific gravity (%)	Conclusion	Strategy
1. Consumer Orientation			Concentrated growth
Social	65	The product is social, therefore, is in great demand among consumers.	
Technological	35		
2. Informatization			
Informatization level	75	The level of informatization of a trading company is quite high, which means that it is necessary to provide the end user with accessibility and ease of use of the services of the organization.	
Consumer awareness level	25		
3. Long-term perspective			
Increase in client base	70	By increasing the customer base, the firm may have the opportunity to maximize market share, which in the long term will allow the organization to become a monopolist in the refrigerator market..	
Market share maximization	30		
4. Competition			
Consumers	43	Increasing sales volume will allow the organization to reach new levels of competitive advantage.	
Competitors	37		
Sales volume maximization	20		

The most common types of firm strategies tested by practice reflect four different approaches to the growth of the firm and are associated with a change in the state of one or more elements: product-market, industry, position of the

firm within the industry, technology. Each of the elements can be in one of two states - existing or new.

Figure 1 shows the main strategies for the development of the organization.

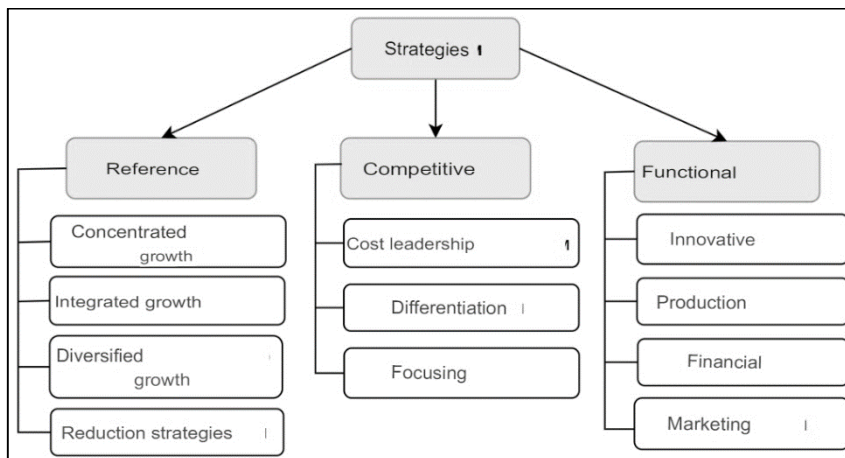

Fig. 1. Types of organization development strategy.

For the successful implementation of the chosen strategy, it is necessary that the goals and plans of the strategy be quickly communicated to the staff in order to achieve from the staff not only an understanding of what the company is doing, but also an informal introduction into the process of implementing strategies, in particular, identifying staff commitments to strategy implementation firm. It is also necessary that top management not only timely carry out the receipt of all important for the implementation of the strategy, but also draw up a plan for the implementation of the strategy in the form of specific standards and record the achievement of each of the goals.

When organizing a business in any field of activity, the essence of global competition strategies is clearly visible when the two components are combined.

First, the unit cost of manufactured products, which depends on:

- Production economies of scale (the cost of production decreases up to a certain volume, then increases).
- The production effect of development (the unit cost decreases as the volume of manufactured products increases).

Secondly, the market for a product with a specific purpose, which can be segmented. At the same time, the capacity of the segment is inversely proportional to the price of the segment's product.

The combination of these facts among themselves makes it possible to have various options for reducing the price of the manufactured product without loss of quality, which makes it possible to successfully compete in a particular sales market.

The most important source of cost minimization is the establishment of a specific value for the volume of production (the effect of scale from production), promotion and marketing (the effect of scale from the marketing strategy).

With a larger load, the wear resistance of the equipment increases, with a smaller load, the cost of the goods increases.

The disadvantage of the cost minimization strategy is the relative contradiction with the differentiation strategy. It partially eliminates the use of flexible commodity production, which requires:

- Low costs of reloading and readjustment of equipment during production.
- Maximum vision of economies of scale from production with small volumes of product creation.

The differentiation strategy is based on the production of a large range of products for one direct purpose. This allows the trading company to maximize the demand for its product.

Differentiation can be divided into two types:

- Horizontal (the price is approximately the same, the average level of income of buyers is similar).
- Vertical (prices and average income of buyers are different).

The application of a differentiation strategy gives success with the superiority of non-price competition, and the industry market has a complex organizational structure.

Disadvantages of Differentiation Strategy:

- Increase in the price of goods due to the need to take advantage of economies of scale.
- High costs of advertising the company's reputation.
- The appearance on the market of a lower-priced product of inadequate quality.
- Strengthening of the price factor in competition.

The focusing strategy contains the focus of the company's activities on the satisfaction of buyers of a smaller segment of buyers, characterized by special needs for this product. The value of this strategy depends on:

- The existence of the largest group of buyers whose requirements for products with special purposes differ from the average.
- The existence of a small group of consumers containing unusual needs that are not satisfied in the proper amount.

- The company's resources do not allow meeting the needs of huge groups of customers with the usual wishes.

Disadvantages of Focusing Strategy:

- Exclusion from a number of differences in the prevailing for buyers of the target segment in the general market.
- Strengthening of differential trends among firms operating in the market.

The innovation strategy involves the creation of new products or technological steps, or the satisfaction of existing tastes with a modern method.

Firms using this strategy create a competitive advantage and the ability to extract more profit by increasing the profitability of the implementation or creating a different circle of buyers. Another way is the implementation of new technologies to other firms in the industry.

The disadvantage of the innovation strategy is a huge part of the risk. A special option for minimizing losses is structured financing based on the results of previous stages, with each subsequent implementation usually higher than the previous one. Such a strategy is most often implemented by small firms that have only two alternatives: lose or win - which is why they are not particularly at risk.

Such a strategy determines the advantage by reacting sharply to changes in the external environment. To provide new buyers of the product market, it is necessary to use the time. Firms using this strategy produce habituation of a new product in a very short time. If, at the same time, this is done an order of magnitude faster than potential competitors, it is provided with an additional percentage of income.

Rapid response strategies are given first place most often by firms engaged in counterfeiting of branded goods from world famous manufacturers.

The portfolio of businesses as a whole is very different from the simple number of businesses that include it. By creating a portfolio of businesses, the company optimizes cash flows, profitability, risks, and more.

The strategy of related diversification is applied by concentrating firms of modern directions in the business portfolio.

The use of diversification in a single portfolio in a business environment can lead to synergistic effects, that is, an increase in the efficiency of the company's functioning as a result of combining, connecting each part into one common system. They affect the reduction of single joint costs and arising from the repeated use of resources. Synergies in strategic management are interpreted by strategic correspondences and are defined as the same cost parameters in the cost structures of other firms that have a single business portfolio that must flow into each other. In strategic management, there are the following strategic certainties:

- Marketing (single buyer, suppliers, same geographic boundaries, distribution channels, advertising capabilities, similar trade logos, after-sales service).
- Production (similar technologies, single production facilities, R&D).

- Managerial (one training and management services, managers).

The diversification strategy can be of two types: connected (assumes the existence of existing strategic alternatives between the business services included in it), unrelated.

Relatedly diversified firms are called concerns. In the usual form, with a general economic decline, it is the concerns that have the maximum chances for success. Reducing costs is the most important task that concerns can easily do better.

Firms that use unrelated diversification are referred to as conglomerates. There are weak strategic uniformities among themselves in their portfolio of business circles.

The advantage of an unrelated diversification strategy comes from risk reduction, i.e. industries of different types can equally appear in different phases of industry life cycles. A decline in some leads to an increase in others. There is a possibility of early reprioritization of services and products that are seasonal in nature as opposed to planned demand.

The well-being of the conglomerate directly depends on the early vision and ability of the management team to profitably command the components of the portfolio of business areas.

The negative qualities of a conglomerate, as mentioned above, are an order of magnitude less effective than reducing costs in an economic crisis or decline.

A change in the external environment or internal changes can lead to the fact that one of the business areas ceases to be profitable, and the best way out may be to stop its functioning. Let's analyze the options for the implementation of this plan:

- Implement the most unattractive organization (in this case, you need to find a company whose business areas contain the greatest strategic fit).
- Liquidation (with this outcome, it is recommended to take into account that the cost of the company's assets sold in parts may be less than their real value).
- Bankruptcy (a method in which it is necessary to come in the very last case, since the business reputation of the entire business may be mired).
- Restructuring and course transformation strategy.

The desire of the corporate management to transform the efficiency of the portfolio, or even to leave its existence unchanged, is a stable motive for the execution of the strategy of changing the course and restructuring.

The following course change strategy options are available:

- Focusing on extracting profitability from declining business areas.
- Measures to increase profitability in all areas of business.
- The introduction of a savings regime in all areas, the sale of weak areas and the acquisition of attractive ones.

- Change of individual corporate level managers.
- Withdrawing resources from weak areas and directing them to more promising ones (harvesting).

The restructuring strategy proposes the elimination of some areas from the portfolio and the inclusion of others.

The strategy is used in such cases:

- The board of directors decides to change the scope of the business.
- The corporation lacks long-term prospects due to the presence in the portfolio of a considerable number of modestly developing or non-competitive and fading business areas.
- Hard times have come for advanced business areas.
- The emergence of new technologies require taking a position in a new promising industry.
- Sale of several business areas in order to acquire a new promising industry.
- Core business areas lose their attractiveness.

The strategy offers the operation of a diversified portfolio in a variety of Russian markets. The strategy received a resonant spread in the mid-70s and 80s, when it became known that "international diversified firms will concentrate an advantage over simple international firms". Such organizations "are able to expose new markets and compete successfully by selling products during a specific period of time at the lowest prices, covering losses with income extracted from already conquered markets".

An *offensive strategy* includes a number of interrelated actions to retain and acquire competitive advantages that dictate the conditions of character. Defensive strategies talk about actions that are in the nature of a response to a challenge.

The main directions of the implementation of the offensive strategy:

Attacking competitor strengths:

- Conquering a part of the market by achieving dominance over the strengths of the most vulnerable competitors.
- Negate the advantages of stronger competitors by holding or reducing prices, using relative advertising within the existing one, as well as endowing the product with qualities that are a priority for competitors' buyers.

It should be noted that the adequacy of the actions used in the company should be distinguished by the margin of stability of the upcoming company.

Attacking competitor's weaknesses:

- Development of areas that the competitor neglects or cannot cope with, concentration of efforts on those products where the competitor's analogues are of low quality business development in geographic entities that are not mastered by competitors.

If an organization has been attacked from outside, it needs to apply a number of measures of a defensive strategy:

- Launch of goods with parameters similar to those of competitors' products.
- Free or inexpensive training of the personnel of the consumer organization in the operation and promotion of the company's goods.
- Active participation in the development and development of new technologies, patenting promising technologies.
- Maintaining low prices.
- Conclusion of exclusive contracts with dealers and distributors.
- Spreading rumors about upcoming product price cuts or new models, which will help reduce the likelihood of consumers switching to competitors' products.
- Extended warranty periods.

The strategy associated with the consolidation of a part of the length of development from the delivery of raw materials to the sale of the finished product to the final buyer is determined by the strategy of vertical integration. Reverse vertical integration refers to the movement back to raw materials, while direct vertical integration is directed forward, that is, to delivery to the buyer of products.

The main method for implementing a vertical integration strategy is to establish a firm's competitive advantage by losing ground to the competitive power of buyers and suppliers.

The current industry advantage is characterized by the volume of the market share. The goal of the winner strategy is to maintain existing positions and assign the status of a leading dominant (significant leadership over other firms).

Three basic strategies need to be analyzed:

- Attack strategy according to the principle "there are only two types of promotion: back and forth" (maintaining innovation, launching new product technologies, high maximization of the increase in the market share);
- A strategy of protection and strengthening, which implies the creation of such factors under which it would be difficult for competitors to maximize the market share at the expense of the leader company (maximization of entry barriers for new companies through the introduction of advertising innovations, maximization of the quality of service, maximization of research costs, access to a new market for products under a private label, etc.);
- A strategy of democratization of force, involving the introduction of the company's business reputation, taking into account the attempts of competitors to restructure the alignment of the parties (when competitors try to enter the market share - the greatest price minimization, hints about punishing any attacking actions, increasing dealer discounts, etc.).

The most common strategies analyzed are ways of the overall strategy of the firm, containing at the moment of delivery a specific advantage.

The choice of strategy is the main point of such strategic management. The choice of strategy is carried out after an in-depth analysis of common new opportunities and external dangers, taking into account them, the entire internal structure of the organization is brought back to normal.

Determining a strategy means taking into account the decision about what to do with a particular business or product, what direction to choose, what niche to occupy in the market. "Social, civic and regulatory, political norms hinder the firm's strategic actions that the organization should or could have foreseen".

Dependence on the external environment, in many cases, can play the biggest role in choosing a company's strategy, compared to other factors. Rigid dependence on the external environment can be determined by legal norms, the state of the economy in the country and abroad, the conditions of interaction with the natural environment, and the like.

IV. BUSINESS PHILOSOPHY, PERSONAL AMBITION, AND ETHICAL VISIONS OF TOP MANAGEMENT

Management decisions are often influenced by personal views on how to compete, what niche the organization should occupy, and what image it should apply. It is rare that such an influence on strategy occurs simply subconsciously. Strengths and weaknesses of the company, the internal structure of the company and its competitive capabilities.

The way in which the proposed strategies are chosen should be what the firm is particularly comfortable doing. It is not recommended to create strategies based on little known or unfamiliar activities. The firm's strategy must be based on what it does with great success, that is, on competitive capabilities and organizational strength. A huge danger to strategy leadership is to focus on what the firm does not do very well, i.e. competitive and organizational weakness.

V. RESULTS AND DISCUSSION

When creating a strategy, it is recommended to take into account both negative and positive results of previous strategies. In addition, in connection with the transition to new strategies, it is impossible to completely renounce all previous commitments. Therefore, it is recommended to take into account the fact that for some time there will be obligations of previous years, which will naturally correct or constrain the ability of implementation strategies.

The firm will not implement the strategy at every moment and not at any time, but only then and at such time as it becomes possible to do so. The company that is better at keeping track of time and, accordingly, more intelligently able to manage processes over time, always succeeds in implementing the strategy and, as a rule, leadership in the competition.

The initial process in developing strategic alternatives is strategic allocation. In this application, analysis is carried out, involving the study of the external environment of the organization for the most precise dangers and the emergence of new opportunities. The object of such an analysis is a strategic business zone - a separate segment of the external environment in which the company works or wants to get out.

The strategic choice should be based on a clear concept of the company's development, since the chosen strategy for a long period of time limits the freedom of action of management and affects deep management decisions.

The relationship of strategic goals forms a strategic map. Figure 2 shows the cause-and-effect relationships that lead to the implementation of higher strategic goals.

It can be concluded that the implementation of the chosen strategy will lead to the achievement of most of the strategic goals of the enterprise.

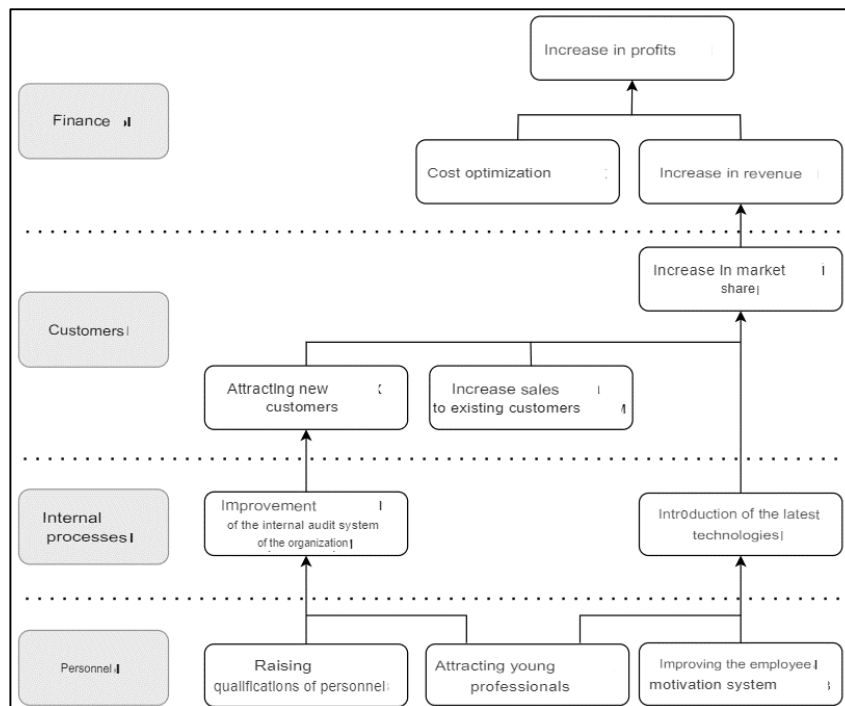

Fig. 2. Enterprise strategic map.

CONCLUSION

The developed method of the development strategy of the organization was applied in practice in the organization for the manufacture of refrigeration equipment and can be applied in the enterprises of the industry, which will allow their managers to apply the developed methodology and plan further development of the organization, bypassing the sharp corners. The developed methodology will help to increase the efficiency of activities, including a more rational approach to strategic development and promotion in this market, taking a competitive advantage.

Abstract—In the article, for a visual representation of the scientific and methodological approach, as a process of strategic development, a model is used that together can solve all the tasks of an organization for the production of household appliances at the stage of strategic development. The roadmap “TechNet” of the national technology platform, the purpose of its creation and the tasks that it performs have been studied. From the whole variety of strategic alternatives, the choice of the most preferred option was made. It was found that the choice of strategy is influenced by many factors that were considered in the work. It was concluded that the information contained in the roadmap is of a reference nature, cannot be considered as a description of directly implemented activities and is not the basis for the allocation of state support funds in any form.

Keywords—component, formatting, style, styling, insert

I. INTRODUCTION

The central place in the economy is occupied by the sphere of material production - a high-tech industry that must meet the requirements of global competitiveness, efficiency and high labor productivity. To meet these requirements, total digitalization, automation and intellectualization of industry are rapidly developing in the world, a transition to cyber-physical systems is underway, and the material and digital (virtual) worlds are merging. These global changes are accompanied by the development of fundamentally new business processes at all levels [1]-

[4].

With the aim of developing Russia in accordance with global technological trends and for the most complete realization of the opening opportunities for increasing the competitiveness of the Russian industry and the final products being created, the “TechNet” roadmap of the National Technology Initiative (NTI) was developed [5]-[8].

II. METHODS AND MATERIALS

For a visual representation of the scientific and methodological approach, as a process of strategic development, a model was used that together can solve all the tasks of an organization for the production of household appliances at the stage of strategic development. In addition, the specificity of the scientific and methodological approach lies in the unified process of applying the strategic development tools necessary for the successful functioning and development of an organization for the production of household appliances. For a detailed analysis shown in Figure 1, it is necessary to understand that this model contains only advisory character [9]-[12].

The figure shows that the use of one or another factor involves the use of a set of tools offered for selection. For each stage of the formation of a strategic plan, it is necessary to take into account the degree of influence of the factor on the environment of the trading company and its future prospects.

From the whole variety of strategic alternatives, the most preferred option is directly selected. The very process of

The work was carried out within the framework of the state support program for leading scientific schools (grant of the President of the Russian Federation NSH-421.2022.4).

strategic choice takes place not only on a rational level, but also on an irrational one - according to intuition, experience, and the ability to foresee the situation. It has been established that the choice of strategy is influenced by many factors. The most important of them [13]-[16]:

- Type of activity and features of the industry in which the trading company operates.
- The nature of the goals that the company sets for itself.
- Values that guide decision-making by top managers.

- Financial resources and obligations of the trading company for already made decisions.
- The state of the external environment.
- Types and degree of risks.
- Entrepreneurial abilities.
- Degree of dependence on the environment.
- Time factor.

Figure 2 shows the priorities of the scientific and technological development of Russia until 2035.

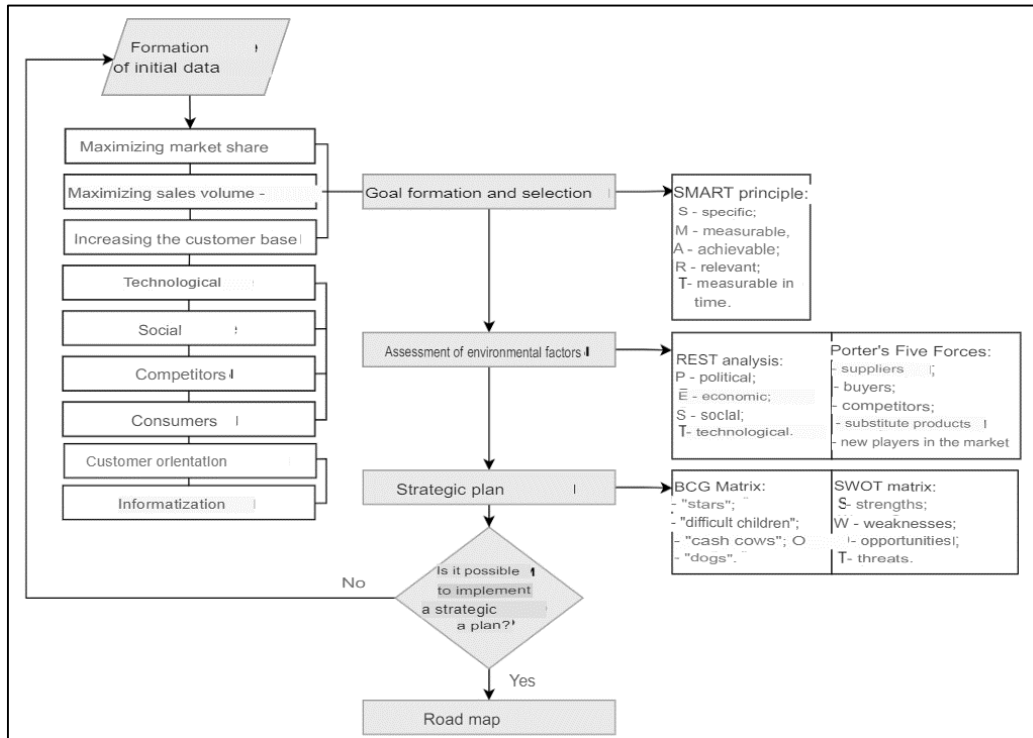

Fig. 1. Strategy Development Algorithm.

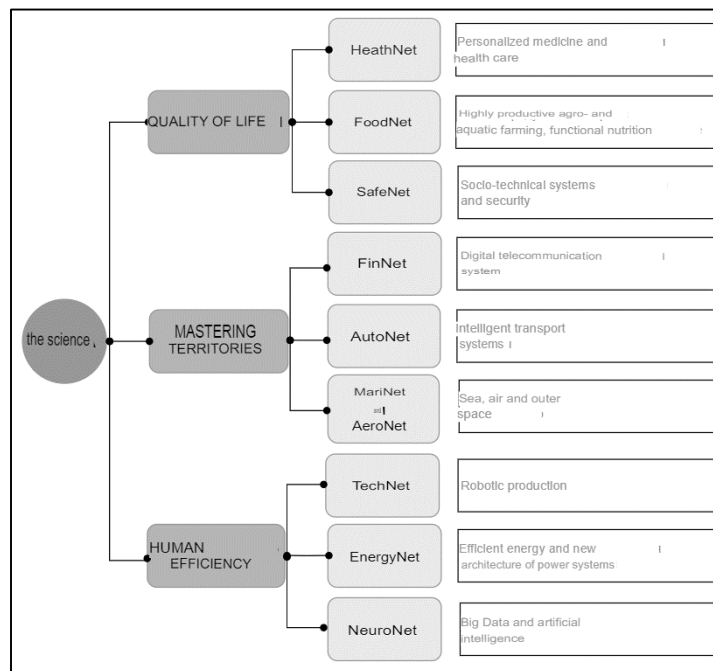

Fig. 2. Strategy Development Algorithm.

Formed strategies are evaluated according to the level of suitability for achieving the main goals of the enterprise and their compliance with the requirements of the environment, as well as the possibilities for the development of the organization.

“TechNet” is an NTI action plan for the development of a cross-market, cross-industry direction “Advanced Manufacturing Technologies” (AMT), which will ensure the competitiveness of domestic companies in the NTI markets and in high-tech industries.

“TechNet” is the first NTI roadmap developed for the development and effective application of “end-to-end technologies”, first of all, new production technologies.

The “TechNet” roadmap covers such advanced manufacturing technologies as digital design and modeling,

new materials, additive and hybrid technologies, robotics, industrial sensors, industrial Internet, big data, information systems for production and enterprise management, virtual and augmented reality technologies, artificial intelligence.

The key importance in the “TechNet” roadmap is given to the formation of “Factories of the Future” (digital, “smart”, virtual factories), which are systems of integrated technological solutions that provide the design and production of globally competitive next-generation products in the shortest possible time.

With successful formation, a strategic plan follows, in this case a strategic map of the development of the *AutoNet* market.

The roadmap is shown in Figure 3, which clearly depicts the essence of market development.

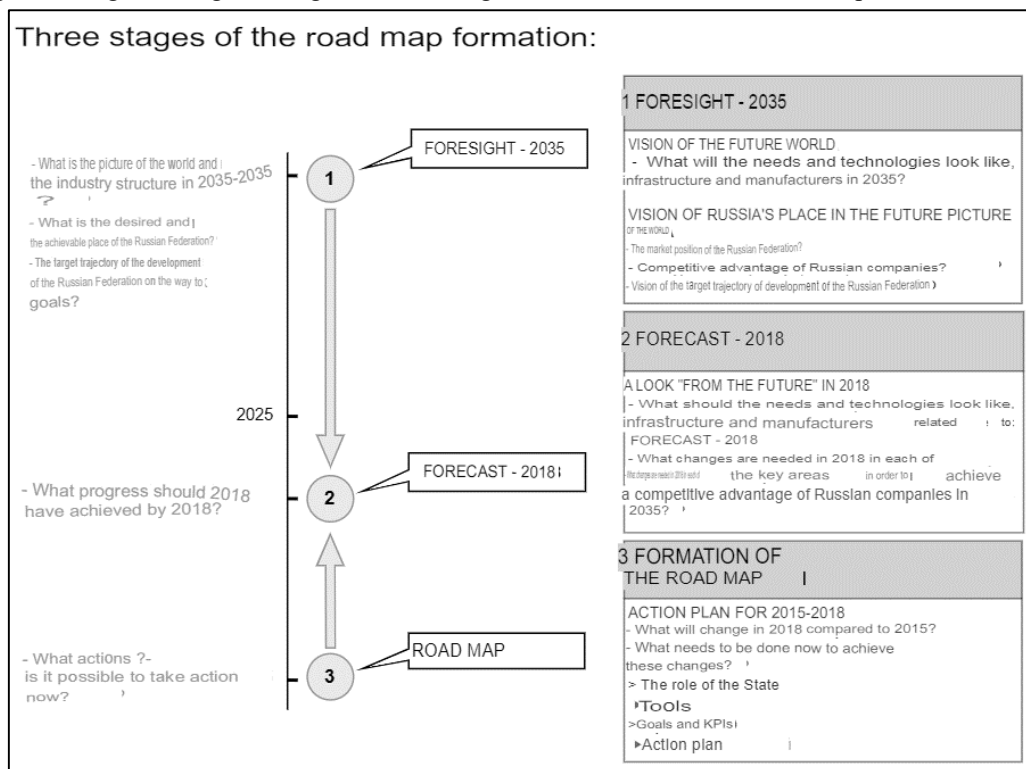

Fig. 3. *AutoNet* Market Development Roadmap.

Thus, the scientific and methodological approach is a kind of sequence of applying strategic tools in strategic development.

When choosing, you must adhere to certain criteria:

- 1) Compliance with the opportunities and threats of the external environment.
- 2) Compliance with the goals of the enterprise and compatibility with its mission.
- 3) Achieving competitive advantages:
 - a) Exploiting the strengths of the enterprise and the weaknesses of competitors.
 - b) Neutralization or compensation of the weaknesses of the trading company and the strengths (advantages) of competitors.
- 4) Strategy feasibility:
 - a) Availability of necessary resources.

- b) Compatibility of strategy with internal organization.
- c) Possible consequences.

III. METHODOLOGY FOR DEVELOPING A DEVELOPMENT STRATEGY FOR THE ORGANIZATION OF HOUSEHOLD APPLIANCES IN THE “TECHNET” MARKET

The implementation of the adaptation of a trading company to market conditions as a management function is necessary in order to bring the processes of the internal environment of the enterprise into line with the target plans or action programs of the organization in relation to the external environment, i.e., adapt the production and marketing activities of the organization to market conditions.

Applying the theory, the management of a trading company should build its activities in accordance with its key principle: "Produce what is sold, and not sell what is produced." The basis for making a decision on expanding or

reducing production volumes, upgrading products or removing them from production is marketing data obtained as a result of market research and the internal potential of the enterprise.

An analysis of the development of the Russian household appliances market made it possible to identify a number of trends in its development [17]:

- Dependence on import supplies.
- Increase in the number of Western enterprises operating in Russia.
- Slowdown in sales growth in the household appliances and electronics market.
- The economic downturn and the decrease in consumer activity will affect the dynamics of the home appliances market, and a slowdown in sales growth in the Russian home appliances market as a whole is predicted.
- Further decrease in profit growth rates of trading companies in this market.
- Switching consumer preferences to cheaper models in all categories of household appliances.

- Further strengthening of competition in all segments of the household appliances market.
- Transition from price competition to non-price.

To further change the situation, major players have developed and are implementing anti-crisis measures [18]:

- Optimization of the assortment, increase in the assortment of the share of the mid-price segment, etc.
- There is an increase in sales of household appliances through the Internet – trade.
- Further promotion of large retail chains of household appliances to regional markets.
- Further growth of basic and additional services.
- Growth in sales of household appliances through mobile applications.
- Further development of multi-channel sales.

The sequence of interrelated work on strategic analysis, selection and implementation of the strategy is the process of strategic management, which is shown in Figure 4.

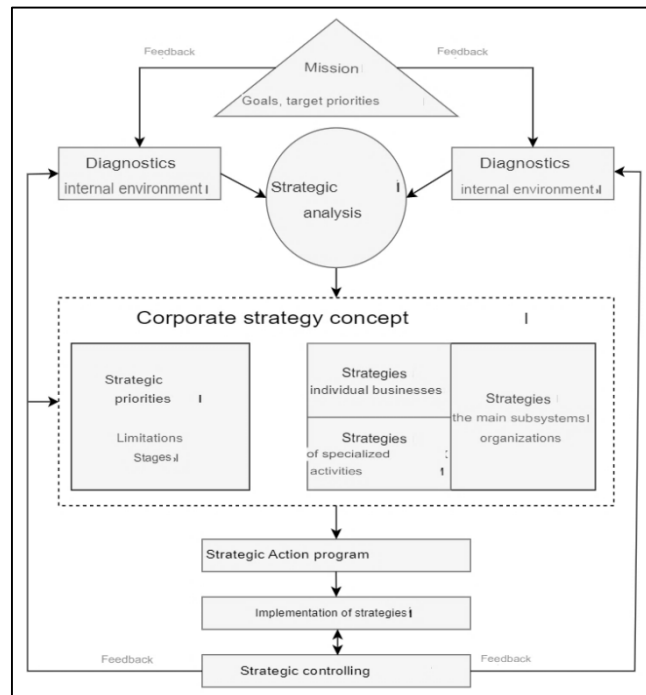

Fig. 4. AutoNet Market Development Roadmap.

Forecast for the development of the Russian household appliances market for 2019 - 2022:

- The economic downturn and the decrease in consumer activity will affect the dynamics of the home appliances market, and a slowdown in sales growth in the Russian home appliances market as a whole is predicted.
- Further decrease in profit growth rates of trading companies in this market.
- Switching consumer preferences to cheaper models in all categories of household appliances.

- Further strengthening of competition in all segments of the household appliances market.

As can be seen from the diagram, the strategy development process is iterative (cyclic). Thus, the definition and selection of a strategy can take place at the stage of analysis of the external environment, and the evaluation of the strategy will require additional external analysis. In addition, a change in strategy leads to the need to monitor and annually adjust strategic decisions and plans.

In the light of the new conditions for the functioning of a production organization, determined by the "rules of the game" in the system of market relations, the organizational

principles and functions of the activities of the upper and middle levels of the management structure should be revised and refined.

Each production organization must develop and consistently implement a program of measures to restructure its capabilities in order to most fully adapt to the new business conditions.

The TechNet roadmap has goals such as [19]:

- Formation of a set of key competencies in Russia that ensure the integration of advanced production technologies and new business models for their distribution as “Digital Factories”.
- Creation of globally competitive next-generation personalized products for NTI markets and high-tech industries.

The purpose of this map is to:

- Creation of infrastructure for the development of a set of key competencies for Digital Factories.
- Implementation of a set of key competencies by creating globally competitive companies in the NTI markets and in high-tech industries.
- Long-term planning for the development of advanced manufacturing technologies and related business models.
- Formation of an ecosystem for creating, attracting, developing and transferring best-in-class technologies.
- Creation of legislative and institutional conditions for the development of advanced production technologies.

IV. RESULTS AND DISCUSSION

Advanced production technologies in accordance with the NTI concept include: digital design and modeling, including supercomputer engineering, new materials (composite materials, metamaterials, metal powders), additive and hybrid technologies, flexible production cells (robotic complexes), various sensors, industrial Internet, big data, virtual and augmented reality technologies, expert systems and artificial intelligence.

A key role in the digital economy will be played by digital factories - this is a certain type of business process system, a way of combining business processes, which has the following characteristics:

- Creation of digital platforms, original ecosystems of advanced digital technologies.
- Development of a system of digital models of both new designed products and production processes. Digital models should have a high level of adequacy to real objects and real processes.
- Digitalization of the entire life cycle of products, everyone understands that the cost of changes is

greater the later we make these changes, and therefore world practice shows that the “center of gravity” is shifting towards design processes, within which the characteristics of global competitiveness or high consumer demands.

At the stage of formation of a digital factory, new key competencies are formed, for example:

- Quick personalization of response to market or customer requests.
- Use of system approaches (“system engineering”).
- Formation of a multi-level matrix of targets and restrictions as the basis of a new design, which significantly reduces the risks, volumes of full-scale tests and the amount of work associated with “finishing products and products based on tests”.
- Development and validation (proof that the requirements of a particular user, product, service or system are satisfied) of mathematical models with a high level of adequacy to real objects and real processes.
- Change management throughout the life cycle.
- “Digital certification” based on thousands of virtual tests of both individual components and the entire system as a whole.

The main directions of the “TechNet” roadmap, in terms of creating advanced Russian technologies for industry [20]:

- Creation and implementation of “virtual machines” (a full-fledged 3D model of the machine, which makes it possible to conduct virtual tests of future products, including those with the ability to connect to real controllers) and real-time collaboration functionality.
- Creation of a single information space of the enterprise, which will allow resolving the contradiction between the unity of the production and administrative activities of the enterprise and the autonomy of management at the level of individual systems.
- Release of the Industrial Internet. The strategy includes cross-platform standardization of open systems for secure data exchange, interoperability, as well as optimization of user experience for customers, implemented in the form of embedded intelligent models. This approach also provides comprehensive automation and informatization of customer production based on a centralized approach and a single integrated architecture.
- Integrated automation of the entire chain of interacting production enterprises, the exclusion of a person and risks associated with the human factor from the industrial production process.

Figure 5 presents the overall picture of the “factory of the future” markets for 2015-2035 years.

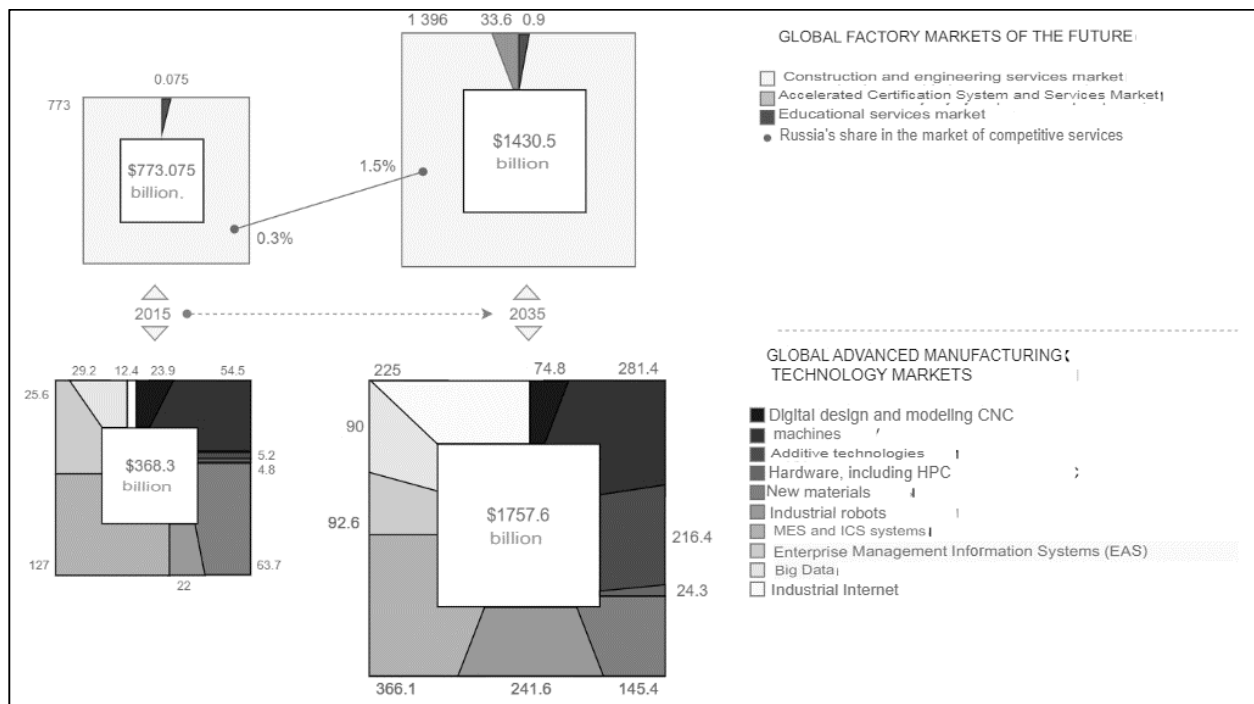

Fig. 5. "Future Factory" Markets.

The diagrams show the growing role of industry, but on fundamentally new solutions, which are now united by the general term "smart factory". Behind this is the end-to-end integration of processes, the total digitalization of workflow and management, the distribution of design functions in space, production quality control, streaming individualization.

The distinguishing features of "smart" industries are the following [21]:

- The ability to act smart and respond smartly, maximizing technical efficiency, cost effectiveness and benefit through planning, continuous monitoring of operations and continuous learning.
- "Operational assets" - workers, plant, equipment, operating models and databases - are integrated and aware of their status through a system of sensors. Each device is able to determine its state and report it to all devices associated with it.
- Smart manufacturing equipment is able to detect abnormal situations and adapt to them. Through constant monitoring and application of the acquired knowledge, the system has the ability to function adequately depending on changing circumstances such as sudden interruption of work processes, changes in the properties of the resulting raw materials, etc.
- The equipment has full access to the necessary information at any time of operation.
- To prevent accidents, smart manufacturing collects real-time information.
- The system has the ability to quickly respond to changes in the process and failures.
- Smart manufacturing is sustainable, recyclable and has minimal environmental impact.

- A necessary feature of smart manufacturing is a highly skilled workforce.
- The system has an understanding of the limits of automatic action and supplies all the necessary information to operators and managers to make the necessary decisions.

The main tasks for the enterprise for the production of household products [22], [23]:

- Flexibility of production: the possibility of restructuring production processes for new types of products;
- Decentralization of management as a mechanism to ensure the required flexibility of production: distribution of decision-making functionality throughout the production system;
- Evolutionary gradual transition to the enterprise of the future: no need to stop production to make changes;
- Service approach as a model of inter-corporate interactions that determines organizational and financial relationships;
- Economic analysis of the possibilities of manufacturing new products in real time with setting the task for partner enterprises;
- Custom computer design, modeling, testing, certification of products in digital format in real time.

CONCLUSION

Thus, it is obvious that the use of marketing information contributes to the development and implementation of enterprise development plans, as evidenced by the experience of effectively operating companies, including some Russian ones. However, the problems of collecting and analyzing marketing data, and most importantly, their

productive application are far from simple for most Russian managers and require professional approaches to their solution.

The implementation of the roadmap is carried out in the form of projects that have been selected in the prescribed manner. The information contained in the roadmap is for reference only, cannot be considered as a description of directly implemented activities and is not the basis for the allocation of state support funds in any form.

Abstract—The purpose of this study is to conduct a statistical analysis of road accidents in the Russian Federation. The article considers ways to reduce accidents and are effective and efficient, as well as statistics given in the period from 1991 to 2019. The main causes of accidents have been identified, which is an essential aspect for reducing the accident rate. The analysis of statistical data on the number of accidents, population, length of roads, number of vehicles other than motorcycles and the general road situation available at the moment and several years ago, as well as the main causes of accidents and measures to reduce accidents. This analysis has led to correct and effective results and solutions to improve the situation on the roads. At the same time, the integrated measures implemented and being implemented at the moment, such as federal targeted, regional and local programs, as well as road safety strategies, are more likely to reduce road accidents. Statistical data and methods used are taken into account, the effectiveness of which is decreasing. Development of methods appropriate to the current situation is a necessity.

Keywords— Public roads, road accidents, statistical data, traffic

I. INTRODUCTION

The topic of accidents has always been a topic deserving special attention in the field of transport, and the accident itself has been and is one of the most important social, economic and dangerous problems in most countries of the world. The Federal Road Agency of the Russian Federation studies sources, main types of road accidents, considers and takes measures to prevent and reduce the number of road accidents [1]-[3].

The total number of road accidents has now declined slightly compared to the late 20th century, as the population has fallen. Thus, in 1992 the number of road accidents in Russia was 185 thousand, with a population of 148 million, in 2007 - 233 thousand, accidents with a population of 143 million, and in 2019 - 164 thousand, accidents with 145 million people [4]-[6].

Fig. 1. The main causes of road accidents in the Russian Federation [1], where: 1 - non-observance of the traffic sequence at the intersection; 2 - incorrect distance and non-compliance with the norms of the distance between vehicles; 3 - traffic violation at a pedestrian crossing; 4 - exit to the oncoming lane; 5 - violation of the speed limit; 6 - movement is not in accordance with the traffic lights; 7 - excess of the set speed; 8 - incorrect overtaking; 9 - other minor factors.

The existing and applied sets of measures are for the most part effective, but it is not possible to assess their economic and non-economic effectiveness at this time. Also, the global complexity in the development and application of emergency measures is that all of the factors of accidents are consequences of wrong decisions of a person - i.e. a human

factor. While an undeniably smaller proportion of the causes of accidents, but still important, are amenable to control by the Federal Road Agency and local municipal authorities [10]-[12].

II. ANALYSIS OF TRAFFIC SAFETY STATISTICAL DATA

To assess the level of road safety in Russia, one should consider the accumulated statistical data for a certain number of years. At the same time, there is a need to study not only accident rates, but also information about the size of the vehicle fleet, the length of the road network, as well as the population (Figures 2-4).

Fig. 2. Traffic safety data analysis graphs, where: a - Dynamics of the relative change in the number of motor vehicles, excluding motorcycles, the length of paved public roads and the total number of accidents in Russia from 1992 to 2002; b - Comparative chart 1992 - 2019.

Fig. 3. Comparison of the population and the number of road traffic accidents in Russia for 1991-2019 *Indicators in Figures 2 and 3 in 1992 are taken as 100%. Further, the percentage change is calculated relative to each indicator.

Fig. 4. Traffic safety data analysis graphs, where: a - Change in the number of road accidents in Russia for 1991-2002; b - Change in the number of vehicles in the Russian Federation by years (excluding motorcycles) [6].

After considering the statistics since 1992, it can be said that the population in Russia has changed insignificantly over the given period of time, the number of car parks in Russia has increased 3 times compared to 1992 and 2 times compared to 2002; the length of hard-surface public roads increased by 2.5 times in comparison with 1992 and 2 times in comparison with 2000; the number of accidents decreased by 1.2 times compared to 1992 and 2002.

III. OVERVIEW OF USED ROAD SAFETY PROGRAMS

Based on the analysis of the above statistical data, the Government of the Russian Federation is developing various federal programs and strategies to ensure and improve road safety.

In order to overcome the current negative situation in 2002, a long-term program for the maintenance of the road network was developed, introduced and launched. The adopted program of measures is consistent with the sub-program “Roads” approved by the Government of the Russian Federation as part of the Federal Target Program “Modernization of the Transport System of Russia (2002-2010)”, according to which the reduction of the road component in the total accident rate and the severity of the consequences of road accidents will be achieved mainly, due to a general increase in the transport and operational condition of public roads [2], [13]-[15].

In addition, this program includes the Informatization subprogram, which contains certain projects for the development of information and telecommunication technologies, communication systems on highways. Providing medical, rescue services, as well as road users with operational communication services will significantly reduce the time of accident detection, rescue and evacuation of victims to the nearest medical facilities, and thereby significantly reduce the severity of the consequences of accidents [3], [16]-[18].

In the Russian Federation, the development of similar systems is provided for by the Federal Target Program “Modernization of the Transport System of Russia (2002-2010)”, which includes subprograms and “Roads”,

Currently, the Government has developed a road safety strategy until 2024 [4], [19]-[21]. The state focuses on the road and transport situation in European countries and assumes the achievement of a zero death rate from injuries in road accidents. At the same time, the emphasis is on the irresponsibility of traffic participants, namely on the human factor - the main reason that affects the level of injuries due to road traffic accidents.

IV. RESULTS AND DISCUSSION

The regulation under consideration and the further increase in accident rates over the past four years (Fig. 4a) shows that the usual generally accepted measures related to the control of the traffic situation, the establishment of measures to influence road users for violating traffic rules and the like, in have lost their relevance to a certain extent due to the development and expansion of the road transport network. Therefore, new, more advanced methods and measures are needed that take into account the specifics of the causes of road traffic accidents. Due to the serious growth in the number of vehicles, it is very difficult to change the situation related to solving traffic safety problems in the country (over the past 10 years, the number of vehicles has increased by almost 1.8 times, and the number of cars - more than 2 times) (Figure 2b) with an increase in the length of the road network by only 1.3 times.

The comparative statistics considered above makes it possible to adjust, if necessary, the goals and objectives of the road transport policy defined in the national programs for improving road safety, taking into account the experience of their implementation in the past years. Also, the results of our statistics indicate the need to improve control over the traffic situation. While the results of the study of the causes of road accidents determine the need for the modernization of the road sector.

As the main ways to improve the level of road safety in Russia, it is necessary to consider the use of effective measures to reduce injuries in road accidents by improving the quality of vehicles, using the latest systems of road engineering equipment, information technology and communication systems to the greatest extent on busy road

sections, improving the discipline of drivers to reduce traffic accidents. The set of ongoing programs to modernize road safety at the regional and local levels is particularly effective.

CONCLUSION

The topic of accidents is really significant, because road accidents happen almost daily. At the same time, the above statistics makes us think about how to correct the current situation on the roads. It is a comprehensive analysis that contributes to the development of modern effective measures in the field of road policy aimed at reducing the number of accidents. Without a doubt, it can be argued that there is no specific answer to this question, but increasing the responsibility of each road user for their actions while participating in it can fully modify the current situation.

Future studies plan to collect and analyse data from other countries, also update data and identify other factors influencing road accidents.

Abstract—The article studies the influence of external factors on the attendance of the shopping center. It is necessary to isolate the essential traits-factors that determine the attendance of the shopping center (SC) and establish their mathematical dependence with the resulting indicator. Thus, in the course of the study, it was made possible to find various data for the construction of a regression model, namely the number of visits to the shopping center «Planet» for October 2017 and various factors such as: whether it was rain or not, the index of weather sensitivity, temperature, wind speed and day of the week, which can affect the visit. The data were formatted to exclude emissions to avoid model inadequacy. Next, a linear regression model was built, on the basis of which it is possible to determine the factors that influence the visits to shopping centers more. If the constructed model is adequate, then it will be possible to draw conclusions on what factors are more worth paying attention to, to determine the peaks of attendance at the SC.

Keywords— Correlation, data, excel, model, regression analysis

I. INTRODUCTION

Today the SC is no longer something new and unknown [1]-[3]. The SC is a set of trade and/or service enterprises that sell a universal or specialized range of goods and services located in a specific area in buildings, Planned, constructed and managed as a single unit and provided car parking within their territory [4]-[6].

The SC is also a large number of additional jobs and the provision of development for small businesses. We are

talking not only about individual stores or retail chains within the SC, but also about shopping “islands” that stand separately in the middle of the pavilion. This type of activity is an example of the effective use of the territory and the expansion of the number of tenants, and hence the increase in profits [7]-[9]. Such a system helps a business that does not have enough funds to rent a separate room or is at the initial stage of development [10]-[12].

However, the main indicator of the effective operation of the shopping center is attendance. After all, visitors are the basis of any trading activity, which means that their increase helps to improve the quantity and quality of sales. But what exactly attracts visitors to shopping malls? What factors influence attendance? [13]-[16]

Visiting the shopping center depends on some of the factors described in this paper. It is necessary to find out on which factors attendance depends, and which factors are interconnected. Using correlation-regression analysis of multivariate data, it is possible to determine what factors affect the number of people in the shopping center and whether they are interconnected [17]-[19].

II. DATA AND RESEARCH METHODS

All collected data for October 2017 are presented in Table I and the explanation in Table II.

TABLE I. INITIAL DATA

Date	Attendance	Was it raining or not	Weather sensitivity index	Temperature	Wind(m/s)	Day of the week
01.10.2017	55300	1	4	6	2.3	7
02.10.2017	36380	2	3	2	3.1	1
03.10.2017	35928	2	3	8	3.4	2
04.10.2017	37140	2	1	3	1.2	3

05.10.2017	38480	2	1	4	2	4
06.10.2017	42580	2	1	4	1.5	5

08.10.2017	56380	1	3	5	3	7
09.10.2017	37020	1	3	5	9.1	1
10.10.2017	34430	2	1	6	4.2	2
11.10.2017	36480	1	3	5	2.8	3
12.10.2017	40360	2	4	0	2.8	4
13.10.2017	41100	2	3	2	2.5	5
14.10.2017	59300	2	1	0	0.6	6
15.10.2017	55830	2	1	3	0.3	7
16.10.2017	36440	2	3	9	0.5	1
17.10.2017	35560	2	1	4	1.5	2
18.10.2017	37730	2	3	4	2.7	3
19.10.2017	37380	2	3	4	3	4
20.10.2017	41770	2	3	5	1.4	5
21.10.2017	62960	2	3	8	2.7	6
22.10.2017	60320	2	3	11	2.7	7
23.10.2017	33960	2	1	2	7.9	1
24.10.2017	35150	1	1	3	7.2	2
25.10.2017	35230	1	1	3	6	3
26.10.2017	38180	2	2	1	1.7	4
27.10.2017	41700	2	2	-1	6.6	5
28.10.2017	61680	2	1	5	4.1	6
29.10.2017	57120	2	1	5	3.5	7
30.10.2017	36460	2	4	-1	6.3	1
31.10.2017	35630	2	4	-3	3.7	2

TABLE II. EXPLANATION OF TABLE I.

Was it raining or not	
1	It was raining
2	There was no rain
Weather sensitivity index	
1	Comfortable weather conditions for weather-dependent people.
2	Weather conditions may affect some people with increased weather sensitivity.
3	There is a high probability of the influence of weather conditions on the well-being of weather-dependent people.
4	The meteorological situation can cause a sharp deterioration in the well-being of weather-sensitive people.

Based on the collected data, 5 factors were identified that may affect the number of people. The main indicator is the number of visits. The next indicator that may affect visits is the presence of rain on a given day, weather sensitivity index, temperature on a given day, wind speed and day of the week [20].

The Bravais-Pearson correlation coefficient ($r_{p_{xy}}$) is -0.262, -0.008, 0.338, -0.283, 0.864. On the Chaddock scale: $0.1 < r_{xy} < 0.3$, $0.3 < r_{xy} < 0.5$, $0.7 < r_{xy} < 0.9$, therefore, in the example under consideration, the correlation between feature Y and factor X in the first, second and fourth cases will be weak, in the third case moderate, and in the third fifth high (Table III).

TABLE III. TABLE FRAGMENT

The Bravais-Pearson correlation coefficient	0,055	-0,008	0,337	-0,282	0,864
Least squares method	42593,333	43598,620	46217,005	45109,820	56548,939
Fisher 's Criterion	0,055	-0,008	0,351	-0,290	1,309
Student's Criterion	2,426E-21	2,427E-21	2,422E-21	2,433E-21	2,417E-21

Let's check the adequacy of the constructed model to the object using the Fisher criteria.

The idea behind the adequacy test is to compare the prediction variance based on the regression model under study with the noise variance. The data are presented in table IV.

TABLE IV. FISHER CRITERIA

	Initial data	Fisher 's Criterion
Factor 1	-0.262	-0.268

Factor 2	-0.009	-0.008
Factor 3	0.338	0.352
Factor 4	-0.283	-0.290
Factor 5	0.864	1.309

Conclusion: In the first, second, third and fourth cases, F_{tab} is almost equal to F, but still a little more, so we can conclude that the model is adequate, and in the fifth case $F > F_{tab}$, because of this, it is concluded that the model is inadequate and it is necessary improve the model.

We carry out regression analysis to check the quality of the constructed models. The data is presented in Tables V-

TABLE V. THE RESULT OF THE REGRESSION ANALYSIS OF THE FIRST FACTOR

<i>Regression</i>	1	99.98	99.98	85.57	3.751E-10	
<i>Remainder</i>	29	33.89	1.1685			
<i>Total</i>	30	133.87				
-						
-	Coefficient	Standard error	t-statistic	P-Value	Lower 95%	Upper 95%
<i>Y-intersection</i>	-4.77	0.96	-4.96	2.8E-05	-6.74	-2.80
<i>Variable X1</i>	0.0001	1.93E-05	9.25	3.8E-10	0.0001	0.0002

One of the main indicators is the R-square, which indicates the quality of the model. In our case, this coefficient is 0.262, 0.008, 0.338, 0.283, 0.864, which corresponds to a low, medium and high quality level of the model.

The higher the value of the coefficient of determination, the more applicable the chosen model for a particular task. It is believed that it correctly describes the real situation when the value of R-square is higher than 0.7.

Another important indicator is located in the cell at the intersection of the “Y-intersection” line and the “Coefficients” column. Here it is indicated what value Y will have, and in our case, this is the visit rate, with all other factors equal to zero. In this table, this value is 0.75, 2.33, -1.1, 6.317, -4.77.

The value at the intersection of the column “Variable X1” and “Coefficients” shows the level of dependence of Y on X. In our case, this is the level of dependence of the visit

indicator on other factors. Coefficient -4.22, 9.5, 0.0001, -6.08, 0.00017.

III. RESULTS AND DISCUSSION.

As a result of the study, it was revealed that factors such as the meteosenstivity index affect shopping center visits to a lesser extent. Temperature, the presence of rain on a certain day and wind speed has a medium effect, and the day of the week has a greater effect. Based on this, all 5 factors can be divided into 3 groups: group 1 - little influencing factors (yellow color), group 2 - medium influencing factors (green color), group 3 - strongly influencing factors (red color). Looking at this table, you can understand that in order to determine the peaks of visiting a shopping center, first of all, you need to look at the day of the week, then at temperature, wind speed and the presence of rain. The data are presented in Table X.

TABLE X. DEGREE OF INFLUENCE OF FACTORS

Date	Attendance	Was it raining or not	Weather sensitivity index	Temperature	Wind (m/s)	Day of the week
01.10.2017	55300	1	4	6	2.3	7
02.10.2017	36380	2	3	2	3.1	1

31.10.2017	35630	2	4	-3	3.7	2

CONCLUSION

Analysis of traffic peaks by day helps to:

- Choose the optimal place and time for promotions: where it is better to hold the promotions, at what time, how long.
- To understand what time and days of the week are key to work. Accordingly, when it is necessary to withdraw the best staff, be present management, strengthen the replacement by additional staff.

The simulation of attendance can be used to solve the problems of assessing the quality of incoming data on the attendance of groups of objects in the construction of market indicators, as well as to solve a wide range of tasks related to the work of the mall.

Abstract—One of the most popular languages of graphic modeling is Unified Modeling Language (UML). This abstract presents an overview of the language UML. A wide range of diagrams were considered, together with a brief description of their application, the main advantages and disadvantages of the UML language, its object-oriented approach. Strengths (Strengths), Weaknesses (Weaknesses), Capabilities (Opportunities) and Threats (Threats) have been formulated for SWOT analysis. The SWOT-matrix is based on them. A detailed structure of diagram types was presented, dividing the above-mentioned diagrams into structural and behavioral diagrams. Among all the applications of the UML language in more detail considered the possibilities of its use in software engineering, and specifically - in software development. According to the study, it was found that the UML diagram language is one of the best tools.

Keywords— Graphic modeling, software, SWOT matrix, UML

I. INTRODUCTION

UML is a graphical description language that has been around for over 20 years, consisting of an integrated set of diagrams and used for object modeling in software development. UML is a generalist language and is suitable for graphical description of abstract system models because it is an open standard. UML was created to design, visualize, document and define, as a rule, software systems. UML is by no means a programming language; however, UML diagrams can be used to generate code [1]-[3].

II. UML DIAGRAM

Since diagrams are an integral part of the UML, it is a good idea to consider the types of these diagrams.

A list of most of the diagrams grouped is shown in Figure 1 below.

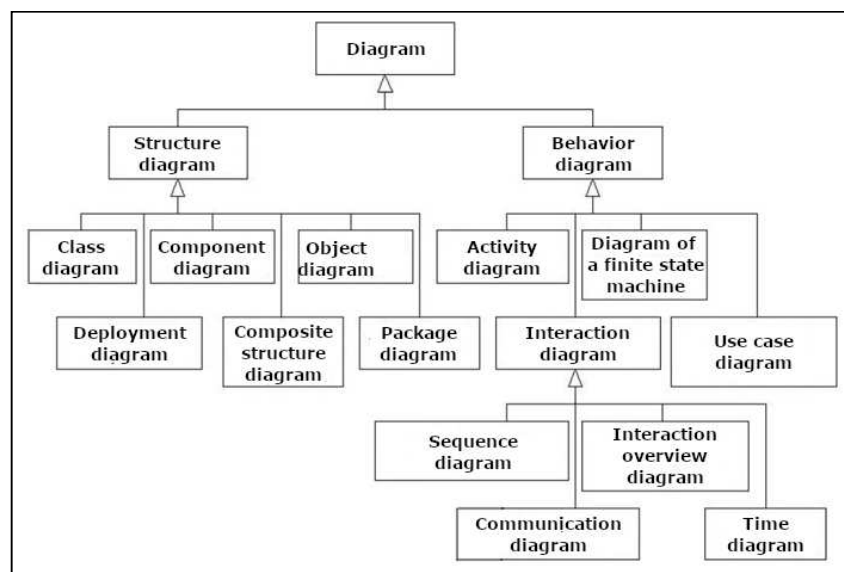

Fig. 1. Types of charts.

III. STRUCTURAL DIAGRAM

A. Class Diagram

A class diagram is used to illustrate the relationship between classes, objects, and other entities of the OOP paradigm. In addition, the class diagram displays in detail the relationship between the entities of a particular subject area. As an example, objects and subsystems [4]-[6].

B. Deployment Diagram

A deployment diagram shows a set of nodes and their relationships. Describes a static representation of an architecture. Associated with a component diagram (each node usually hosts one or more components) [7]-[9].

C. Component Diagram

This diagram illustrates the physical state of the system. It describes each of its files and how it functions with other files.

On it you can see both databases and code files, hardware components or business logic.

D. Composite structure diagram

A composite structure diagram represents the internal structure of a class or collaboration. There is little difference between a component diagram and a composite structure diagram, which is why they are treated as component diagrams in this book [10]-[12].

E. Object Diagram

This type of diagrams will inherit from class diagrams, as a result, they have a one-way dependency.

If you follow the OOP paradigm, then an object diagram is an instance of a class diagram. Their main meaning is the same, the only difference is that the object diagram is a "snapshot" of a certain moment during system modeling [13]-[15].

F. Package Diagram

Package diagrams show the dependencies between the packages that make up the model.

IV. BEHAVIOR DIAGRAM

A. Activity Diagram

The activity diagram shows the flow of calculations step by step. An activity describes a set of activities, their sequencing or branching flow, and the values generated or used by the activities. Activity diagrams illustrate the dynamic view of a system. They are especially important when modeling system functions. Focus on the flow of control when implementing some behavior [16]-[18].

B. State Machine Diagram

A diagram that shows a state machine with its associated states and transitions. The state machine is a linear display of state transitions of a certain element of the system. A CA always has an initial and final state. In other words, with the help of such a diagram, you can see what decisions any object makes, based on the current situation.

C. Interaction Diagram

Interaction diagram is a common name for sequence and communication diagrams. All sequence and communication

diagrams are interaction diagrams, and all interaction diagrams are either sequence diagrams or communication diagrams. They are based on the same model, although in practice they include different entities.

D. Use Case Diagram

This diagram allows you to see the relationship between the system actant and use cases, and is used to ensure that the customer, end user and developer can interpret the functionality and requirements of the system in the same way.

V. USING UML

The UML language is used in business process modeling, system design, displaying the structure of an organization, describing technical processes, and so on [19]-[22].

UML allows software developers to use one standard for graphic representations of classes, roles, generalizations, components, which allows them not to waste time on the agreement of the general form of the diagram, but to concentrate more on design and architecture.

A. Practical Application In Software Engineering

Quite often, when developing software, there is a need for a graphical, more accessible to many, way of representing abstract system models. The most common in UML are class diagrams, use case diagrams, and sequence diagrams.

A class diagram is necessary to illustrate the structure of classes in a program, class attributes, and class interactions.

The Use Case Diagram is necessary to illustrate the possible interactions of the actors with the program and the outcomes for each of these interactions.

A sequence diagram is needed to illustrate the life cycle of an object and the interaction of actors within a given use case.

VI. SWOT-ANALYSIS

A SWOT analysis of the UML methodology was carried out, the result of which was the SWOT matrix shown in Table I.

A. Strengths

- The UML is object-oriented, which allows it to function very well with the OOP paradigm that is popular these days.
- UML allows you to build diagrams with such detail that all the details of the system will be shown in an understandable way.
- UML methodology is easy enough for people with different levels of education to understand.

B. Weaknesses

- Newer versions of UML introduce new diagrams that are hardly ever used.
- UML uses only two classes of models, the diagrams of which were described above: structural and behavioral. Thus, the functional model remains

unaffected, and for its implementation, if required, it will be necessary to use other methodologies, for example, IDEF0 or DFD.

C. Opportunities

- UML is easily applied in the construction of various technical processes or in business processes.
- Due to its popularity, the UML is still getting updates, including new diagrams.

D. Threats

- Due to the widespread use of UML, it tries to become as versatile as possible, but for some projects where details and formalities are important, UML diagram engineers have to limit its functionality.
- Not all programming languages in which projects are implemented support an object-oriented approach. For such projects, this methodology is not suitable.

E. SWOT Matrix

TABLE I. SWOT MATRIX

	Opportunities	Threats
Strengths	Significant potential of using UML diagrams in technical and business design	Within the framework of an object – oriented approach , it provides the widest possibilities for modeling with varying degrees of detail
Weaknesses	Application of rarely used diagrams in particular cases in technical and business design	Using new diagrams to solve new problems

CONCLUSION

UML is a good tool for creating diagrams of any system. Its functionality allows you to clearly demonstrate almost any process during project development. In addition to IT - the UML sphere has established itself in other professional fields, where it is also necessary to demonstrate the details of the system.

UML is versatile, convenient and understandable for any person, and its object-oriented approach allows you to integrate into most modern programming languages.

Almost all its flaws are special cases, in general, it is one of the best tools to date.

Abstract—Recently, there has been a large-scale integration of renewable sources to keep pace with the enormous increment of consumers' load demand. The integration of these devices on a large scale can violate the technical and regulatory constraints of the smart power grid. Therefore, a proper control system must be designed to increase their power output and maximize the system owners' benefit while meeting power grid standards. This paper is a collection of information to provide its reader with a holistic view of the implementation of a cyber-physical system to aid in distribution system planning. The goal of this paper is to review the current literature and identify research gaps that have yet to be fully explored. This is followed by making proposals for areas to be researched in order to improve the knowledge bank surrounding this important topic. This paper will begin by addressing the concept of a cyber-physical system by elaborating on its structure through its various layers. It will also describe the role of the Internet of Things (IoT) in improving the monitoring and control abilities of cyber-physical distribution systems. Furthermore, a detailed literature review is given to highlight the current state of distribution system research being done surrounding the implementation of cyber-physical systems to improve system planning. Based on this review, an analysis is given to better explain how a successful cyber-physical based distribution system can be constructed to achieve automation. Finally, gaps in current research are discussed to provide an understanding on which aspects of cyber-physical based distribution system planning have not been fully explored yet and where more exploration needs to be done. A list of research questions are provided to help aid potential researchers dive deeper into the area of fully automating distribution systems that consist of both renewable and non-renewable sources of energy.

I. INTRODUCTION

A. Cyber-Physical System (CPS)

In recent times, there has been a continuous effort to develop appropriate techniques so that the monitoring and control of the physical system can be improved. On the other hand, researchers are also focusing on cyber system-related issues to improve the performance of communication and computing systems [1]. Nowadays, new technology has evolved in the form of a Cyber-Physical System (CPS) that integrates both the physical and cyber systems [1]-[2]. This can be defined as a multi-dimensional system with integrated computing and communication technology (cyber system) in order to monitor the stability, reliability, and efficiency of physical systems. Using different types of sensors, the cyber system collects data from the physical system and sends the control signal to the physical system so that appropriate action can be taken [2]. The working of a cyber-physical system is presented in Figure 1.

B. Need for Cyber-Physical Power Distribution System (CP-PDS)

As of late, with the enormous load growth and rising environmental concerns, there has been a large-scale integration of renewable energy sources all over the world [3]. These devices provide significant benefits in terms of voltage profile enhancement, load reduction, pollution minimization and benefits maximization. However, the large amount of renewable energy integration with the grid is causing different

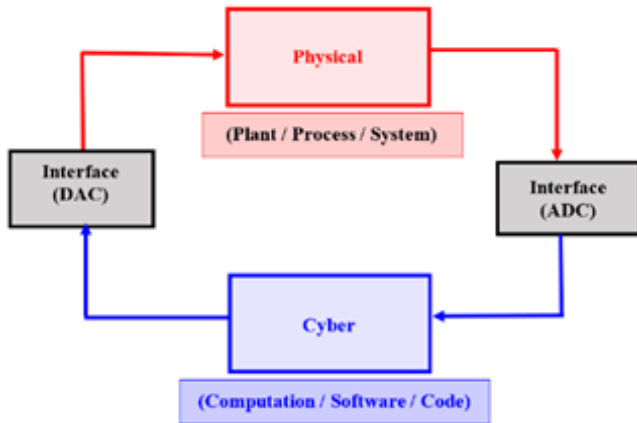

Fig. 1. A sample Cyber-Physical System (CPS).

technical constraint violations such as reverse power flow, voltage stability issue, etc. Apart from changing distribution system characteristics, they also degrade the power quality. These factors change the concept of a distribution system to an active distribution system where a variety of control methods must be adopted to improve energy efficiency and enhance system performance [4]. To do so, the future distribution system must be integrated with computing and communication networks so that the measurement and control instructions can be transmitted to and from the control center [5]. This type of active system management and control cannot be attained without integrating information and communication technology (ICT). ICT is important for timely and accurate decision-making with the utilization of an active control function. However, the random failure of the ICT system may lead to adverse situations such as blackouts, deterioration of system performance, etc. In such context, to maintain the efficient and secure operation of the power systems, the physical distribution system must be integrated with the cyber system, which can be regarded as a Cyber-Physical Power Distribution System (CPPDS) [5]-[6].

C. Structure and Function of Cyber-Physical Distribution Systems

A cyber-physical power distribution system (CPPDS) consists of two parts, namely the cyber system and the physical power system [7]. There are different types of traditional system equipment and new-age technologies such as renewable energy sources, energy storage elements, and electric vehicles in physical power systems. On the other hand, the cyber system consists of communication networks, metering instruments, controllers and computing devices. The main function of this cyber system is to automatically operate the physical power system. A typical structure of CPPDS can be divided into mainly three layers [7].

1) *Physical Layer*: In this layer, there are distribution system equipment and corresponding cyber components such as different types of renewable sources, intelligent electronic devices, battery storage systems, fixed capacitors, circuit breakers, feeder terminal units, manual and remote-control switches etc. Apart from this, this layer also includes the control and measurement units and communication systems. In this layer, the acquisition of measuring data and the control commands execution is achieved through data interfaces between primary equipment and secondary devices.

2) *Network Layer*: A two-way data communication between the control center and the physical system is necessary for stable operation, fast malfunction response, and renewable energy sources management [8]. This layer describes a distributed communication network that exhibits the transmission process of mass data using various network components. The power line carrier networks work through coupling capacitors, carrier equipment, power lines, and modems. The Ethernet networks work using switches, optimal fibers, cable, routers etc., whereas the wireless networks work through mobile communication and WIMAX technologies [9].

3) *Control Layer*: The control layer uniformly collects all the transmitted data from different communication systems and accordingly generates control demands and sends them to the physical layer in order to respond to different physical operation scenarios. This layer consists of multiple sub-servers to transfer traffic from different communication networks. After analyzing the received data, this layer acquires the current physical state of the distribution system and generates control demand for each piece of equipment of the physical layer.

4) *Operation Procedure*: Initially, local metering units and sensors measure the physical operating state of the distribution system, which includes bus voltages, renewable sources output, load values, and the on/off status of automation equipment. Then, this physical layer converts these physical states into digital states before sending them to the control layer through multiple communication networks. Based on the received information, the control layers determine the operational state of the distribution system and generate a series of control commands. These commands are sent back to the physical layer to be executed by system equipment for regulating the unsuitable physical state of the distribution system.

D. Role of IoT in the operation of Distribution System

To combat the challenges of the traditional distribution grid, the concept of the smart distribution grid has come into existence where complete coordination can be established with a two-way flow of information and electricity between the consumers and the power suppliers under a fully automated power network. However, one of the major concerns with the smart grid implementation is the increased use of information and computation technologies, which rely on the Internet as well as computing and processing power to run. Moreover, the requirements of response time and reliability are especially critical, as the entire system operation has to be carried out automatically and to do so, the data transmission and decision-making technologies shall be optimized. In order for the smooth process of all the necessary data, IoT-based modern information communication technologies play an important role in improving the monitoring and control abilities of the cyber-physical distribution systems.

II. COMPREHENSIVENESS

A detailed review of the existing literature in this field reveals that in recent times, the planning of IoT-based cyber-physical systems is gaining researchers' attention and, in most articles, researchers concentrated on the modelling of system equipment and improving reliability with adequate control techniques. In [10], researchers designed an accurate cyber-physical system with different sets of communication, control and physical system equipment under a smart grid environment. They also generated several attack scenarios to explore cyber-physical impacts on the voltage profile and rotor stability. Authors in [11] presented a comprehensive survey on the cyber-physical system considering the smart grid implementation. They discussed the development scope by providing taxonomy and insightful guidelines. Moreover, they also identified the key features and different design decisions. From the perspective of industry automation, researchers presented a detailed review of the IoT-based cyber-physical system in [12]. The design and characteristics of IoT architecture and IoT applications were discussed, and the authors have mainly considered the three key aspects of IoT systems, namely, networking, computing and control. Authors in [13] designed a cyber-physical system-based navigation system for fulfilling electric vehicle charging demands. The power distribution system was taken as the physical layer and interaction between the electric vehicle and control center is studied to assist the vehicle owner with the proper charging station. A cyber-physical system was studied in [14] for application in active distribution systems where an uncertain load control strategy was proposed based on the output values of renewable energy sources. This paper also discussed the modelling of control systems and control techniques considering a hybrid system. As of late,

there is a growing number of installations of distributed energy resources in the power grid, which could impact the grid operation through coordinated attacks. In this regard, the authors in [15] designed an IoT-based cyber-physical grid model and presented a risk assessment methodology to analyze the impact of IoT integrated cyber systems on physical grid operations. In [16], a secure control system was designed for identifying the possible cyber-attack in the communication channel of a cyber-physical system. In [17], the authors proposed an analytical method to quantify the impact of networks and information systems on the reliability analysis of cyber-physical distribution systems. Regarding the assessment of reliability, the impact of element failures, network topologies and information network traffic was taken into account. Researchers in [18] designed a cyber-physical distribution system to deploy feeder remote terminal units with an aim to increase system reliability. In [19], the scheduling problem of packet transmission over wireless communication networks was studied to widen the stability margin. In this regard, the authors proposed a new algorithm for scheduling the distributed data traffic. Authors in [20] designed an IoT-based cyber-physical system to handle industrial informatics regarding location, sensor and unstructured data for big data mining.

III. ANALYSIS

The cyber-physical system consists of a control layer and a physical layer. In between these layers, there is a network layer through which the information flow occurs through different communication channels. With the integration of different devices in the physical system, there is a significant increment of data transferring between the control and physical layers, which heightens the risk of cyber attacks. Therefore, special concentration must be given to the development of IoT-based smart computation, control and communication techniques for identifying possible cyber-attacks in the communication channel so that the reliability, safety, and secure operation of the cyber-physical system can be ensured.

A cyber-physical system consists of networking computing and communication devices. The random failure of computing software, communication network link and intelligent services can influence the control ability of the distribution system. On the other hand, to integrate a dependable i.e. failure-free control system, distribution companies have to compromise in the economic benefits since such system demands high construction and maintenance costs. In such a context, the failure rate of cyber components must be considered for cyber-physical planning of distribution systems. Moreover, the economic, reliability and safety aspects of the cyber-physical system must be taken into account for realistic planning. Apart from the failure of the cyber system,

there are quite a few pieces of equipment in the physical system and there is a high chance that they can also fail. Therefore, the uncertainty in physical system failures also needs to be considered for system planning.

Under the circumstances of a smart grid, the integration of renewable energy sources is one of the main aspects to reduce the distribution system grid dependency. Lately, there has been an acceleration in the integration of renewable sources in the system, which increases various technical and regulatory constraints and violations. This is basically due to the intermittency in load demand and renewable sources output. If the renewable power generation is more when the load demand is less, there may be a possibility of over voltage. On the other hand, if renewable energy generation is less when the load demand is more, there will be an unhealthy voltage profile. Therefore, the system operators must address the proper energy management technique, which can be accomplished only with real-time measurement and control. In this regard, the IoT-based advanced information and communication technologies must be utilized to assist the system operator to efficiently control the generation-demand mismatch by ensuring a two-way information flow.

Under any type of system disturbance, the system must act immediately so that the adverse effect of the disturbance can be minimized and accordingly, a system blackout can be prevented. In order to achieve this, the cyber-physical distribution system must be equipped with automation devices such as a phasor management unit (PMU), remote-controlled switch (RCS), circuit breaker (CB), automatic recloser (AR), and feeder terminal unit (FTU). Moreover, IoT technologies must be utilised, which enable a two-way communication flow to make the system fully automated.

IV. RESEARCH GAPS AND QUESTIONS

Following a detailed literature review, it is worth mentioning that researchers have done great work and made a significant contribution in the advancement of this field. However, there are some areas which are important from the cyber-physical distribution system planning point of view which are yet to be explored. In this regard, the research gaps of existing literature are summarised in the following section:

- Researchers mostly concentrated on the modelling of system equipment, improving reliability with control techniques. But recently, with the integration of various devices in the physical system, there is an increase in data transfers through the communication network, which increases the risk of cyber-attacks. In this regard, advanced IoT-based computing, control, and communication technologies must be used that can detect the possible cyber-attack and accordingly maximize system reliability and safety.
 - In most literature, researchers concentrated on only the modelling of cyber-physical system equipment. However, there may be a random failure of computing software, communication network link and intelligent services, which can influence the control ability of the distribution system. Therefore, the uncertainty in cyber system failure must be considered regarding realistic planning. However, researchers mostly neglected this factor.
 - In existing articles, the increment of the penetration level of renewable energy sources was accomplished with the integration of the DFACTS device. However, this is a costly solution that may not be affordable for the distribution system owner. In this regard, IoT-based control methods must be applied which can efficiently handle the uncertainty of renewable energy by ensuring two-way information and power flow between the supplier and consumers. Thus, it will help to increase the renewable penetration in the physical distribution system without affecting grid standards.
 - The physical distribution system must be converted into a fully automatic system so that the adverse effect of sudden disturbances can be prevented. However, in the existing literature, the physical distribution system was mostly converted into a semi-automatic system. The recent development of the smart distribution grid demands the system to be equipped with the automation devices such as PMU, RCS, CB, AR, and FTU to achieve the highest level of reliability and IoT technologies must be used to develop a two-way communication flow.
- The research questions are summarised below:
- Can the utilization of smart computing and control technologies identify possible cyber-attacks and take preventive measures to ensure safety and reliability?
 - Will the consideration of intermittency in cyber-failure result in a practical cyber-physical distribution system planning?
 - Will the IoT-based control methods increase the penetration level of renewable sources? If so, will the planning solution be economically feasible for the distribution system owner?
 - What will be the impact on system reliability with the installation of automation devices in the physical distribution system?

V. PROPOSED WORK

To keep pace with the enormous load growth, there is an integration of a large number of renewable energy sources. In such context, it is essential to configure these renewable energy systems in such a way so that their power generation capacity is increased and there is a maximization of the economic benefits of the power grid while meeting the

grid security requirements. To accomplish this, a proper control system must be designed. Therefore, regarding the execution of planning activities, distribution system planners must consider the following major directions:

1) To increase the penetration level of the renewable energy sources for coping with the load growth and improving the financial benefit received by the system owner.

2) To integrate various automation devices so that the overall reliability of the system can be significantly improved.

3) To convert the physical distribution system into a cyber-physical distribution system with the integration of IoT technologies.

In this regard, a planning method is proposed for the cyber-physical distribution system that will consider the incorporation of different types of renewable energy sources under a cyber-physical environment. The main objective of this planning study will be to meet the enormous load growth in an efficient way considering the financial benefit maximization. Moreover, different types of automation devices will be equipped with the distribution system so that there will be an improvement in the fault management procedures, which ultimately increase the system's reliability. On the other hand, under the smart grid environment, there is an integration of new dynamics loads in the distribution system and therefore, there will be a huge amount of data interchanging between the control layer and physical layer. It increases the chances of cyber-attacks in the communication channel of the cyber-physical system. In such context, an IoT-based advanced and secure control system will be designed for identifying and taking measured steps to defend against possible cyber-attacks. Moreover, IoT-based control technologies will also be utilized to increase the penetration level of renewable energy sources.

In the first step, solar energy systems, wind energy systems, battery storage systems, and different types of automation/protective devices will be integrated with the physical system. Then, in the next step, different types of devices will be introduced in the cyber system and an investigation will be carried out to find the effect of the cyber system on the operation of the physical system. Since the optimal location, capacity and quantity are important parameters to be appropriately chosen. In such a context, a suitable soft computation technique will be utilized to find out the capacity, types, location, and quantity of different devices. The random failure of the cyber-physical system equipment as well as the uncertainty associated with the non-

renewable and renewable power output will also be taken into consideration to derive the optimal planning solution. The popular Monte Carlo Simulation can be utilized to check the voltage stability issues due to cyber failures and large renewable penetration.

Abstract—Electric vehicles have had great success in the US, as seen from the rapid rise of Tesla cars and its pioneer Elon Musk. But there is an ongoing less known parallel revolution in Bangladesh, with the rise of about a million electric rickshaws. A preliminary survey of these electric rickshaws was conducted, and their stakeholders were interviewed. These rickshaws are basically a home-grown solution to the local transportation problem, and have developed without any central organized support or design. In view of their new technology and questionable stability, they don't yet have official recognition, and are permitted only in side roads and in rural areas. Several different designs were encountered in the streets of Dhaka city. The main problem is that their high speeds are not what the rickshaw chassis was designed for, which makes them prone to accidents. They are driven by four lead-acid batteries in series with an inverter supplying a brushless DC motor. This paper recommends enforcing speed limits, lowering seats, installing coiled spring suspensions, and adding brakes on rear wheels, all of which are likely to improve stability and safety. As the electric rickshaw is contributing greatly to the economy and convenience of the people, it is suggested that the vehicles be accommodated phase-by-phase within new rules and regulations. The preferred strategy would be to work with the industry, rather than be prescriptive and impose difficult and expensive standards for their construction and operation.

Keywords—electric vehicles, EV, Bangladesh, motor, BLDC motor, lead acid, battery, power electronics, inverter, standards, regulations, survey, recommendation, center of gravity, suspension.

I. INTRODUCTION

The Electric Vehicle (EV) has been a major success in the US, as evidenced by the success of manufacturer Tesla, and its pioneer Elon Musk. However, there is a parallel ongoing revolution in Bangladesh, where more than a million rickshaws have become powered as electric rickshaws, changing the living standards of the people and the economy of the country.

A. Proliferation of Electric Rickshaws

The older pedal-driven rickshaws were slow and depended on the strength and health of the driver. But they are being fast replaced by electric rickshaws, less tiring to drivers, and keeping with the worldwide trend towards

electric vehicles. The descriptive term *electric rickshaws* is preferred in this paper, than the less-descriptive terms *Easy bikes*, *Auto rickshaws*, *Battery-run Three Wheelers (BRTWs)* or *Battery rickshaws*.

Fig. 1. An electric rickshaw with a motor assembly attached to a pedal driven rickshaw

Because of the new technology and their questionable safety record, the electric rickshaws do not have official recognition, operating papers, or road permits. But they have become popular in rural areas and among the side roads of the capital city of *Dhaka*. The million electric rickshaws are a silent revolution, contributing to incomes nationwide, convenience to passengers, jobs for the drivers, and revenue for the economy. The world is moving towards electric vehicles, and sooner or later, the country is likely to move towards modification, acceptance and integration of electric rickshaws.

A preliminary survey and analysis of electric rickshaws was conducted, so as to find possible areas of improvement, to make suggestions for recognition by authorities, and for bringing them under standard rules and regulations.

II. LITERATURE REVIEW

The pedal driven rickshaw, popular in the country for at least 70 years, was mostly made by small entrepreneurs, and mostly did not follow any central or optimized design. Recommendations by academia for an improved design had been mostly ignored by the industry.

The first electric rickshaws in the country were being reported as early as 2009 [1]. More recently, they have been analyzed and documented in the literature [2,3,4,5]. Better control of the vehicles [6,7], better charging stations [8], and powering with solar energy [9,10] have been proposed. New power electronic drives for their motors have been proposed [11].

Electric rickshaws and their positive impacts on the country been reported in newspaper articles [12]. According to a 2017 report, "more than 5,00,000 battery-operated auto-rickshaws operate across the country, consuming 450 megawatts of electricity per day, and are being charged through residential connections [13]. From 2013 to 2018, the local battery market went up from 3000 crore to 8000 crores, largely from the growth of EV rickshaws [14].

In 2017, a joint study by *Rahimafrooz* and the *Asia Foundation* showed that EV rickshaws "currently transport 2.5 crore passengers in both townships and rural areas every day and has created jobs for 30 lakh people." According to Prof. Ejaz Hossain of BUET, easy bikes have expanded massively without any government intervention, but there is no vision and control. He said that the government needs to formulate a policy to allow the sustained growth of electric rickshaws [15].

A June 20, 2021 report announced a decision to ban electric rickshaws for their poor braking and poor safety record [16] At least 13,000 illegal motor-run rickshaws and vans have been destroyed so far. A few days later, a number of reports suggested the ban should be reconsidered [17,18].

The socio-economic impact of electric rickshaws have been studied [19,20]. The theory behind the motor and power electronics have been discussed in text books [21,22].

III. METHODOLOGY

A. Survey and Interviews

With the goal of investigation, interviews were conducted of stakeholders in the industry, including passengers, drivers, owners, technicians, etc. Their numbers were as follows:

- (a) Electric rickshaw drivers: 10 persons
- (b) Technicians: 5
- (c) Owners (*Mohajons*): 20
- (d) Importers, assembling shops: 2
- (e) Battery distributors: 1
- (f) Battery scrap shop: 3-4 staff
- (g) Office peon: 1

- (h) People in authority: 4-5
- (i) Resident of Rajshahi: 1

The questions mainly explored their operating locations, how they are made, types of batteries used, their safety record, the experience of passengers and drivers, etc.

The questions were mostly informal and conversational, without a set script and a set list of questions, and were mostly related to their professional connection with electric rickshaws. When told that the intentions of this study was to investigate and promote electric rickshaws, they were quite cooperative.

The survey included locations outside of *Dhaka*, and at 14 places in the *Dhaka City Corporation*. The *Dhaka* locations included *Uttara, Dakkhinkhan, Khilkhet, Ashulia, Jigatola, Rayer Bazaar*, etc.

IV. CONSTRUCTION

It was found from the surveys, that the electrical and motor assemblies are being designed and assembled by local technicians with less in-depth knowledge on the subject.

Most electric vehicles have a set of four 12 V lead-acid batteries, and an inverter for DC to three-phase conversion powering a Brushless DC motor with maximum speed of 3000 rpm (figure below). The handle is rotated for controlling the speed.

All electrical components were found to be imported, except for the batteries which were made in Bangladesh or China. At about tk 15,000 for a set of four, the batteries are the most expensive component.

The total cost for the electric components is about tk 20,000 (US\$ 220). In addition, there is the added cost of mechanical changes to the chassis, such as adapting the rear axle for fitting with the motor (figure 3).

Fig. 2. Electrical components and assembly of the EV rickshaw.

TABLE I. COST OF ELECTRICAL COMPONENTS OF ELECTRIC RICKSHAWS

Component	Cost (in taka)
Batteries (set of four, locally made)	15,000 (total)
BLDC motor (imported)	2,000
Power electronics and hand control (imported)	2,000
Recharger (imported)	1,500
Total	20,500

According to the five technicians surveyed, the operation and maintenance of electric rickshaws are rather simple.

A. Comparison with Electric cars.

The Electric rickshaw costs about US\$ 500, compared to the US\$ 50,000 for the electric car in the US (factor of 100). The Lithium ion batteries are a major expense for electric cars, but they are prohibitively expensive for electric rickshaws, and are mostly not even being considered as an option.

V. MECHANICAL ISSUES

Different areas of Bangladesh were found to have different design and constructions for the rickshaw body. Less skilled technicians are doing the mechanical constructions differently, without the assistance of uniform standards or professional designs. The constructions were mostly improvised, following the designs being handed down for years.

The chassis is basically made by welding of steel pipes, the standards of which are not properly regulated. There have been reports of the electric rickshaws breaking into two when being driven at high speeds.

The motor to rear-axle connection for two different types of electric rickshaws in Dhaka city are shown below.

Fig. 3. A common electric rickshaw (seen in Dhaka city), with the motor (in left, gold) connected to a modified rear axle

Fig 4. An older chain driven model (seen in Dhaka city) with the motor (in left, gold) connected with a chain to the axle.

A. Speeds

The rickshaws had originally been designed to be pedal driven at low speeds, and not motor-driven at higher speeds. No rickshaw, electric or pedal-driven, is equipped with a speedometer. The maximum speed of an electric rickshaw is about twice that of a pedal-rickshaw. Speeds can be greater in wide open paved roads with less obstructive traffic, such as in rural areas. In the main roads of Dhaka, speeds can become high late at night, when there is less traffic. Speeds as high as 25 mph (40 km/h) have been observed in the main roads of Dhaka city, and in rural areas.

B. High seats

The major complaint about EV rickshaws is that they overturn too easily, causing injury to driver and passengers. This draws attention to their high seats.

The problem with present pedal rickshaws and especially electric rickshaws is height of the seats (about 3 ft. 2 in above ground) which increases likelihood of overturning during turns. High seats also increases wind resistance, implying greater power consumption and shorter battery life.

C. Hard Suspension

The suspension of most rickshaws is not on coiled springs, but on two pieces of curved steel bars, appearing to be mostly inflexible (figure below). A ride is often hard that any spring effect can hardly be felt by passengers. An unyielding suspension means the whole chassis will rotate, as a rear wheel hits a pothole or a bump, increasing the likelihood of overturning.

Fig. 5. The suspension is the circular iron behind the wheel and above the axle.

D. Brakes

The complaints of poor braking are quite justified, as most rickshaws, electric and pedal-driven, only have brakes on the front wheel. According to drivers interviewed, it is possible to have brakes attached to the rear wheels at some extra cost.

E. Better Designs

There are some better constructed rickshaws with lower seating and softer spring suspensions (figures below). Costing tk 55,000, just tk 5,000 more than the common electric rickshaws, these better designs are still in the minority (US\$ 1 = BD tk. 90)

Fig. 6. An electric rickshaw, with lower seats and spring suspension on the roads of Dhaka

Fig. 7. Spring suspensions in a better constructed electric rickshaw. The motor and attachment with the rear axle is also visible.

A. Characteristics of the Roads

Electric rickshaws are better adapted to bitumen-paved roads, which can sustain their relatively-high speeds. They do ply on brick-paved roads, but are subject to vibration because of the uneven surface. In rural areas, pathways may not be paved at all (plain soil), and the ride may be uncomfortable or impossible, especially in rainy weather. In all cases, the lack of an effective suspension makes the ride quite bumpy.

VI. BATTERIES AND CHARGING

According to those interviewed, the charging time for the four 12 V batteries was about 6 hours, which led to an operating time of about 4 hours with about 125 km of travel.

Charging is often done in the slots of 10 pm - 6 am and 1 pm - 4 pm, because this is when there is less demand for transportation. The cost was about tk. 20 per hour of charging. This translates to about tk. 100 per day and tk 3000 per month.

As described by technicians, the battery set lasts for about 8-12 months, after which they must be replaced.

It was observed that most of the recharging stations were not properly documented, and it was unclear how the electricity service providers were paid.

A. Recycling of batteries

Everyday, thousands of used-up batteries are replaced by new batteries. According to 3-4 people interviewed at battery scrap shops, the plates inside the battery are recycled into new batteries. There appears to be some syndication in the scrap industry, meaning it may be controlled by a small number of people, and newcomers find it difficult to enter the business.

Fig. 8: The inside of a battery scrap shop, where the batteries and the lead plates are visible.

VII. LOCATIONS WHERE PERMITTED

In the streets of capital city of *Dhaka*, EV rickshaws are generally found in narrow roads, and in the suburbs. They are not permitted in the main areas of *Dhanmondi, Bashundhara, Uttara, Banani, Gulshan, etc.* They are not permitted in the wide main roads and highways of the city before about 11:00 pm, after which they may be found in small numbers.

Electric rickshaws run mainly on small streets in the areas of *Pallibi, Darus Salam, Turag, Dakkhin Khan, Uttar Khan, Banasree, Azimpur, Kamrangirchar, Zingatola, Basabo-Madartek, Jatrabari, Kadamali, Demra, Jurain, Shyampur, Mohammadpur, Adabor, Rampura, Khilgaon, Sipahibag, Badda, Meradia, Moghbazar, Modhubagh, Mohakhali Wireless Gate* and *Uttara*.

In much of the rural areas, most of the pedal rickshaws have been replaced by electric rickshaws. According to preliminary reports, electric rickshaws are popular in all districts, The authors have seen these vehicles in *Bogra, Rangpur, Gazipur, Comilla, Jhinaidaho, and Magura*. Those interviewed were in *Dhaka, Gazipur, Rangpur, Magura, and Jhinaidaho*.

According to residents of the district of *Rajshahi*, about 85 % of rickshaws in the city areas, and 70 % of rickshaws in rural areas are electric.

VIII. ECONOMICS

Electric rickshaws are creating a silent revolution in the transportation sector, and have become popular among lower and middle-income groups, and in areas where there are few other means of transport. Low fare was a major reason for the popularity of the electric rickshaw. Fares for a typical trip range from tk 10 - 50. According to the owners (*Mohajons*) and the drivers, their purchase cost is about tk. 50,000. The daily rent was tk 400 in Dhaka city and tk. 200 in rural areas, payable by the driver to the owner (*Mohajon*).

TABLE 2. COMPARISON OF PEDAL RICKSHAW WITH ELECTRIC RICKSHAW

(US\$ 1 = BD tk. 90)	Human-powered rickshaw	Electric rickshaw
Cost	tk 10,000	tk 50,000
License	tk 10,000	- NA -
Daily rent and parking in Dhaka	tk 200	tk 400
Daily rent and parking, rural areas	tk 100	tk 200

The cost per day for charging and parking is tk 100. After paying the daily rent as 200, the earnings left over for the driver per day is in the range of tk. 800-1000.

The drivers was found to be working about 10 hours per day, making a total of 40 trips, with a total mileage of about 100 km. In comparison, human-powered rickshaws are slow and expensive for the passengers. Their earnings are less at tk. 600 - 900 per day.

A. Employment for the workforce

Although employment has improved greatly over the last few decades, there is still some shortage of job opportunities, especially in the rural areas. From our survey and the interviews, it was found that the electric rickshaw has produced many job opportunities. During the pandemic, some under-age youth became drivers, owing to the closure of the schools.

While interviewing the mayor of Magura municipality. it was found that crime rate has reduced significantly owing to improved standard of living of the people.

During our interviews, it was found that the electric rickshaws were a major source of employment in agriculture-dependent areas, with no nearby industries. For migrating workers, driving the vehicles was a secondary income source and agriculture was the primary income source. These drivers had families and agricultural activities in the home in rural areas. During the time of harvesting and crop cultivation they left the cities and go back to their villages, leading to a shortage of EV-rickshaw drivers, and consequently high fares in the city.

The availability of drivers was affected by the availability of jobs in nearby industries. Workers laid off in a garments factory would become drivers for EV rickshaws, leading to an over-supply of transportation, more competition among the drivers, and lower fare for the customers.

Similarly, when a factory re-starts its operation by employing workers, there is a shortage of drivers, and rickshaw fares go up.

B. Impact on Environment:

Although the vehicles are zero emission, they are charged by power stations running on gas and coal. They do not directly pollute the air, but move the pollution to the fossil-fueled power stations.

IX. RECOMMENDATIONS

Regardless of the problems with EV rickshaws, they are a convenient mode of transportation and have brought prosperity to the country, But the pedal-driven rickshaw chassis is designed to be powered by humans at low speeds, and is not ready for higher-speed operation with motors. Recommendations are now made as to how to best face the challenges for electric rickshaws in the coming years.

A. Strategy of Working with the EV rickshaw Industry

A prescribed product that is imposed upon manufacturers is unlikely to be accepted without opposition by manufacturers, especially if it leads to greater expense. It is not feasible to mandate nationwide a single design and construction prescribed by a central authority.

Small entrepreneurs tend not to innovate when the profit margin is too low. They tend to be risk-averse small businesses and low income people. But helping in new product development by academia can overcome these barriers to modernization.

Technical support may be provided to manufacturers in the country, so that the academicians work with the manufacturers and not impose a central, apparently optimized design.

To safely promote this technology in the country, the authorities may choose to:

(a) Enforce speed limits for the electric rickshaw, so as to limit speed, the greatest cause of accidents.

(b) Mandate vehicle construction requirements for strength of chassis and to improve their stability and comfort. A maximum seat height may be imposed to improve stability and reduce drag.

(c) Mandate brakes on the rear wheels (mostly not present at this time)

(d) Mandate an effective coiled spring suspension (replacing present curved bars) for greater comfort, and improved stability when going over a bump or pot hole. Coiled springs and low seats are already found in some better designed electric rickshaws.

(e) To register and license the vehicles and drivers, phase by phase, across the country, bringing them under government rules and regulations.

(f) To better document the charging stations of electric rickshaws, so that the utility companies are properly paid through proper metering. Lithium ion batteries are not discussed in the industry owing to their much greater expense.

(g) Require drivers to undergo some hours of training, and then a take a test, just like for a vehicle driver's license. This is because drivers may be moving at relatively high speeds side by side with cars and heavy vehicles,

X. CONCLUSION AND FUTURE WORK

Electric vehicles like Tesla have become a booming industry and are in the news, but there is a parallel ongoing silent revolution in Bangladesh with electric rickshaws. Although these rickshaws are providing convenience in transportation and contributing to the economy, they lack official recognition, have no licensing, and have not been brought under standard rules and regulations.

The surveys and interviews conducted by this paper identified some simple bottlenecks and problems, such as excessive speeds, no brakes on the rear wheels, high seats and center of gravity, hard suspension and a weak structure. The motor allows high speeds, which the rickshaw was not originally designed for. Different areas of Bangladesh have different models of electric vehicles without any standard design. Lithium ion batteries are much lighter and popular for electric cars in the US, but are not discussed for electric rickshaws because of their much greater expense.

Based on the survey, recommendations are made about how to best face the challenges for EVs in the country in the coming years. Maximum speed limits can be enforced, the seats and center of gravity can be lowered, and softer suspension may be implemented with springs. Lower seating and better spring suspensions are already being seen in some rickshaws.

This industry should be nurtured by cooperation between authorities, manufacturers, owners, drivers, and electric utilities, This will ensure that electric vehicles are yet another innovative step towards continued development of the country.

Abstract:--First invented in 1891, the Tesla coil supplied high voltage at low current, demonstrating spectacular feet-long arcing discharge. The Tesla coil has been used more for demonstration and entertainment, and less for teaching and research, partly because of its inherent dangers. Today's diodes, transistors and microprocessors allow low voltage Tesla coils with new capabilities and improved safety. Still, there are few commercial applications, and the Tesla coil remains mostly for demonstration and exhibition. The improvised miniature 5 V USB port supplied Tesla coil built by the author is worthy of investigation and documentation because of its exotic phenomena like lighting up a nearby fluorescent lamp, making a common filament bulb act like a plasma ball, and producing an imperceptible continuous discharge on the finger. The fluorescent lamp lights up not from the RF from the coil, but from the induced currents in the mercury vapor. The filament bulb produces moving plasma, proving that conditions exist for such interesting phenomena. The visible continuous arc at the finger, far from giving a shock, was imperceptible because of its RF frequencies. The constructed miniature Tesla coil illustrates boosting of voltage, the air-core transformer, resonance at tuned frequency, and other electrical principles. With some simple precautions, this easily constructed low-voltage, Tesla coil with \$20 of components, shows much promise for promoting teaching and research at schools, colleges and universities.

Keywords:-- Tesla, coil, fluorescent, lamp, arc, discharge, filament, bulb, plasma, ball, air core, transformer, RF, UV..

I. INTRODUCTION (HEADING 1)

First invented by Nikolai Tesla in 1891, the high voltage Tesla coil impressed audiences, and inspired wireless energy transfer and long distance RF communication. After the invention of solid-state devices in the 1960s, new opportunities and adaptations with the Tesla coil have become possible. The dangers of its high voltages have been mostly overcome with low voltage supply, and miniaturization with solid state diodes, transistors, capacitors, microprocessors, etc. Today, the Tesla coil is used to impress and entertain, with the decorative Plasma globe, music by modulated streamers, etc.

Mainly because of its few applications, and the dangers of its high voltages, the Tesla coil is less used in academic curriculums and research. Today's commercial applications are not as great as Tesla had hoped for, but there are great

opportunities for using the low-voltage, safe Tesla coil as a teaching aid, and for motivating and inspiring the younger generation.

A. Construction for this study

The low-voltage DC powered Tesla coil was constructed with a bug zapper using theories of resonance, transformers, and with instructions found online. It created moving plasma inside a filament bulb, caused a nearby compact fluorescent lamp to glow, and produced visible but almost imperceptible arcing discharge on the finger.

These exotic phenomena have been demonstrated in the past for larger Tesla coils, but have been less investigated in the literature for smaller Tesla coils. The construction of this study and its associated phenomena merit further description, examination and analysis. The fluorescent lamp glows not because of the effect of the RF on the phosphors, but by the RF-induced current in the vapor in the lamp. The common filament bulb acts like a plasma ball with visible moving plasma, due to some similarities in construction with the plasma ball. The visible continuous discharge on the finger does not hurt as the frequency is much greater than 10 KHz.

The constructed miniature Tesla coil may be used to promote interest, and to demonstrate numerous electrical engineering principles to school, college, and university students.

II. THE TESLA COIL - PAST AND PRESENT

The Tesla coil is a capacitor-tuned oscillator that drives an air-core resonant transformer to produce high voltages at low currents [1,2,3]. A high voltage transformer steps up the AC mains voltage up to a high enough voltage to jump a spark gap acting as a switch at the primary, generating high voltage in the secondary.

The secondary is connected to ground and to a metallic dome. An iron core transformer would have too much losses due to eddy currents and hysteresis. The only available path for the high voltage is to go through the air to the ground as a discharge streamer. Output voltages can range from 50 kV to

millions of volts, at low frequency RF between 50 kHz to 1 MHz.

A. Dangers and Safety

Nikolai Tesla used to impress his audience with spectacular discharges without getting any electric shock, and even glowing in the dark himself.

For a mains-supplied (220 V or 110 v) Tesla coil, every part of the circuit is capable of giving a shock or being fatal. The most dangerous part of the circuit is the intermediate section at thousands of volts, where arcs can jump fatally for severally cm. Owing to charged capacitors, for many minutes, the circuit can give a shock after disconnection from the mains.

A mains-supplied Tesla coil can damage electronics in the room, like smart phones, hearing aids, cardiac pacemakers, etc., and those connected to the same consumer power supply. Discharge from the coil can travel in any direction, inflicting harm to equipment or personnel. Dangerous levels of Ozone may be created in the room.

The coil must be connected to a three-pronged electric plug, with a ground pin, as insufficient grounding may shock nearby personnel, and damage the equipment.

B. Literature Review

Considering that the Tesla coil was invented 130 years ago, there are relatively few publications in the literature. The miniature low-voltage Tesla coil is a relatively new invention, only some decades old. Today's trends are towards miniaturization, with DC supplies and solid state devices [4,5,6]. The streamer discharge from the coil can be modulated with sound, a feature which has been used by the musical group *Arc Attack* [7]. New developments are making it better than ever as a teaching tool [7].

III. CONSTRUCTION

In our construction, the DC supply from the 5 V, 250 mA USB port is fed to the PCB of the Bug Zapper, which is connected to the Tesla coil through capacitors and a spark gap (figures below). The yellow wires at the right were for recharging the batteries and have no function in our circuit.

Fig 1. The printed circuit board of the bug zapper, supplying the Tesla coil.

Figure 2. The PCB from the Bug zapper is connected to the Tesla coil through tuning capacitors and a spark gap

The output of the bug zapper (2–2.5 kV) is connected to three propylene capacitors and the Tesla coil.

The metal gas pipes are used as pillars to make the base. The bolts are drilled on the cardboard, which holds the electronics (figure below). The cardboard base was of minimum size so as to fit the bug zapper PCB, spark gap, and polypropylene capacitors. The spark-gap was with 2-inch nuts and bolts.

Fig. 3. The cardboard base with Spark gaps and capacitors

A. The Tesla Coil

The Tesla coil was built around a PVC pipe of external diameter 3.8 cm and length 9.5 cm, with the metal drawer knob placed on top. The primary has 1.5 turns, insulated from the primary with electrical tape.

Fig. 4. The Tesla coil had 1.5 turns in the primary and 300 turns in the secondary

The secondary coil has about 300 turns of 0.2 mm enameled copper wire, wrapped around the plastic pipe, and is connected to the metal knob on top and the aluminum foil below for grounding. Without this grounding, no discharge was observed. The 0.2 mm copper wire was sufficient for the current, minimized expense, and fit more wire around the pipe.

B. Components and Costs

The bug zapper racket was the most expensive component at \$ 6, and the total came to about \$ 17. Further details of the components and their costs are given below.

TABLE I. DETAILS OF COMPONENTS AND THEIR COSTS

Component	Remarks	Cost (\$)
PCB from <i>Bug Zapper</i>	Mosquito racquet	6.00
Copper wire for Coil	0.2 mm diameter, 100 ft	3.00
Capacitors	3KV Polypropylene	3.00
Plastic pipe for coil	4" long	1.00
Nuts, Bolts, Aluminium foil, connecting wires		2.00
Card board	6mm wide, 10" x 4"	1.00
Drawer knob	Used as dome	1.00
Total		17.00

C. Further details on Construction

A number of changes and adjustments were needed in order to have a well-functioning coil.

Bug zapper racket are available on the streets from \$ 4.00 but a more expensive \$ 6.00 racket was used for greater reliability.

Fig. 5. The bug zapper racket from which the PCB circuit was taken out..

Early attempts with 6.5 turns in the primary gave a weak arc. The turns in the primary were progressively reduced one by one, with the arc getting stronger each time. The present 1.5 turns in the primary gave the strongest arc.

The polypropylene capacitors in the primary of the coil were available two years ago in the street markets, but are no longer available now. So alternatives must be found for new constructions.

The spark gap was expected to be between 1-3 mm, and was adjusted for the best performance around 1 mm. Its nearby constructions are shown below.

Fig. 6. Dimensions of the spark gap and nearby constructions.

D. The Lamps

The filament bulb used for showing plasma was rated for 25 W, and was 9 cm long and 4 cm wide. The fluorescent lamp was 11 cm long and 3.5 cm. Both lamps were bought from local stores.

Fig. 7. The fluorescent lamp and the filament bulb used in the construction.

IV. EXPERIMENTAL RESULTS

With the circuit turned on, the spark at the spark gap appears as a bright point of light (figure below) (that may be harmful to the eyes over many seconds).

Fig. 8. The arc at the spark gap appears as a bright point light.

A. The Fluorescent Lamp

A compact fluorescent lamp lit up, when held by the glass near our constructed coil. But the phosphorescent coating on the lamp is mainly sensitive to ultra-violet (UV) light, whereas the Tesla coil only produces Radio Frequencies (RF).

The explanation is the currents and magnetic fields in the air are small and insufficient to cause the fluorescent coating to glow. But the high voltage on the dome and the electrostatic field are strong. These induce currents in the vapors in the glass tube, giving off UV light, causing the phosphors to glow. To a young observer, this is amazing considering the low power of the USB supply.

Phosphors on fluorescent lamps are a mixture of rare-earth oxides; mostly Yttrium (Y) oxide, with Europium (Eu), Terbium (Tb), Cerium (Ce) and Lanthanum (La). Their peak sensitivity is at 253.7 nm, which falls within UV.

Fig. 9. Glowing compact fluorescent lamp held by the hand

Fig 10. Glowing compact fluorescent lamp in the dark

B. Discharge Through the body

An arc through the body, as with a *Stun Gun*, is expected to be shocking and painful. Also unpleasant are touching the spark of a piezo-electric lighter, or a stove lighter. But our constructed coil gave a continuous discharge, hardly perceptible to the fingers (figure below).

Fig. 11. Continuous steady discharge on finger

Tesla had found that discharges greater than 10 KHz do not give an electric shock, and may be hardly perceptible to the body. Considering the low power of the USB supply, this discharge is likely to be within acceptable safety standards, provided it lasts no longer than a second or two.

C. Moving Plasma in a Lightbulb

When a filament bulb's metal base was touched on our Tesla coil, moving plasma was seen inside the bulb (figure below). With a hand placed on the bulb, the plasma moved with the movement of the hand.

Fig. 12. Moving plasma discharge inside a common lightbulb,

Fig. 13. The moving plasma in the dark.

This is similar to the commercially available decorative plasma ball (also known as plasma globe /sphere). The artistic discharges move with the movement of a hand placed on the glass.

The streaming plasma on our filament bulb placed on our Tesla coil is significant, because of

(a) the low voltage of the Tesla coil

(b) the filament bulb is designed to preserve a white hot tungsten filament, and not to function as a decorative plasma sphere.

(c) The electric light bulb is at slightly less than atmospheric pressure (0.7 atmosphere), with Argon, Nitrogen, Krypton, Xenon, etc. The plasma globe often has neon at close to atmospheric pressure. Argon and Xenon make the plasma more intricate and beautiful in appearance.

V. THE TESLA COIL AS A TEACHING AID

The Tesla coil is suggested here as a teaching aid for a number of reasons:

A. Low cost and Easy Construction

The circuit can be easily constructed by students from easily available inexpensive components, worth less than \$ 20.

B. Inspiration and Motivation

The observed phenomena can be of great interest to students. Advanced students can try to investigate and research the observed phenomena.

C. Safety

The 5 V, 0.25 amp USB supply ensures the output power is too low to cause any serious bodily harm by the arcing discharge or the RF radiation. For added safety, students may approach the coil for only a few seconds at a time.

D. Moving plasma inside a lightbulb

The Tesla coil shows moving plasma inside a filament bulb, which can inspire the student to understand the flow of current through inert gases.

E. Glow of a Fluorescent Lamp

The student will understand that the glow of the fluorescent lamp is not so much from the RF discharge from the coil, but from the currents induced inside the tube, giving off ultra-violet light, making the phosphor coating glow.

F. Barely perceptible visible discharge on the skin.

The student can observe that arcs and discharges on the skin need not give a shock and will be barely perceptible, as they are at Radio frequencies. In comparison, the bug zapper and piezoelectric lighter have a one-time discharge which can give a painful and uncomfortable shock.

VI. DANGERS OF THE SETUP

Any Tesla coil can pose dangers, both known and unknown. When supplied by a 220 V or 110 V, it has dangers which are well known and well established. The dangers of a USB supplied 5 V Tesla coil falls largely in the unknown.

A. Electromagnetic Radiation

The construction can induce a current in the nearby fluorescent lamp, and so it can induce currents in the body, which are not perceptible. Prolonged exposure, for more than a few seconds may be harmful, the details of which are mostly unknown.

B. Discharge through the Finger

The discharge current through the finger is not perceptible, the common explanation for which is that the current remains close to the skin surface because of the skin effect. However, according to the literature, the current still has the potential to cause a small burn on the skin. The precaution to users is to allow discharges for only a few seconds, enough for demonstration, but not enough to cause such a burn.

CONCLUSION

The original Tesla coil of 1891 has undergone great transformation today, with the advent of diodes, transistors, microprocessors etc. The miniature Tesla coil of this study was built with a "bug zapper" PCB, and showed not-so-easily explained phenomena, including moving plasma streamers in a lightbulb, glowing of a compact fluorescent lamp, and an imperceptible continuous visible discharge through the finger. Partial explanations for these phenomena are provided in this paper, but still merit further research.

This circuit can be inexpensively built with a bug-zapper PCB and a coil of wire with about \$20.00, and can be the subject of further study. Further documentation and investigation of this circuit and associated phenomena is only

appropriate, considering its great potential for its usage as a teaching and research tool in schools, colleges and universities.

Abstract— In the past decade or so, there has been a dramatic rise in the number of Three wheeler Electric Vehicles (EV) in Bangladesh. As the technology is new and unknown, these EVs have been largely unrecognized and unregulated by the government. But these EVs are only a part of the worldwide shift towards EVs. Most of the local small three-wheeler EVs are being produced as solutions by low-income small entrepreneurs, who cannot afford much innovation. Past attempts to prescribe the academic "perfect" pedal-rickshaws have been mostly unsuccessful. A better approach may be to provide technical support to this growing "home-made" industry, with the intention of organizing and promoting the growth of EVs. With these goals in mind, selected electrical components of the common electric rickshaw were purchased and assembled in the lab. Preliminary waveforms were obtained, with the intention of obtaining more detailed performance curves at a later date. The technical data can be used for assisting in better designs of commercial EVs in the country. The road, transportations and economic conditions for Bangladesh are applicable for many Asian countries, meaning that the electric vehicle technologies developed in this paper may be transferred to other countries as well.

Keywords—electric vehicle, EV, rickshaw, electric rickshaw, Bangladesh, experimental, waveforms, three-wheeler, waveforms, entrepreneurs.

I. INTRODUCTION (HEADING 1)

Over the last decade or so, there has been a dramatic rise in electric vehicles in Bangladesh. Owing to the new and unfamiliar technology, these electric rickshaws have been largely unrecognized and unregulated by the government. But this proliferation in electric rickshaws is only the local manifestation of the worldwide shift towards electric vehicles. This industry should be rightfully nurtured, explored, recognized and regulated.

Local EVs range from the common three-wheeler electric rickshaw to larger three-wheeler 4, 6, and 8 seaters, named *Tom Toms* or *Easy bikes*. The two-wheeler electric rickshaws are small enough to have option to be pedal-driven, and so can be called a Hybrid Electric Vehicle.

Most of the electric rickshaws are being produced by low-income small entrepreneurs, who are not equipped for, or cannot afford much innovation. Past attempts to prescribe the academically "perfect" pedal-rickshaw have been mostly unsuccessful, and not adapted by the manufacturers. Rather, a better approach may be to work with the small-entrepreneur manufacturers, and nurture the growing industry through technical support. Towards these goals, selected electrical components of a local electric vehicle were assembled in the lab, with the intention of testing them, and overcoming bottlenecks holding back their progress.

II. LITERATURE REVIEW

A wide range of electric vehicles, ranging from the hover board to heavy trucks, are gaining popularity worldwide, and have been the subject of studies [1]. DC motors are being replaced by AC motors, with power electronics to interface with batteries, which bring advantages in weight, efficiency and increased range. The induction motor was used for electric vehicles, but the Brushless DC motor (BLDC) has the lightest weight and highest efficiency, and is the most popular for EVs in Bangladesh.

The first electric rickshaws in the country were being reported as early as 2009 [2]. More recently, they have been analyzed and documented in the literature [3,4,5,6].

Better control of EVs [7,8], better charging stations [9], and powering with solar energy [10,11] have been proposed. New power electronic drives for their motors have been proposed [12].

Electric rickshaws and their positive impacts on the country been reported in newspaper articles [12]. According to a 2017 report, "more than 5,00,000 battery-operated auto-rickshaws operate across the country, consuming 450 megawatts of electricity per day, and are being charged through residential connections [14]. From 2013 to 2018, the local battery market went up from tk 30 to tk 80 billion (US\$ 300 - 890 million), largely from the growth of EV rickshaws [15]. (assuming US\$ 1 = BT tk. 90)

A 2017 study showed that EV rickshaws "currently transport 25 million passengers in both townships and rural areas every day and have created jobs for 3 million people." According to a prominent professor, easy bikes (a type of EV) have expanded greatly without any government intervention, but there is little vision and control. The government needs to formulate a policy to allow the sustained growth of electric rickshaws [16].

The socio-economic impact of electric rickshaws have been studied [17,18]. The theory behind the motor and power electronics have been discussed in text books [19,20]. Papers aimed at better organization of the growth of electric vehicles have been submitted for publication [21,22].

III. MOTORS

The first local electric rickshaws from a decade ago, had the rear-axle driven by a chain connected to a motor. This older chain model is seen less often nowadays, and the differential speed motor has gained popularity.

A. 48 V Differential speed motor

This differential speed motor for the electric rickshaw features "a high precision motorhead with 16 tooth and anti-rust aluminum shell. Compliance with specifications allows this motor to be "mixed and matched" with other electrical components such as the power electronics drive.

Fig. 1. The Differential speed motor is very popular for new electric rickshaws.

Further specifications are given below for a smaller and a larger motor.

TABLE 1. SPECIFICATIONS OF A SMALLER MOTOR

Power	1000 Watt
Voltage	48 V
Rated speed	3000 RPM
Max speed	30-35 KM/H

TABLE 2. SPECIFICATIONS OF A LARGER MOTOR

Power	12000 Watt
Voltage	48 V
Rated speed	450 rpm/min
Max speed	25-30 km/h
Amp	70

B. The 48 V chain-driven motor

The older chain driven motor and its specifications are given below. The addition of a gear head to a motor reduces the speed while increasing the torque.

Fig. 2. The chain-driven motor setup popular in earlier electric rickshaws

TABLE 3. SPECIFICATIONS OF THE 48 V 1 KW MOTOR

Power	1000 Watt
Voltage	48 V
Rotted speed	480 rpm/min
Max speed	25-30 KM/H
Amp	10.8

C. Larger motor for 4-8 passenger EV

Larger BLDC motors are used for heavier 4-8 seater EVs, as seen below. Higher voltages are used with 5 - 6 batteries kept in series. The specifications are also shown.

Fig 3. The larger BLDC motor used for 4-6 seater local EVs

Fig. 4. The larger BLDC motor attached to the chassis of an 8-seater EV.

TABLE 4. SPECIFICATIONS OF THE 60 /72 V, 3 KW MOTOR

Power	3000 Watt
Voltage	60 V/ 72 V
Rotted speed	600 rpm/min
Max speed	35-40 KM/H
Amp	10.8 A

D. Another 60 V BLDC motor

This different type of motor was found to be quite reliable too as they usually last for more than 3-4 years. The motor usually cost 3500-4000 tk in the local market.

Fig. 5 Another type of BLDC motor

TABLE 5. SPECIFICATIONS OF THE 60 V, 1 KW MOTOR

Power	1000 Watt
Voltage	60 V
Speed	2500 rpm

IV. SUPPORTING ELECTRICAL EQUIPMENT

A. Batteries

Numerous types of EV Batteries are available in the local market. According to the surveyed technical personnel, batteries with warranty battery last longer: one year before replacement.. Batteries without warranty are shorter lasting: 4-

6 months. According to our survey, most rickshaws use batteries without warranty.

According to those surveyed, only a few manufacturers make good batteries. Most batteries have performance levels well below the published values. Batteries made in China are reported to be cheaper and more popular those made in Bangladesh.

Fig 6. Batteries used in electric vehicles in the country. Most batteries are reported to perform below their published values.

Fig 7. Most electric vehicles in the country use four batteries connected in series.

B. Chargers

Various chargers were seen in the market, as seen below.

Fig. 8 . A commonly used charger

Fig. 9. Chargers, as seen in the field.

Fig. 10. An electric rickshaw being recharged

According to preliminary estimates, the efficiency of charging is about 83 % . This means it takes about 7.2 kWhr to recharge 5 batteries of 6 kWhr.

C. Controllers

Controllers change the DC supply from the batteries (usually 48 V) to the AC required for the motor. Some controllers encountered in practice are shown below.

Fig. 1. A controller about to be assembled into an EV

Fig. 11. A controller removed from an EV

V. EXPERIMENTAL SETUP

A. Components

Following the findings of equipment in the field, a typical BLDC motor, a controller, a speed control handle and a lighting, display and key panel were put together for the experimentation. The BLDC motor (figure below) was rated at 48 V, 800 W (name not legible as it was in a foreign language).

Fig. 12. The BLDC motor used in the experiment, rated at 48 V, 800 W.

The controller used (figure below) was of Model *Yinpin*, and rated for 48V, 800 W, 35A \pm 1.

Fig. 13. The controller *Yinpin*, rated for 48 V, 35A \pm 1, 800 W.

The display panel had the headlight and key socket attached (figure below).

Fig. 14. the headlights with the attached key socket.

Fig. 15. The display panel, headlights and key socket are attached together.

B. Cost of equipment

The total costs of the equipment was about BDT 17,500, which came to \$ 194 at an exchange rate of US\$ 1 = BDT 90 (table below).

TABLE 6. COSTS OF EQUIPMENT

Components	BD Taka	US\$
Batteries	12,000	133.00
BLDC motor	3,500	39.00
Controller + Display + Light + Key slot + Speed controller	2,000	22.00
Total	17,500	194

C. Connections

The experimental equipment were connected as shown below.

Fig 16. The batteries in series with the power electronics and the BLDC motor

Fig. 17. Authors Abdullah Shahriar and Amartya Bhakat are seen with the experimental setup

VI. EXPERIMENTAL RESULTS

As expected turning the hand controller varied the output voltage to the motor and the speed from 0 to maximum.

TABLE 7. TWISTI ANGLE OF HAND CONTROLLER VARIED THE OUTPUT VOLTAGE AND THE SPEED.

Twist angle of Hand controller	Output voltage (across motor)
0	33.4 mV
10 %	245.2 mV
20 %	5.6 V
30 %	14.3 V
40%	16.3 V
50%	20.21 V
60 %	26.01 V
65%	29.4 V
70%	32.5 V
75%	33.7 V
80%	35.3 V
85%	37.5V
90%	38.7 V
95%	39.1 V
100%	41.5 V

Fig. Increase in voltage at motor, with the angular twist at the handle

The output waveforms from the controller to the motor, for various positions of the hand controller, with corresponding speeds is shown below.

Fig. 18. The output voltage of the controller fed to the motor.

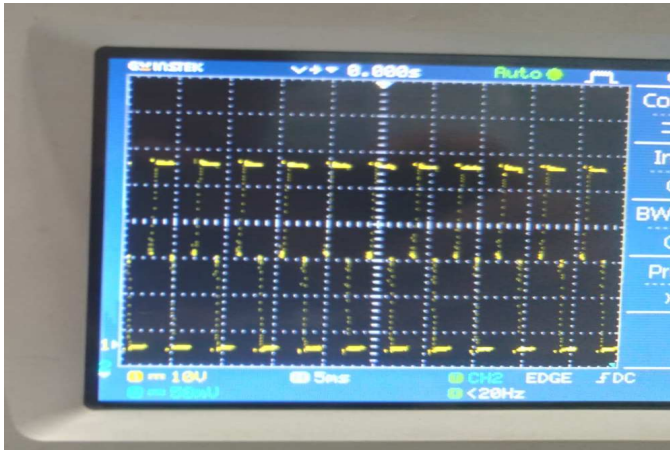

Fig. 19. The output voltage of the controller fed to the motor for a different speed. .

VII. CONCLUSION

With the intention of organizing and promoting the growth of electric rickshaws in the country, a brief survey of the electrical assembly was conducted. Selected equipment were purchased and put together, as for a commercial electric rickshaw. Preliminary waveforms were obtained, with the intention of obtaining more detailed performance curves at a later date. These can be used for assisting in better designs of commercial electric rickshaws.

A limitation of the existing setup was that no significant mechanical load was attached to the motor. A mechanical load will be attached in future, attempting to replicate the EV mechanical load as much as possible. The motor behavior will be simulated at a later date with available parameters, and compared to the observed experimental waveforms.

Abstract— The ongoing dramatic growth in electric vehicles (EV) worldwide has been accompanied by a parallel growth in small 3-wheeler EVs in Bangladesh. The estimated one million local small electric vehicles means there is about one electric vehicle for every 170 residents of the country. A survey was conducted of the local EV industry, trying to find the status and patterns and trends in the growth. A wide range of vehicles of 2, 4, 6, and 8 seats were seen. An EV in the US can be 20-40 kW with speeds of 120 km/h, whereas a local 3 kW three-wheeler can carry up to 8 passengers at up to 35 km/h. Unlike the US, where Hybrid electric vehicle (HEV) means additional IC engine, in the local context, HEV means the option to be human-powered or solar powered. The two-seater electric rickshaws had option to be pedal driven. Amazingly, solar power supplemented EVs are already being used for 8-seaters, showing the great advances made by the local industry. These EVs have grown without central organizational support or official recognition. Rather they are solutions by low-income entrepreneur manufacturers in response to the special needs of the local market. A problem was that vehicles are all known by different names all over the country. The terms Tom Tom and Easy bike were used interchangeably for various vehicles. We found it best to classify local EVs according to their number of seats. Low power (may be pedal driven) and high power (cannot be pedal driven). The trend towards EVs have been surveyed and documented here for better recognition, regulation and generally for better progress.

Keywords—rickshaw, electric rickshaw, three-wheeler, Bangladesh, experimental, solar power, hybrid, electric vehicle, Tom Tom, Easy bike.

I. INTRODUCTION (HEADING 1)

The worldwide growth of EVs in the last decade, has been accompanied by a parallel dramatic growth in small three-wheeler EVs in Bangladesh. Battery powered three wheeler rickshaws are replacing human-pulled rickshaws at a rapid rate. The estimated 1 million electric vehicles nationally means there is one EV for about every 170 residents of the country.

A survey was conducted of local EVs, trying to find the status and patterns in the growth. The end goal was better documentation, recognition and promotion of the EV industry.

A problem encountered was that different types of electric vehicles are known by different names. An electric rickshaw costs US\$ 600-800, compared to US\$ 200 for a pedal driven

rickshaw. Amazingly solar (plus battery) powered small EVs are already in the market, showing the great advances made by the local EV industry. The growth of EVs may be better regulated, recognized, and benefitted by better organization and support, as has been attempted in this paper.

II. LITERATURE REVIEW

A wide range of electric vehicles ranging from the hover board to heavy trucks are gaining popularity across the world, and have been the subject of studies [1]

The first electric rickshaws in the country were being reported as early as 2009 [2]. More recently, they have been analyzed and documented in the literature [3,4,5,6]. While petrol engines have a maximum efficiency of about 35 %, EVs, which are zero emission, can have efficiencies of 90 %. However, EVs move the emissions from the car to the power station, where the efficiencies can be 60 % for combined cycle power plants.

Better control of EVs [7,8], better charging stations [9], and powering with solar energy [10,11] have been proposed. New power electronic drives for their motors have been proposed [12]

Electric rickshaws and their positive impacts on the country have been reported in newspaper articles [12]. According to a 2017 report, "more than 5,00,000 battery-operated auto-rickshaws operate across the country, consuming 450 megawatts of electricity per day, and are being charged through residential connections [14]. From 2013 to 2018, the local battery market went up from 3000 crore to 8000 crores, largely from the growth of EV rickshaws [15]

A 2017 study showed that EV rickshaws "currently transport 2.5 crore passengers in both townships and rural areas every day and has created jobs for 30 lakh people." A prominent professor said easy bikes have expanded massively without any government intervention, but there is no vision and control. The government needs to formulate a policy to allow the sustained growth of electric rickshaws [16].

A June 20, 2021 report announced a decision to ban electric rickshaws for their poor braking and poor safety record [17] At least 13,000 illegal motor-run rickshaws and vans have

been destroyed so far. A few days later, a number of reports suggested the ban should be reconsidered [18,19].

The socio-economic impact of electric rickshaws have been studied [20,21]. The theory behind the motor and power electronics have been discussed in text books [22,23]. Papers aimed at better organization of the growth of electric vehicles have been submitted for publication [24,25]

III. NEEDS OF THE LOCAL MARKET

An analysis of the EV industry in Bangladesh should first analyze its great differences with the US and Western markets (table below).

EVs in the US are four-wheeled, are large at 20 - 40 kW, whereas Bangladeshi EVs are small and three-wheeled at 1 - 3 kW only.

Hybrid EVs in the US means there is the option to power with the internal combustion engine. In Bangladesh, hybrid EV means the option to be pedal-powered, for the smaller 1 - 1.2 kW electric rickshaws, or solar-powered for the slightly larger vehicles.

The roads and highways in the US are wide and long, stretching for thousands of miles. In contrast, the roads in Bangladesh are narrow and stretch for hundreds of miles. US roads are smooth, paved with bitumen and concrete. In Bangladesh, roads are paved with bitumen, bricks or are unpaved. The maximum speed limit in the US can be 128 km/h, compared to the 30-35 km/h capabilities of most local EVs. The users and riders in the US are mostly high-income whereas they are not so in Bangladesh. Ride-sharing is rare in the US, whereas it is common with the local 4-8 seater EVs.

TABLE . NEEDS OF THE US VS. NEEDS OF THE LOCAL MARKET

	Electric Vehicles in US	Electric Vehicles in Bangladesh
Width of Roads	Wide roads, considering large country	Narrow roads, as country is smaller country size
Length of Roads	Freeway, Highways of Thousands of miles	Highway networks of Hundreds of miles
Quality of Roads	Smooth bitumen and concrete paved roads,	Bitumen, rough brick paved and soil and sandy roads
Speed limits	75 mph limits on freeways and 35 mph on city roads	Much lower speed limits
Users and Riders	Mostly high-income, typical for US	Mostly low-income, typical for a middle income country
Ride-sharing	Ride sharing (mini-busses, micro-buses less common)	Ride sharing common with EVs with capacities of 4 - 8
Who drives	Self - driven	Professional drivers.
Power of vehicle	20 - 40 KW	1 kW to 3.5 kW
Meaning of Hybrid EV	Has supplementary IC engine	Has supplementary pedal-power or solar power

IV. CLASSIFICATION

According to our survey, local EVs range from the popular smaller 2-seater electric rickshaws, to the larger 8-seater Tom Toms used for shared rides from point to point.

A problem is that different vehicles are known by different names by locals, all over the country. The term Easy bike is

used interchangeably for small and large EVs. The term Tom Tom is used interchangeably for larger EVs. We find it best to classify local EVs according to their seating capacity. Lower power 2-seater electric rickshaws may have added pedal drive, and higher power 4-8 seater EVs are too heavy to be pedal driven.

The low power electric rickshaws mainly have local made components, except for the electric motor, controller, and sometimes the batteries. The larger EVs may parts of the chassis imported from abroad (China).

The low-power 1 - 1.2 kW EV may be hybrid, with option to pedal-drive, meaning it be driven even with discharged batteries.

The motor and chassis may be of two types – The older chain driven and newer cog-wheel differential driven now gaining popularity.

The high power EVs have up to 3 kW motor, and are too heavy to be pedal-driven. In case of discharged batteries, they must be towed to the next charging station. A solar panel may be connected for supplemental power. More comparison is provided in a later section.

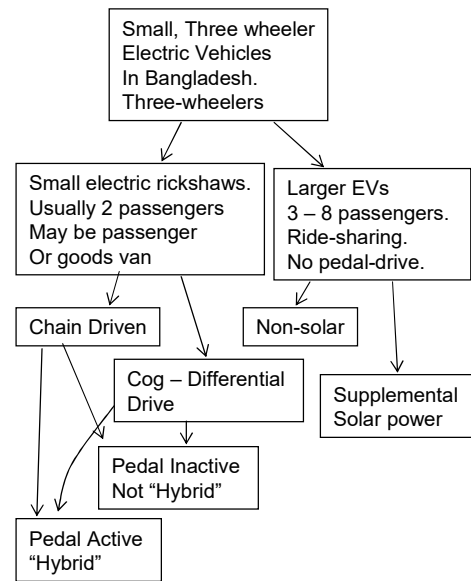

Fig. 1. Classification of local EVs

According to our conducted survey, the following were some types of three-wheeler small electric vehicles available in the country.

- 2-seater Electric Rickshaw.
- Electric Van/Auto Van.
- Electric covered van.
- 6-seater Mishuk Auto /Tom Tom/ Borac .
- 8-seater Mishuk Auto Rickshaw
- 8-seater Solar Electric Auto

These have been described below

V. THE ELECTRIC RICKSHAW

As the name suggests, the electric rickshaw has is basically the 2-passenger pedal-driven rickshaw fitted with the electric motor and accessories. Its cost is in the range of tk 50,000 – 80,000 (compared to tk. 15,000 for a pedal-driven rickshaw). It is the largest in number of all types of EVs in the country. It is seen frequently seen in the districts and rural areas of the country. In Dhaka city, it is seen in the side roads (e.g. *Rayerbazar*) and in the suburbs (e.g. *Shatarkul*).

Fig 2. The electric rickshaw found in the side roads and suburbs of Dhaka, and outside of Dhaka city

According to mechanics and the nameplate, the motor is rated for 1.2 kW, 48 V (four 12 v batteries). The maximum rickshaw speed is 30 -35 km/h. The charging time is 6-8 hours, which allows operation for 8-10 hours or 120 km -140 km. The rated capacity of the battery is 90-120 Amp.hr. Its controller is rated for 48-volt, 1200 W.

A. Construction and Assembly

Electric rickshaws may or may not have the option to be pedal driven (Hybrid EV). For a hybrid electric rickshaw, the pedal driven chain will be attached to the center of the rear axle. The four batteries may be placed in the seats (figure below), or outside, saving space in the seats for other purposes. The motor can be connected with the rear axle either with a chain in earlier models, or a direct differential drive in newer models.

The motor controller can be attached at a convenient place on the body of the rickshaw.

Fig. 3 The differential drive motor, with pedal-driven chain attached to the center of the rear axle.

Fig. 4. The differential drive attached at the center of the axle. There is no pedal-driven chain.

Fig. 5. The older type chain driven rickshaw.

Fig. 6. Another view of the differential drive motor, with the option to pedal-drive. The silver colored controller is seen above, attached to the wooden body.

B. Improved Versions of the Electric Rickshaw

Newer and somewhat improved versions of the electric rickshaw are now being produced in smaller numbers (figure below):

Fig. 7. An alternative version of the electric rickshaw, with lower chassis

Fig. . Another alternative version of the electric rickshaw with lower chassis.

These advantages of the new versions include

(a) they have lower seats and centers of gravity, meaning their likelihood of toppling over and wind resistance are less.

(b) they have softer suspensions, relevant for their higher speeds than the pedal-driven rickshaw. Their softer suspensions allow for a smoother ride and greater stability.

VI. 6-SEATER ELECTRIC VAN/AUTO VAN:

The electric van or Auto van is the electric rickshaw modified to carry up to six passengers. Seen in rural areas, this EV has a questionable safety record.

Fig. 8.. The electric passenger van - rear view

Fig 9. The electric passenger van - front view. There is no chain for driving by pedal.

A. Construction

The lower chassis of the electric van is shown below. In this case, a chain driven axle is seen.

Fig. 10. Chain-driven motor for the electric van. There is no chain for riding by pedal.

VII. ELECTRIC COVERED VAN/AUTO VAN:

The electric covered van is the same as the electric rickshaw but is locally modified to just to carry loads.

Figure 11. The electric covered van, being examined by authors Amartya and Murad .

The observed electric van had a chain-driven motor, and did not have a pedal driven chain (non-hybrid EV).

Fig. 12. Chain-driven motor of electric van, with no option to drive by pedal.

VIII. THE 4-SEATER MISHUK AUTO RICKSHAW

The 4-seater EV, sometimes called the Mishuk Auto Rickshaw is seen below. It is too heavy to be conveniently pedal-driven.

Fig. 13 The Mishuk Auto rickshaw, sometimes known as the Auto rickshaw.

The body appears well designed and constructed, and apparently some components of the chassis are imported (from China).

A. Specifications

The four-passenger Mishuk Auto rickshaw was found to use a motor rated for 1 kw, 48 v (4 x 12 v batteries), 3000 – 3400 rpm. The batteries were rated for 120-200 Amp.hr, and charged for 6 - 8 hours and ran for 8-10 hrs for 120 – 140 km. The max speed is 30 - 35 km/h. The controller was 48-v, 1200 W

B. Visible construction.

The attached motor and controller are shown below.

Fig. 14. Electric motor of the 6-seater Mishuk, as seen from above

Fig. 15 . Electric motor – view from below

Fig. 16. The controller attached to the chassis in the Mishuk Auto Rickshaw

IX. 8-SEATER MISHUK AUTO /TOM TOM/ BORAC AUTO:

The 8-seater Mishuk Auto seen below is also known as Tom Tom or Borac or Easy Bike in different parts of the country. This EV is often seen in rural areas and side roads of Dhaka city.

Fig. 17. The 8-passenger capacity of the Mishuk Auto

A. Specifications

The 8 passenger capacity requires a larger 60v motor. Here five batteries giving 60 v (12 x 5 pieces) are used for the 3 kW motor.

B. Construction

The universal drive connected to the axle is seen below

Fig. 18. The 3 kW motor and drive for the 8-seater Mishuk or Tom Tom.

Fig. 19. The motor connected to the wheels for a Mishuk Auto/ Tom Tom. A well-functioning suspension (yellow) is also visible.

X. THE 8-SEATER SOLAR AUTO

The 8-seater auto or solar Tom Tom is becoming popular in Rajshahi division and other areas the country. The picture below was taken in the *Mugda* area of Dhaka . This is similar to the 8-seater Tom Tom, but with an added solar panel and drive. The solar panel, connected to a charge controller (figure below) in this case increases the running time.

Fig. 20. The 8-seater Tom Tom, with Solar panel attached.

Fig 21. The Charge controller inside the solar Tom Tom

A. Specifications

The motor is rated for 1000 kW, 48 V (12 v 4pieces) with rated speed of 2500-3000 rpm and max speeds of 35-40 km/h. The battery charging time is 6-8 hours, battery capacity is 200 Amp.hr, and the running time is 10-12 hours, allowing a range of 120 – 140 km. The supplemental solar power is 350 w, allowing an extra range of 40-50 km.

XI. COMPARISON OF LOCAL EVS

A comparison of the different types of EVs are seen below. They can have 2, 4, 6 or 8 seats. Most motors are rated 1 – 1.2 kW, with some rated higher at 3 kW.

TABLE. COMPARISON OF VARIOUS TYPES OF EVs IN THE COUNTRY

	2-Seat Electric Rickshaw	6-Seat Electric Van, Auto van	4-Seat Mishuk Auto Rickshaw	8-seat Mishuk Auto, Tom Tom or Borak	8-seat, Solar Tom Tom
Passengers	2 seats	6 seats	4 seats	8 seats	8 seats
Motor	"DC motor"	"DC motor"	"DC motor"	"DC motor"	"DC motor"
Brand	Bengal Tiger (Happy motor)	Luke	Kun Ray, PK plus	Lunyee	Luke
Model		SLZ-48V		LY-60300	MT005
Power	1200w	1000 w	1000w	3000 w	1000 w

Solar power	(none)	(none)	(none)	(none)	350 w
Extra miles with solar	- NA -	- NA -	- NA -	-NA-	40-50 km

CONCLUSION

A wide range of electric vehicles are now being made in the country, as solutions to the local needs of transportation. Most of the electric rickshaws are solutions by low-income small entrepreneurs who have improvised and innovated in the absence of official recognition and regulation.

The estimated one million local small electric vehicles means there is about one electric vehicle for every 170 residents of the country. The range of vehicles today may have 2, 4, 6, or 8 seats. Known by various names, varying according to region, the imported parts include the motor, batteries, controller, and parts of the drivetrain and chassis.

There is an ongoing worldwide move towards electric vehicles, as seen in the rising stock market valuation of EV manufacturer Tesla. The proliferation of small EVs in Bangladesh is another manifestation of this worldwide trend. The country is somewhat ahead as small electric rickshaws may or not have pedal connections. These Hybrid EVs have supplementary power with pedals or with solar panels, which are unknown in the West.

It is expected that the survey and analysis of this paper will help to organize, recognize, regulate and then promote these small electric vehicles in the country.

Analog Front-End CMOS Temperature Sensor Interface for Optogenetic Devices

Shahrzad Ghasemi, Soliman A. Mahmoud
Electrical Engineering Department
University of Sharjah
Sharjah, United Arab Emirates
{u18105750, solimanm}@sharjah.ac.ae

Abstract— This work presents a CMOS temperature sensor interface based on a second-generation current conveyor (CCII) and a transimpedance amplifier (TIA) with a high linear and temperature-independent pseudo-resistor. Since the LED in optogenetic implantable devices generates heat, a temperature sensor is required to monitor the temperature. Thus, the reverse current of the LED can be employed as its own sensing element. This paper will utilize the LED reverse current as a temperature-sensitive parameter (TSP) to sense the junction temperature. The sensor interface operates under a supply voltage of ± 0.6 V. The reverse current driving capability is ± 1.7 μ A. The total power consumption of the CMOS sensor interface is 192 μ W. The circuit provides an operational frequency of up to 2.08 MHz. The transimpedance gain of the proposed temperature sensor interface is equal to 300×10^3 V/A. The proposed circuit is designed using 90 nm CMOS technology and simulated using LTspice.

Keywords— CMOS temperature sensor interface, optogenetics, second-generation current conveyor (CCII), transimpedance amplifier (TIA).

I. INTRODUCTION

Over the past few decades, biomedical researchers have been focused on utilizing microtechnologies and nanotechnologies in healthcare applications [1]. Microtechnologies and nanotechnologies' main advantage is developing devices with micrometer and nanometer scales. These technologies provide the interface between nervous system disorder treatments and electronic components. The invasive micrometer and nanometer scales technologies are known as neural probes [2].

Optogenetic technology is a combination of optics and genetics. The technology is used to provide stimulation and suppression in brain tissue photosensitive cells. The stimulation and suppression are achieved by light-emitting. Therefore, the stimulus can be provided through light pulses. The light sources of optogenetic are optical fibers and light-emitting diodes (LEDs). The LED neural probe overcomes light losses and maximizes light power delivery [3].

Manufacturing and implanting optogenetic neural probes have some challenges. One of these main concerns is preventing tissue damage. During the stimulation, the overheating process could damage the human body tissues. Hence, providing a temperature sensor in the optogenetic device is particularly important. The challenge of implementing a temperature sensor for an optogenetic probe occurs when the sensor is required to be designed by taking the power consumption, temperature dependency, and dimensions into consideration [3], [4].

The human body temperature remains almost constant (37°C) over a specific range of environmental temperatures. Nevertheless, the human body is sensitive to temperature fluctuations [5]. Approximately a 2 °C temperature rise

represents a threshold temperature to prevent the brain from overheating damage. However, the threshold temperature varies based on the brain activity state and other factors discussed in [6], [7].

In order to design and implement a temperature sensor for optogenetics, the sensor interface must include an analog front-end (AFE) element, analog-to-digital converter (ADC), and digital signal processor (DSP). One of the techniques of implementing a temperature sensor is the current-mode temperature sensor. The LED reverse current (I_R) can be utilized to sense the temperature variation. Thus, I_R is considered a temperature-sensitive parameter (TSP). The LED that is used as a light source for optical stimulation can be utilized as a sensing element. Based on that, the LED used in optogenetic can be used in two phases, which are stimulation and sensing phases [8].

Gallium nitride (GaN) and indium gallium nitride (InGaN) LEDs are widely utilized in optogenetic devices to target a range of opsins, which are photoreceptive proteins, owing to the tunability feature of the emission wavelength across the visible spectrum [9]. As presented by [10] and [11], the I_R of the InGaN and GaN LEDs can be used for junction temperature (T_J) determination, respectively. Therefore, the I_R can be used to measure the T_J and surface temperature (T_S), which is related to T_J [10]. As introduced in [8] and [4], the I_R is used for temperature sensing purposes. The research proposed a method to determine the T_S of implanted devices by reusing LED, which is utilized for light emission, as a temperature-sensitive element. Thus, the I_R can be employed to measure the T_J , and I_R is named TSP for the optogenetic temperature sensor interface. The I_R is exponentially proportional to the T_J inverse [8]. The technique has been proposed by [4], [8] with the power consumption equal to 260 μ W. This current mode temperature sensor optogenetic has been implemented in 0.35 μ m CMOS technology and it operates under supply voltage +5 V. Moreover, a current mode temperature sensor interface technique has been presented by [12]. The designed temperature sensor AFE has been designed in 0.25 μ m CMOS technology. The circuit has been designed with a supply voltage of ± 0.75 V. In order to achieve compatibility with different types of LEDs, the gain of the designed temperature sensor interface is digitally controlled. The current summing network (CSN) was utilized to provide the digital programmability. The total power consumption of the presented temperature sensor varies between 240 μ W and 700 μ W.

In this paper, an AFE CMOS temperature sensor interface is proposed. The realized temperature sensor interface consists of voltage biasing and current sensing using a second-generation current conveyor (CCII). Moreover, it consists of a transimpedance amplifier (TIA). The TIA is used to sense the current of the CCII and convert

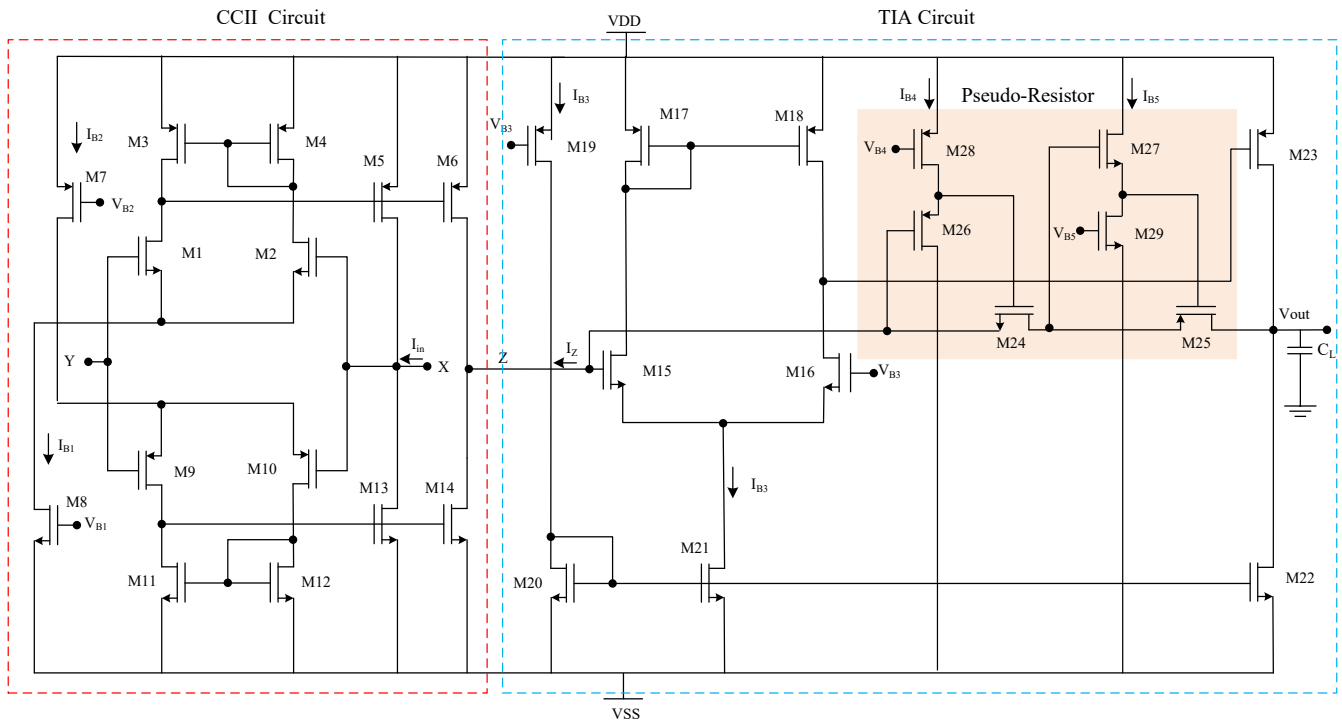

Fig. 1. The proposed CMOS realization of the temperature sensor AFE circuit.

it to a voltage signal. The feedback resistor of the TIA is realized using a pseudo-resistor. Therefore, the proposed AFE is designed based on CCII and TIA with an embedded pseudo-resistor in the feedback of the TIA. The temperature-independent pseudo-resistor has been used to prevent the AFE from temperature dependency. The CCII has been employed as a voltage buffer to ensure stable biasing voltage using Y and X terminals. Additionally, it is used for current sensing to convey the LED reverse current from X terminal to Z terminal. The TIA has been employed to convert and amplify the output current of the CCII to an amplified voltage signal. The amplified voltage signal is the input signal of the ADC block. The temperature sensor AFE operates under a supply voltage of ± 0.6 V.

This paper is organized as follows: The proposed temperature sensor interface design is discussed in Section II. The implemented circuit is evaluated and tested in Section III. The circuit is simulated and evaluated using LTspice with 90 nm CMOS technology. Finally, Section IV concludes the work.

II. PROPOSED CMOS TEMPERATURE SENSOR INTERFACE

The proposed CMOS AFE temperature sensor structure is designed using a CCII cascaded with a TIA. The designed AFE circuit is shown in Fig. 1.

The LED I_R is the X terminal input current of the CCII, and it conveys to the Z terminal current of the CCII. Moreover, the X terminal voltage follows the Y terminal voltage, which represents the LED biasing voltage. Therefore, the CCII provides voltage and current buffers. The CCII circuit has been realized by relying on the CCII presented by [13]. The input stage of the CCII circuit is designed by utilizing two complementary differential pairs. These two pairs are NMOS matched differential pair and

PMOS matched differential pair. The NMOS and PMOS pairs are connected in parallel. Thus, the voltage follower between X and Y terminals has been provided. Moreover, to achieve a rail-to-rail operation, the differential pairs are biased with a constant tail current. The CCII is designed to provide a high input impedance. Hence, the current that passes through the Y terminal is equal to zero in the realized circuit. On the other hand, the output stage is class AB; thus, it guarantees high current driving capability. The X terminal current is mirrored to the Z terminal using matched transistors pairs.

The voltage follower between X terminal and Y terminal has been provided using two matched differential pairs. These differential pairs are (M1, M2) and (M9, M10), representing NMOS and PMOS differential pairs, respectively. These differential pairs are biased using transistors (M7, M8) with currents I_{B2} and I_{B1} , respectively. Two matched current mirror pairs (M3, M4) and (M11, M12) are used for current mirroring for the complementary differential pairs in the input stage. The current of the X terminal is conveyed to the Z terminal using two matched transistors pairs (M5, M13) and (M6, M14).

As mentioned previously, The CCII output current is the input signal of the next block used as a converter and amplifier. The proposed TIA is a modified version of the two-stage operational transconductance amplifier (OTA) given by [14]. The modification has been achieved by replacing the feedback resistor with a pseudo-resistor. The TIA circuit is utilized for sensing, converting to voltage, and amplifying the output current of the CCII. The output voltage is the input signal of the ADC block.

Differential pair (M15, M16) has been used to implement the TIA circuit. In order to get a single output voltage, transistor M17 mirrors the current to transistor

Fig. 2. The voltage follower between Y and X terminals of the proposed temperature sensor AFE.

Fig. 3. The X and Z terminals current of the temperature sensor AFE.

M18. The differential pairs are biased through transistors M19, M20, and M21 with biasing current I_{B3} . The output stage of the TIA consists of transistors (M23, M22) and it forms class A output stage.

The pseudo-resistor has been designed using two MOS transistors. One NMOS transistor M24 and one PMOS transistor M25. The combination of these two MOS transistors mitigates the nonlinearity of the pseudo-resistor. Each transistor is connected to a source-followers.

These two source-followers afford dynamically adjusting the two transistors' gate to source voltages. This adjustment will provide constant V_{GS} on the pseudo-resistor for large output voltage swings. The resistor value of the pseudo-resistor can be varied by adjusting the biasing currents I_{B4} and I_{B5} . The proposed pseudo-resistor is used to design a temperature-independent feedback resistor within a specific range of temperature variation.

The output signal, which is voltage, of the temperature sensor AFE is given by

$$V_{Out} = R_f I_{in}. \quad (1)$$

Fig. 4. Transresistance gain provided by the feedback pseudo-resistor.

Fig. 5. The DC characteristics of the temperature sensor AFE.

The total power dissipation of the temperature sensor AFE with the pseudo-resistor circuit can be driven as

$$P = 2V_{DD}(I_{B2} + 2I_{M3} + 2I_{M5}2I_{B3} + I_{M23} + I_{B4} + I_{B5}). \quad (2)$$

III. SIMULATION RESULTS

The temperature sensor interface circuit has been simulated by LTspice using 90 nm CMOS process technology based upon the BSIM4 (level 54) MOSFETs model under the supply voltage ± 0.6 V. The circuit has been simulated at 37 °C as a base human body temperature.

The NMOS and PMOS differential pairs are biased with 1.3 μ A and 3.9 μ A tail currents, respectively. The circuit is used to provide constant bias voltage by buffering the voltage from the Y terminal to the X terminal of the CCII. The voltage follower action between Y and X terminals has been simulated by varying the Y terminal DC voltage. Fig. 2 represents the voltage follower of the CCII used for the temperature sensor interface to provide stable biasing voltage. The voltage of the Y terminal is transferred to the X terminal in the dynamic range of ± 0.4 V.

Fig. 6. The magnitude response of the temperature sensor AFE.

Fig. 8. The output voltage time response of the AFE.

Fig. 7. The input and output currents time response of the sensor AFE.

Fig. 9. The magnitude response of the temperature sensor AFE under temperature variation.

The voltage follower has been provided with a bandwidth equal to 171 MHz and the DC voltage gain equal to 1.0038.

As mentioned earlier, the CCII conveys the reverse current of the LED from X terminal to Z terminal. Fig. 3 shows the X and Z terminals currents when the X terminal current is varied from -3 to 3 μA . As shown in the figure, the X terminal conveys the current to the Z terminal with a dynamic range $\pm 1.7 \mu\text{A}$. The total power consumption of the CCII circuit is less than 119 μW .

As discussed in the previous section, the output current of the CCII block amplification and conversion occurs by the TIA block. The feedback resistor of the TIA has been designed using a pseudo-resistor. Therefore, the total transimpedance gain of the AFE temperature sensor interface is equal to the pseudo-resistor resistance value. The constant transimpedance gain has been achieved by pseudo-resistor for the input current range of $\pm 1.8 \mu\text{A}$, as shown in Fig. 4. The transresistance gain of the temperature sensor interface which is provided by the pseudo-resistor is equal to $300 \times 10^3 \text{ V/A}$. Therefore, the feedback resistor value equals 300 k Ω with V_{B3} equals zero, representing the common-mode voltage.

The DC characteristic of the temperature sensor interface has been simulated by varying the input current

and measuring the output voltage. The TIA converts the input current to voltage linearly with constant transimpedance gain equal to $300 \times 10^3 \text{ V/A}$, as shown in Fig. 5. The total power consumption of the TIA with pseudo-resistor is 72 μW .

The magnitude response of the temperature sensor interface is demonstrated in Fig. 6. The bandwidth of the implemented circuit is equal to 2.08 MHz.

Since the optical stimulation has been achieved by applying current pulses, the designed circuit has been simulated and evaluated by applying input pulses. The reverse current of the current pulses is temperature-dependent and changes with temperature variations. The transient response of the input current pulses is demonstrated in Fig. 7. The output voltage of the temperature sensor interface circuit represents the converted and amplified signal of the input signal. The output voltage is represented in Fig. 8 for the input current given in Fig. 7. The total power consumption of the temperature sensor interface is 192 μW .

The circuit is implemented to sense the reverse current of the LED in order to sense the temperature variation. The temperature variations can affect the transistors' parameters used in the analog circuit [15]. Therefore, the

designed circuit is required to be temperature independent within a specific temperature range. Considering implantable optogenetic devices, human body temperature, which is equal 37 °C, is considered a base temperature. The magnitude response of the temperature sensor interface has been simulated for temperatures 37 °C, 42 °C, and 47 °C. The temperature variation result is shown in Fig. 9. The summary of the performance parameters of the proposed temperature sensor interface is given in TABLE 1.

TABLE 1. TEMPERATURE SENSOR AFE RESULTS

Parameters	Proposed Sensor Interface
CMOS technology (nm)	90
Voltage supply (V)	±0.6
Transimpedance gain (V/A)	300×10 ³
3-dB bandwidth (MHz)	2.08
Power consumption (µW)	192
Voltage dynamic range (V)	±0.4
Current driving capability (µA)	±1.7
I _Z -I _{in} Offset current (nA)	10
IRN (nA/√Hz) at 100 Hz	1.3
Temperature Range (°C)	28-60

IV. CONCLUSION

This paper presented a CMOS temperature sensor interface based on a CCII and a TIA with a temperature-independent pseudo-resistor. The circuit was designed and simulated using 90 nm CMOS technology under ±0.6 V supply voltage. The method used the LED for the optical stimulation in optogenetic implantable devices as a TSP to permanently sense the T_s, which depends on the T_j. Therefore, the temperature sensor AFE was designed to provide a biasing voltage for the LED and sense the reverse current. Moreover, the TIA has been utilized for signal conversion and amplification. The total power consumption of the designed circuit is equal to 192 µW. The transimpedance gain of the circuit is equal to 300×10³ V/A. In future work, the sensor interface may include the reduction of the total power consumption.

Abstract—A high-order temperature-compensated bandgap voltage reference (BGR) with a low-temperature coefficient (TC) for high-precision applications is proposed, manufactured in a 0.18- μm CMOS process. Strong-inversion MOSFETs and forward-biased Bipolar Junction Transistors (BJTs) are employed in the proposed high-order temperature-compensated circuit, which eliminates the curvature in base-emitter voltage (V_{BE}), so to achieve a low TC. Measurement results prove that a minimum TC of 0.7 ppm/ $^{\circ}\text{C}$ over the temperature range of -25°C to 125°C is realized with a resistance trimming network. The line sensitivity is 0.0146%/V when supply voltage changes from 3.2 V to 3.7 V.

Index Terms—BGR, High order, Temperature coefficient, Line sensitivity

I. INTRODUCTION

Precise voltage references undoubtedly are important in data converters, operational amplifiers linear regulators, etc [1], [2]. As it is all known, the base-emitter voltage (V_{BE}) of a diode-configure bipolar transistor (BJT) is well characterized in temperature. Therefore, bandgap reference (BGR) technology, whose output is highly independent of temperature [3], is popular in on-chip reference voltages. To get an accurate reference voltage, attention must be paid to process variations, voltage, temperature.

For first-order temperature-compensated BJT-based BGRs, the standard design method is to use the component ΔV_{BE} , which is proportional to the absolute temperature, to compensate for the component V_{BE} that is complementary to the absolute temperature. Most modules need a reference

voltage with a low TC for power supply, so the purpose of the BGR design is to find a way to generate an insensitive-temperature output. While the temperature sensitivity is usually limited to 20 ~ 100 ppm/ $^{\circ}\text{C}$ [4]–[6] for first-order BJT-based BGRs, which is not enough for high-performance applications. Therefore, a high-order compensation circuit must be used to eliminate the interference of curvature content. In the reported designs [7]–[11], a TC of sub-1 ppm/ $^{\circ}\text{C}$ is still hard to achieve. This paper proposes a high-order temperature-compensated BGR with a low TC, by simply combining two strongly inverted MOSFETs and two forward-biased BJTs. The generated compensation current is expressed in the form of $T \exp(f(T))$ after theoretically analyzing and can be designed to approach the $T \ln(T)$ term in V_{BE} , realizing the non-linear compensation.

II. PROPOSED STRUCTURE

In the vast majority of BJT-based bandgap [1]–[3], [12], the bandgap-energy-related component is provided by V_{BE} of the diode-configure BJT. According to previous works, the nonlinear relationship between V_{BE} and temperature can be expressed as [13]

$$V_{BE}(T) = V_{GO}(T_r) - \left[\frac{V_{GO}(T_r) - V_{BE0}(T_r)}{T_r} - (\eta - \theta) \frac{k}{q} \ln T_r \right] T - (\eta - \theta) \frac{k}{q} T \ln T \quad (1)$$

where $V_{GO}(T_r)$ is the silicon bandgap voltage at a reference temperature T_r and it is 1.2 V at 0 K, $V_{BE0}(T_r)$ is the base-emitter voltage at T_r , η is process related, with a nominal value of 3 ~ 4 [14], θ is collector current temperature-dependent order, expressed as $I_C(T) = I_{C0}(T/T_r)^{\theta}$, where

This work was partly sponsored by Natural Science Foundation of Chongqing, China, No. cstc2019jcyj-zdxmX0014, and by the Research Foundation of Chongqing Science and Technology Bureau No. cstc2018jzcx-cyztzxX0049.

The second and the third term in (5) are used to compensate for the linear and the nonlinear term in V_{BE} , respectively. The resistor R_1 is fulfilled by an 8-bit resistor array to trim the linear compensation term, as shown in Fig. 3(b). MOSFETs are working in the linear region to be acted as switches, and they have the same unit size, in Fig. 3(b). The size of switches should be large enough to minimize the effects owing to the drain-source voltage V_{DS} . Therefore, the size of $19.8\mu/600n$ is chosen. The fixed resistor on the right side is to make sure the trimming code has a wide range. The equivalent resistance value of the trimming networks varies from 33.42% to 100% of R_t , broadening the trimming range.

III. SIMULATION AND MEASUREMENT RESULTS

Fig. 4 compares the simulation currents of $\frac{1}{p}I_{PT}, I_{CT}$ and I_{b5} (base current of Q_5). The result shows that ignoring I_{b5} is reasonable in Section II. Fig. 5 compares the output

Fig. 4. Simulated currents of $\frac{1}{p}I_{PT_C}$, I_{CT_C} and I_{b5}

temperature dependency of this proposed circuit with that of an optimized first-order BGR. To compare fairly, the output voltage of optimized first-order BGR is equal to that of the proposed compensated BGR. The TC performance of the first-order BGR is about $3.166 \text{ ppm}/^\circ\text{C}$, and that of the proposed BGR is $0.623 \text{ ppm}/^\circ\text{C}$. Therefore, it can be seen that the existence of this high-order compensation circuit significantly improves the output's performance in terms of TC (about 5 times better). In order to verify the sensitivity of the designed BGR to mismatch and process variations, Monte Carlo simulations of all components (MOS transistors, BJT, resistors and capacitors) were carried out 1000 times. Fig. 6(a) shows the temperature curve of V_{ref} , and Fig. 6(b) shows the corresponding statistic TC distribution. Consider the TC distribution is non-Gaussian, therefore sigma is not meaningful [3], [15]. The result shows that the average TC of 1000 runs is $6.794 \text{ ppm}/^\circ\text{C}$ from -25°C to 125°C and the proportion of TC greater than $12 \text{ ppm}/^\circ\text{C}$ is 13.3%.

Fig. 5. TC performance comparison between the optimized first-order BGR and the proposed BGR with high-order compensation

Fig. 6. (a) Monte Carlo simulation results and (b) the histogram of the calculated TC from (a)

The chip micrograph is shown in Fig. 7. Fig. 8 presents the line sensitivity of this proposed BGR. The change of reference voltage is 0.156 mV and the line sensitivity is calculated as $0.0146\%/V$ at room temperature, when the supply voltage is from 3.2 V to 3.7 V , embodying high stability. Six samples were tested for TC, in which

Fig. 7. Chip microphotograph with an active area of $908 \mu\text{m} \times 282 \mu\text{m}$

the OYO1000 programmable temperature chamber with a temperature range of -70°C to 150°C was used for temperature scanning. The voltage was measured using a Keysight 34401A digital multimeter with a resolution of $1 \mu\text{V}$. The temperature dependencies of 6 samples are shown in Fig. 9, where the peak to peak measured difference is 0.82 mV . A minimum measured TC of $0.706 \text{ ppm}/^\circ\text{C}$, a maximum one of $1.535 \text{ ppm}/^\circ\text{C}$, and an average one of $1.076 \text{ ppm}/^\circ\text{C}$ are achieved respectively, making the proposed BGR competitive in terms of temperature sensitivity.

TABLE I
PERFORMANCE SUMMARY AND COMPARISON

	[7] TCASI'21	[8] JSSC'21	[9] JSSC'21	This work
Tech.(nm)	65 CMOS	180 CMOS	130 CMOS	180 CMOS
Supply Voltage (V)	2.5~3.6	1.8	2~3.3	3.2~3.7
Line Sensitivity (%/V)	NA	NA	0.03	0.0146
Temp. Range (°C)	0~80	-40~125	-40~150	-25~125
TC (ppm/°C)	0.8(min) 0.87(max)	3.2(min) 5.5(max) 4.3(avg)	5.78(min) 13.5(max) 8.75(avg)	0.706(min) 1.535(max) 1.076(avg)
# of samples	3	18	7	6

NA: No Information Available

Table I compares the performances of this design with other reported BGR designs. The proposed BGR obtains a comparable TC with [7]; while it obtains a wider temperature range than [7]. Compared with [8], [9], the proposed BGR obtains a better TC; while it obtains a better line sensitivity than [9].

IV. CONCLUSION

This paper proposes a high-order compensation circuit to correct the curvature of bandgap reference, by simply combining MOSFETs and BJTs (biased in their strong-inversion region). The topology diagram of Fig. 1 constructs a complex function of temperature. By adjusting the parameters in this function, the compensation term can be used to compensate for the nonlinear term in V_{BE} well. Hence a low TC can be achieved. The recommended compensation current has been manufactured in the standard 0.18- μ m CMOS process. Measurement results show that the proposed BGR is competitive in terms of TC and line sensitivity.

Abstract—The heart is one of the crucial parts of the human being. The graphical recording of the cardiac cycle produced by an Electrocardiograph is called an Electrocardiogram (ECG) signal. To predict the occurrence of an arrhythmia, an electrocardiogram (ECG) is generally used by doctors to identify the condition of the patient. Hence, to accurately detect the abnormalities of the heart in advance and classify those diseases without human involvement many machine learning algorithms are used. The MIT-BIH Arrhythmia database is being used to classify the beat classification performance. This paper presents the hardware implementation of a classifier using an Artificial Neural Network (ANN) to classify four abnormalities (Normal beat, Supraventricular ectopic beat, Ventricular ectopic beat, Fusion beat) of heartbeat with high accuracy. To an appropriate input vector for the classifier, several preprocessing stages have been applied. Discrete Wavelet Transform (DWT) is used to extract the features from the ECG signal. To implement this work, Xilinx Artix-7 NESYS 4 DDR FPGA board is used. This model got 86% testing accuracy in simulation and 85.6% in hardware.

Keywords—ECG (Electrocardiography), ANN (Artificial Neural Network), DWT (Discrete Wavelet Transform), Xilinx, Field Programmable Gate Array

I. INTRODUCTION

The electrocardiogram (ECG) shows the plot of the bio-potential generated by the activity of the heart and is used by physicians to predict and treat various cardiovascular diseases. Classification of ECG plays an important role in the early and accurate detection of arrhythmia types and is important in choosing the appropriate treatment for a patient. The MIT-BIH data Arrhythmia database is available online that has around about 48 ECG recordings [11] obtained from

patients and each recording contains approximately 30 min duration, which was digitized at 360 Hz per channel, and they have a resolution of 11 bits over a 10mV range. The flow diagram of the work is given in Fig. 1.

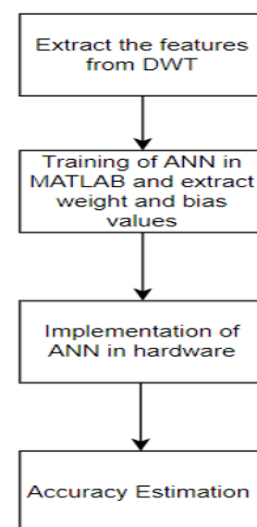

Fig1. Flow diagram of Hardware Implementation

Different types of classifiers are available for classifying the ECG signal. Among all, ANN is most widely used because of its ease of implementation in hardware.

ANN consists of several layers named input, hidden, and output layers. In each layer, it consists of several neurons. These neurons will imitate our biological neurons in the

brain. Each neuron will perform a certain task according to the application. The output of one neuron will give the input to the other layer neuron. One layer of neurons will be connected to the other layer of neurons using links. Each link is associated with a weight value, these values will get by the feed-forward backpropagation algorithm [12]. For each neuron, there is an activation function that performs certain functions according to the application. The simple ANN Architecture is given in Fig. 2.

A neuron consists of pre-activation and activation functions and Fig. 3 depicts the structure of a single neuron.

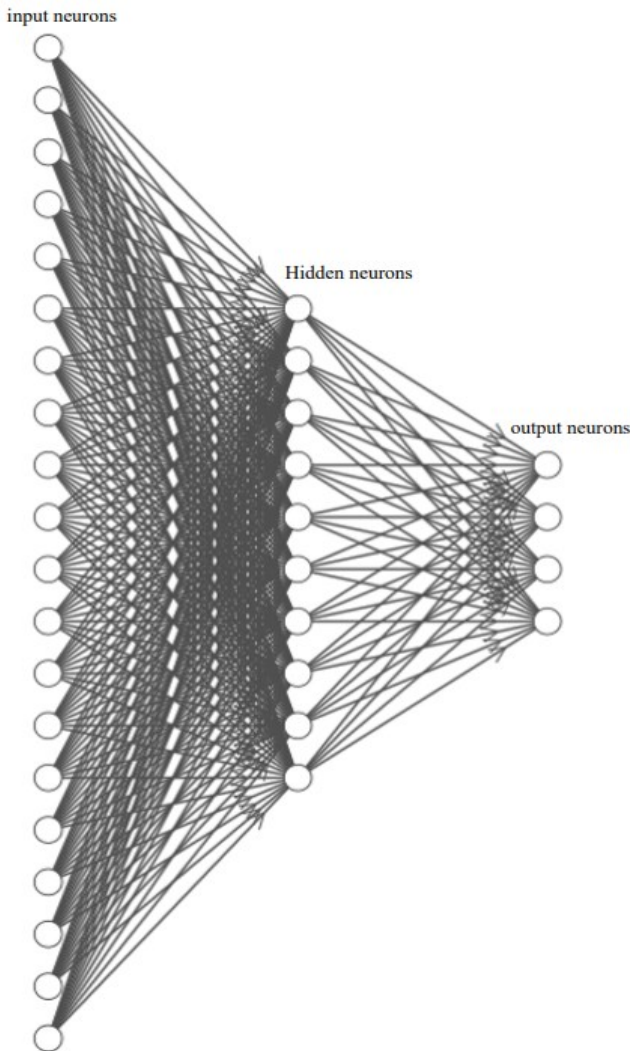

Fig 2. ANN Network of this paper

Fig 3. Structure of a single neuron

The pre-activation can be calculated by the below equation, [10]

$$a_i(x) = b_i + W_i h_{i-1}(x) \tag{1}$$

Where, $a_i(x)$ = pre-activation output of i^{th} node

b_i = bias value of i^{th} node

W = Weight matrix

h = input vector

The activation at layer i is given by,

$$h_i(x) = g(a_i(x)) \tag{2}$$

$g(\cdot)$ indicates the activation function of the neuron. The most common activation functions used in ANN are linear, sigmoid, SoftMax, ReLU, Leaky ReLU, etc. Depending on the application appropriate activation function can be used.

Field Programmable Gate Arrays [9] can be programmed or configured by the user during implementation. These boards can be rapidly used to prototype ASICs, or as a substitute for a place where ASIC will be eventually used. The programming of FPGA is done by writing Verilog code or circuit diagrams using Hardware Description Language (HDL). The basic components present in the FPGA board are CLBs, memory units that are part of look-up tables, I/O Blocks, etc. Free versions are available, High-end processors/ Processor platforms, IP cores (like MATLAB Functions), Clock Multipliers, Dedicated Memories, MAC units, ARM Bus Architecture and Bus accessories, Separate Clock tree network to minimize clock skew and delay in clock distribution to all corners of the ICs Available in different capacities and facilities.

In 2015, S. H. Jambukia, [8] gave a detailed survey on preprocessing techniques, ECG databases, feature extraction techniques, and ANN-based classifiers. In 2016, M. G. Egila, [1] Implemented FPGA- based ECG signal analysis using a least-square linear-phase finite impulse response filter. The main aim of this filter in this design is to remove low-frequency noise in the ECG signal. But in the classification part, only one node is used at the output, it will give the information only on whether the ECG signal is normal or abnormal.

In 2019, Zena N. Abdelkader, [3] proposed a design of ECG Classification using Xilinx System Generator. In this paper, an ANN classifier with two layers and four neurons with an activation function of type "tan-sigmoid" is implemented and provides 99% training accuracy, 80% validation accuracy, and 81.9% of Testing accuracy. In 2014, K. Muthuvel, [4] proposed a design to extract and classify the ECG signal using Harr Wavelet Transform and Neural Network. The only simulation result is carried out in this paper with 62% of accuracy, 73% of sensitivity, and 63% specificity.

In this work, hardware implementation of Classifier is carried out with 20 input, 10 hidden, and 4 output neurons. The sigmoid function is used for the hidden layer with piece-wise linear approximation and the Softmax function is used for output layer classification. Accuracy has been improved in MATLAB simulation and the same functionality is implemented in Verilog for hardware.

The rest of the paper is organized as follows. Section 2 explains the hardware implementation of ANN. Section 3 illustrates simulation results in MATLAB and Verilog and Error estimation. Finally, Section 4 concludes the paper.

II. HARDWARE IMPLEMENTATION OF ANN

The main aim of this work is to implement the ANN in Verilog after the ANN has been trained in MATLAB (offline) [10]. After testing the ANN using several test cases offline and measuring the value of accuracy, the same feed-forward ANN algorithm will be implemented in hardware using any one of the HDL languages and this result will compare with the MATLAB result. The weight and biases values are obtained, after training the ANN offline. These values are loaded in a text file and will be called to the main module through the test bench. Since all the values are in real numbers, they are converted to integers by multiplying with the scaling factor 1024 and rounding off that number, because Verilog will take only integers as input and will get integers as output. After getting the final output every value will be right-shifted by 10. Since at the input side all values are multiplied by 1024.

The ANN feed-forward algorithm consists of multipliers and adders. After the multiplication of inputs with corresponding weights, the accumulated sum will give as input to the activation function. The ANN model for this project is shown in Table I. This model consists of a total of 14 neurons, 10 for the hidden layer and 4 for the output layer.

Table I. ANN Model of this paper

Number of classifications	4
Number of training samples	1000
Number of input neurons	20
Number of hidden neurons	10
Number of output neurons	4

From Table I, it requires 20 multipliers 20 adders for each neuron in the middle layer, and 10 multipliers and 10 adders for the last output layer. In total it requires 240 multiplications and 140 additions. And this cost increases if the number of input neurons or the number of hidden neurons increases significantly. In this implementation, all the neurons in the hidden layer are triggered at the same time as well as output neurons, so this ANN implementation is very faster.

The above approach requires more resources, as there are more multipliers and adders. There is another approach where a much less number of multipliers and adders are used compared to the above method. In this ANN architecture, each layer will execute one after the other. Each neuron in the corresponding layer computes the product of the input at the positive edge of the clock. In this way, one can reduce the number of multiplications as equal to the number of input neurons, but the number of clock cycles will be increased. For this work, 20 input neurons are available so, it will take a total of 20 clock cycles and 1 clock cycle for bias input, and to calculate the accumulation of product and activation function output it will take two more clock cycles, in total it requires 23 clock cycles for hidden layer alone and 13 clock cycles for the output layer. But the drawback of this method is it will take more time from input to output.

The feed-forward algorithm for ANN implementation consists of parallel processing capabilities of the hardware, where each node in the layer will trigger at the same time (positive edge of the clock). The hierarchy of ANN is shown in Fig. 4. The corresponding weight and bias values are loaded into the main module through the test bench.

This algorithm will start from the module main.v. All the weight and bias values are stored in the text file and will be read from the test bench. From the test bench, these values will pass to the main module. After processing the ANN algorithm, the result will send back to the testbench from the main module. Since in each layer there are different number of neurons, we created two different modules for these layers named hidden.v and output.v .

The modules hidden.v and output.v are instantiated in the module main.v . Total of 10 neurons in the hidden layer and 4 neurons in the output layer are instantiated. During the processing of the hidden layer, all the neurons will receive inputs and corresponding weights one at a time and perform multiplication operations on them, after storing the result in registers they all accumulated. The number of clock cycles it requires to perform to compute for the hidden layer is equal to the number of input values. The main.v module sends inputs and weights to the hidden layer neurons at each positive edge of the clock. The same procedure is followed in the output layer also.

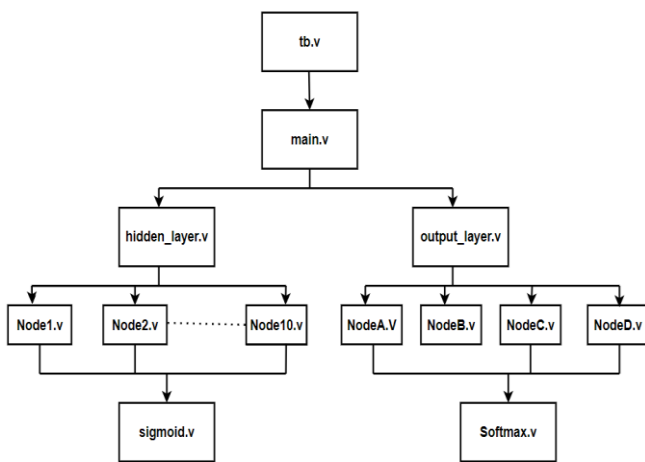

Fig 4. ANN Hierarchy

After generating the cumulative sum of the hidden layer the result will go to the sigmoid.v module , where the sigmoid activation function is performed and the result will store in the corresponding registers. And these values go to inputs to the next output layer. Like the hidden layer, the same process will perform in output_layer.v . This cumulative sum will go to the softmax.v , which is the activation function of the final layer, The output of this module is the final classification result of the ANN model.

The activation function used for the hidden layer is given by $f(x) = \frac{1}{1+e^{-x}}$ (3)

It is very difficult to implement exponential and division operations in Verilog and it will require more resources and more area [5]. The above function will be implemented by the

piece-wise linear approximation method [2]. In this method, the approximation is performed using the following expression (4). But this PLAN approximation will give the average error of 0.00587.

$$f(x) = \begin{cases} 1, & |x| \geq 5 \\ 0.03125 * |x| + 0.84375, & 2.375 \leq |x| < 5.0 \\ 0.125 * |x| + 0.625, & 1.0 \leq |x| < 2.375 \\ 0.25 * |x| + 0.5, & 0 \leq |x| < 1.0 \end{cases} \quad (4)$$

But the expression (4) contains real values, so one can convert the above expression by multiplying its terms without variable |x| with scalar factor 2¹⁰. The equation (4) is performed only with a positive value of x. Since sigmoid is an even function, the equation (5) is used for the negative value of x.

$$f(-x) = 1 - f(x) \quad (5)$$

For the final layer of the ANN model, the Softmax function is used as an activation function. The equation of the softmax is given by,

$$f(z)_i = \frac{e^{z_i}}{\sum_{j=1}^K e^{z_j}} \quad (6)$$

Where,

z_i = input feature vector

K = number of output classes

This function represents the probability of that class. If it is getting more input value than the output corresponding to that class. But, as the equation contains exponential and division operators, it's very difficult to implement that function in hardware [6] and [7] and will utilize more resources. So, consider whatever value coming in the pre-activation function is high, given high probability to that corresponding neuron, for all remaining neurons considered as zero probability.

III. RESULTS AND DISCUSSION

In this study for Dataset classification, Intra-patient Data set [11] scheme is used. According to this, random subsampling is conducted to train and evaluate classifiers. Data is randomly selected from the whole database. To implement this work in hardware Xilinx Artix-7 NESYS 4 DDR FPGA board is used. In this work, training of the ANN model is done offline in MATLAB [10] and obtained the values of weights and bias values of corresponding layers.

Here, using nntool in MATLAB, the ANN model is trained with one hidden layer containing 10 nodes with a sigmoid activation function and 4 output nodes with a SoftMax activation function.

As shown in the flow diagram in Fig. 1, from DWT one can extract the features of ECG beat and these features are input to the ANN model. A total of 20 features are getting from each beat. From the database total of 1000, 20*1 vectors will be getting, in which 70% is used for training, 15% for validation, and the remaining 15% is used for testing for training the algorithm. And this result is tested with 1000 more data samples.

In the hidden layer total of 10 neurons are instantiating with each having a pre-activation function and sigmoid activation function. Fig. 5 shows the simulation of the hidden layer.

Fig 5. Verilog Simulation of Hidden layer

In the output layer total of 4 neurons are instantiating with each having a pre-activation function and softmax activation function Fig. 6 shows the simulation of the final layer.

Fig 6. Verilog Simulation of Output Layer

The hardware utilization design summary is given in Table II.

Table II. Hardware utilization design summary

Logic Utilization	Used	Available	Utilization
Slice LUTs	84	63400	~1%
Fully used LUT pairs	0	84	0%
BUFGs	1	32	~3%
DSP48E1s	10	240	~4%

Since, in Verilog, it takes only integers and neglects fractional parts, there is some error produced compared to the MATLAB result. Table III, and IV shows the Error estimation of the hidden layer and output layer respectively. One random beat of sample is considered for this error estimation.

Using the confusion matrix from the MATLAB simulation, one can get the accuracy of the ANN model. From Fig. 7, it is noted that, 90.1% training accuracy, 84.7% validation accuracy, 85.3% testing accuracy, and 88.6% overall average accuracy when we take the total 1000 samples and are divided into 70% for training, 15% for validation, and 15% for testing. Once the model is trained, testing can be done using another 1000 random samples. The 86% of testing accuracy is obtained and shown in Fig. 8.

Table III. Error estimation of Hidden layer

	MATLAB	Verilog	Error
Node1	0.4704	0.4716	0.0012
Node2	0.8301	0.8232	0.0069
Node3	0.8309	0.8232	0.0077
Node4	0.2422	0.243	0.0008
Node5	0.2569	0.258	0.0011
Node6	0.9323	0.9248	0.0075
Node7	0.4512	0.4521	0.0009
Node8	0.9252	0.9218	0.0034
Node9	0.4735	0.4746	0.0011
Node10	0.2729	0.2705	0.0024
Overall average error of the random one sample			0.0033

Table IV. Error estimation of the Output layer

	MATLAB	Verilog	Error
Node1	3.5239	3.5509	0.0270
Node2	0.9593	0.9590	0.0003
Node3	-0.9900	-0.9872	0.0028
Node4	-0.5966	-0.5964	0.0002
Overall average error of the random one sample			0.0075

From the Table III and Table IV, it may be noted that the overall average error 0.0033 and 0.0075 are obtained from hidden layer and output layer respectively.

After verifying this, the hardware implementation using 1000 testing samples are carried out and the results are shown in Table V. From the Table V, it may be noted that 85.6% of testing accuracy is obtained. Out of 1000 samples, 856 samples are correctly classified and 144 samples are not correctly classified.

IV.CONCLUSION

Artificial Neural Network (ANN) is one of the main research topics nowadays everyone working with. For this biomedical system, ANN is used as a classifier with one hidden layer consisting of 10 nodes and an output layer consisting of 4 nodes corresponding to 4 classes. Piecewise Linear Approximation (PLAN) is used to implement the sigmoid activation function with an average error of 0.00587. And the accuracy observed for classification is 86% in simulation and 85.6% in hardware.

Abstract— With the advancement of technology and increase in world's population, the demand for the consumption of fresh drinking water has increased worldwide. Utilization of clean energy sources for purification of water is the need of today's world. This paper focuses on modelling the solar powered reverse osmosis system using the bond graph modelling technique which is very effective for multidisciplinary systems. The model contains electrical, mechanical and hydraulic domains merged together using the bond graph language. It further utilizes the 20-Sim software to implement the dynamic model and simulate the system. The paper eventually provides a detailed analysis on how the system will respond to the changing system parameters.

Keywords— *Solar, Reverse Osmosis, Bond Graph, Dynamic Modelling, Simulation, 20sim Software*

I. INTRODUCTION

Pakistan economy mostly relies on agriculture and around 22.2% of that contributes to its overall gross domestic product (GDP) [1]. Approximately 42.3% of the labor in Pakistan is employed from the total labor strength [2]. In 1950s Pakistan has the water capacity of around 5000 m^3 per capita and it has decreased now to 1000 m^3 per capita [2]. According to the United Nations Educational, Scientific and Cultural Organization report, Pakistan available water supply is just above 1000 m^3 per capita which puts the country in the list of water stress countries [3]. Overall worldwide, the countries that are facing difficulty in availability of freshwater are now relying on water desalination processes using ground water as this method allows to generate fresh water supply but at the cost of electricity consumption. According to an estimate it take 10,000 ton/yr. of crude oil to produce 1000 m^3 /day of desalinated water from the process of thermal desalination [4]. This energy requirement is a big challenge as the world is already heading towards a big global climate change. The renewable energy is the solution to that problem and solar powered reverse osmosis plants can be very beneficial when it comes to elimination of utilization of fossil fuels. Hence renewable technology based reverse osmosis (RO) systems can be a good source of sustainable fresh water [5]. Thankfully, Pakistan lies on the region of good solar irradiance ranging from 5–7 kWh per m^2 per day and sunshine hours of 1,500–3,000 [6] which can be used as an

advantage for solar powered RO systems. The desalination process now is used worldwide and its utilization trend has shown an increase in the recent years [7]. The Solar powered reverse osmosis is a unique idea for converting the saline or brackish water to fresh water as the water passes through membranes and remove approximately 98% - 99.5% salt from it [8]. With all of these factors being said and issues that Pakistan as a country has, powering a reverse osmosis system for extracting drinking water for a community in Pakistan using renewable energy sources makes a very favorable solution. Modelling of such multi-disciplinary systems which involves electrical, mechanical and hydraulic domains require complex modelling techniques. This paper utilizes the bond graph modelling approach which facilitates different domains using the explicitly graphical power flow paths among interconnected system elements, and leverage analogies among different energy domains such as thermal, fluid, mechanical, and electrical. This modelling technique is then utilized to understand the behavior of desired outputs in relationship to the changing parameters of the system.

II. LITERATURE REVIEW

In this section several papers were reviewed related to the photovoltaic (PV) based reverse osmosis system and their conclusions are discussed. S. Sobana and Rames C. Panda [9] have reviewed more than 65 literatures for identifying different process parameters, dynamic modelling and control of desalination system. Their work mainly gives an account of two types of phenomenological models of desalination processes, namely, mechanistic model or membrane transport model and lumped parameter model. Many researchers have presented identified transfer functions from input – output data of reverse osmosis process. Alatiqi et al. (1989) [10] used system identification techniques to estimate a MIMO structure of RO plant at Doha. Assef et al. (1995), Riverol and Pilipovic (2005), and Robertson et al. (1996) [11] [12] [13] also developed multivariable transfer function models from the plant's input – output data. Zilouchian (2001) [14] worked and find the reverse osmosis desalination system transfer function and also in steady state matrix form using recursive least square method. Ramaswamy et al. (1995) [15] implemented connected multilayer feed forward neural network using the back propagation algorithm to identify the nonlinear

multivariable multistage flash desalination plant. Fkirin et al. (1997) [16] presented an algorithms which focus on optimal identification for the timevarying dynamic process based on linear combination of the recursive least square method. Saengrung et al. (2002) [17] modeled two reverse osmosis plants using system identification. Gambier et al. (2007) [18] derived a lumped parameter dynamic MIMO model from first principle laws and used it in carrying out diagnostics of system and even in finding faults in system. Ahmad et al. (2007) [19] developed and simulated a membrane transport model suitable for the multiple solutes system in reverse osmosis for unsteady-state condition. Chaaben et al. (2008) [20] developed a MIMO model relating input and output variable for a small photovoltaic reverse osmosis desalination unit. All these research approach provides a great insight on how to model the reverse osmosis system.

III. BOND GRAPH LANGUAGE

Due to the increasing number of sophisticated and interdisciplinary systems, multidisciplinary techniques are becoming increasingly crucial in the modelling process. Bond graph approach establishes a common vocabulary for understanding relationships and similarities among various modelling methodologies. It provides a uniform domain-independent graphical representation of multidisciplinary models [21]. Bond graph provides a clear graphical representation from which other representations can be derived, e.g. linearized state equations, system transfer functions, or differential equations. The bond graph is a modelling technique that is based on energy transfer between system components. Bonds connect the component ports, demonstrating how power is transferred between them. A half-arrow on one end of the bond indicates the direction of power transfer. In a bond graph, there are two variables: effort (e) and flow (f). The system, which is composed of many energy domains such as mechanical, electrical, and hydraulic, is turned into a single model in order to simplify the system's analysis. The figure 1 shows analogies of different bond graph variables utilized in different domains [22].

Energy Domain	Effort (e)	Flow (f)	Generalized Momentum	Generalized Displacement
Translational Mechanics	Force	Velocity	Momentum	Displacement
Rotational Mechanics	Torque	Angular Velocity	Angular Momentum	Angle
Electro-magnetic	Voltage	Current	Flux Linkage	Charge
	Magneto-motive Force	Magnetic Flux Rate	-----	Magnetic Flux
Hydraulic	Total Pressure	Volume Flow	Pressure Momentum	Volume
Thermodynamic	Temperature	Entropy Flow	-----	Entropy
Chemical	Chemical Potential	Molar Flow	-----	Molar Mass

Figure 1 – Analogies of different bond graph variables utilized in different domains [22]

IV. SYSTEM DESCRIPTION

The overall system will comprise of an electrical, mechanical and hydraulic system. The figure 2 below shows the complete block diagram of the system.

Figure 2 –Block Diagram of Complete System

A. Electrical System

The electrical system will use the energy of the sun and by using the photovoltaic cell convert that energy to electrical direct current form. This energy will be fed to the batteries through charge controllers so that it can be used to provide power to the reverse osmosis system. The major load of reverse osmosis system is the dc motors that is coupled with the centrifugal pressure pump to run the hydraulic system. The block diagram for a solar powered dc motor is shown in figure 3 [23].

Figure 3 –Block Diagram of Solar Powered DC motor [23]

B. Reverse Osmosis Desalination System

Reverse osmosis system converts unfiltered feed water to clean water when feed water is pressurized and passed through a membrane. The water flows through the membrane and more contaminants are accumulated to the more concentrated side of the membrane whereas clean drinking water is accumulated to less concentrated side of the membrane. The cleaned water is then stored in a storage tank and usually the system is designed in a way that when the storage tank is full the RO system shut downs automatically. The brine water is drained as a water waste [24]. The brine water can be used for dishwashing and other cleaning purpose so that system efficiency is increased. The basic components of a RO process are: pre-treatment system used for cleaning brackish water, High-Pressure Centrifugal (HP) pump used to provide required pressure to membrane, and post-treatment system for smell and odor removal [25]. The overall block diagram of reverse osmosis system is shown in figure 4.

Figure 4 –Block Diagram of Reverse Osmosis System

V. SYSTEM MODELLING

A. Generalized Bond Graph Model of System

The generalized interrelation of multidisciplinary system can be seen in figure 5. The distinct systems are connected with the power variable defined as effort and flow. Electrical domain output of motor torque and motor speed is used as the input to the mechanical domain. The mechanical domain outputs the Pump Pressure and pump flow rate that is used as the input to the hydraulic domain and eventually producing clean and reject water.

Figure 5 –Generalized Bond Graph Model of System

B. Detailed System Based Bond Graph Modelling

1) Electrical System Bond Graph Modelling

In order to reduce the complexity of the system, the solar panel and battery are modelled as a voltage source. The rated voltage of battery is 24V DC. The DC motor model is created in which motor resistance and inductance are modelled as R-element and I-element respectively. The conversion from electrical domain to mechanical domain is executed with the help of gyrator that relates effort to flow with the motor constant (K_m). The selected parameters of the model are shown in table 1. The bond graph model of the system is shown in figure 6.

Table 1 - Electrical Model Parameters

Element	Description	Value	Unit
Se	Voltage Source	24.0	V
R	Winding Resistance	5.0	Ohm
I	Winding Inductance	0.03	H
GY	Motor constant	0.02848	Nm/A

Figure 6 –Bond Graph Model of Electrical System

2) Pressure Pump Bond Graph Modelling

The pump is defined as a machine used to generate a pressure differential in order to propel liquid through a piping system from one location to another. An electric motor rotates an impeller in a centrifugal pump that adds energy to the water after it is directed into the core of the

rotating impeller. The pump is coupled directly to the motor and the load of the pump is modelled using the equations (1) and (2) [26] [27].

$$T_l = (K_1 \cdot \omega - K_2 \cdot Q) \cdot Q \tag{1}$$

$$P = (K_1 \cdot \omega - K_2 \cdot Q) \cdot \omega \tag{2}$$

Where:

T_l is the load torque of the pump

P is the pressure of the fluid

ω is the rotational speed of the machine

Q is the flow rate of the pump

K_1 and K_2 are the pump parameters

The modelling of a single stage pump is done in the bond graph by the help of the gyrator element whereas R-element represent losses due to impeller/diffuser wear and fluid disk friction, I-(inertia) element models the rotating fluid of the pump and another R-element represents the pipe loss when water is transmitted from pump discharge to the reverse osmosis system inlet. The selected parameters for the model are shown in table 2. The bond graph model of the system is shown in figure 7.

Table 2 - Pump Model Parameters

Element	Description	Value	Unit
GY	Centrifugal Pump Equations Modelled	Pressure & Flow rate	Bar & GPM
R	Impeller Loss	0.05	Bar
R	Pipe Loss	0.0005	Bar
I	Rotating Fluid Inertia	0.125	kgm ²

Figure 7 –Bond Graph Model of Centrifugal Pump

3) Membrane Modelling

The reverse osmosis system works opposite to the phenomena of osmosis system. By applying the external pressure which is from the centrifugal pump clean water and dirty water are separated. The feed water pressure from the pump must be large enough to overcome the osmotic pressure and the membrane resistance, as well [28] [29]. The flow inside the membrane is cross in nature resulting in clean water being diffused to the other side of membrane and all brine (dirty) water being collected on the other side. Figure 8 shows the water flow inside the membrane [30].

Figure 8 – Water flow inside reverse osmosis membrane [30]

Therefore, a quantity of the feed water permeates through the membrane reducing strongly the water salt concentration to get the fresh water (purified water), and the remaining feed water becomes very concentrated brine (waste/dirty) water. It can be seen that the feed water flow is used by both the clean water and rejected water. To reduce this complex modelling the system is converted to complete hydraulic system. The system is modelled using a C-element that represent the water storage under pressure inside the membrane. The membrane is considered as a tank which has radius 0.025 meters with water density of 1000 kg/m³. The area was calculated using equation (3) and used to calculate the value of capacitance using equation (4).

$$A = \pi \cdot r^2 \tag{3}$$

$$C = \frac{A}{\rho \cdot g} \tag{4}$$

Where A is the area in m^2 , π is the constant with value of 3.142, r is the radius of the membrane, C is the capacitance value of the tank, ρ is the density of water and g is the acceleration due to gravity. Two R-elements are used to model the hydraulic membrane resistance on the clean water side and on dirty water side which depends highly on the membrane temperature and conductivity. To control the pressure of reject water, a non-linear valve is modelled using the R-element. The valve is modelled using the valve law equation (5) [31].

$$Q = \frac{P^2 \cdot \rho}{2 \cdot (C_d \cdot A_0)^2} \tag{5}$$

Where:

- Q is the flow rate of the valve
- P is the pressure across valve
- ρ is the density of the water
- C_d is the discharge coefficient of the valve
- A_0 is the nominal area of the valve

The clean water pressure, hydraulic load losses and osmotic pressure are all modelled using the Se-element with its summation. In order to keep the dirty water at required pressure Se-element is also used to model that. The selected parameters for the model are shown in table 3. The generalized bond graph model of the system can be seen in figure 9.

Table 3 – Reverse Osmosis System Parameters

Element	Description	Value	Unit
C	Membrane Water Storage	2.0e-07	m ³ /bar
R	Clean water resistance	1.0	bar
R	Reject water resistance	0.0005	bar
R	Reject water valve	Eq. (7)	bar
Se	Clean water	5.0	bar
Se	Reject water	2.0	bar

Figure 9 –Bond Graph Model of Reverse Osmosis System

C. Complete System Model

After combining all the individual systems, the complete bond graph is established as shown in figure. The multi-disciplinary systems (electrical, mechanical and hydraulic) are all combined with their effort to flow relationship as shown in figure 10.

Figure 10 –Complete System Bond Graph Model

VI. ANALYSIS AND RESULTS

The system was modelled in 20sim software and using the simulation feature, dynamic response was analyzed after which system reaches the steady state response. The normal response of the system was shown in the first part. The comparative results are shown later. In comparative parts the dark color line represents the system response based on changing the system parameter whereas the light color line represents the normal system response.

A. Normal System Dynamic Response:

Figure 11 shows that the source voltage is stabilized at 24V DC and the current reaches the maximum value of 5 Ampere. Figure 12 shows that the motor torque is stabilized at 1.13Nm and the motor angular speed reaches a value of 1.25 rad/s. Figure 13 shows that at the start the pump pressure becomes negative and the flow rate is also disturbed but once the pump reaches its capacity a pressure of 0.15 bar is achieved and flow rate of 5 GPM is stabilized. Figure 14 and 15 shows that the pressure of clean and reject water is maintained at 5 bar and 2 bar where as the flow rate reaches a value of 5.2 GPM and 0.0004 GPM respectively which is optimum condition as there is minimum dirty water and the system is operating at the most efficient point.

Figure 11 – Source Voltage and Current Response

Figure 12 – DC Motor Torque and Angular Speed Response

Figure 13 – Centrifugal Pump Pressure and Flow rate Response

Figure 14 – Clean Water Pressure and Flow rate Response

Figure 15 – Dirty Water Pressure and Flow rate Response

B. Voltage Reduced due to Intermittent Solar Source (Comparison with normal response):

The voltage source is now reduced and dynamic response is analyzed compared to the actual dynamic response of the system. This happens because the state of charge of battery is not fixed and dependent on the charging and discharging of battery which in turn depends on the availability of solar energy and conversion efficiency of the photovoltaic system. Figure 16 showed that now the voltage is reduced to 20V DC and the current is also reduced. Figure 17 verifies that torque of motor is dependent on the voltage and it can be seen that torque is reduced whereas the angular speed of the motor is still the same.

Figure 16 – Source Voltage and Current Response

Figure 17 – DC Motor Torque and Angular Speed Response

C. Increased Clean water side hydraulic resistance (Comparison with normal response):

The clean water side hydraulic resistance is increased and the dynamic responses are analyzed as shown in fig 18, 19, 20 and 21. It can be seen that the motor speed has drastically reduced because of the load on the impeller. Also the pump now has low negative pressure and reaches the stability quickly but due to high hydraulic resistance the flow rate of pump is now reduced significantly resulting in very low flow rate of clean water and same flow rate of dirty water.

Figure 18 – DC Motor Torque and Angular Speed Response

Figure 19 – Centrifugal Pump Pressure and Flow rate Response

Figure 20 – Clean Water Pressure and Flow rate Response

Figure 21 – Dirty Water Pressure and Flow rate Response

VII. CONCLUSION

Based on the results, it can be concluded that the system has transient and steady state response. The transient response is finished after a time period of 50 – 80 milli seconds. The paper uses mathematical models of multidisciplinary system and merge them as single model using bond graph language. Simulation is performed using the 20Sim software and the results concluded that if voltage source is decreased due to intermittent nature of renewable energy system the motor torque is also affected. Also when the hydraulic resistance of clean water side is increased the system becomes highly inefficient as all the water is thrown to the dirty side rather than being cleaned in reverse osmosis membrane. The practical understanding is that when the membrane is clogged with impurities the resistance to flow is increased resulting in poor performance of system which is visible from the modelling results. A differential pressure sensor can be used with alarm values to indicate an operator managing the system so that he can clean the membrane and efficiently run the system.

Abstract— The demand for fresh drinking water has increased globally due to technological advancements and an increase in the world's population. The world is also witnessing climate change due to excessive emissions from conventional power generation procedures. Today's world necessitates the use of renewable sources for water purification. Using the HOMER Pro software, this study elaborates on a design for a solar-powered drinking water reverse osmosis system for a community in Black Tickle-Domino. This study also uses the HOMER Pro software's optimization feature to conduct an economic analysis to develop the most cost-effective system design. The Steady-state analysis was conducted in HOMER Pro Software whereas the dynamic modelling and analysis of the proposed design was also validated in MATLAB Simulink. Also a comprehensive instrumentation design with important protection controls schemes is designed to ensure system stability and reliability for operation.

Keywords— Solar, Reverse Osmosis, Water Desalination, HOMER Pro Software, MATLAB, Instrumentation and Protection.

I. INTRODUCTION

The human body needs water more than it needs anything else. It is surprising to hear that we will die of thirst quicker than we would die of hunger. It is equally surprising to hear that, in any given month, well over 100 communities in Newfoundland and Labrador do not have continuous access to clean, safe drinking water [1]. The Indigenous community of Black Tickle-Domino, located in Labrador, does not have piped-in water and forcing the 126 residents of the community to travel around 2 kilometer's to retrieve water. The community's regular water supply is several unmonitored local streams, brooks, and ponds. A Potable Water Dispensing Unit (PWDU) was installed in Domino in 2004.

Still, access to water was strictly limited and expensive, with residents paying up to two dollars per liter of drinking water. The PWDU is unsustainable without consistent government funding [2]. Aside from water, the high cost of transportation, such as snowmobile gas, is another significant deterrent to continuous PDWU operation. Water retrieval from a stream about 25 kilometers away is hindered by adverse weather, substantial snowfalls, and storms [3]. Local shallow water holes known as 'wells' arise as water sources, while some wells become inaccessible due to snow covering in the winter and spring. Many residents continue to use untreated brooks and still ponds for their water needs, as they did before installing the PWDU [3]. It is important to note that this is an issue concerning drinking water and severe mental and physical health risks associated with using untreated or inadequately treated water. This project mainly aims at designing and simulating a PV System to power a community-size water filtration system to solve the freshwater scarcity issues. The fresh water-scarce areas in the world now rely on water desalination processes. Desalination has emerged as a potential method to produce freshwater in recent times due to technological advancement. Keeping this in mind, a small-scale solar-based filtration system seems to be the most feasible, environment-friendly, and accessible solution for the continuous availability of water.

II. LITERATURE REVIEW

In this section, several papers related to the photovoltaic-based reverse osmosis system were reviewed, and their conclusions were discussed. The article published on the MIT website [4] in 2013 elaborates how a small Mexican village produces clean water with a solar-powered system. The system runs autonomously, producing 1,000 liters per day. The solar-powered setup can produce at least 1,000 liters of drinking water on a cloudy day - enough for 450 residents [4].

A simulation-based RO design system was used to find the performance of the solar-powered RO system. Three Pakistan cities were assessed, including Lahore, Hasil Pur and Faisalabad [5]. According to WHO quality requirements, the TDS concentrations for these three cities were reduced from 1495 to 295.44, 2190 to 237.69 and 7683 to 241.98, respectively [5]. The required energy turns out to be 60, 95, and 311 kWh/month for Lahore, Hasil Pur, and Faisalabad, respectively. The paper used PVsyst software for solar calculation and deduced that 19, 15, and 40 PV panels would be used by Lahore, Hasil Pur, and Faisalabad, respectively [5]. Another study was conducted for a photovoltaic-based reverse osmosis system in which a 500 L/hr. system was designed using a 2KW PV system with a 5KVA hybrid inverter. Analysis and comparison of cooling and no-cooling of the PV system were also carried out. It was concluded that around 18% more daily PV energy was utilized using the tracking system, and 10% more PV energy was used when the panels were cooled [6]. Abdel Kareem's [7] analysis was based on capturing desalination water using solar, wind and geothermal energy. His conclusion defined that good design is very important when off-grid PV systems are designed. He further concluded that solar tracking and cooling of PV cells eventually make the process efficient. Ali et al. [8] did a further analysis of combining reverse osmosis and adsorption desalination systems. He further used MATLAB for simulations of different scenarios. His work concludes that if both are run together, the permeate salinity is slightly decreased, which will make the process more efficient. Charcosset [9] also carried out his analysis on the same topic. His research involves merging renewable energy with different designs and mathematical models to achieve the best economical solution. His work concluded that PV-based RO plants are most efficient in energy consumption when utilized on a small scale. Ahmad and Schmid [10] study water desalination in Egypt desert using a PV system for energy. Gocht et al. [11] carried out their study for reverse osmosis using photovoltaic energy sources in Jordan. Richards and Schafer [12] worked on PV based desalination plant for remote communities in Australia. Tzen et al. [13], kalogirou [14] also carried out analyses for the same systems. Goosen et al. [15] work were slightly different from others as he studied and compared the challenges in a renewable-based desalination system.

III. REVERSE OSMOSIS DESALINATION SYSTEM

A reverse osmosis setup will be used for water filtration in this design. Reverse osmosis converts unfiltered water to clean water when water is pressurized and passed through a membrane, as shown in Figure 1. When water flows through the membrane, the unfiltered water flows to the more concentrated side of the membrane while clean water moves to the region of low concentration. The unfiltered water can also be referred to as feed water, the clean water as permeate

and the concentrated contaminated water as the waste or brine. A membrane is a tool with filtering pores that allow only clean water molecules to pass through it. In regular osmosis, equilibrium is obtained on both sides of the membrane. Still, in reverse osmosis, constant pressure is applied to the feed water while ensuring that the brine and permeate do not mix up but are collected separately [16].

Figure 1 - Reverse Osmosis Plant Flow Diagram [16]

IV. SITE SELECTION AND SYSTEM DESIGN

A. Site Characteristics and Water Supply System:

Black Tickle - domino is in the southern Inuit community on the pond's island; this community is one of the minorities in Canada that still suffers insufficient water supply. This vicinity has no piped water supply causing 126 people of its residents to have little access to water supply or rather must travel 1 km away or more to access this supply. The community has only one portable drinking water supply located 2 km away, and it is costly for residents to access. The average water consumption per household size consisting of 3 people in this community is 394 Liters, which is less than the standard consumption rate of 274 Liters of water per day per person as the average usage in Canada [17]. Herring Cove pond is 2km from the furthest house in Black Tickle and about 1km from the nearest place [18]. The water quality in the pond was tested to check for its drinking safety; further testing [19] found out the water E-coil was absent, but a certain amount of coliform was present and recorded to be satisfactory for drinking. Based on the reports, this site has been selected.

B. Selected Water Source and Water Requirement:

For the Black Tickle community, Herring Cove Pond is the best fit for the source of water to solve the current state of water scarcity and accessibility. The pump selection depends on the bore depth and flow rate. Ponds elevation is 143 meters with the pump placement at 120 meters; 23 meters were left to avoid the accumulation of underground impurities and pump damage from stones or sands. The pump selection depends on the energy demand, total dynamic head, performance efficiency, energy discharge and maintenance. Choosing the correct sizing for the solar system is very important to meet the energy demand. A poorly sized system can affect energy production and economic cost. The average

daily water consumption per person in Canada is 272.55 Liters [17], including drinking and household activities. However, due to the cost and proximity inefficiency, residents of black tickle consume as low as 88.2 Liters, i.e. about 32% of the standard consumption rate per day. This design will provide the standard water requirement per day per person to solve the issue. Hence the total water requirement per day by whole community is 34,341.3 Liters/day based on the population of 126 people. Figure 2 below shows a schematic diagram for the water extraction setup that will be used for resolving the water scarcity at Black Tickle.

Figure 2 - Block Diagram for Ground Water Extraction

C. Water Energy Calculation:

In order to calculate the total energy required to bring the water from ground to usable level, the total dynamic head needs to be calculated. The total dynamic head is the entire pipe length for the configuration, plus the frictional elbows and horizontal pipes. Assuming that the pump is 120 meter above the water level and has to raise a water to height of two tanks which are 4 meters high each and have 5, 90° elbows will require a total dynamic head of 134 meters. The total head and water consumption requirement per day is required to calculate the pump size. The shaft power required is calculated to be 5.2 KW using the hydraulic power required to raise the water given in equation 1 and then using the shaft power required by the motor as given in equation 2.

$$\text{Hydraulic Power} = \rho * g * h * Q \tag{1}$$

$$\text{Shaft Power} = (\text{Hydraulic Power}) / (n) \tag{2}$$

Where

ρ is the water density of 1000 kg/m³

g is the gravitational constant 9.81 m/s²

h is the total dynamic head i.e. 134 meters

Q is the water flow rate i.e. 0.002361 m³/s

n is the system efficiency i.e. 60%

D. Electrical Load Requirement:

The significant components of load in the system are submersible pump motor, complete RO system load and miscellaneous load. The entire system will run for 04 hours a day to produce sufficient drinking water for the whole community. Based on the total dynamic head of 134 meters, the liquid flow rate of 37.4 gallons per minute, and pump

efficiency of 60%, a 7.0-kilowatt single phase induction motor is selected to be coupled with the submersible pump [21]. The complete RO system for producing 37.4 gallons per minute has a power requirement of 12.0 kilowatt [22]. Some miscellaneous energy required, including area lighting, control equipment, etc., would need a maximum of 1.0 kilowatt. Hence the total energy required will be approximately 20.0 kilowatts for running the system smoothly at a production rate of more than 37.4 gallons per minute. The table 1 summarizes the total electrical energy requirement of the system.

Table 1 - Electrical Load Summary

Component	Load (KW)
Submersible pump motor	7.0
Reverse Osmosis System	12.0
Miscellaneous	1.0
Total Load	20.0

V. SYSTEM STEADY STATE MODELLING AND ANALYSIS

A. System Design in HOMER PRO:

The HOMER Pro software is used for the techno-economic analysis to optimize the system and introduce the most feasible solution. The system design includes a Photovoltaic (PV) array, lead-acid battery and inverter feeding the load. The system has a daily energy requirement of 80-kilowatt hours with a peak load of 35.01 kilowatts. The PV has 32.9 kilowatts of maximum power and uses a 38.0-kilowatt inverter. The result of Homer Pro with optimization suggests 72 12-volt batteries with four batteries in each string to keep the DC bus voltage at 48 volts. The system configuration in HOMER software is shown in figure 3.

Figure 3 – System Design in HOMER Pro Software

The figure 4 below shows the available solar irradiance and clearness index at the proposed site location.

Figure 4 – Solar Irradiance at Herring Cove Pond

B. System Steady State Modelling Results:

The figure 5 shows comparison of total electrical load served, PV Panel Power output and battery input power for three consecutive days in the month of June. It can be seen that when the photovoltaic is sufficient for the load battery is being charged otherwise battery is providing power to the load.

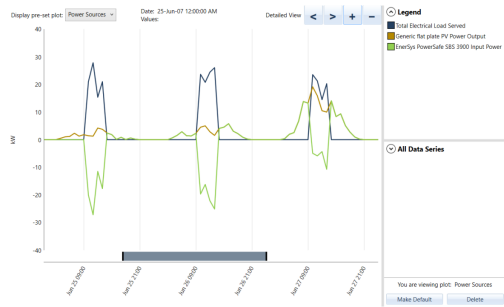

Figure 5 - Power flow comparison on three random days of June

In figure 6, the summary of the optimized electrical data is shown, which shows the electricity production, consumption and the renewable fraction constraints. It can be seen that the system is environmental friendly as all the energy used is from the renewable energy sources.

Production	kWh/yr	%
Generic flat plate PV	35,467	100
Total	35,467	100

Consumption	kWh/yr	%
AC Primary Load	29,179	100
DC Primary Load	0	0
Deferrable Load	0	0
Total	29,179	100

Quantity	kWh/yr	%
Excess Electricity	7,864	22.2
Unmet Electric Load	20.6	0.0704
Capacity Shortage	27.4	0.0939

Quantity	Value	Units
Renewable Fraction	100	%
Max. Renew. Penetration	281	%

Figure 6 - Electrical Summary

Figure 7 shows cash flow analysis for 25 years according to the type of cost, including replacement, salvage, operating and capital. The cost in all systems was selected from the internet and is put in Canadian Dollars for economic analysis.

Figure 7 - Cost Analysis

VI. SYSTEM DYNAMIC MODELLING AND ANALYSIS

A. System Modelling in MATLAB Simulink:

MATLAB is a programming software that is used worldwide for developing algorithms and creating models of systems.

Simulink is a sub program of MATLAB which allows the user to create multidisciplinary systems with the power of writing and integrating the code and finding the response of that system. The figure 8 shows the complete electrical model of the system in which photovoltaic source is used followed by boost converter for charging the battery. The battery is connected with the inverter and the motor load is considered as resistor for simplification in model.

Figure 8 – Complete System Model in Matlab Simulink

B. System Dynamic Modelling Results:

The system dynamic response was analyzed using the Simulink. The figure 9 shows the photovoltaic voltage response and it can be seen that in start the transient behavior of PV increases the voltage to 100 volts whereas after reaching the steady state it stabilizes to actual 65V.

Figure 9 - PV Voltage Response

The boost charging response is shown in figure 10. It can be seen that the voltage has fast switching spikes as duty cycle is used for increasing the voltage level for battery charging.

Figure 10 – Battery Boost Charge

Figure 11 shows the response of voltage across the load. It can be seen that the voltage waveform has both positive and negative cycles and DC waveform is converted to AC waveform using the inverter. The waveform is not pure sine

wave as filtering circuit was not implemented across the load for simplification purpose of model.

Figure 11 - Load Voltage Response

VII. SYSTEM PROTECTION CONTROL DESIGN

The protection control of the water filtration system aims at increasing the reliability in operation in case of any fault/loss of any individual system/component. The proposed protection system will have valves to control water flow and an over-current relay to protect motors, flow rate sensors, pressure sensors and level switches. The figure 12 depicts the proposed PV-powered water filtration system's protection system process and instrument diagram using several field instrumentation. The table 2 elaborates the instruments used in order to implement the protection control of the system. The complete protection control strategy is elaborated further and 6 major protection schemes are explained.

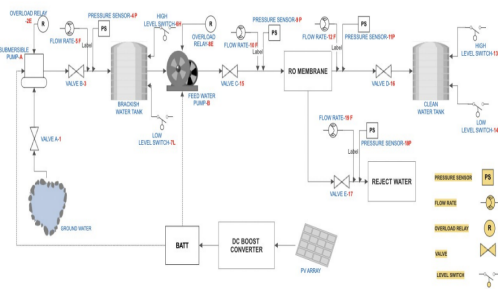

Figure 12 - Protection System Process and Instruments Diagram

Table 2 - Field Instrument List

Identifier	Description
1	Valve-A Open/Close
2E	Overload relay for Pump-A
3	Valve-B Open/Close
4P	Pump-A Pressure sensor
5F	Pump-A Flow rate sensor
6H	Brackish water tank High-level limit switch
7L	Brackish water tank Low-level limit switch
8E	Overload relay for Pump-B
9P	Pump-B Pressure sensor
10F	Pump-B Flow rate sensor
11P	RO Membrane clean water outlet pressure sensor
12F	RO Membrane clean water outlet Flow rate sensor
13H	Clean water tank High-level limit switch
14L	Clean water tank Low-level limit switch

15	Valve-C Open/Close
16	Valve-D Open/Close
17	Valve-E Open/Close
18P	Reject water outlet Pressure sensor
19F	Reject water outlet Flow sensor

A. Pump – A Protection Control

If pump-A has faults like over current, thermal, phase loss and undercurrent the overload relay 2E gets activated and trips the pump-A.

B. Pump – B Protection Control

If the overload relay 8E senses any abnormal conditions in the running parameters, it trips the pump-B.

C. Clean Water Tank Protection Control

Two level switches, 13H and 14L, monitor the clean water tank level for high and low levels. If the clean water tank level reaches the high-level set point and holds for more than 15 seconds, the level switch contact initiates a signal to trip the complete system.

D. Brackish Water Tank Protection Control

Two level switches are also installed on the brackish water tank to monitor the liquid levels in the tank. The high-level switch, 6H, initiates a partial shutdown of the system by first sending a stop signal to pump-A followed by closing the valve-B. In this condition, the liquid inflow to the brackish water stops, but the rest of the system remains in operation. The system normalizes when the 6H level switch resets back to its normal condition.

E. Reverse Osmosis Membrane Protection Control

This protection function considers the differential pressure across the membrane. The inputs are taken from the pressure sensor, 11P at the outlet of the RO membrane and the pressure sensor, 9P at the inlet of the RO membrane. If the differential pressure reaches a defined set point, the emergency shutdown is activated and the whole system is shut down. The filtration system can be restored after checking the healthiness of the RO membrane. This condition indicates the healthiness of the membrane.

F. Reject Water Outlet Protection Control

This function monitors the productivity and efficiency of the system by monitoring the flow rates of 12F and 19F, the flow rate sensors at the RO membrane outlet and the reject water inlet, respectively. If the system's efficiency falls below 50%, an emergency shutdown signal is initiated to shut down the complete system.

V. CONCLUSION

Based on the optimized results from the HOMER Pro Software, the most economical design of a solar-powered based drinking water reverse osmosis system is designed, which provides enough drinking water to the whole

community of the Black Tickle-Domino. The system is based on solar power, which means no carbon dioxide emission in the environment. The results depict that 32.9 KW of maximum power from the solar panels and battery arrangement of 72 batteries of 4 strings will be sufficient for the smooth operation of the water filtration system. The system dynamic response concludes that with minor changes the system will be able to operate in stable zone. Further the detailed protection control scheme of the system ensures that the system operation remains reliable irrespective of any faults that can occur. Considering the advantages of the system and the need of the residents of the community, the initial investment cost is high but justified, and the final design turns out to be the most feasible solution for providing drinking water to the whole community.

Abstract—Induction machines are extensively utilized in many commercial and industrial applications. Simulations of such machines to analyze their starting and operational performance require numerically accurate and efficient models. The conventional qd models, although simple to implement, require snubber circuits for interfacing with an external network, which reduces the accuracy and makes the model computationally expensive. This paper extends the prior work and presents a reconfigurable star-delta constant-parameter voltage-behind-reactance (CPVBR) model of a three-phase squirrel-cage induction machine considering the low-frequency deep-rotor-bar phenomenon. The eigenvalue analysis and computer studies demonstrate that the proposed model yields superior computational performance while providing an efficient machine-network interface as compared to the established qd model. It is envisioned that the new model can be useful for efficient simulation of power systems including induction machines with star-delta starters.

Keywords—Constant-parameter voltage-behind-reactance (CP-VBR) model, delta-connection, deep-rotor-bar effect, Induction machine (IM), qd model, star-delta starting method, wye/star-connection.

I. INTRODUCTION

Induction machines (IMs), due to their robustness, reliability, low cost, simple design, and self-starting capability are extensively utilized in many commercial and industrial applications, such as pumps, mills, crushers, conveyor belts, centrifugal machines, drilling machines, etc. [1]–[4]. Depending on performance requirements and applications, various stator windings configurations of induction machines may be used [5], [6], wherein the star-connected and delta-connected stator winding configurations are commonly used.

The direct-on-line (DOL) starting of induction machines has several issues [7], [8], including high starting inrush currents, pulsating torque, large real and reactive power to counteract the moment of inertia at rest, increased stresses on power system equipment, and voltage dips across the system buses. All of these parameters return to their normal values once the steady-state is reached.

Conventionally, several starting methods of induction motor have been proposed in the literature which can include DOL starting, star-delta starting, auto-transformer starting, AC

voltage regulators, variable frequency drives (VFDs), microcontroller-based starters, [9], [10] etc. The choice of each motor starting method generally depends on specific applications, speed and torque requirements, cost, space, and weight restrictions. For example, the star-delta starting method provides an effective and economic solution to improve both starting and operational performance of the induction machine. The advantages of this method include lower starting currents and lower starting torque pulsations. Also, depending on the motor loading and switching time, a star-delta starter with an open transition can cause voltage dips, current spikes, and torque surges. To overcome this limitation, an alternative approach namely a star-delta starter with closed transition can be useful which uses one additional contactor and a few power resistors/reactances to reduce the current and torque spikes during the transient.

Simulation studies utilizing numerically efficient and accurate induction machine models in electromagnetic transient (EMT) simulation programs have become indispensable for the design, analysis, operation, and control of power systems. Traditionally, in EMT simulation programs, induction machines are modeled using $qd0$ equivalent circuit [11]. In the classical qd model, both stator and rotor variables are transformed into qd coordinates, thus resulting in decoupled and rotor position-independent inductances. However, the indirect interface of the qd model with external inductive or switching circuits using resistive or capacitive snubber circuits enforces additional numerical error in the solution and leads to numerical stiffness and simulation inefficiency [12].

To overcome the limitations of qd model, the constant-parameter voltage-behind-reactance (CP-VBR) formulations of the induction machine model; namely VBR-I, II, III models, have been proposed in [13]. The VBR formulations represent the stator interfacing circuit in abc phase coordinates as three-phase controlled voltage sources behind three-phase RL branches and the rotor subsystem in qd coordinates with rotor flux linkages as state-variables. As a result, the VBR models become non-stiff, numerically accurate, and efficient because they enable direct interconnection of the stator interfacing circuit with arbitrary inductive or power-electronic circuits without snubbers, thus making them useful for power system simulation studies. According to [13], the VBR-I and VBR-II models are suitable to represent both wye/star (Y) and delta (Δ) machine stator winding configurations. The VBR-III model has decoupled RL

branches and is suitable to represent the wye (Y) machine stator winding configuration only.

To employ the advantageous properties of the CPVBR models, it can be preferable to switch between the star- and delta-connected stator windings under different conditions of starting and operational performance of the induction motor. Therefore, this paper presents a reconfigurable star-delta CPVBR model considering the low-frequency deep-rotor-bar phenomenon for a three-phase squirrel-cage induction motor. It is shown that the proposed Y-Δ CPVBR model provides superior numerical performance compared to the alternative/conventional $qd0$ model when considering the star-delta starting transients.

II. VBR FORMULATION WITH VARIABLE ROTOR RESISTANCE

This paper assumes a three-phase squirrel-cage induction machine with either wye-connected or delta-connected stator windings. For simplicity, magnetic saturation is not considered. All rotor parameters are referred to the stator side, and motor sign convention is used. The CPVBR formulations of the induction machine proposed in [13], are based on the classical $qd0$ equivalent circuit model in an arbitrary reference frame [11] as shown in Fig. 1. The interested reader can find a more detailed derivation of the CPVBR models in [13].

Fig. 1. Classical $qd0$ equivalent circuit in arbitrary reference frame for a three-phase squirrel-cage induction machine.

It is important to note that during the starting electromechanical transients, the rotor resistance may change significantly with the changes in slip and frequency of the rotor currents due to the deep-rotor-bar effect in the squirrel-cage rotor structure. To account for this effect, the single equivalent rotor resistance can be made speed-dependent using a simple linear approximation method proposed in [14]. According to [14], the speed-dependent rotor resistance can be written as

$$r_r(\omega_r) = r_{r1} + s(r_{r2} - r_{r1}), \quad (1)$$

where, r_{r1} and r_{r2} correspond to low-slip ($s \approx 0$) and stand-still ($s = 1$) rotor resistance values, respectively. The slip s is expressed as

$$s = \frac{n_s - n_r}{n_s} = \frac{\omega_s - \omega_r}{\omega_s}. \quad (2)$$

Herein, the VBR-II model [13] is considered as it remains valid for both wye and delta stator windings connections. To better predict the low-frequency deep-rotor-bar phenomenon, the VBR-II model is modified by assuming the speed-dependent variable rotor resistance $r_r(\omega_r)$ in the model equations. Based on the $qd0$ model equivalent circuit of Fig. 1 and considering the low-frequency deep-rotor-bar effect, the rotor flux linkages λ_{qdr} chosen as state-variables, can be expressed as

$$p\lambda_{qr} = -r_r(\omega_r)i_{qr} - (\omega - \omega_r)\lambda_{dr}, \quad (3)$$

$$p\lambda_{dr} = -r_r(\omega_r)i_{dr} + (\omega - \omega_r)\lambda_{qr}. \quad (4)$$

where p is the Heaviside's derivative operator d/dt , $r_r(\omega_r)$ is the variable rotor resistance as a function of rotor speed, ω is the electrical angular frequency of the arbitrary reference frame, and ω_r is the electrical angular frequency of the rotor. The rotor currents can be expressed in terms of rotor flux linkages and magnetizing flux linkages as [11]

$$i_{qr} = \frac{1}{L_{lr}}(\lambda_{qr} - \lambda_{mq}), \quad (5)$$

$$i_{dr} = \frac{1}{L_{lr}}(\lambda_{dr} - \lambda_{md}). \quad (6)$$

where L_{lr} denotes rotor leakage inductance. Replacing the rotor currents from (5)–(6) in (3)–(4), the final rotor state equation becomes

$$p\lambda_{qr} = -\frac{r_r(\omega_r)}{L_{lr}}(\lambda_{qr} - \lambda_{mq}) - (\omega - \omega_r)\lambda_{dr}, \quad (7)$$

$$p\lambda_{dr} = -\frac{r_r(\omega_r)}{L_{lr}}(\lambda_{dr} - \lambda_{md}) + (\omega - \omega_r)\lambda_{qr}. \quad (8)$$

In (7)–(8), the q - and d -axes mutual flux linkages are

$$\lambda_{mq} = L_m'' \left(i_{qs} + \frac{\lambda_{qr}}{L_{lr}} \right), \quad (9)$$

$$\lambda_{md} = L_m'' \left(i_{ds} + \frac{\lambda_{dr}}{L_{lr}} \right). \quad (10)$$

where L_m'' is defined as [13]

$$L_m'' = (L_m^{-1} + L_{lr}^{-1})^{-1}. \quad (11)$$

The stator flux linkages can be written in terms of stator currents and rotor flux linkages as

$$\lambda_{qs} = (L_{ls} + L_m'')i_{qs} + \frac{L_m''}{L_{lr}}\lambda_{qr}, \quad (12)$$

$$\lambda_{ds} = (L_{ls} + L_m'')i_{ds} + \frac{L_m''}{L_{lr}}\lambda_{dr}, \quad (13)$$

$$\lambda_{0s} = L_{ls}i_{0s}. \quad (14)$$

where L_{ls} denotes stator leakage inductance. Substituting the stator flux linkages from (12)–(14) into stator voltages equations in [13] gives,

$$\begin{bmatrix} v_{qs} \\ v_{ds} \\ v_{0s} \end{bmatrix} = r_s \begin{bmatrix} i_{qs} \\ i_{ds} \\ i_{0s} \end{bmatrix} + \mathbf{L}_{qd0}'' p \begin{bmatrix} i_{qs} \\ i_{ds} \\ i_{0s} \end{bmatrix} + \begin{bmatrix} \omega(L_{ls} + L_m'')i_{ds} \\ -\omega(L_{ls} + L_m'')i_{qs} \\ 0 \end{bmatrix} + \begin{bmatrix} e_q'' \\ e_d'' \\ 0 \end{bmatrix}. \quad (15)$$

where \mathbf{L}_{qd0}'' is defined as

$$\mathbf{L}_{qd0}'' = \begin{bmatrix} L_{ls} + L_m'' & 0 & 0 \\ 0 & L_{ls} + L_m'' & 0 \\ 0 & 0 & L_{ls} \end{bmatrix}. \quad (16)$$

In the CPVBR-II model, the sub-transient back-emf voltages in q - and d - axes are calculated as

$$e_{qs}'' = \frac{\omega_r L_m''}{L_{lr}} \lambda_{dr} + \frac{L_m'' r_r (\omega_r)}{L_{lr}^2} \left(\frac{L_m''}{L_{lr}} - 1 \right) \lambda_{qr} + \frac{L_m''^2 r_r (\omega_r)}{L_{lr}^2} i_{qs}, \quad (17)$$

$$e_{ds}'' = \frac{-\omega_r L_m''}{L_{lr}} \lambda_{qr} + \frac{L_m'' r_r (\omega_r)}{L_{lr}^2} \left(\frac{L_m''}{L_{lr}} - 1 \right) \lambda_{dr} + \frac{L_m''^2 r_r (\omega_r)}{L_{lr}^2} i_{ds}, \quad (18)$$

Transformation of (15) into abc phase coordinates by applying the inverse Park transformation matrix $\mathbf{K}_s^{-1}(\theta)$ gives the constant-parameter stator interfacing circuit model as follows

$$\mathbf{v}_{abc} = r_s \mathbf{i}_{abc} + \mathbf{L}_{abc}'' p \mathbf{i}_{abc} + \mathbf{e}_{abc}'', \quad (19)$$

where the transformed sub-transient back-emf voltage sources in abc coordinates are defined as

$$\mathbf{e}_{abc}'' = \mathbf{K}_s^{-1}(\theta) \cdot [e_{qs}'' \quad e_{ds}'' \quad 0]^T. \quad (20)$$

In (19), the constant-parameter inductance matrix \mathbf{L}_{abc}'' of the stator interfacing circuit is calculated as

$$\mathbf{L}_{abc}'' = \mathbf{K}_s^{-1}(\theta) \mathbf{L}_{qd0s}'' \mathbf{K}_s(\theta) = \begin{bmatrix} L_S & L_M & L_M \\ L_M & L_S & L_M \\ L_M & L_M & L_S \end{bmatrix}, \quad (21)$$

In (21), the self and mutual inductances of the stator interfacing circuit are defined as

$$L_S = L_{ls} + \frac{2}{3} L_m'', \quad (22)$$

$$L_M = -\frac{1}{3} L_m''. \quad (23)$$

The electromagnetic torque and electrical rotor speed equations can also be written as [13]

$$T_e = \left(\frac{3P}{4} \right) (\lambda_{md} i_{qs} - \lambda_{mq} i_{ds}), \quad (24)$$

$$p\omega_r = \frac{P}{2J} (T_e - T_m). \quad (25)$$

Finally, the CPVBR-II model [13] constitutes a rotor state-space model (7)–(10), (17)–(18), stator interfacing circuit (19), and mechanical subsystem (24)–(25). The implementation of the CPVBR-II model and its interfacing circuit for both wye- and delta- connected stator windings is shown in Fig. 2, where three-phase controlled voltage sources behind three-phase RL branches representing stator interfacing circuit are used to enable its direct interface with an arbitrary external network without shunt snubbers. The stator currents in CPVBR-II model are selected as inputs to the rotor and mechanical subsystem to calculate the sub-transient back-emf voltages in abc coordinates, as inputs to controlled voltage sources. This model utilizes two three-phase switches “1, 2” to re-configure the machine stator windings connections into either Y or Δ in the run-time. For example, closing of the three-phase switch

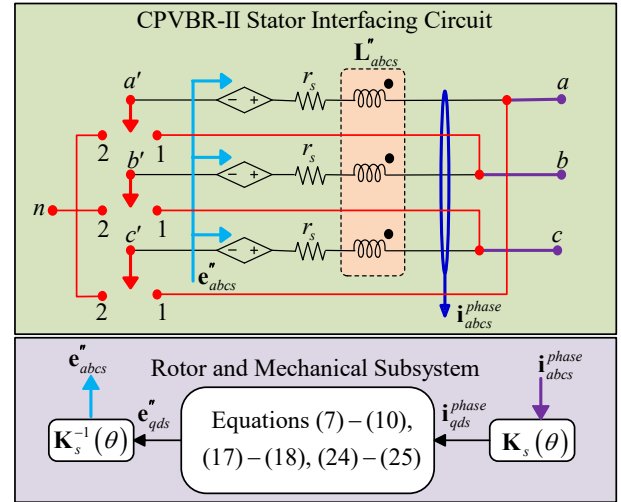

Fig. 2. Implementation of CPVBR-II model of a three-phase squirrel-cage induction machine for reconfigurable wye- and delta-connected stator windings.

Fig. 3. The test system consisting of a three-phase squirrel-cage induction machine connected to a power grid through power cables: (a) Wye-connected machine, and (b) Delta-connected machine.

“2” connects the stator winding terminals (a' , b' , c') to terminal points (2), consequently resulting in Y-connected IM configuration and vice versa.

III. SIMULATION STUDIES

To validate the simulation results and numerical performance of the considered models, a simple case system depicted in Fig. 3 is considered. Herein, a 460V 50hp squirrel-cage induction motor with either wye- or delta-connected stator windings, is connected to the power grid (represented by ideal voltage sources \mathbf{e}_{abc}^g) through power cables (represented by r_{line} and L_{line}). The system parameters are summarized in Appendix.

For the purpose of accuracy and efficiency comparison, both the classical qd and the proposed CPVBR models considering the deep-rotor-bar phenomenon, have been implemented and simulated in MATLAB-Simulink software. The models were solved using *ode3* fixed time-step solver (with different time-steps), and also *ode45* and *ode23tb* variable time-step solvers (with absolute and relative tolerances set to 10^{-4}). Synchronous reference is used in all subject models. Due to the qd model's indirect interface with external inductive or switching circuits,

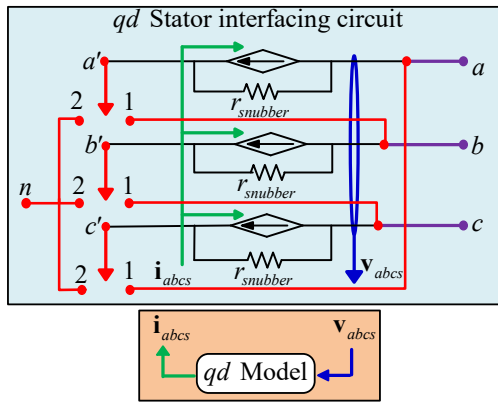

Fig. 4. Implementation of *qd* model of a three-phase squirrel-cage induction machine for wye-connected and delta-connected stator windings.

the shunt resistive snubbers of 982Ω (corresponding to 100pu) are considered to limit the solution error to 1% for the *qd* model. The interfacing circuit of *qd* model for both wye- and delta-connected stator windings is shown in Fig. 4, where three-phase controlled current sources connected in parallel with snubber resistors are used to obtain its compatible interface with external inductive or switching power networks. For consistency, all simulations have been run on a PC with Intel® Core™ i7-10750H @ 3GHz processor.

A. DOL Starting of Delta-connected Motor

In this study, the squirrel-cage induction motor with delta-connected stator windings is assumed to start from zero initial conditions under nominal operating voltages. The configuration of this study is shown in Fig. 3(b). A no-load start-up transient study followed by a load torque change is simulated for 4 s. At $t = 2$ s, the step change in load torque from zero to 198 Nm is applied to the machine, and the simulation is run until 4 s. Fig. 5 presents the transient responses of several variables obtained by the subject models. As it can be observed in Fig. 5, the CPVBR-II model and the *qd* model are consistent, and both accurately predict the system’s transient and steady-state response. Also, for better clarity and comparison purposes, the magnified plots of selected variables from Fig. 5 are depicted in Fig. 6.

In the considered study, the machine’s stator windings are energized from a three-phase voltage source with the phase-phase voltage of 460V, so the rotor of the machine begins to accelerate from a standstill to reach a steady-state speed. As it was observed in Figs. 5–6, the starting inrush current and torque pulsations are significant, which consequently causes voltage dip across the machine terminals. During the start-up, the voltage dip level reaches to about 15% and it recovers approximately at $t = 0.8$ s when the motor reaches steady-state. Then, as a result of a step-change in load torque at $t = 2$ s, the machine establishes a new operating condition as illustrated in Figs. 5–6. Finally, it is deduced from the simulation results that starting squirrel-cage IMs in delta-connected stator windings will give poor starting performance in terms of high starting inrush currents, increased voltage dips, and increased stresses on power utility equipment during their start-up, which may lead to power system instability.

Fig. 5. Transient response of system variables of Δ -connected IM as obtained by the subject models during start-up followed by a load change: (a) $v_{ab, line}$, (b) $v_{ag, phase}$, (c) $i_{as, line}$, (d) $i_{as, phase}$, (e) w_m , and (f) T_e

Fig. 6. Magnified plots of selected variables during start-up of Δ -connected IM: (a) RMS line voltage $v_{ab, rms}$, (b) line current $i_{as, line}$, and (c) electromagnetic torque T_e

It is worth mentioning that the new CPVBR-II model with low-frequency deep-rotor-bar-effect has been verified against the *qd* model with the low-frequency rotor-bar-effect. The inclusion of the deep-bar-rotor effect in the subject models

produces more accurate simulation results during starting transient and steady-state periods, as has been demonstrated in [14]. While the models without deep-rotor-bar effects, will consequently result in incorrect estimation of stator-currents and steady-state speed [14].

B. Wye/Delta Starting of SCIM

In this study, the wye-delta starting of the squirrel-cage induction motor is demonstrated. This method allows the motor to operate in wye configuration as shown in Fig. 3(a), at reduced operating voltages (generally by $1/\sqrt{3}$). This leads to reduced power and inrush currents during start-up. Then, after some time, the motor is switched into delta-configuration. A no-load start-up transient study followed by wye-delta switching and load torque step change is simulated for 4 s. At $t = 2$ s, the stator winding configuration is switched from wye- to delta-connection resulting in switching transients. Then, at $t = 3$ s, a step-change in load torque from zero to 198 Nm is applied to the machine and continued to run until 4 s. The transient responses of selected variables obtained by the subject models are demonstrated in Fig. 7. For comparison purposes, the magnified views of selected variables from Fig. 7 are also shown in Fig. 8.

During this study, the machine’s stator phase windings are initially energized from a voltage of $460/\sqrt{3}$ V, due to which

Fig. 7. Transient response of system variables of Y-Δ starter-based IM as obtained by the subject models during start-up followed by Y-Δ switching and load change: (a) $v_{ab, line}$, (b) $v_{ag, phases}$, (c) $i_{as, lines}$, (d) $i_{as, phases}$, (e) w_m , and (f) T_e

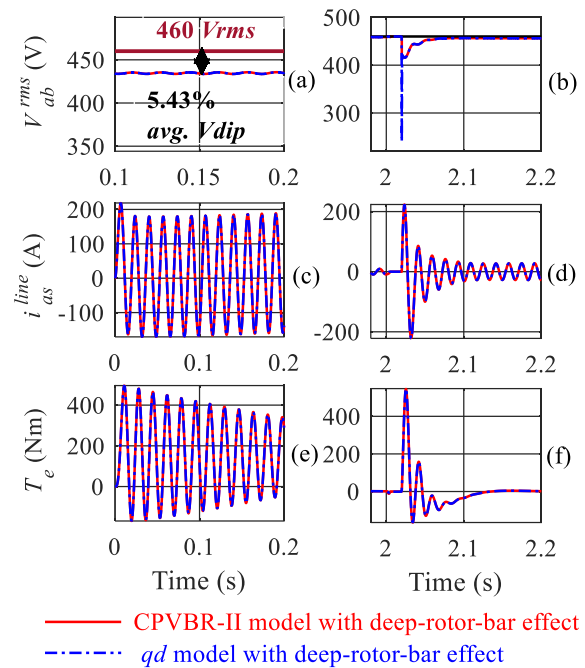

Fig. 8. Magnified views of selected variables under: (1) wye- connected IM starting condition and (2) Y-Δ switching transition

motor starts to accelerate from standstill to steady-state. As observed from Figs. 7–8, the machine draws lower starting inrush currents, produces lower torque pulsations, and has a slower dynamic response as compared to the delta-connected study in Figs. 5–6. This happens due to a reduction in operating voltages across the stator phase winding terminals. Consequently, it improves the motor starting by reducing starting inrush currents flowing through stator windings, and also, reducing the voltage dips across the machine terminals. For our case, the voltage dip is now reduced to about 5.43%, which is in the appropriate range. This voltage dip is cleared after $t = 1.8$ s once the steady-state condition is reached.

After reaching the steady-state operating condition, the stator winding configuration is switched from star to delta causing switching transients in the system which vanishes quickly. It is worth noting that this open transition star-delta switching causes voltage dips, currents spikes, and torque surges, which sometimes may become much worse depending on the switching time and loading condition, consequently leading to failure of power system operation. Therefore, for safe operation, a small switchover transition delay of 20ms is introduced due to which star-connection switches open at $t = 2$ s and delta connection switches close at $t = 2.02$ s resulting in switching transients and voltage dip of 9.78% for CPVBR-II model which is within an acceptable range and cleared in very short time duration. Then, at $t = 3$ s, a load torque of 198 Nm is applied to the machine causing it to establish a new operating condition.

It is also seen in Figs. 7–8, that the proposed CPVBR model and the qd model produced consistent results. However, the qd model produces a deviation in predicting voltage dips due to interfacing error introduced by 1% of current flowing through the snubbers.

C. Computational Performance

Although the considered models produce consistent and matching simulation results, their computational properties are quite different. The computational performance of the subject models simulated using both fixed- (*ode3* solver) and variable-time-step solvers (non-stiff *ode45* and stiff *ode23tb* solvers) are summarized in Tables I, and II. It is observed in Table I, II that CPVBR possesses better-scaled eigenvalues and a lower stiffness ratio as compared to the *qd* model. As seen in Table I from results obtained using the non-stiff *ode45* solver, the CPVBR model is computationally more efficient than the *qd* model in terms of faster simulation speed (3.4 s vs 264.2 s), fewer steps (13177 vs 3122687) and larger average time-step size (258 μs vs 84.6 μs).

Since *qd* model becomes numerically stiff due to shunt snubbers, so it can be observed in Table I that when it is simulated with the stiff *ode23tb* solver, the computational burden is reduced significantly by allowing smaller steps (38418) and CPU time (7.6 s) for the same 4 s transient study. However, the CPVBR model using *ode23tb* solver, still works faster than the *qd* model in terms of much smaller steps (16543 vs 38418) and CPU time (3.5 s vs 7.6 s) due to its lower numerical stiffness.

As observed in Table II from the results obtained using fixed time-step solver *ode3*, the *qd* model is only capable of producing results at smaller time steps. However, it yields a faster simulation speed (90.8s vs 333.9s) when run using fixed time-step solvers at a very small time-step as compared to the CPVBR model. The CPVBR model works slower due to the use of snubber resistances in the switches for both subject models for fixed-time step study. The CPVBR model still has the advantage of running with larger time steps using fixed time-step solvers. This is particularly advantageous for large-scale power system studies where it is desirable to run the simulation with larger time-steps.

Finally, it is deduced that the proposed CPVBR model possesses excellent numerical properties and simulation performance, while accurately predicting the waveforms for several variables. The *qd* model produces a deviation in simulation results due to interfacing error and small currents

flowing through the snubbers leading to reduced numerical efficiency and accuracy.

IV. CONCLUSION

This paper presented a reconfigurable star-delta starter CPVBR model for a three-phase squirrel-cage induction machine. The new model also considers the low-frequency deep-rotor-bar phenomenon by utilizing linear approximation for a speed-dependent equivalent rotor resistance. The new model accurately predicts the transient and steady-state responses under star-delta switching transitions, and also remains valid for both wye- and delta-connected configurations. The computer studies validate the improved model and demonstrate that it offers superior numerical performance even at larger time-steps as compared to the conventional *qd* model. It is envisioned that this model can be extensively utilized in the many EMT simulators for efficient and accurate simulations of large-scale power systems employing several induction machines with star-delta starters.

Abstract—Power system fault type classification and location prediction is critical in assessing the reliability of the power system, and later restoring it to a stable operating point followed by a fault. State of the art methods include sequence component, impedance measurement from the origin of the fault, and traveling wave based methods for fault type detection and classification problem. It is important to identify and classify the fault as quickly as possible for restoring power system stability to normal operation. Machine Learning and Deep Learning methods allow the analysis of large data of fault voltages and currents by using fast and efficient algorithms. These methods require large amount of data, however, with the recent advances in the field of power system, data acquisition using smart meters and Phasor Measurement Units (PMU), huge amount of system-wide data can be made available to analyze the problem of fault type classification and location prediction. This paper presents a comparative study of Stochastic Gradient Descent (SGD) based Deep Neural Network (DNN) and Machine Learning (ML) applied to power system fault type and location prediction problem. DNN architecture uses 10 hidden layers, each layer having 60 units with hyperbolic tangent as activation function, and a combination of Support Vector Machine (SVM) and Principal Component Analysis (PCA) method are considered. Comparative results in terms of time taken to run the algorithms, and accuracy of the results obtained are presented for a 3 machine 9 bus system. Results indicate that SVM method is an optimal choice for fault classification with high accuracy for location prediction and low computational requirements compared with DNN.

I. INTRODUCTION

An increase in the deployment of devices such as smart meters, and phasor measurement units in the power system to monitor and collect the system wide data is critical to improve the stability and reliability of the system. The data collected from these devices is generally of high dimension and need to be analyzed. Machine learning methods are good choice for analyzing this large amount of data as they are fast and accurate. Deep Learning (DL) is subset of ML and

they can approximate highly non-linear complex functions by increasing depth of the network. But as the network is more and more deep, computational burden will increase. On the contrary ML methods involve less computational burden compared to DL methods but they may suffer accuracy for highly non-linear problems. To choose an optimal algorithm among ML and DL, a comparative study is carried out for a fault classification problem of a small scale 3 machine 9 bus power system. The most widely used ML algorithm for analysis of such high dimensional dataset is SVM and PCA also known as dimensionality reduction technique. These are closely related and mostly used on a dataset containing high dimensional data matrix and converts it to some useful dataset containing less number of features (Principal Components in PCA), while at the same time preserving the variance in the original dataset. Another method to analyze the high dimensional dataset is to use the DL based techniques. Both ML and DL based techniques have certain advantages and disadvantages. For example, ML based techniques requires lesser amount of data and time to train whereas the DL require higher amount of data and time to train. However, DL based method does not require any feature extraction procedure which is generally required for ML based methods. State of the art research has proposed many methods for fault classification problem [1-6]. An S-transform based Decision Tree (DT)-Fuzzy rule approach is proposed for fault classification in [7]. In this method, S-transform is used for extracting features, DT for primary classification and then based on obtained DT decision boundaries, fuzzy membership function is developed for final classification. Machine learning methods like bagging, boosting, radial basis function and naïve Bayesian are used for power system fault type and location prediction in [8]. As these methods are validated on Single Machine Infinite Bus (SMIB) system, their applicability can't be generalized to multi-machine systems. SVM based fault classification methods are proposed in [9-11]. In [9], authors proposed combination of two SVM algorithms for fault classification. SVM-1 will determine the involvement of particular phase where as SVM-2 will determine the involvement of ground in

the fault. This method is complex as it involve running of two algorithms and also dimensionality reduction technique like PCA is not used. In [10-11], authors proposed the combination of wavelet transform and SVM where in the former method uses fault current features and the later method uses phase angles as input features. PMU measurements based fault detection method considering the effect of communication network delays on fault detection time is proposed in [12]. Symmetrical component technique along with PCA is used in [13] which uses quarter cycle of phase current for fault detection. With the increase of computational power and availability of large data, application of DL methods in power system gained importance and a DL based power system fault classification and location prediction is proposed in [14-16].

This paper compares the performance of both the ML (combination of SVM and PCA based technique) and DL techniques to address a very important problem of fault classification and location detection in power system network. A benchmark 3 machine 9 bus test system is designed and data is collected which mainly consists of the three phase voltages and currents for various types of fault and their locations. Both the DL and ML methods are then trained on this dataset. Later, a comparative analysis is presented to show the performance of both these methods to identify the fault type and location using precision, recall, F1-score, and time taken. The rest of the paper is divided in the following sections. Section II describes the SVM and PCA methods for Power System (PS) fault classification and location prediction; section III describes the stochastic gradient descent based Deep Learning method. Section IV describes the simulation results of 3 machine 9 bus test system and the procedure for data collection. It further describes and compares the results obtained from both the ML and DL techniques on fault type classification and fault location identification followed by conclusion in Section V.

II. SVM AND PCA BASED METHODS FOR PS FAULT CLASSIFICATION AND LOCATION PREDICTION

One of the most influential approaches to supervised learning is SVM, since it provides decision boundaries with large margins; it tends to have lower generalization errors and is less prone to over fitting. Another advantage of SVM is, we need only a small number of samples. It can easily be kernelized (Linear, RBF, Poly, Gaussian, etc.) to solve non-linear classification problems which allows us to learn models using convex optimization techniques that are guaranteed to converge efficiently. Although the PCA and SVM are commonly used in pattern recognition, an effective methodology using both the PCA and SVM for fault classification remains unexplored.

This study proposes a novel framework combining both of these algorithms and coming up with a classifier system which is much more versatile, reliable and is effective in fault classification. It employs a feature-based scheme that integrates PCA with an SVM for effectively detecting patterns in the system. The detailed explanation of the algorithm as well as the implementation technique is explained in the subsequent

sections. Support vectors is one of the most widely used clustering algorithms for unsupervised or unlabeled data. Since the dataset obtained by modeling three machines and nine bus system is highly nonlinear, the Radial Basis Function (RBF) kernel is used for representing the decision boundary in hyper plane for nonlinear data matrix. Taking accuracy into account, RBF kernel gives better performance rate compared to linear or polynomial kernels. RBF classifier is a class of functions which can basically be implemented with linear as well as non linear models with any kind of network considering single layered or multilayered. It is classified as non linear network where the basis function can be changed or adjusted, basically used for linearly non-separable features. An RBF function makes it easier to create the complex decision boundaries having high dimension (even infinite dimensional) features. RBF kernel looks similar to Gaussian kernel except for $\frac{1}{2\sigma^2}$ replaced by γ . For a non-linear feature matrix RBF kernel considering two data points $x^{(i)}, x^{(j)}$ can be represented as

$$\phi : x \rightarrow \varphi(x) \quad (1)$$

$$K(x^{(i)}, x^{(j)}) = \phi(x^{(i)})^T \phi = \exp(-\gamma \|x^{(i)} - x^{(j)}\|^2), \gamma > 0 \quad (2)$$

Where $x^{(i)}, x^{(j)}$ are the two data points

$\|x^{(i)} - x^{(j)}\|$ represents the Euclidean distance between $x^{(i)}, x^{(j)}$

equation(1) is mapping into higher dimensions.

γ , gamma represents the spread of the kernel function.

Since many functions are available in the Scikit-learn library, the kernel functions need not to be estimated manually. The value of $\gamma (> 0)$, represents the spread of the kernel function and hence the decision boundary. Having lower values for γ may result in under fitting while keeping higher values can cause over fitting. C (Regularization parameter) is defined as a parameter for SVM learner which trades off correct classification of training examples against maximization of the decision function's margin, having small values of C depicts high bias and low variance (Under fitting) while the larger values represents low bias and high variance (Over fitting). Thus, an optimal value of γ and C is determined using grid search algorithm which allows us to select from a proper range of values for each hyper parameter to increase the solution in hyper plane. Using a hybrid combination of both of these algorithms can therefore improve the overall performance of the discussed fault classifier algorithm. The number of features to be extracted as PCs can be determined by various methods. The proposed scheme evaluates the cumulative variance so as to attain nearly 80% of the variability in the data to determine the components. The procedure involved in PCA includes the estimation of covariance matrix $X^T X$ where, X is the $m \times n$ data matrix. The covariance matrix can be calculated as

$$Cov(X) = \frac{1}{n} (X - \bar{X})(X - \bar{X})^T \quad (3)$$

Where, \bar{X} is the mean of n dimensional dataset. It also includes the calculation of Eigen vectors and Eigen values representing

the direction and magnitude of the features in the multidimensional plot. The magnitude therefore represents the importance of respective vectors in the final estimation of classifier algorithm. The system is trained with the obtained labelled dataset to recognize the fault patterns. The complete schematic of the proposed algorithm is given in the Fig.1. Scikit learn is used, importing all the useful libraries, since it provides built-in library functions for the defined algorithms. Instead of simply using test and train dataset, 4-fold cross validation

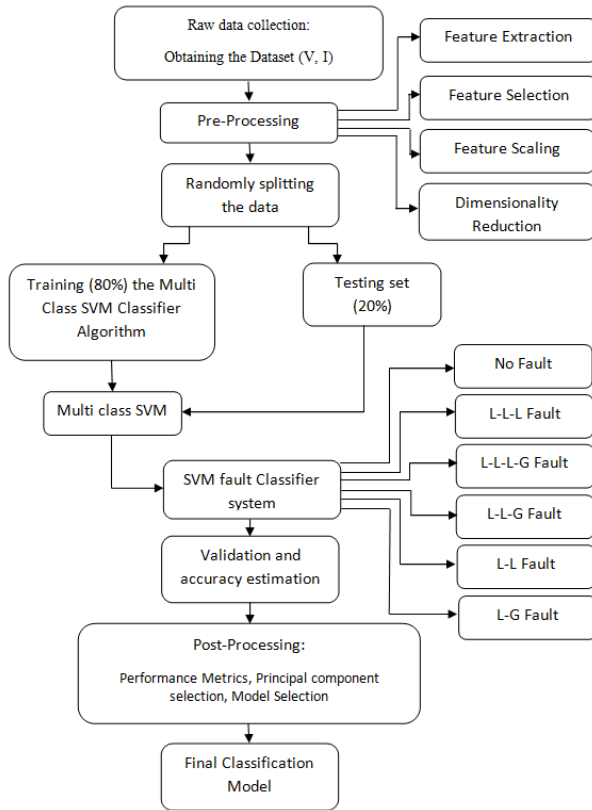

Fig. 1. Proposed Hybrid ML classifier algorithm.

is used resulting in better training and classification of the unforeseen dataset which therefore increases the effectiveness of the classifier algorithm with limited data. The basic aim of k-fold cross validation is to randomly divide the complete data into k different non overlapping subsets where each of these is used to train and rest is used to validate the classifier system and simultaneously recording the accuracy scores.

III. SGD BASED DL METHOD FOR PS FAULT CLASSIFICATION AND LOCATION

DL system performance can be enhanced mostly by three approaches. Firstly, by improving the structure of the model. Secondly, by improving the model initialization, and thirdly by trying more powerful learning algorithm. This paper chose the third option to enhance the model performance. Gradient descent methods are core of deep neural network learning algorithms. These are mainly two types;

- Batch gradient methods

- Stochastic gradient methods.

Batch gradient descent methods are very slow and require more memory as we need to calculate the gradients of whole dataset to perform just one update towards the optimal solution. SGD based optimizers are of core practical importance in the field of DL. SGD proved itself as an efficient and effective optimizer in many machine learning techniques and recent advances in deep learning [17-18].

A. Root Mean Square Propagation (RMS Prop)

‘RMS Prop’ is an adaptive learning rate method proposed by Geoff Hinton. It uses the sign of the gradient and divides the learning rate(α) by an exponentially decaying average of squared gradients. Following are the update rules of weight (W) and bias (b) parameters in ‘RMS Prop’ algorithm;

$$S_{dw}^t = \beta S_{dw}^{t-1} + (1 - \beta)dW^2 \quad (4)$$

$$S_{db}^t = \beta S_{db}^{t-1} + (1 - \beta)db^2 \quad (5)$$

$$W^t = W^{t-1} - \alpha \frac{dW}{\sqrt{S_{dw}^t}} \quad (6)$$

$$b^t = b^{t-1} - \alpha \frac{db}{\sqrt{S_{db}^t}} \quad (7)$$

Where $S_{dw}^t, S_{db}^t, S_{dw}^{t-1}, S_{db}^{t-1}$ are average of squared gradients of weight and bias terms respectively at iteration t and (t-1). dW, db , are change in weight and bias terms and α, β are hyper parameters. The default values of α, β are 0.001 and 0.9 respectively. $W^t, b^t, W^{t-1}, b^{t-1}$ are updated weight and bias terms at iteration t and (t-1) respectively

IV. EXPERIMENTAL RESULTS

A. Test System & Data Collection

Fig. 2. IEEE 9 Bus system simulated in MATLAB-SIMULINK.

IEEE 3 machine 9 bus system is taken as test system for the application of proposed method. MATLAB & SIMULINK

is used to simulate the test system shown in Fig.2 and the respective data is collected. Each fault case is simulated using a 3 phase fault block in SIMULINK library and all three phase voltages and currents are recorded at both from-Bus and to-Bus. A sample size of 100 points is collected for each simulation experiment and the data is accumulated for all fault case experiments. The collected data is then processed with python scripts using PANDAS library. Transmission line parameters used for the simulation experiment are shown in the Table I. There are 3 generators, each having terminal voltage of 17.16kV,18.45kV, and 14.145kV respectively at 50Hz. Transmission voltage level is 230kV which is also taken as base voltage and 100MVA is taken as base MVA for per unit conversion of parameters. All fault cases are mainly classified in the following four categories:

- L-G Fault
- L-L Fault
- L-L-G Fault
- L-L-L Fault

TABLE I
TRANSMISSION LINE PARAMETERS OF IEEE 9 BUS SYSTEM

Line		R(p.u/m)	X(p.u/m)	B(p.u/m)

5	7	0.0320	0.1610	0.3060
6	9	0.0390	0.1738	0.3580
7	8	0.0085	0.0576	0.1490
8	9	0.0119	0.1008	0.2090

Fig. 3. Line to Ground (LG) fault simulated at Bus 6.

For location prediction problem, the transmission line 4-6 is segmented in 10 equal parts. Various fault experiments are carried out with different fault resistances $R_f = 0.1, 0.1, 1, 10, 100$ ohms. Fig.3 illustrates the voltage and current waveforms when a single phase (L-G) fault is applied at bus 6. A window of 1 cycle data starting from the fault inception time is taken

Fig. 4. Line to Line (LL) fault simulated at Bus 6.

Fig. 5. Double Line to Ground (LLG) fault simulated at Bus 6.

Fig. 6. Triple Line (LLL) fault simulated at Bus 6.

for preparing the dataset. Similarly Fig.4 represents voltage and current waveforms during line-line fault at bus 6. Fig.5 illustrates the current and voltage waveforms when line-line-ground (LL-G) fault is applied. Fig.6 illustrate the current and voltage waveforms during triple line (L-L-L) fault. From Fig.6, it can be observed that even though the triple line fault occurrence is very rare, it impacts the system severely.

B. Training of ML and DL models

The data collected from MATLAB-Simulink is processed and labeled using python script. The processed dataset is then shuffled to avoid biasing problem. Total dataset is split in two parts, 70 % for training and 30 % for testing. Training and testing of model are performed on a CPU with i5 processor, 8GB RAM. Jupyter Notebook is used as python script editor and it also includes Google’s TensorFlow library for working on DNN, ML algorithms.

C. Fault Type Prediction–SVM and PCA

The proposed hybrid algorithm uses PCA as a metric for ranking features in the data space based on the variance prior to classifying faults for each of the ten class pairs by analyzing the Eigen values and Eigen vector distribution. SVM is a robust technique in full feature dimension and is here incorporated with PCA to utilize the efficiency of both the techniques. The best parameters for C and gamma for SVM with radial basis function kernel is obtained using Sklearn and is applied by fixing the number of principal components. The parameters are chosen so as to avoid over fitting and

Fig. 7. Variance plot- Fault Type(ML).

less prediction errors. Also, the process is repeated with varying components. Each of these calculations is done on 4-fold cross-validation with the specified classifier system. Fig.7 shows the variance plot with respect to the varying Principal Components (PCs) for determining the fault type in electrical system. It can be observed that there is no significant variation as we move from 6 to 7 PCs. Therefore, only 6 PCs is enough to retain the variance of the complete dataset. The obtained confusion matrix as well as the precision, recall, F1-score and support is given is Fig.8 and Table II. For example, the asymmetric fault type from line C to line A, it is predicted as

high as 62 times correctly while for 6 times it is predicted as CAG fault. And therefore the recall is 1.0 while the precision came out to be 0.8. The F1 score became 0.9.

Fig. 8. Confusion Matrix- Fault Type (SVM with PCA).

TABLE II
CLASSIFICATION SCORE-FAULT TYPE(ML)

	Precision	Recall	F1-Score
AB	0.8	0.69	0.74
ABG	1	0.91	0.95
BC	1	1	1
BCG	1	0.97	0.99
CA	0.8	1	0.89
CAG	0.97	0.96	0.97
AG	0.99	0.95	0.97
BG	0.76	0.78	0.77
CG	0.72	0.79	0.75
ABC	1	0.93	0.96
Average	0.9	0.9	0.9

The accuracy rate with varying PCs can be observed from the Table III. The efficiency of the hybrid algorithm in predicting the type of faults with only 5 PC is nearly 89%, which gives a sense that 5 of the components account for all the multivariate variability. The first component accounts for 40%variability while the second component accounts for 36%variability of the overall data space. The average time for processing the hybrid algorithm to predict fault type is 0.95 seconds, which is obtained after sampling the voltages and currents from the corresponding bus within two cycles for each of the fault resistance values.

D. Fault Location prediction –SVM and PCA

The complete electrical system is divided into ten equal parts based on location of faults and is classified into various classes which are used as the dataset to train, validate and test the system using hybrid classifier algorithm. The features are extracted using PCA and the classification is done for different fault case to train and test these PCs over SVM based classifier. The accuracy is computed considering different number of components based on the PCA and simultaneously applying SVM. Fig.9 shows the variance plot with respect

TABLE III
TYPE PREDICTION REPORT USING SVM AND PCA

S.No	PCs	Variance ratio	Accuracy(%)

Fig. 9. Variance plot- Fault Location.(SVM and PCA).

to the varying principal components for determining the fault location. It is observed that the variance decreases as we go on moving from one principal component to the last one depending upon the importance of the given feature. The

Fig. 10. Confusion Matrix- Fault Location (SVM with PCA)..

variance and proportion of variance contributed by each of the given feature is used to determine the number of PCs to be retaining the properties of the dataset. The principal components are selected based on the significant cumulative variance proportion. It can be clearly seen that the variance

nearly saturates with 5 to 6 components. And hence, only 6 PCs are sufficient to analyze the fault location with minimum variation in prediction efficiency. Henceforth, from the Table IV, the accuracy attained with six principal components is seen to be nearly 76%. Comparably, considering 9 PCs would enable the accuracy as high as 85%. The variance ratios and the accuracy rate are tested with varying number of PCs to analyze the versatility of the classifier system. The proposed framework, which employs a feature-based PCA algorithm and incorporates SVM classification, provides the accuracy rate of nearly 86%. Also, predicting the location of fault using feature based scheme with SVM takes about 1.4 seconds. Table.V depicts the accuracy attained using machine learning classifier algorithm. Fig.10 shows the confusion matrix of classifier for location prediction task.

E. Fault Type prediction –DNN

Fig. 11. Training accuracy of RMS Prop DL model-Fault type.

Fig. 12. MAE of RMS Prop DL model-Fault type.

Fig. 13. Confusion matrix- Fault type(DL).

Fault types are mainly classified into 10 types and are encoded as binary numbers to classify using softmax classifier. The DNN model is trained for 200 iterations on training dataset and then tested with test dataset. Fig.11 shows the model training accuracies of RMSProp DL learning algorithm against number of iterations. Mean Absolute Error (MAE) is taken as the performance metric for the model. From Fig.12 it is observed that after 175 epochs, the MAE is not considerably reducing therefore the number of epochs is limited to 200. Fig.13 shows the confusion matrix of DL based classifier for fault type prediction task. It can be seen that for 116 test points, 88 times the double line fault between A & B phases is correctly predicted but for 18 times, double line fault between A and B phases is incorrectly predicted as line to ground fault between C phase and ground. Therefore, in Table VI, the recal corresponding to AB fault suffers.

F. Fault Location prediction – DNN

Fault locations are categorized in 9 parts starting from 10% of the length of transmission line to 90 % of the line. The DNN model is trained for 500 iterations on training dataset and then tested with the test dataset. Fig.14 , Fig.15 shows the accuracy and MAE plots for fault location model. Fig.16 shows the confusion matrix for fault location prediction. It

can be seen that for 85 test points, fault at 0.4 times the length of the line is correctly predicted but for 22 times, it is incorrectly predicted as fault at 0.3 times the length of the transmission line. Therefore in Table VII, the precision corresponding to 40% fault suffers. Similar conclusion can be drawn for the 20% fault location as well. But for the remaining fault locations the precision is close to 0.8 and 0.9. From Table VIII, it is observed that for fault type classification problem the model accuracy is 94 % with mean absolute error 0.0118 whereas the location prediction model accuracy is 82 % with mean absolute error 0.0483.

TESTING ACCURACY & MAE OF TWO CLASSIFIERS- DNN

	Type Classification	Location Classification
Accuracy	93.79	82.15
MAE	0.0118	0.0483

G. Comparison of ML and DNN for PS Fault Type & Fault Location prediction

From Table IX, it is observed that fault type prediction accuracy is slightly higher for DL method when compared to that of with ML method whereas the location prediction accuracy is high for ML method when compared to that of with DL method. However, for the given test system, the model training times are significantly low for ML methods compared to the DL method, therefore they can easily be deployed onto real time fault detecting circuits.

TABLE IX
COMPARISON OF ML & DL METHODS

	DL Method RMSProp (Accuracy in %)		ML Method SVM with PCA(Accuracy in %)	
	Type Prediction	Location Prediction	Type Prediction	Location Prediction
	94	82	90	86
Model Training Time	105 sec (200 epoch)	230 sec (500 epoch)	0.95 sec	1.4 sec

V. CONCLUSION

Analysis and results demonstrated that machine learning method dominates with high accuracy of location prediction and low model training time. As ML method has low execution time, it can be easily deployed on to an embedded target for real time fault detection. Also location prediction is more critical in fault-clearing process when compared to the type prediction. Therefore in small scale electrical system, the proposed ML method can predict the fault with a much higher accuracy rate and provides an efficient fault selection technique which is proved to be faster, reliable and is more efficient than the traditional selector modules.

Abstract—Transportation facilities are becoming more developed as society develops, and people’s travel demand is increasing, but so are the traffic safety issues that arise as a result. And car accidents are a major issue all over the world. The cost of traffic fatalities and driver injuries has a significant impact on society. The use of machine learning techniques in the field of traffic accidents is becoming increasingly popular. Machine learning classifiers are used instead of traditional data mining techniques to produce better results and accuracy. As a result, this project conducts research on existing work related to accident prediction using machine learning. We will use crash data and weather data to train machine learning models to predict crash severity and reduce crashes.

Index Terms—Accident, Machine Learning, Predict, United States

I. INTRODUCTION

The Association for Safe International Road Travel showed around 37000 persons die in automobile accidents each year, with another 2.35 million wounded or incapacitated by car accidents. Children under the age of 15 were responsible for 1600 deaths, while approximately 8000 persons between the ages of 16 and 20 were killed in automobile accidents [1]. As a result, vehicle accidents have become a societal hazard and one of the four leading causes of mortality in the metropolitan population. Every year, traffic accidents cost citizens hundreds of billions of dollars. Most of the losses were caused by a few big incidents. The purpose of major accident prevention is to avoid potentially hazardous road conditions. We can take appropriate actions and better manage financial and human resources if we can identify the primary reasons for catastrophic accidents. This case study’s data is a nationwide accident data collection encompassing 49 states in the United States. From 2016 to 2020, there will be 1.5 million road accidents.

A. Problem Statement:

The goal of this paper is to conduct a statistical analysis of the data, investigate the states with the most accidents, investigate when accidents are most likely to occur and the weather conditions at the time of accidents, and create a visual display: summarize and analyze the information, tell the overall situation of accidents in the United States, and discover the factors influencing the occurrence and severity of accidents; finally, the severity of the accident is predicted and evaluated.

B. Significance:

This research studies the current state of road accidents in the United States and offers recommendations for reducing the number and severity of accidents based on several data parameters. We shall examine this data from many perspectives. First, examine the distribution of accidents in the United States based on geography. Second, from a time perspective, examine the period of concentrated accidents and the volatility of total accidents in recent years. Next, the weather dimension is used to examine the diverse effects of various meteorological elements on severity. Finally, analyze the POI variables that may be easily increased and decreased to raise and decrease the accident rate from the POI dimension, and give appropriate adjustment suggestions. As a result, in this study, we will utilize Python’s panda module to evaluate and comprehend if current road accidents in the United States are rising or decreasing year by year, as well as which period is the peak period during which traffic accidents are most likely to occur. A simultaneous accident is a severe type of accident. Most of the accidents happen in either good or bad weather. We can clarify the causes of road

accidents and minimize the accident rate based on the findings of these data analyses.

C. The Reason For Using Big Data Solution:

Road safety has become a key focus of current social concerns as the number of traffic accidents has increased. The location of the accident, the time of day, the driver's emotions, the weather, and other unpredictable and complicated elements all play a role in road accidents [2]. As a result, the correlation between data from various components of the car accident data must be investigated. Understanding the factors that impact vehicle accidents and forecasting car accidents through data analysis can help reduce the number of fatalities and injuries. As a result, fast and accurate data collection, rapid analysis, and the creation of appropriate models have become critical requirements for big data traffic accident investigation.

II. LITERATURE REVIEW

Researchers used meta-analysis to assess the impact of bad weather on accident rates, demonstrating that weather has an impact on traffic safety. Extreme weather in the United States, according to the study, will have an impact on injuries and automotive accidents, notably on wet and snowy days, with the average percentage of collision rate on rainy and snowy days being 71 percent and 84 percent, respectively [3]. The severity of traffic accidents was assessed and forecasted using K-means clustering. This study compared the performance of two machine learning applications, random forest (RF) and Bayesian additive region trees (Bart), to investigate alternative machine learning approaches for predicting the severity of traffic accidents. It is discovered that, when compared to the prediction of the Bayesian additive region trees (Bart) model, the random forest (RF) model with meteorological circumstances has a greater prediction probability in estimating the severity of a traffic collision. The variable importance technique reveals that the mode of traffic accidents and weather circumstances are two major factors that might give significant information in the modeling and estimating processes [4].

Their study analyzes data from 50 states to discuss traffic accident patterns and causes, as

well as what can be done to prevent them, for US government agencies and the general public. Several variables that related to the severity of the accident were examined and analyzed using logistic regression [5].

Their analysis includes the number of accidents by year, number of accidents by state, the best time to travel by month, day, and hour, accident-prone areas in each state, factors that cause accidents such as weather, wind flow, temperature, location, and so on, deaths in each state, age groups of fatalities, drivers involved in accidents, drivers age groups, vehicles involved in accidents, and drivers who have consumed alcohol. Tableau was used to create the analysis platform. [6]

Another study tries to address this issue and go deeper into the elements that contribute to the rise in the number of car accidents. The data used in this study was collected constantly in the United States from 2016 to 2020 from traffic accident incidents captured by the Department of Transportation, law enforcement agencies, and traffic cameras. Two models were used to anticipate the impact of car accidents on traffic, with an emphasis on the primary causes of traffic accidents. The primary two factors determining car accident rates, according to the findings, are traffic induced by work rush hour and population density. [7]

Another research study was to present a model that can be used to explain why different countries have different rates of road deaths. As potential variables, national infrastructure, transportation, and socioeconomic indicators from international databases were explored. Stepwise regression analyses were used to create the model. [8]

R language demonstrates how data is related by analyzing traffic statistics and graphs. Locations of the accidents and the accident thermal chart were obtained after data preprocessing and data selection using R language Remap package remap and remapH functions. In addition, to model the data, they used decision trees, linear regression, and the random forest approach. We can check the model's correctness and obtain the most accurate model based on the actual findings, which will help in predicting the model's accuracy with comparable data in the future. After validating the model and examining the data properties and relationship

between the variables, the ultimate purpose of data analysis is to identify the most correct model. [9]

III. AIMS AND OBJECTIVES

Traffic accidents are the greatest cause of death worldwide, taking the lives of millions of people each year due to their regularity. As a result, technology that predicts traffic accidents or accident-prone areas may be able to save lives. Nowadays, there is an increasing emphasis on traffic accident data mining and analysis, which can improve in-depth investigation and reduce traffic-related deaths.

We will use Python pandas to analyze car accidents in the United States in this project. Real-time data, accident sites, casualty analysis, driving speed, traffic conditions, road structure, and weather may all be used to anticipate accidents. Therefore, we can predict accidents based on a variety of factors. We'll consider factors such as road conditions, speed limits, and the state in which the accident occurred. The analysis of historical accident data will assist in determining the likely causal relationship between these factors and road accidents, enabling the creation of accident predictors to reduce the risk of injury caused by accidents. As a consequence, utilizing this data collection, a machine learning model is built and applied that can accurately anticipate when and where accidents will occur, reducing the number of automobile accidents.

IV. METHODOLOGY

The vehicle accident dataset was obtained from the Sobhan Moosavi website, which has 1.5 million entries [10]. To undertake data analysis, the dataset must be preprocessed and has to be cleaned up by eliminating null values and filling in blanks, which will aid in data normalization. Data insights may be obtained for analysis and better decision-making using a variety of machine learning methods. Charts, graphs, and ordered tables can be used to visualize the data. One of the most significant jobs in road accident analysis is to predict the severity level of the event using various classifier methods such as logistic regression, decision trees, and random forest.

Fig. 1

V. PROPOSED APPROACH TO SOLVE PROBLEM

A. Focus:

Accidents in the United States may be utilized for several purposes, including real-time accident prediction, investigating the location of accident hotspots, fatality analysis and deriving causal principles to anticipate accidents, and researching the potential influence of climate on accidents. The analysis's goal is as follows:

- 1) Which state has the highest number of accidents in the United States?
- 2) What time of day is the most prone to accidents, and what is the pattern of accident change?
- 3) What connection exists between the accident and the weather?

B. Stages:

The project is broken into five stages:

1) *Problem Definition:* Every year, traffic accidents account for a high share of serious injuries reported. However, establishing the conditions that cause these occurrences is frequently difficult, making it more difficult for local law enforcement to handle the frequency and severity of traffic accidents. Many questions, however, remain unsolved. As a result, it is critical to forecast and investigate traffic accidents that we want to know which elements are the most important in causing automobile accidents and to understand which factors of the accident will have a bigger influence on traffic accidents.

2) *Data Collectin:* The practice of gathering and measuring data, information, or any variable of interest in a regulated and defined method that allows the collector to answer or test hypotheses and assess the findings of a specific collection is known as data collection. As a result, we gathered the accident dataset from Sobhan Moosavi's website which include 47 columns and 1.5 million records.

3) *Data Cleaning*: Data cleaning is an important phase in the data analysis process, and the quality of the findings is strongly related to the model impact and the conclusion. In practice, data cleansing often consumes 50% - 80% of the time allotted to the analysis process. Data cleaning can help to enhance data quality, reduce interference, and acquire useful and trustworthy data to aid decision-making.

4) *Data Visualization*: Data visualization is a way of communicating information more simply and effectively by conveying facts through data, primarily using graphical approaches. The goal of visualization is to present facts more naturally, making the data more objective and compelling. And data visualization is significant because graphs and charts may be more effectively represented, people, want to see different graphs, and it is simpler to recall. In a sea of data and information, it might be difficult to uncover connections, but graphs and charts can deliver information in seconds, and it gives people all the information they need at a look.

5) *Machine Learning*: One of the most significant study areas for machine learning algorithms is prediction. Using machine learning techniques, researchers may create traffic accident, prediction models. Among several models, the traffic accident prediction model is the most challenging to develop. Because the elements that influence automobile accidents are complex and changing. Because our goal is to forecast traffic accidents.

VI. PRELIMINARY RESULTS

Exploratory data analysis has been done on the dataset where cleaning and preparation of the data and then analyze it with different plots and visualizations. In the data preparation, the dataset file has been loaded using pandas, and cleaning is done by fixing missing or incorrect values. Some of the columns that we analyzed were State, start time, Start Lat, Start Long, Temperature, and Weather condition to analyze the severity of the accidents state-wise weather-wise. Some of the results produced on analysis are below. From that, we can see that during thunder weather conditions, accident severity is highest.

From the map, we see that California is recorded to be the highest accident-prone state

Fig. 2

Fig. 3

According to this graph, the top ten states have the highest rate of auto accidents. As can be seen, the top three states with the most accidents are California, Florida, and Oregon, all of which are at the top of the US in terms of population and GDP. The expansion of traffic will be fueled by the economy's prosperity, and the likelihood of traffic accidents will rise as well.

The higher the number of accidents in the morning peak, the greater the traffic flow; and as the evening peak comes to an end, the serious accident rate continues to rise, reaching a peak at 17:00 and then gradually decreasing; it is speculated that this is due to fatigue driving after normal working hours. As a result, fatigue is more likely than low

Fig. 4

Fig. 5

Severity & Distance of accidents

Fig. 6

visibility to cause serious accidents.

According to the findings, the number of car accidents in 2020 will be significantly higher than in 2016-2019, with many accidents occurring in the second half of 2020.

On analyzing the severity & distance of the accidents, we can see that severity 3 is spread more across the states although there are fewer states with severity 4 their distance is not widely spread.

The pie chart depicts the severity of the accident, with 1 being the least serious and 4 being the most serious. According to the findings, the majority of traffic accidents have a severity of 2. According to annual accident severity statistics, the severity of traffic accidents in 2020 is 2, and the severity of most traffic accidents in 2019 is also 2.

Considering the climate conditions such as temperature and pressure, on analyzing them, can infer that all the severity 2 is more when the pressure is between 29.5 and 30.5 and found that other severities are recorded to be more at that particular pressure point.

Severity of accidents

Fig. 7

Fig. 8

Considering temperature as a factor, severity 2 is highest when the temperature is recorded between 40F and 80F.

Abstract— In this research, the optimal PV size of the system was first determined with the aid of OpenSolar, PVWatts and REopt software for an annual energy consumption of 969,000kWh as compared to that obtained from HOMER Pro software. The result obtained was then used to design and simulate the dynamic model of the campus microgrid system in MATLAB/Simulink environment. The designed system in Simulink consists of PV size of 675.2kW comprised of 1350 modules each of 500W, with 25 connected in series and 54 in parallel, a utility grid of 50Hz, 6MVA, 33 kV transmission network with a power transformer of 2.5MVA, 33/11 kV and a distribution transformer of 750 kVA, 11/0.415 kV and a back-up generator of 1.5 MVA rating. The system dynamics was considered under three conditions which includes PV + grid mode, PV + generator mode and only generator mode. Simulated results include transient responses observed when the utility grid and the generator were connected to the network separately through their respective toggle switches. Waveform of power, voltage and current through the varied electric load of the system for various conditions are presented in this paper.

Index Terms— Dynamic simulation, MATLAB/Simulink software, microgrid, PV sizing, renewable energy.

I. INTRODUCTION

A microgrid consist of a network of electricity consumers with a local source of supply usually attached to a centralized national grid but it can function separately. In this case the consumers include residential homes, stores, streetlights, health centers, churches and even schools. Microgrids are more efficient, low-cost, clean energy, resilient, and improve the operation and stability of grid system. They can be classified into remote, grid-connected and networked type. In this research, the dynamics of a microgrid system for a university community in Nigeria that is grid connected is considered.

II. LITERATURE REVIEW

Research [1] work explain that for future power systems, the deficiency in power supply can be solved by a microgrid system which consists of renewable power sources such as

wind, solar and hydro. In this research, a microgrid system with wind and solar power sources was used to solve the issues relating to operation, control and stability of the system. With the aid of MATLAB/Simulink, the system was modeled and simulated based on the renewable power generation units to know the relevant technical issues associated with the operation of a microgrid system.

The paper [2] reveals that microgrid application at different voltage levels for power system networks are in the increase. To increase energy efficiency, reduce electricity bills and reduce the problems with power delivery to customers, community microgrid systems are encouraged. In that work, a simulation-based electricity analysis scheme for a community microgrid with the aid of proposed modelling methodology, simulation mechanisms, and a power balancing control strategy in MATLAB environment was developed. That paper also presents an effective simulation mechanism using MATLAB/Simulink software for the electricity analysis in microgrid systems which can be flexibly modified to comply with different simulation requirements when faced with various system topologies.

In paper [3], a solar PV powered DC microgrid that was proposed and designed in Nigeria at Umuokpo Amumara community with a household population of 800 was presented. The component sizes selected always meets the load demand of the community with energy requirement of 3.16MWh/day. A battery capacity of 21,944Ah was sized as the battery storage to meet the energy required by the community for one day without any renewable energy source. In this research, the dynamic model of the microgrid was simulated in MATLAB/Simulink to observe the system's dynamic response in view of the power quality, load impact, and battery storage charging. Results obtained from simulation indicates that the stand-alone DC microgrid can meet the daily electric energy of the system with relatively good voltage stability.

Study [4] stated that the main aim of microgrid (MG) system was to integrate microsources and load into a controlled system to supply electric energy to the end

consumers. In this work the dynamic characteristics of a grid connected system associated with power conditioning system (PCS) to regulate its power was discussed. The system investigated consists of grid, microsources, lumped static loads and other components. To cater for the dynamic behaviour of the system, a detailed model of the system was developed in MATLAB/Simulink in which two operational modes were investigated which includes: four-quadrant operation of PCS and use of PCS to control the power of MG. Simulation results indicate that MG can operate satisfactorily in these operational modes.

Paper [5] presents the dynamic operation of a low-voltage microgrid system with various distributed energy sources and the system consists of a low-voltage microgrid with a 30 kVA micro-hydro generator, a 30 kVA diesel engine generator, a 30 kVA gas engine generator, and a 15 kVA micro-wind turbine generator including the loads. In this research, the individual components of the system were modeled and integrated to form a microgrid system whose dynamic simulation was simulated in MATLAB/Simulink environment. Results obtained provide information on the dynamic characteristics of AC low-voltage microgrid systems and help in the development of microgrid system in Taiwan.

In this paper [6] the development of a microsources booster converter and PWM inverter in MATLAB/Simulink and combining them to form a microgrid was presented. The system was designed such that it can operate both in islanding mode and in grid mode. The purpose of this work was to lay foundations which allow further investigation and development of more complex microgrid models to know the behaviour of microgrid systems.

In paper [7], the design of a network-based scheme for inverter-based sources was studied. This scheme provides proper current control when connected in grid and voltage control during islanding mode. In that work, the algorithm for international islanding detection and synchronization controller needed for the grid connection was developed. When the dynamic modeling and simulation of system was conducted in Simulink, results reveal that the controllers provide the microgrid with a deterministic and reliable connection to the grid.

In this work [8] behaviour of hybrid AC/DC microgrid system was analyzed when it was grid tied. The microgrid in this case was developed by photovoltaic system, wind turbine generator and battery. For proper coordination from AC sub-grid to DC sub-grid, a control mechanism was developed for the converters. The system was simulated with the results obtained in MATLAB/Simulink. The results obtained indicate that the hybrid grid system provides efficient power with high quality and more reliable power to the consumers which may be feasible for small isolated industrial plants with both PV systems and wind turbine generator as the major power supply.

In research [9], the modeling and performance of a

microturbine generating (MTG) system in grid connected and islanding mode was analyzed with the aid of MATLAB/Simulink software. Based on the various conditions considered in that study, simulated results show that MTG system follows the load with variation of fuel flow, power and temperature of the system. It was also observed that the MTG system contributes clean, reliable and cost-effective energy for future distributed generation (DG) systems.

In paper [10], the design and operation of a microgrid (MG) for the main campus of the Technical Institution Hawija was considered. That microgrid design includes a battery energy storage system (BESS), photovoltaic (PV) generation system, and controllable loads. The efficacy of their intended design was simulated in MATLAB/Simulink. Simulated results indicate that the distribution system obtained is more robust, reliable and resilient against weather disaster or technical issues.

In this research, the dynamic simulation of a microgrid system for a university community in Nigeria is presented. The system consists of a PV size of 675.2 kW comprising of 1350 modules each of 500W, with 25 connected in series and 54 in parallel with a utility grid system and a diesel generator set is incorporated in case of emergency. The system was then designed and simulated in MATLAB/Simulink environment to test its dynamics. This work is novel in a sense that it provides a Nigeria case study, include design, dynamic modeling and simulation.

III. METHODOLOGY

Based on the campus annual electric load (kWh), a microgrid for the university community was designed in HOMER Pro software to obtain the PV size (kW) of the system. Further design from OpenSolar, PVWatts and REopt softwares were done based on the same annual energy consumption (kWh) of the selected site to determine the optimal PV size (kW) of the system as compared to that obtained from the HOMER Pro software. Based on the optimal PV size selected, the system was then simulated in MATLAB/Simulink software to determine its dynamics.

IV. SYSTEM DESIGN

The university campus ($7^{\circ} 8'8.25''N$, $6^{\circ}18'28.13''E$) at Kilometer 7, Auchi-Abuja Road, Iyamho-Uzairue, Edo State, Nigeria is located as shown in Figure 1 and the annual energy consumption of the site selected was determined as 969,000kWh based on the monthly energy consumption of the campus as shown in Table 1.

Fig. 1 Overview of university campus

TABLE I
SUMMARY OF MONTHLY ENERGY CONSUMPTION OF THE
SELECTED SITE FROM OCTOBER 2020 TO SEPTEMBER 2021

Month	Previous meter reading (kWh)	Present meter reading (kWh)	Energy consumption (kWh)
January	3635000	3655000	20000
February	3655000	3689000	34000
March	3689000	3781000	92000
April	3781000	3836000	55000
May	3836000	3893000	57000
June	3893000	3986000	93000
July	3986000	4097000	111000
August	4097000	4254000	157000
September	4254000	4324000	70000
October	4324000	4411000	87000
November	4411000	4516000	105000
December	4516000	4604000	88000

Annual energy consumption 969000

The load profile of the designed system based on HOMER Pro software is shown in Figure 2 and the solar irradiance of this site is shown in Figure 3. The average solar irradiance per annum of this location is 5.10 kWh/m²/day.

Fig. 2 Load profile of university campus

Fig. 3 Monthly solar irradiance of university campus

Based on this annual energy consumption and selected components, a microgrid system of the site was designed. This microgrid consist of solar panel of 0.5kW, the grid system, diesel generator of 1.5MVA rating and inverter sinexcel 500 with the aid of HOMER Pro Energy software to accommodate the annual energy consumption (kWh). The schematic diagram of the microgrid system obtained is shown in Figure 4.

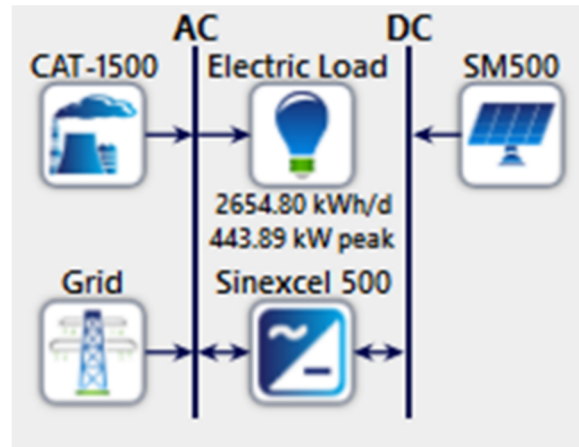

Fig. 4 Schematic diagram of microgrid system

The result obtained from the HOMER Pro software indicates that the system would need 1,868kW PV size for system installation to meet the 87.8% consumption of the

proposed microgrid system as shown in Figure 5.

Fig. 5 Simulated result from HOMER Pro showing system PV size

To determine the optimal PV size of the microgrid system of the site with the same annual energy consumption (kWh) for dynamic simulation, PVWatts, OpenSolar and REopt were used to design the system.

A. PVWatts simulation

Based on the site location and energy demand of the campus, PVWatts was used to design and simulate the system to determine the PV size that would be required. Result obtained indicates that the system would require 670.5kW PV size for the system installation this is depicted in Figure 6 and Figure 7.

results of REopt from NREL are more reliable and we used that for the next section.

IV. DYNAMIC SIMULATION

The dynamic system design of the university campus microgrid was then carried out with the aid of MATLAB/Simulink software. The system consists of a PV size of 675.2kW comprised of 96 cell modules each of 500W, with 25 connected in series and 54 in parallel. To ensure that the PV gives maximum power, MPPT is applied to the PV. Figure 11 shows the simulation results of I-V and P-V curves of the PV output.

The inverter of the system was selected based on the PV size as 700kW. Since the microgrid system is an on-grid system, a utility grid of 50Hz, 6MVA, 33 kV transmission network with a power transformer of 2.5MVA, 33/11 kV and a distribution transformer of 750 kVA, 11/0.415 kV was incorporated to the network through breaker 2, which is controlled by toggle switch 2. Also incorporated into the network is a permanent type 1.5MVA rating generator through breaker 3, that is controlled by toggle switch 3. This stands as a backup when the PV and grid system fails. The electric load of the university campus is also connected and varied through breaker 4 which is controlled by toggle switch 4 to network. Figure 12 shows the diagram of the dynamic simulation of the entire system in MATLAB/Simulink environment.

Fig. 11 Irradiation, temperature, power, voltage and duty cycle signal of PV module

V. SIMULATION RESULTS

The Irradiation, Temperature, Power, Voltage, and duty cycle graphs of the PV module are shown in Figure 13. Simulated results shows that the duty cycle varies according to the solar resources and the MPPT is able to track the variation of the solar input.

Fig. 13 Irradiation, temperature, power, voltage and duty cycle signal of PV module for 30 seconds

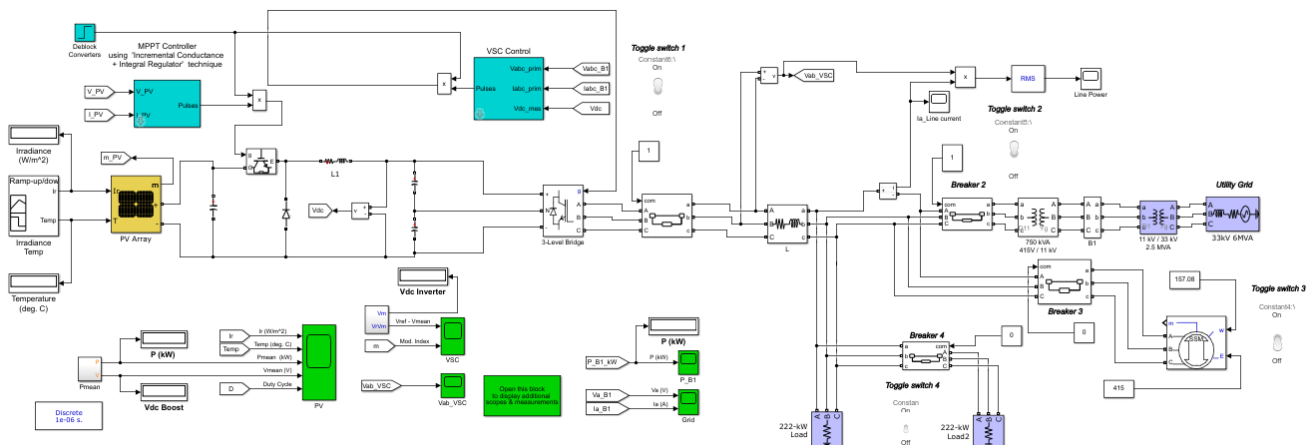

Fig. 12 Dynamic simulation of campus microgrid in MATLAB/Simulink software

Dynamic modeling and simulation of systems shows how the system behaves under proposed conditions using Simulink. In this case, the dynamic simulation shows the behaviour of the campus microgrid system when the utility grid and generator are connected to the network separately. For the purpose of analysis, the system dynamics are considered in three cases.

- i. PV + Grid mode i.e normal operating condition of the proposed system.
- ii. PV + Generator mode i.e when the grid fails.
- iii. Generator only i.e when the generator supplies energy to the entire load of the system.

The behaviour of the system based on the three cases stated above are illustrated as depicted in the respective graphs.

i. PV + grid mode

This mode is achieved when the toggle switches 1 and 2 are in closed state as shown in Figure 12. This is the normal operation of the system. In this case, the PV modules and the grid system supplies energy to the electric load of the network. Figure 14 shows the power curve and Figure 15 and Figure 16 shows the voltage and current through the load during this mode. The dynamic behaviour of the network is summarized as follows. The PV and grid generate energy to accommodate the load of the system which is divided into two by breaker 4 controlled by toggle switch 4. The variation in the ac power, voltage and current curves between the offset time $t = 1.15\text{secs}$ to $t = 1.53\text{secs}$ was when the balance half of the load was connected to the network through the toggle switch 4.

Fig. 14 Power variation with load for PV + grid mode

Fig. 15 Voltage curve on the load for PV + grid mode for a changing load

Fig. 16 Current curve on the load for PV + grid mode for a changing load

ii PV + Generator mode

PV + generator mode is achieved when the toggle switches 1 and 3 are in the closed state while breaker 2 is open as shown in Figure 12. In this case, the switches were closed throughout the simulation while the electric load was varied through breaker 4. The transient behaviour of the system in response to this new state is depicted in Figure 17, Figure 18 and Figure 19 which shows the power curve and the voltage and current curves across the electric load. Load varies from 222kW to 272kW at $t = 0.95\text{secs}$ and $t = 1.43\text{secs}$.

Fig.17 Power variation with load for PV + Generator mode

Fig. 18 Voltage curve on the load for PV + Generator mode for a changing load

Fig. 19 Current curve on the load PV + Generator mode for a changing load

iii Generator only

The generator is introduced into the network as an emergency backup in case the grid system fails when the PV system is not generating energy to supply the system load. Toggle switch 3 controls the generator circuit in the network. When it is ON, the generator is connected to the network and when it is OFF, the generator is out of the system. Figure 20, Figure 21 and Figure 22 shows the graphs of the power and voltage and current through the load when the electric load of the system is varied through toggle switch 4. This transient response on the graphs indicates the behaviour of the system when only the generator is connected to the network. At $t = 1.0\text{sec}$ and $t = 1.32\text{secs}$, load increased from 222kW to 444kW.

Fig. 20 Power variation with load for only generator mode

Fig. 21 Voltage curve on the load for only generator mode for a changing load

Fig. 22 Current curve on the load for only generator mode for a changing load

VI. CONCLUSION

In this research, the dynamic simulation of a microgrid system for a university community in Nigeria is presented. The system designed was simulated in MATLAB/Simulink environment. The system consists of a PV size of 675.2 kW comprising of 96 cell modules each of 500W, with 25 connected in series and 54 in parallel. Also, a utility grid system and a diesel generator set in case of emergency were connected through toggle switches 2 and 3. Simulated results indicates that the system realized has acceptable dynamics as it responds appropriately when a new state was introduced to the network by varying the electric load of the network for three different cases. This was shown by the transient responses indicated on the system when the toggle switch 4 was turned ON and OFF to vary the electric load during simulation to meet the load demand of the university campus. We recommend Nigerian university community to find funds for implementation of such a system to have a reliable low cost electricity.

Abstract—Existing methods to put white and yellow marking on the road are based on manual measurement of the road dimensions and manual marking of guide lines. It is a time consuming, cumbersome and labour intensive process. This was the motivation for this work to develop a system which can automatically apply road markings according to the width of the road. In this paper, a stereo-vision based road marking system is presented. Computer stereo-vision has been used to measure the width of the road which helps us decide the number of lanes on the road. To generate the disparity map, a semi-global matching algorithm has been used, incorporating the advantages of both local and global matching algorithms. Efficient algorithms have been used for camera calibration and to estimate the road width. For deciding the number of lanes, the standards laid down by Indian Road Congress (IRC) have been followed..

Index Terms—Road markings, stereo vision, disparity map, semi-global matching, computer vision, image processing, automation

I. INTRODUCTION

Computer vision is a popular field of science and technology. With the surge in usage of artificial intelligence in last two decades, extensive work was done by researchers in this field. From the medical field to industrial robotics and space exploration, computer vision has played an important role. Computer vision is the field that deals in understanding the features of the objects present in the workspace by computer which provide useful information about the environment. Computer vision has many techniques for analysing and understanding the captured image data. Application of these techniques depends upon the problem in hand.

There are two methods to capture the environment data in image format: Mono-Vision and Stereo-Vision. The Mono-Vision method incorporates a single camera to capture the image and extract 2D information from the image. Mono-Vision technique has many applications like object detection (e.g. cancer cell detection, plant disease detection etc.), object recognition and object classification. Stereo-Vision method incorporates two cameras that are placed a known distance apart. In this method, two cameras capture the images of the same scene of the environment simultaneously. This method

reconstructs the 3D information by correlating the two images taken from the pair of cameras.

According to a World Health Organisation report of 2018, every year around 13 million people die in traffic accidents while 20 to 50 million people become disabled in these accidents [1]. Roads are the economic arteries for a nation; they allow the flow of services throughout the whole country which helps in rising of the nation economically. These are the most important infrastructure in the present era. However, they deteriorate with time. Deterioration of road includes the decaying of road marking lines. Poorly maintained road markings cause many problems like reduced traffic mobility, increased number of accidents, traffic congestions etc.

Now-a-days, we are moving towards automation in every industry, organization and service. Every new vehicle comes with some ADAS (Advanced driver-assistance system) features like parking assist system, cruise control system and lane centering system. In case of self-driving cars, appreciable research is going on to increase accuracy and ease of operation. Many companies have launched self-driving cars in the developed countries. All these technologies rely on the road markings to guide or assist the movement of vehicles. Therefore, good quality, accurate road markings are very important.

In this paper, a road marking system is designed using computer vision. Using stereo vision, the width of road is measured and a center line is drawn on road if width of road is more than the two lane road according to the Indian Road Congress (IRC) protocol.

II. RELATED WORK

There are many methods to apply road markings which make use of different approaches. They can be broadly classified into two categories – manual and automatic. In manual methods, an extended bar [2] [3] [4] and periscope [5] are used which align the paint sprayer with guideline markings. Manual processes require complete attention of the manual human operators. Automatic methods require only marginal attention from the machine operator. While manual approach may work in reviving marking of old roads where previous

marking has faded, it is highly unsuitable and undesirable for new roads. In automatic methods for reviving the old faded markings, people have used different types of detectors to detect the old line-markings as guide marks for applying the new paint. These types of detectors are combination of cameras and laser scanner [6] [7], electromagnetic radiation [9] [10] [11], UV light scanners [11] and video cameras [12] [13] [14]. In other automatic systems, people have used GPS technology to record and locate the marks to paint the road markings [15] [16]. All these systems have some drawbacks. Manual system has human error while the radiation-based system is affected by illumination. These systems fail if the old road markings are eroded. GPS based systems cannot work in an area where there is no availability of the Internet or some obstruction is there to the signal. All these systems can work only on the roads which have been marked earlier which are still not in bad condition. They cannot work for newly constructed roads.

III. METHODOLOGY

The aim of this research is to develop a method for obtaining the width of the road and calculate the position of road markings. For applying Road marking, dimensions of the road need to be measured. On a two-lane road, centre line of road is drawn to define the area of road access to the motorist, order the traffic and maintain a smooth flow. Centreline defines that each half of the road will provide access to one-sided driving in opposite direction. For example, in Indian road scenario, traffic has to be on the left side of the centre line while driving.

To determine the width of road, depth map has to be generated using stereo-matching algorithm. Following steps are required for implementation of marking lines:

- Camera calibration
- Image rectification
- Road segmentation
- Disparity map generation
- Calculation of road width
- Determination of marking position

These tasks are discussed in sequence in next subsections.

A. Camera Calibration

In general, two cameras from the same manufacturer are never identical and stereo camera pair cannot produce two horizontally aligned images. Camera calibration is the process of estimating the intrinsic and extrinsic parameters of camera with the help of images captured by the camera. These parameters help in rectification of images (make epipolar lines parallel to the x-axes) to prevent distortion of the images. The cameras are calibrated by repeatedly shooting a calibration pattern with known points for which their relative positions in space are known. Generally, a chessboard with known number of squares is used as a calibration pattern. In this work, 82 image pairs of a chessboard pattern containing 7×9 boxes, each box of 35mm × 35mm size, were captured. Camera calibration

Fig. 1: Images of calibration pattern (a) from left camera (b) from right camera

was done by using Heikkila, J, and O. Silven [17] method by using MATLAB Stereo Camera Calibrator application.

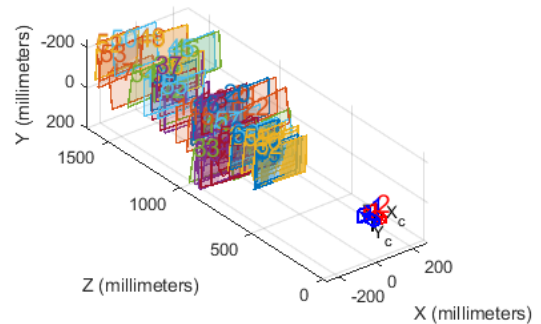

Fig. 2: Camera centric view of calibration showing camera pair and all images for calibration

Figure 3 shows the reprojection error for all the captured images of calibration pattern. The reprojection error is a geometric error corresponding to the image distance between a projected point and a measured one. It is used to quantify how close a 3D recreated point is to the point's true projection [18].

Fig. 3: Reprojection errors of all calibration image pairs

B. Image Rectification

Images taken from both the cameras simultaneously are of 480×640×3 pixel resolution with intensity of pixels as 8-bit unsigned integer data type. As two cameras can never be identical and cannot align perfectly along horizontal axis,

image rectification is required. Rectification is the projection of two or more images on the same plane so that the image lines correspond to the epipolar lines [19]. After rectification, all pixels of the right image will be in one line with the corresponding pixels of the left image. Figure 4 shows the rectified images of calibration pattern and figure 5 shows the rectified images of road.

Fig. 4: Rectified images

Fig. 5: Road image (a) from Left camera (b) from Right camera (c) After rectification

C. Road Segmentation

In order to determine the width of the road, it is required to get the location of road edges in 3D depth map. To achieve this, all the edge points of the road are to be extracted. By doing road segmentation, exact boundary of the road may be obtained. However, the workspace contains many objects and directly applying edge detection algorithm would give edges of every object whereas only road edges are needed. Therefore, the image is made binary and morphological operation ‘Erosion’ is applied to fill the gaps. To get the edge points of road, Sobel operation is applied along x-axis [20].

The road segmented images of both left and right camera are used for disparity map calculations. As a result, disparity map value for every pixel of edge is obtained. In figure 7, disparity map has been shown and in figure 8, corresponding 3D map of the images appears. It may be seen that 3D map for every pixel of road boundary was obtained.

Fig. 6: Road segmentation process (a) Grayscale image, (b) Gaussian filtered image, (c) Erosion operation result on binary image and (d) Sobel filter along x-axis to extract edge points of road

D. Disparity Map Generation

As road edges are the objects of interest, getting disparity for edges is more important as compared to the rest of the region of image. Disparity map of an image is the matrix each element of which stores information about the number of pixels between the projection of an object point on the left and right cameras. The principle behind the disparity map is that for each pixel of the left image with coordinates (x_0, y_0) there is a pixel of the right image. It is assumed that the pixel of the right image will have coordinates (x_0-d, y_0) where d is the offset (disparity).

There are 2 types of approaches for finding a Disparity map - Local and Global. Local map has low computational complexity, but it is less accurate. This method calculates the disparity of each pixel individually. Global map has high computational complexity, but with low execution speed. They, unlike local methods, look for the best disparity map immediately for the entire image. Such algorithms are quite difficult to implement.

To generate the disparity map, Semi-Global Matching algorithm [21] was used in this work. This method incorporates the advantages of both local and global method.

E. Calculation of road width

The distance to the object varies inversely with the disparity. Points with larger disparity values represent points that are closer to the camera, and smaller disparities represent points

Fig. 7: Rectified images

Fig. 8: Rectified images

that are farther away from the camera. The accuracy of the distance measurement depends on the resolution of the camera images, the optical properties of the lens, and the distance between the optical axes of both cameras. For distance measurement, first, 3D point cloud is constructed with the help of disparity map and stereo parameters. Then 3D Cartesian coordinates for the road boundary points are extracted from 3D point cloud of the scene. After getting the 3D Cartesian coordinates, Euclidean distance between the left boundary point P1 and right boundary point P2 is calculated from

$$Distance(P1, P2) = \sqrt{((x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2)} \quad (1)$$

Here, the problem is how to decide the points of boundary between which width of the road is to be measured. For this, the whole image is divided into small segments horizontally with the size of 100 vertical pixels. In every segment, we take a point from left side and calculate the distance to every point of right boundary. The minimum distance points are decided as the corresponding boundary points.

By using Equation (1) for all left and right boundary points of selected segment calculate the distance

$$D(m, n) = Distance((X_{Left}(m), Y_{Left}(m)), (X_{Left}(n), Y_{Right}(n)), \text{ for } 0 < m < 100, 0 < n < 100 \quad (2)$$

Find the points of left and right boundary, in which the distance is minimum

$$(A, B) = Index(min(D(m, n))) \quad (3)$$

From Equation (3), we got the index value of left and right point

$$P1 = ((X_{Left}(A), Y_{Left}(A))) \quad (4)$$

$$P2 = ((X_{Right}(A), Y_{Right}(B))) \quad (5)$$

Width of Road is calculated between point P1 and P2

$$WidthofRoad = Distance(P1, P2) \quad (6)$$

When width of road is in the range of two-lane road width, then position of the center line is given by

$$(Cx, Cy) = (X_{Left}(A) - X_{Right}(B)), (Y_{Left}(A) - Y_{Right}(B)) \quad (7)$$

IV. RESULTS AND DISCUSSION

The proposed method was implemented using two Logitech C270 HD webcams. A testing setup was built for testing the performance of developed system. The results for some distance measurement using Equation (1) tests are presented with respect to actual distance. Figure 9 shows final output in which width of road, center line, 3D coordinates of left and right boundaries and boundary lines are shown.

Fig. 9: Final output with road width and centerline

A. Measurement Validation

Three simulated stretches of the road having 10 cm, 15 cm and 20 cm width have been used for the analysis of the developed measurement system. The maximum width values obtained are 10.30 cm, 15.40 cm, 20.30 cm and minimum values are 9.70 cm, 14.90 cm and 19.80 cm respectively for the above stretches. Average of all obtained values are 10.00 cm, 15.00 cm, 20.00 cm respectively. Error in measurement may be calculated from:

$$Error = Measuredvalue - Actualvalue \quad (8)$$

TABLE I: Width measurement result for different road Widths

Actual width (cm)	Measured Width(cm)	Error from Average (cm)
10 cm	10.10	+0.10
	10.00	0.00
	10.00	0.00
	9.80	-0.20
	9.90	-0.10
15 cm	15.20	+0.20
	15.10	+0.10
	14.90	-0.10
	15.00	0.00
	15.20	+0.20
20 cm	19.90	-0.10
	20.00	0.00
	20.10	+0.10
	19.90	-0.10
	19.80	-0.20

TABLE II: Width measurement Deviations from Average calculated Widths

Actual width (cm)	Deviation(cm)
10 cm	Maximum 10.30
	Minimum 9.70
	Average 10.01
15 cm	Maximum 15.20
	Minimum 14.90
	Average 15.00
20 cm	Maximum 20.30
	19.80
	Average 20.00

So, for 10 cm, 15 cm, 20 cm road width, by using Equation(8) maximum positive errors are +0.3 cm, +0.4 cm, +0.3 cm and maximum negative errors are -0.3 cm, -0.1 cm, -0.20 cm respectively. From this, it can be concluded that maximum deviation in the measurement system is +0.4 cm and -0.3cm. The results show that there is ±0.4 cm error in width measurement and it remains the same for every width range from 10 cm to 20 cm. The deviation column shows the maximum or minimum values provided by the system for a particular width and the average tells the mean value of all measurement results for a particular stretch of road of fixed width. It may be observed that the average width is equal to the actual width which indicates that the deviation of the values has equal proportion in negative and positive direction.

B. Practical Scenario

For measurement validation, road was made having straight boundaries which is not practically possible. In reality, roads have irregular boundaries for the asphalt layer. A road with rough boundary was, therefore, simulated for testing. The following images depict the rough road scenario.

In Fig 10, marker position is shown on a straight road having an irregular boundary. Horizontal measuring line and a dot on the center showing the actual marker position can clearly be seen.

Fig. 10: Straight Road with rough boundary

In Fig 11, marking is shown as we move forward. For visualisation purposes, old markings are shown. The top line with a dot defines the current marker position.

Fig. 11: Moving forward on straight road

In Fig 12 and 13, marking at curved roads are shown. In Fig 13, it can be visualized how marking is done on a curved road.

Fig. 12: Marking on curved road

C. CONCLUSION

An automatic road marking system using stereovision method is proposed. Image thresholding technique has been used for segmentation of the road from environment and for getting the road boundary points. Semi-global matching algorithm was used for disparity map generation. Euclidean distance was used to calculate the distance between two points in 3D Cartesian coordinates. The distance measurement has ± 0.4 cm as the maximum error. The designed system was tested in lab for different stretches of road on in lab generated road Environment. No need to place the camera at a fixed position and angle. Improved performance is possible through the use of more modern cameras with high resolution, or a single stereo camera. Limitations of the system: • In Real environment we have lots of colors for different object to thresholding-based segmentation can not work there, so we can use a deep learning based approach to segment the area of interest.

D. FUTURE SCOPE

This system is designed only for two lane roads. System can be developed for more numbers of lane roads by maintaining the government road authority standards for that particular place. Deep learning model can be used for better accuracy.

Abstract—Longer life spans in today's society have contributed to the growth of degenerative disease prevalence, especially dementia. Dementia causes a deterioration in thought process and a decline in cognitive function, specifically thinking, reasoning, and remembering. While dementia cannot be completely prevented, its early detection can delay the onset of the disease. With the help of a machine learning algorithm, relevant attributes to detect the disease in its early stages can be refined and successful predictions can be made. To conduct this analysis, the Alzheimer Features and Exploratory Data Analysis for Predicting Dementia datasets were utilized. The following machine learning models were applied to the dataset: Naïve Bayes, Decision Trees, K-Nearest Neighbors, and Fully Connected Neural Networks. After evaluation of accuracy scores, confusion matrices for both Naïve Bayes and Decision Trees were determined to provide the best results among the models. While further investigation with a larger dataset is necessary, such models suggest that machine learning algorithms are a promising tool to detect and mitigate the growth of dementia in older populations.

Keywords— *machine learning, dementia, Naïve Bayes, Decision Trees, K-Nearest Neighbors, Fully Connected Neural Network, K-fold Cross Validation*

I. INTRODUCTION

The development of advanced medical technology has shown to be successful through an increase in the quality of life and average lifespan, especially in Western countries. Longer life expectancy, consequently, contributes to the growth in senior populations and presents changing patterns in degenerative disease prevalence. In recent years, the aging society has seen a growth of older individuals with dementia, a disease that results in the loss of cognitive function when thinking, reasoning, and remembering. In 2020, the number of people worldwide living with dementia reached over 55 million. This number is expected to double every 20 years, much of the increase occurring in developing, or low and middle income, countries [1]. The effects of dementia are not experienced individually. Economic, psychological, and physical strains affect patients' families and even society [2]. An overall lack of awareness, understanding, and early prevention cause barriers to diagnosis and proper care.

Dementia leads to deterioration in thought processing beyond the predicted amount from biological aging, affecting comprehension, judgment, and orientation. There are three stages to dementia-related cognitive decline: preclinical, mild cognitive impairment (MCI), and mild through severe dementia [3]. Most studies have focused on the treatment process post diagnosis or disease onset, while current research aims to prevent development of mild through severe dementia in those with MCI. Research shows that three quarters of people with dementia haven't been diagnosed, meaning that they do not have regimented treatment and care that could be provided if a formal diagnosis was received [1]. While dementia cannot be completely prevented, studies point to several factors that can delay the onset of the disease, encouraging discovery of technology focused on early detection and diagnosis.

This research aims to contribute to existing research in risk reduction, early intervention, and timely diagnosis of dementia in older adults. The goal is to develop and refine a machine learning algorithm which identifies relevant attributes that can detect the disease in its MCI stage. To conduct this analysis, the Alzheimer Features and Exploratory Data Analysis for Predicting Dementia datasets were utilized. These datasets target variables such as age, gender, socioeconomic status, years of education, and mini-mental state examination (MMSE) scores. These features are classified into a clinical dementia rating (CDR), determining whether an individual has dementia. [4, 5]

In initial stages of analysis, data preprocessing was formed to transform raw structured data into a complete and useful format. From there, each feature was ranked based on its relevance to the class variable (whether the person has dementia) using a correlation matrix. After feature selection was completed, the dataset was split to train the machine learning algorithms and classify whether the individual had dementia. The prediction was compared to the CDR column in the dataset to determine accuracy of the methodology. A comparative analysis of supervised learning algorithms such as Naïve Bayes, Decision Trees, K-Nearest Neighbors, Fully Connected Neural Networks, and K-fold Cross Validation were conducted to determine which are the best predictors of dementia. The

influence of each feature was determined using the correlation coefficient functionality in Python, showing that the MMSE score, gender and age had the highest correlation to the CDR. Each machine learning algorithm used on the dataset was evaluated using their accuracy rate.

II. RELATED WORK

Along with the methodology proposed in this paper, various studies have been focused on the detection of dementia using machine learning algorithms. While current processes exist in clinical settings for the detection and diagnosis of dementia, the underlying goal for the proposed models are to serve as an additional decision-making aid and a way to identify incipient stages of the disease. While the same supervised machine learning algorithms are utilized, researchers have selected different features to conduct their analysis, altering the accuracy and efficiency of the models. The methodology Bansal and colleagues discuss in their article “Comparative Analysis of Various Machine Learning Algorithms for Detecting Dementia” makes use of two brain MRI data sets provided by Randy Buckner [6], from the Open Access Series of Imaging Studies (OASIS) data set [6]. Regarding preprocessing the data sets they are using, Bansal and colleagues reference other works which have dealt with incompleteness by filling in values with the averages of the entire column. Bansal’s team does likewise. Using WEKA, they make use of J48, Naïve Bayes, Random Forest, and Multilayer Perceptron to visualize data and to make their predictions. After attribute selection, only four of the nine attributes remain in their set. However, they do not mention which four remained. The results for most of the algorithms on the first data set are significantly accurate, though for Random Forest it is only 76% accurate [6]. For the second set, a Cross-Sectional OASIS, their use of Multilayer Perceptron results in the weakest accuracy. The exclusion of the attributes they use in making their predictions is an obvious drawback to Bansal and his team’s work, as it makes repetition of their results difficult.

The basis for understanding the Clinical Dementia Rating (CDR) of each of the datasets comes from Shankle and colleagues’ [7] article on detecting dementia from normal aging patterns. According to Shankle and colleagues, the main range of the CDR column is from 0-5, with 0 and 0.5 indicating normal and mildly demented, respectively. Every value above these means increasing levels of impairment. Like Bansal’s team, Shankle made use of Decision Tree learners and Naïve Bayesian classifiers. Also, like Bansal, Shankle filled in incomplete data with the mean of the column, specifically the mean of the classification accuracy. Shankle included the features age, sex, education, as well as the Functional Activities Questionnaire (FAQ). They also made use of the MMSE. According to Alagiakrishnan and colleagues, this exam has been used for several decades and features specific tasks which must be completed in a certain range and measures somewhere around six cognitive domains [8]. Although the effectiveness of this specific test is considered dubious and faced some controversy [8], it has proven to be at least somewhat efficient to the task of early dementia prediction, and therefore earns its place in these studies. They list the MMSE scores as going from 0-30, with 0 meaning severe impairment and 30 meaning none [7]. Another approach used a two-layer method, mimicking the clinical practices of early diagnosis of dementia using machine learning

techniques. So and colleagues utilized various machine learning algorithms to classify data into normal, MCI, and dementia with a two-step process [2]. The first step is composed of a screening test which classifies the data into a normal group and a cognitive decline group. The second step relies on a closer examination where cases are allocated into MCI or dementia. Feature selection was performed using chi square and information gain. Supervised machine learning algorithms used included Support Vector Machine (SVM), Naïve Bayes, Multilayer Perceptron (MLP), Bayesian Network, Bagging, Logistic Regression, and Random Forest. Multilayer Perceptron proved to have the highest accuracy for phase 1 (97.2%), followed closely by Random Forest (96.3%), and Naïve Bayes had the lowest classification accuracy (94.4%) [2]. For phase 2, SVM was the most accurate in the diagnosis of dementia (74.03%), with a close second being Logistic Regression (73.71%), with MLP being the least accurate (68.12%) [2].

While these findings were shown to be consistent with several other researchers, this method aligned closely with the three stages of dementia diagnosis: screening tests for cognitive ability, neuropsychological assessment, and diagnosis for dementia or MCI by doctor consultation. The first stage mimicked a precise screening using MMSE data. In the second stage, CERAD data is added to classify MCI versus dementia. This provides a fast way to interpret test results through classification criteria of the patient. The limitation of this model is the lack of lifestyle or disease information relating to individual patients, which could improve the accuracy of the algorithms [2]. Such data is to be utilized in this research paper.

New research has emerged which uses a combination of signal processing, machine learning, and natural language processing to diagnose dementia based on the patient’s speech. Linguistic processes such as syntax and phonetics are processes uniquely affected with disease progression. Luz and colleagues capitalized on language impairment as a clinical indicator of cognitive status, exploring patterns in dialogue of conversational data [9]. Machine learning models were trained on the data to differentiate between dementia and non-dementia speech. They hypothesize that dementia patients will show identifiable patterns in dialogue interactions via disrupted turn taking and speech rate differences. Also included in the data are demographic and clinical variables. Conversational fluidity data was gathered with speech-silence patterns and basic prosodic information.

This study used classification algorithms such as Logistic Regression, Real Adaboost, Decision Trees, Support Vector Machine, and Random Forest. Real Adaboost and Decision Trees clocked in with the highest accuracy rate at 86.5%, with a close competitor being Support Vector Machine at 83.7% [9]. While this research represents several promising linguistic parameters for the assessment of dementia, the main limitation stemmed from its small sample size of conversations and a degree of bias in the data collection [9]. While the analysis in our paper does not focus on data collected using spontaneous dialogue, future considerations can be made in the data collection process to include these predictors and yield a mostly accurate detection of dementia at the time of onset. This research paper makes use of the same two OASIS sets as Bansal, though the issue of incomplete/inconsistent data presented itself. It has

been found that somewhere around 200 values are missing on average for the EDU, SES, MMSE, and CDR columns each. This makes up around half of the total number of rows, so the usefulness of the OASIS set is dubious at best, especially given the extreme importance of the CDR column. As a result, this team will be working mostly with a different dataset titled Alzheimer Features for Analysis [4]. This set features nearly identical attributes but is more complete. However, the OASIS sets will be scrapped for complete data, and will be combined into a larger set. The remaining data (missing the CDR column) will be used as test data. As a result of surveying this other literature, this experiment will be making use of Naïve Bayes, J48, and Decision Trees, as these appear to provide the most consistently accurate results. The exclusion of the attributes Bansal and his team use is an obvious drawback to their paper, one this team will avoid by listing the features that are utilized. Preprocessing the data is the next key issue. This team will follow in Bansal and Shankle’s footsteps and fill in incomplete data with average values of columns. For the Alzheimer’s set, this was only necessary for the SES column, as other fields were filled. Two rows containing null values in the MMSE set had to be dropped, but this exclusion will not have a significant impact given the scope of the dataset.

III. DATASET AND FEATURES

This research analysis found that the CDR column is rated on scale from 0-3, and in most cases only reached 2 as a maximum. To combat this and create categorical attributes, 0 and 0.5 were defined as 0 (no dementia), and 1 and 2 were defined as 1 (dementia). Like Shankle, the MMSE score will play an important role in our predictions. A correlation coefficient test was run, revealing that the MMSE score provided the most important data in making predictions. The main dataset this paper will focus on is Alzheimer Features for Analysis [4]. Fig. 1 is an example of the dataset when initially loaded into a Pandas data frame. As can be seen visually, the data required some processing. First off, the Group column has proven to not be as helpful as it would seem. This column is directly related to the CDR column, and at first glance appears to function as the class column however, there are two reasons why this is not the case.

	Group	M/F	Age	EDUC	SES	MMSE	CDR	eTIV	nWBV	ASF
0	Nondemented	M	87	14	2.0	27.0	0.0	1987	0.696	0.883
1	Nondemented	M	88	14	2.0	30.0	0.0	2004	0.681	0.876
2	Demented	M	75	12	NaN	23.0	0.5	1678	0.736	1.046
3	Demented	M	76	12	NaN	28.0	0.5	1738	0.713	1.010
4	Demented	M	80	12	NaN	22.0	0.5	1698	0.701	1.034
5	Nondemented	F	88	18	3.0	28.0	0.0	1215	0.710	1.444
6	Nondemented	F	90	18	3.0	27.0	0.0	1200	0.718	1.462
7	Nondemented	M	80	12	4.0	28.0	0.0	1689	0.712	1.039
8	Nondemented	M	83	12	4.0	29.0	0.5	1701	0.711	1.032
9	Nondemented	M	85	12	4.0	30.0	0.0	1699	0.705	1.033
10	Demented	M	71	16	NaN	28.0	0.5	1357	0.748	1.293
11	Demented	M	73	16	NaN	27.0	1.0	1365	0.727	1.286
12	Demented	M	75	16	NaN	27.0	1.0	1372	0.710	1.279

Fig. 1. The initial Alzheimer’s dataset

Firstly, this set has classified anyone with a CDR of 0.5 or higher as “demented.” However, according to Bansal, 0.5 only indicates possible dementia, not confirmed. Secondly, this paper will be making use of two data sets provided from OASIS, neither of which define a Group column, but feature the CDR column. It should be therefore obvious that the Group column was dropped in favor of using the CDR column as our class variable. The gender column, “M/F,” poses the obvious obstacle of string types, which interfere with the ability of Python to use correlation metrics to select attributes. A simple solution was to map the number 0 to “M” and 1 to “F.” Another issue is with the NaN values in the Socioeconomic Status (SES) column. To combat this, this team followed in suit with Bansal and Shankle and filled in the NaN values with the mean of the entire column. Although this approach could be up to debate, it was taken for two reasons. First off, this approach is recommended and often used by researchers. Second, this team does not see SES as having a profound impact on the study. As seen in Fig. 2, running a Correlation test revealed that the correlation between SES and the CDR column is minimal, and somewhere around 0.01. As a result, this team will most likely drop this column in the future, though this has not yet been decided.

The MMSE column is shown in Fig. 2 to have the most correlation with the CDR column, around 0.6. The rest show minimal correlation, which is believed to be a result of much of the data being continuous rather than discrete. Most of the work conducted thus far has been focused on the age column and turning this into discrete data. The variety of the age data is shown in Fig. 3.

12	0	3.0	16	2.460452	27.0	1.0	1372	0.710	1.279

Fig. 5. The dataset after preprocessing.

To make the data more discrete, and therefore make it easier to find correlation, the data was split into 9 separate bins, ages 60-65 in bin 1, 66-70 in bin 2, and so on. The resulting data distribution is shown in Fig. 4. However, when running the correlation metrics again, the correlation of the age column and the CDR column was listed as NaN. The reasons for this and the solution will be the next step of the team, as right now there is no obvious one. For some reason the data is appearing as NaN. This may be related to the methods used to split the data, in which case the solution may simply be using a different method of mapping. The data set processed up to this point is shown in Fig. 5.

To expand the scope of the algorithms, it was necessary to increase the dataset. To do this, the team combined the Alzheimer dataset with the OASIS dataset. Initially the OASIS set had around 200 rows with multiple null values (including within the CDR column), so preprocessing the data was

necessary. Dropping the null values left the OASIS set with about 200 rows. The issue with the Age column was also resolved here. The reason for the issue was that when separating the ages into bins, a few ages fell out of the assigned intervals, and therefore defaulted to null values. To mitigate this and to help with the combination of the datasets (since there is a greater range of ages in the second set), they were sorted into a greater number of bins: approximately 12. Any null values in the age column were replaced with the average of the column. The CDR column was split into the same intervals as the previous set. The 200 rows were then concatenated to the end of the Alzheimer set. The resulting set contained 600 rows, and 6 columns: Gender, Age, Education level, Socioeconomic Status, Mini-Mental State Examination, and the CDR column (the class variable). The correlation metrics are shown in Fig. 6.

IV. METHODOLOGY

The following classification techniques have been applied to the dataset: Naïve Bayes, Decision Trees, K-Nearest Neighbors, Fully Connected Neural Networks and K-fold Cross Validation.

A. Naïve Bayes

Naïve Bayes relies on the assumption of independence between attributes in the class to provide classification accuracy [10]. Put simply, the occurrence of one feature does not signify the occurrence of another, hence why it is called naive. It utilizes Bayes theorem and sample data to evaluate the probability of a class A, given B. In this dataset, the goal is to classify whether dementia is found, given the eight attributes to describe the patient’s condition. This can be shown in (1), where y is the class variable, representing if the patient has dementia given the variables X that represent the features [10].

$$P(y|X) = \frac{P(X|y)P(y)}{P(X)} \tag{1}$$

Here, X will be given as $X = (x_1, x_2, \dots, x_n)$. Expanding our equation with multiple features that are conditionally independent given the class, (2) becomes the result [10].

$$P(y|x_1, x_2, \dots, x_n) = \frac{P(x_1|y)P(x_2|y)\dots P(x_n|y)P(y)}{P(x_1)P(x_2)\dots P(x_n)} \tag{2}$$

Due to the static nature of the denominator across entries in the dataset, the denominator can be removed. In the case of the class variable for this research, the outcome is either yes (dementia) or no (no dementia). Equation (3) shows the equation being used for this experimentation, where x^i is the value of the i^{th} attribute in x, and n is the total number of attributes [10].

$$P(y|x_i) = \sum_{i=1}^n P(x_i|y)P(y) \tag{3}$$

Fig. 6. The combined dataset’s correlation.

B. Decision Trees

Decision trees consist of internal nodes that split into sub-spaces, dependent upon the values of the inputted attributes [11]. Each iteration of the decision tree considers a single attribute which is then partitioned according to its value [11]. Each leaf node of a decision tree represents the predicted class outcome variable. Within this research, navigation will happen from the root of the tree to the leaf, with the path being dependent on the values read for a person’s age, gender, and MMSE. Note that both numeric and nominal values may be used. The algorithm will predict dementia by sorting the data down the tree with corresponding values [11]

C. K-Nearest Neighbor

K-nearest neighbor classification is a simple methodology, especially used when little prior knowledge about the data’s distribution is known [12]. It looks through all examples in the data and finds the distance between one query and all the others. It performs both classification and regression. In the case of classification, which is the technique used in this research, it finds “K” number of examples like the query and votes for their most frequent label to correctly classify the outcome variable [12].

D. Fully Connected Neural Networks

Contrary to the assumptions in Naïve Bayes, Fully Connected Neural Networks do not utilize any assumptions on input, meaning that they are structure agnostic [13]. As a result, they are broadly applicable to learning any function, but can lack efficiency compared to special-purpose networks [13]. All neurons are connected to those in the previous layer, meaning the output is partly dependent on the input. While this model may be impractical for computationally demanding tasks, the classification used within the framework of this paper is acceptable.

E. K-fold Cross Validation

K-fold Cross Validation is an approach to data partitioning where the dataset is split into k folds/subsets [14-17]. The dataset is split into k equal parts, with each subset being utilized iteratively to either learn or evaluate the performance of the model [14]. One fold is used at a time to test the model, but each fold is incorporated into the testing at some point. Each iteration of cross-validation has a model trained independently than the iteration before and then the test set is validated [14]. By the end of the algorithm, each fold will have been validated and the results will be averaged.

V. EXPERIMENTAL RESULT

A. K-Nearest Neighbors, Naïve Bayes, and Decision Tree

The K-Nearest Neighbors (KNN), Naïve Bayes (NB), and Decision Tree (DT) were used initially to test, each with encouraging results. The model was trained with 80% of the set and tested with 20%. After combining the dataset, the experiment using the same algorithms gave slightly improved results in KNN. Table 1 shows the accuracy comparison of these three models on two dataset.

B. Fully Connected Neural Network

The next step the team took in the model was to create a neural network which could be used to label the data. The architecture used to accomplish this goal was essentially four layers, including an input layer, two hidden layers, and an output layer. This was done using the Keras module in Python. Following the previous experiments, the 6 columns were passed as the input shape. Both hidden layers were defined as “Dense” to create a fully connected layer. The data was split into training and testing sets in similar ways to the earlier experiments, and then run through the model for 100 epochs. The accuracy of the model improved by nearly eleven percent by the end.

The accuracy of the model fluctuated quite a bit during the epochs, specifically with the validation data. The accuracy of the training data remained constant. This is shown in Fig. 7. The overall accuracy of the model was initially reported as around 89%. However, after only running the model several more times, the accuracy increased to and remained at 1.

TABLE I. ACCURACY COMPARISON OF THREE MODELS ON TWO DATASETS

Dataset	Train data	Test data	KNN	NB	DT
Alzheimer’s dataset	296	75	85%	100%	100%
Combined dataset	424	182	91%	100%	100%

C. K-fold Cross Validation

A final test that the team ran was performed using K-fold Cross Validation. It was decided that 10 would be the number of folds used for testing purposes. The team used K-fold Cross Validation alongside logistic regression to make their predictions. According to the results given by the Python program, the accuracy when using 10 folds was about 0.998, with a standard deviation of 0.005. Adding more folds increased the accuracy to 100%, but again, the dataset’s size makes these results tentative at best.

Fig. 7. Models performance in terms of accuracy

VI. CONCLUSION

This research set out to expand on existing research regarding the early detection of dementia through machine learning algorithms. The goal was to conduct a comparative analysis on various methods that best identified relevant attributes and provided the highest classification accuracy in its predictions. Both the Alzheimer Features and Exploratory Data Analysis for Predicting Dementia datasets were utilized and preprocessed to clean up all the missing or inconsistent data. The dataset was used to train the following algorithms: Naïve Bayes, Decision Trees, K-Nearest Neighbors, Fully Connected Neural Networks, and K-fold Cross Validation. Evaluation measurements included accuracy, confusion matrix, and the ROC curve. For the utilized dataset, Naïve Bayes and Decision Trees recorded the best results.

There were two major limitations of this study. Firstly, there was a lack of available data. After combining two datasets and conducting data preprocessing, the dataset only featured approximately 600 rows. Consequently, the models had less data to work with to learn and improve their accuracy scores. As with all machine learning research, the more data provided leads to improved accuracy due to a greater amount of training and testing data. The second limitation was the performance of the Fully Connected Neural Network. At times, the accuracy was extremely low, while also occasionally reaching 100%. The high accuracy scores indicate room for growth, so the focus of the team’s future research will be on increasing the power of the neural network and experimenting with deeper levels of the network. Once a larger dataset is procured, the team will look to explore the optimal number of folds with K-fold Cross Validation. Along with utilizing a larger dataset, additional machine learning models, such as Logistic Regression, Support Vector Machines, and Multilayer Perceptron, will be used to improve this research.

Abstract—Scene understanding of urban streets is a crucial component in perception task of autonomous driving application. Semantic segmentation has been extensively used in scene understanding which further provides assistance in subsequent autonomous driving tasks like object detection, path planning and motion control. But, accurate semantic segmentation is a challenging task in computer vision. U-Net is a popular semantic segmentation network used for segmentation task. In this paper, we improve the accuracy of U-Net model by replacing its encoder part with Convolution Neural Network (CNN) architecture. We compared the performance of VGG-16 and ResNet-50 CNN architectures. Extensive analysis was performed on Cityscapes dataset and the results demonstrated U-Net with VGG-16 encoder shows better performance than ResNet-50 encoder. The model is compared with semantic segmentation CNN architectures like Fully Convolutional Network (FCN) and SegNet with mean Intersection over Union (mIoU) improved by 2%.

Index Terms—Semantic segmentation, U-Net, Autonomous Driving

I. INTRODUCTION

In recent years, autonomous driving have gained popularity with the ease of deep neural networks. An autonomous car need to sense its surrounding environment and plan its navigation without human intervention. Hence, accurate perception and decision making of the environment becomes crucial task. Scene understanding becomes the basic building block for the important modules in autonomous driving cars which comprises SLAM, path planning and motion control. Semantic segmentation assists the autonomous driving cars to perceive better understanding about the surrounding.

Scene understanding refers to identification of

lanes, maneuver, cars, pedestrians, cyclists and traffic signs. The key choice to achieve this goal is to apply semantic segmentation based on deep learning which helps to increase the detection accuracy. Semantic segmentation is a pixel level classification that assigns class label to each pixel in an image with different categories like cars, pedestrians, buildings, lanes, traffic lights, sky, trees etc.,. Though many traditional computer vision algorithms [1]–[3] were proposed for semantic segmentation, the recent progress in deep learning based approaches witnessed a large margin with CNN based semantic segmentation methods [4]–[6].

Camera sensors are most widely deployed in urban driving scenarios and traffic surveillance systems. Most of the deep learning based semantic segmentation networks proposed to process RGB images generated by monocular images mounted in autonomous driving car. Various CNN based networks are proposed for semantic segmentation, for example, U-Net, FCN, SegNet, ENet etc. In this paper, we modified the most widely used real time semantic segmentation network U-Net [5] by changing the encoder part. We applied 2 different structures to the encoder such as VGG-16 [7] and ResNet-50 [8]. Extensive analysis on Cityscapes dataset [9] demonstrates that U-Net+VGG-16 shows better performance with mIoU increased by 2%.

The major contributions of this paper is given as follows :

- Modified the encoder part of the U-Net with CNN such as architectures VGG-16 and ResNet-50.

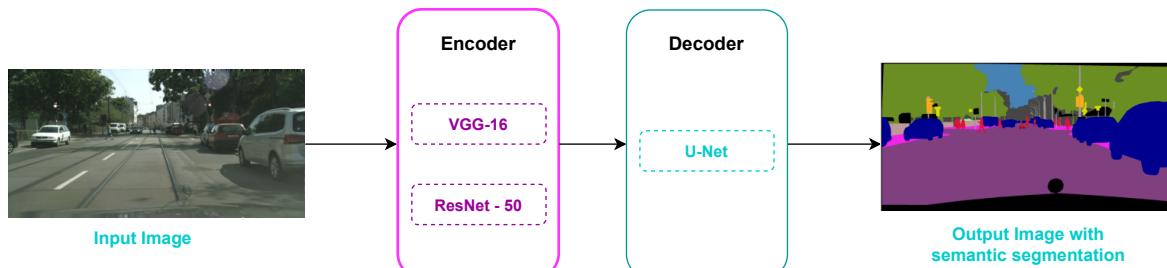

Fig. 1: Block diagram of proposed model

- Analysed the results based on the mIoU and found the accuracy increased with VGG-16 encoder.
- Extensive experiments were carried out on Cityscapes Semantic Segmentation dataset and achieved 2% improvement in mIoU.

The remaining sections of the paper is organized as follows : Section II describes the detailed explanation of various existing techniques used for semantic segmentation. Section III explains the proposed modified U-Net. The experimental results and performance analysis of the proposed method is provided in Section IV. Finally, Section V concludes the paper.

II. RELATED WORK

Computer vision achieved remarkable progress with rapid improvement in deep learning. CNN based object classification and detection methods created a huge impact in improving models accuracy and speed. Many CNN based models were proposed for object classification tasks. Example includes LeNet [10], AlexNet [11], VGGNet [7], GoogleNet [12], These methods aimed at improving accuracy by increasing the hidden layers. But, it resulted in vanishing gradient problem. Then few models like ResNet and DenseNet introduced skip connections to overcome the problem of vanishing gradient. But, it increased the number of trainable parameters which restricted the models from being deployed in real time applications. Later, InceptionNet [13], ShuffleNet [14], MobileNetV1 [15], MobileNetV2 [16] were developed with depthwise separable convolutions which made them suitable for real time deployment.

Evolution of semantic segmentation models increased by the first end-to-end FCN proposed in [4]. It is the first encoder-decoder based architecture which replaced fully connected layers with

fully convolutional layers. ESNet [17] is a symmetric encoder-decoder structure with convolution done in 3 levels : parallel convolution, dilated convolution and pointwise convolution. This resulted in reduced inference time and network complexity. ShelfNet18 [18] adopted multiple encoder-decoder structure. It used residual block which has convolution layers and imposed weight sharing among them. This decrease network parameters which in turn decreases the inference time. ERFNet [19] used residual connections while LEDNet [20] is an asymmetric encoder-decoder structure. It deployed receptive field enlargement with channel shuffling and attention pyramid network. ENet [21] applies early downsampling to decrease inference time and computation cost.

Of all the semantic segmentation models discussed above, we chose U-Net architecture and modified its encoder with CNN architectures such as VGG-16 and ResNet-50.

III. PROPOSED WORK

[5] proposed a U-shaped network with encoder decoder architecture for semantic segmentation. Figure 1 shows the block diagram of the proposed model and the algorithmic steps are given in Algorithm 1. Figure 2 shows the architecture of U-Net. The encoder part also called as contracting path to extract the features and the decoder path otherwise called as expanding path to infer class labels. The encoder and decoder are linked by means of skip connections and deploys end-to-end segmentation. The contracting path recognizes what the object is and the expanding path recognizes the pixel positions. The encoder follows typical architecture of convolution network with two convolutions and one pooling at each step. It increase the number of feature maps per layer by downsampling. The decoder comprises of one transposed convolution

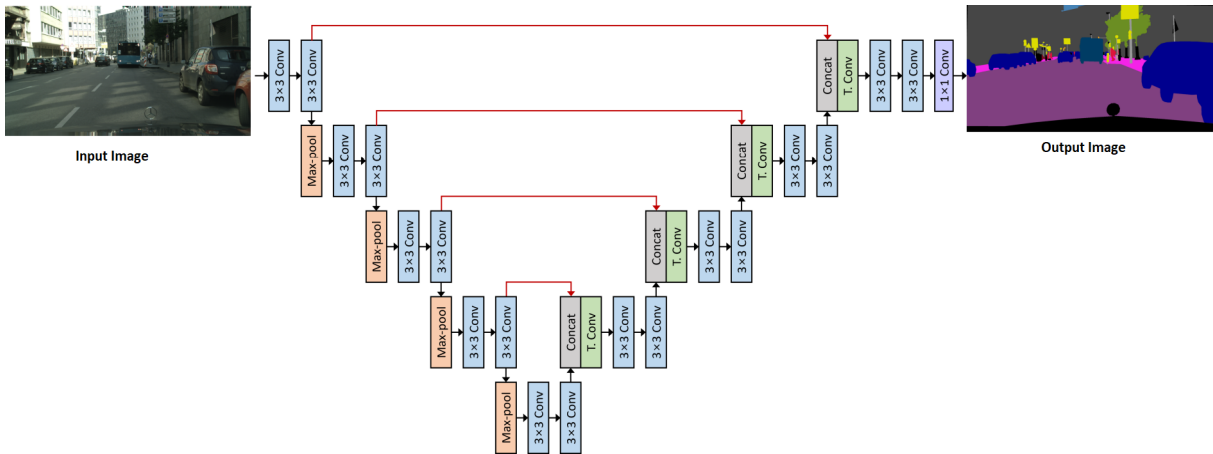

Fig. 2: U-Net architecture for semantic segmentation [5]

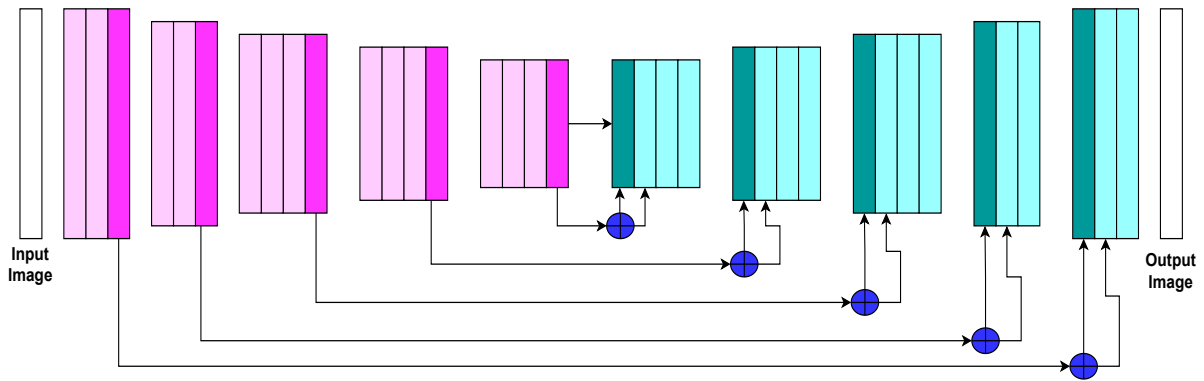

Fig. 3: VGG16 + U-Net architecture

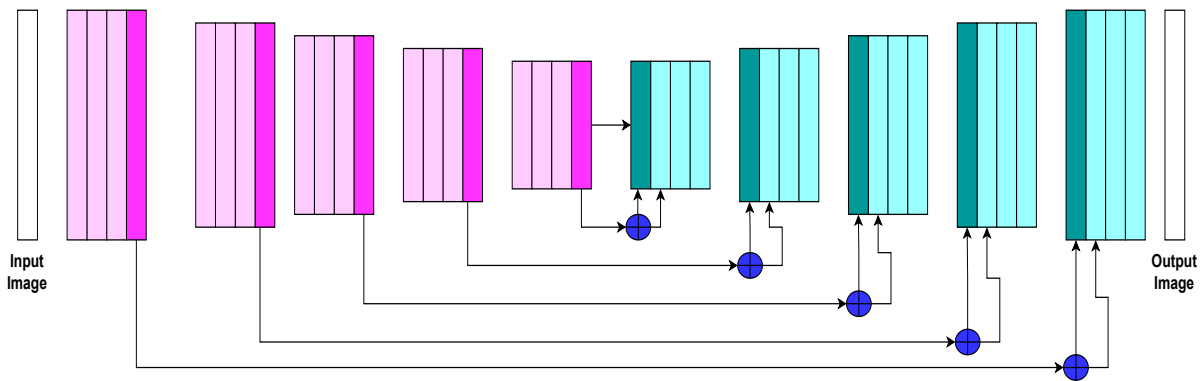

Fig. 4: ResNet-50 + U-Net architecture

and 2 convolutions which performs upsampling of feature map followed by convolution. Hence, the decoder part is meant to improve the resolution.

To infer the class labels, the upsampled features obtained in the decoder through transposed convolution concatenated with the high-resolution

TABLE I: Comparison of two proposed models with existing semantic segmentation models

	Precision	Recall	F1-Score	mIoU
U-Net [5]	0.86	0.85	0.85	78.8
Seg-Net [6]	0.84	0.81	0.82	78.6
FCN [4]	0.83	0.81	0.82	74.3
U-Net+ResNet-50 (proposed)	0.87	0.86	0.86	79.4
U-Net+VGG-16 (proposed)	0.89	0.86	0.87	80.5

features obtained in encoder part via skip connections. The architecture of U-Net was small and elegant with significantly less convolutions which makes it suitable for real time semantic segmentation. This motivated us to choose U-Net for the semantic segmentation in autonomous driving. In this work, we modify the encoder part of U-Net with CNN architectures : VGG16 and ResNet-50. VGG-16 consists of 7 sequential layers, 2 convolution layers followed by ReLU activation function and 5 max pooling layers. ResNet-50 is a CNN architecture which introduced identity mapping the idea of skipping some layers. ResNet-50 has convolution layers followed by ReLU activation function and maxpooling layers. The proposed model uses original layers from VGG-16 and ResNet-50. Upsampling is done to restore image dimensions and concatenation is performed to deploy skip connections which integrates feature maps with their class labels. Figure 3 and 4 shows the modified U-Net with VGG-16 and ResNet-50 in its encoder part.

Algorithm 1 : Modified U-Net for semantic segmentation

Input: Input image 'I'

Output: Semantic segmented image

Step 1: Extract feature maps with encoders VGG-16 and ResNet-50 for each pixel (x,y) in I

Step 2: Send extracted feature maps to decoder of U-Net

Step 3: Infer class labels

Step 4: Perform concatenation of feature maps with class labels using skip connections

Step 5: Generate output image with semantic segmentation of various categories

IV. EXPERIMENTAL RESULTS AND DISCUSSIONS

Environment Setup : The model was implemented in PyTorch.

Dataset : Cityscapes dataset is most widely used large scale autonomous driving dataset which includes images from urban street scenes. The images were captured in the sheets of 50 different cities in Germany. It has 5000 and 20000 fine labelled and rough labelled images respectively. We utilized 2975, 500 and 1525 images for training, validation and testing. It comprises of 19 different classes important for autonomous driving like car, bus , train, sidewalk, cyclist, etc.

Training details : The model was trained on an NVIDIA 1080 Ti GPU for 50 epochs. We set the learning rate to 0.001 and used Adam optimizer and ReLU activation function.

Evaluation Metrics : The metrics we used to evaluate our model are :

(i) **mIoU** measures the accuracy of semantic segmentation and it denotes the average of the ratio of IoU of all classes with the ground truth and the union of ground truth with the segmentation results.

(ii) **F1-score** is the harmonic mean of precision and recall. Precision, Recall, F1 Score, mIoU are calculated using equations 1, 2, 3, 4 respectively. TP, FP and FN denotes True Positive, False Positive and False Negative.

$$\text{Precision} = \frac{TP}{TP + FP} \tag{1}$$

$$\text{Recall} = \frac{TP}{TP + FN} \tag{2}$$

Fig. 5: Semantic Segmentation with VGG16+U-Net architecture

Fig. 6: Semantic Segmentation with ResNet50+U-Net architecture

$$F1 \text{ Score} = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \quad (3)$$

$$MIoU = \frac{1}{k} \sum_{i=0}^k \frac{TP}{TP + FP + FN} \quad (4)$$

Results & Analysis : Figure 5 and Figure 6 shows the performance of modified U-Net with VGG-16 and ResNet-50 encoders. Figures (a), (b), (c), (d) shows the input image, corresponding ground truth, results of U-Net, results of U-Net with VGG-16 and ResNet-50 encoders. The dotted rectangles in Figures 5 and 6 shows the portions where VGG16+U-Net and ResNet-50+U-Net performed better than original U-Net. Table I shows the comparison among Modified U-Net with CNN architectures VGG-16 and ResNet-50 and other semantic segmentation networks such as FCN and Seg-Net. From the results, we observed that U-Net with VGG-16 encoder gives better performance than ResNet-50. It is because VGG-16 has less number of convolution layers than ResNet-50.

V. CONCLUSION

Semantic segmentation plays a major role in scene understanding which helps in the urban street perception. It is very important for an autonomous car to have complete understanding about their surrounding in order to plan their maneuver. With the improvement in deep learning models in the last decade, many CNN models were proposed for semantic segmentation. In this paper, we improved the accuracy of U-Net model by replacing the encoder with CNN architectures. The model was trained and tested on Cityscapes dataset and inferred that U-Net with VGG-16 showed better performance. In future, we would like to test with other variations of VGG-Net models like VGG-11 and VGG-19.

VI. ACKNOWLEDGEMENT

This publication is an outcome of the R&D work undertaken in the project under TiHAN Faculty Fellowship of NMICPS Technology Innovation Hub on Autonomous Navigation Foundation being implemented by Department of Science & Technology National Mission on Interdisciplinary Cyber-Physical Systems (DST NMICPS) at IIT Hyderabad.

Performance Analysis of a New Non-contact, Potentiometric Angle Sensor

¹Mithun Sakthivel and ¹Utpol Tarafdar

Department of Electrical Engineering, National Institute of Technology Calicut, India

Abstract – Resistive, potentiometric type of transducers find lots of applications in angle sensing due to their simple operation and linear outputs. However, they have a major disadvantage that their wiper undergoes wear and tear in course of time. So, a floating wiper is the solution to this problem. Hence in one of the previous works, a new non-contact potentiometric transducer was developed by the authors by modifying a conventional, contact-type resistive transducer. As the wiper is now floating with respect to its fixed terminals, an air gap capacitance got included in the equivalent circuit of this transducer and therefore, to get linear results from it, a novel signal conditioning circuit was developed by the authors. The principle of operation of this circuit has been discussed in a follow-on paper by the authors. This paper is a continuation of these previous works and it reports the performance analysis conducted on this sensor for a few features.

Keywords: Angle sensor, Non-contact transducer, Potentiometer, Precision, Repeatability, Sensing range, Sensitivity, Speed of operation.

I. INTRODUCTION

Resistive potentiometers or pots can be used as angle or sensors that display angle information by measuring the voltage across a movable contact that is sliding over a coiled resistive wire which is supplied with a fixed dc voltage [1]. Their characteristics, such as sensitivity, accuracy, resolution, and dependability, as well as their cost, may vary depending on the application. While the first four features should be very high for medical applications [2], angle sensors for automobiles (for steering rotation detection, throttle position detection and so on [3 - 5]) must be inexpensive and long-lasting. The key advantage of resistive potentiometric sensors is that they produce an output that varies linearly with its shaft position using simple potentiometric principle [5]. Furthermore, its straightforward operation reduces the complexity and expense of the signal conditioning circuit. Their primary downside, however, is that their moving contact or wiper is prone to wear and tear, resulting in poor performance [3]. However, by employing a wiper which does not make any physical contact with the resistive coil as shown in Fig. 1, wear and tear can be greatly reduced. So, the authors developed this non-contact type potentiometric transducer in [6] by slightly modifying a conventional contact-type pot available in the lab and studied the advantages of using it for developing an auxiliary Steering Angle Sensor (SAS) that can be utilized for sensing the front-wheel orientation of automobiles. In Fig. 1, the air gap between the resistive coil

and the wiper constitutes a coupling capacitance C whose value is in pF range, potentially affecting the transducer's sensitivity. Hence, a high frequency alternating current (ac) was utilized to stimulate it. Furthermore, to obtain linear outputs for the measured angles, a novel signal conditioning circuit was developed by the authors in [7]. Its simulation results were found to be quite good and when developed on hardware, it displayed linear outputs as expected. As this is a new sensor in development, it needs to be evaluated for some important features such as sensitivity, sensing range, repeatability, precision and speed of operation with regard to its intended application. The results obtained during the analysis of these parameters are presented in this paper. The results indicate that this new sensor has adequate sensitivity, adequate sensing range, good repeatability and good speed of operation, making it suitable for the developing the auxiliary SAS. However, its precision needs improvement.

II. PRINCIPLE OF OPERATION

Fig. 2 shows the signal conditioning circuit used to obtain angle information from the new non-contact potentiometer. The authors had explained the operation of this circuit in detail in [7]. It essentially uses a differential sensing technique to overcome the effect of C and then gather angle information in a linear fashion from its outputs. The circuit can be split into two branches: the sensing branch on the upper half and the reference branch on the lower half. Each half has two identical potentiometers with equal resistance R and inductance L . While pot-1 & pot-3 in Fig. 2 are conventional pots, pot-2 & pot-4 are non-contact pots. In each branch, the conventional pot acts as the input impedance, whereas the non-contact pot acts as the feedback impedance of an integrator. Here, pot-2 of the Integrator I-1 depicts the angle sensor with its R and L varying with respect to angle in the form of $(1 - k)R$ and $(1 - k)L$, where k denotes the proportion of the coil between the moving contact and the fixed contact 2. So I1's output will be always varying. I-2, on the other hand, provides a output that is always fixed since it always includes the total R and L of pot-4 during operation. The outputs of the two integrators are fed to an Instrumentation Amplifier (IA) which amplifies the difference between the two signals. In Fig. 2, the integrators contain a feedback resistor R_f which prevents their saturation due to opamp offset voltage. But for easy explanation of the

Fig. 1. The new non-contact potentiometric transducer. The air-gap capacitance is indicated by C .

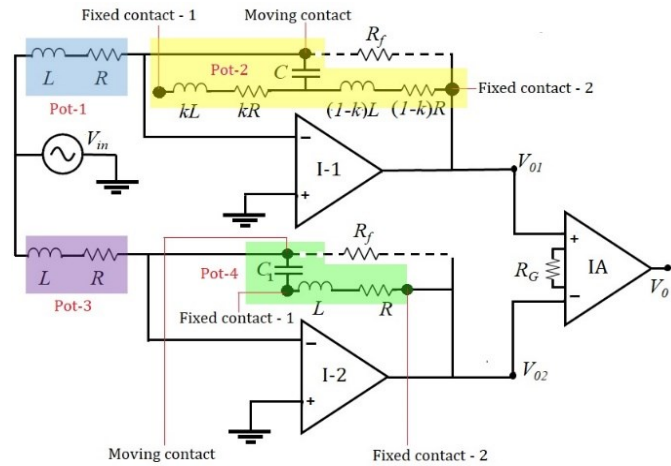

Fig. 2. The novel signal conditioning circuit developed for the non-contact transducer.

theory of operation of this circuit, the equations below have been presented without accounting these R_f .

The output of the integrator I-1

$$V_{01} = -\frac{\frac{1}{jC\omega} + (1-k)[R + jL\omega]}{R + jL\omega} \times V_{in} \quad (1)$$

This is derived from the general equation for an integrator's output. Here, V_{in} is the input voltage, and ω (or f) is the excitation frequency. Rearranging,

$$V_{01} = -\left[\frac{1}{jC\omega(R + jL\omega)} + (1-k) \right] \times V_{in} \quad (2)$$

Similarly the output from I-2 is obtained as in eq.(3). Here, C_1 is the air-gap capacitance of pot-4.

$$V_{02} = -\left[\frac{1}{jC_1\omega(R + jL\omega)} + 1 \right] \times V_{in} \quad (3)$$

The final output of this circuit which is the output of IA is obtained as eq. (4).

$$V_0 = G(V_{01} - V_{02}) \quad (4)$$

Substituting (2) and (3) in (4), the final expression of V_0 is obtained in eq. (5) when $C_1 = C$. Here G is the gain of the IA, determined by the resistor R_G .

$$V_0 = GkV_{in} \quad (5)$$

From the above eq. (5), it is clear that the new signal conditioning circuit produces linear outputs with respect to angle (indicated by the parameter k). However, when $C_1 \neq C$, the equation of V_0 is as follows:

$$V_0 = GkV_{in} + j \frac{1}{(R + jL\omega)\omega} \left[\frac{1}{C} - \frac{1}{C_1} \right] GV_{in} \quad (6)$$

In the above eq. (6), the second term is the offset voltage of the sensor. This can be reduced by the following methods:

- Replace pot-4 with a normal contact-type pot and substitute its air-gap capacitance with a physical variable capacitor whose value closely matches C .
- Raising the excitation frequency and
- Using pots with large value of R (and hence L)

Incorporating these corrective measures, the R value of the non-contact transducer finally selected for performance analysis was $50 \text{ k}\Omega$ and f was chosen as 150 kHz for most of the measurements. The results of the performance analysis are presented in the following section.

III. PERFORMANCE ANALYSIS

As it is required to evaluate the performance of any new sensor under development to establish its efficacy, the new non-contact potentiometric transducer along with its linear signal conditioning circuit was tested for the five parameters mentioned in this section. Since this angle sensor is being developed for making an auxiliary SAS for automobiles, the

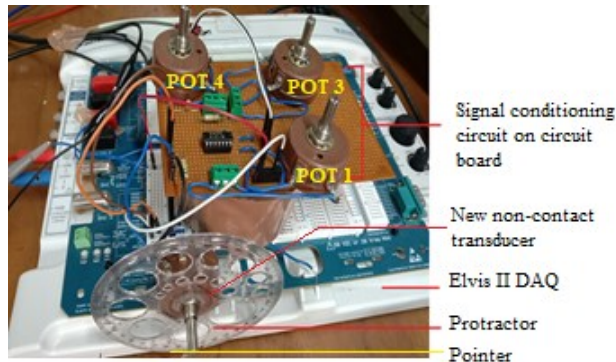

Fig. 3. Experimental setup of the transducer and the signal conditioning circuit on ELVIS II

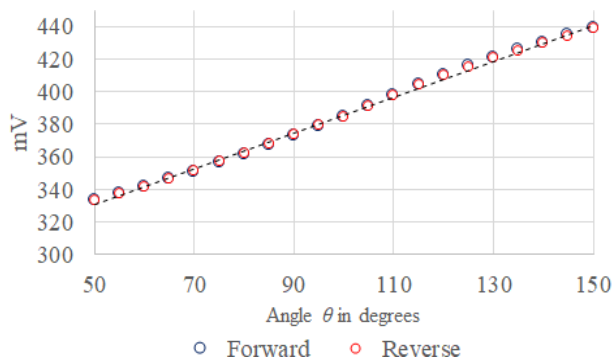

Fig. 5. Results of repeatability analysis, V_{p-p} versus θ for $G = 6.03$. Here, the forward and reverse output at each angle is the average of 100 sets of readings.

interpretation of the results obtained for each parameter is with respect to this application, that is, it will be explained if the performance of the new sensor is adequate for this application or not. The setup used for the performance analysis is shown in Fig. 3. The transducer and its circuit were soldered on a dot board and interfaced with NI ELVIS II [8] data acquisition (DAQ) board that provided the input V_{in} as well as the power supply for the various ICs in the circuit. The opamp IC and the IA used in the circuit were TL084 from Texas Instruments and AD620 from Analog Devices respectively. The voltage outputs from the IA for different angular displacements of the shaft of the angle sensor were measured either using the same ELVIS board or a separate DSO (Digital Storage Oscilloscope) depending on the frequency of excitation used. When ELVIS was used to take the reading, a LabVIEW program was used to display the IA's output on a computer screen. To identify the angular position of the shaft, a stationary protractor was placed around it as seen in Fig. 3. When the pointer connected to the shaft of the angle sensor was placed over a particular marking

Fig. 4. Results of sensitivity analysis

TABLE I
RESULTS OF SENSITIVITY ANALYSIS

k	Angle in degrees	$G = 6.03$	$G = 11.74$	k	Angle in degrees	$G = 6.03$	$G = 11.74$
		V_{p-p} (mV)	V_{p-p} (mV)			V_{p-p} (mV)	V_{p-p} (mV)
0.83	50	334	651	0.65	105	391	771
0.82	55	338	663	0.63	110	397	784
0.8	60	342	671	0.62	115	404	797
0.78	65	346	681	0.6	120	410	812
0.77	70	351	691	0.58	125	415	819
0.75	75	357	702	0.57	130	420	829
0.73	80	362	713	0.55	135	425	835
0.72	85	368	724	0.53	140	430	842
0.7	90	373	736	0.52	145	434	852
0.68	95	379	751	0.5	150	439	859
0.67	100	385	756				

on this protractor, the corresponding angle was noted down along with the magnitude of the output waveform seen on the DSO or the computer screen. This activity was repeated one after the other for different angles within the sensing range of the sensor. The parameters that were evaluated are as follows:

a. Sensing range

Sensing range of a sensor is the range of magnitude of the measurand within which it produces effective outputs. For this angle sensor, it was taken as the angles within which it produced linear outputs as per the theory. It was determined while estimating the sensitivity of the sensor. Although, the total span of the commercially available pot that was tweaked to develop this non-contact transducer was 300 degrees, its sensing range was found to be 100 degrees within the limits of 50 degrees and 150 degrees (refer Fig. 4). The reason for this small range is the variation in the value of C along the perimeter of the transducer from fixed contact 1 to fixed contact 2. Between 0 & 50 degrees and 150 & 300 degrees, this air gap capacitance was observed

to be varying and therefore, the expected linear trend in the output with respect to angle was not observed. So, further work will be done to eliminate this issue. The reason for this variation of C is the variations in the radius of the resistive coil with respect to the axial shaft. However, for the proposed auxiliary SAS that was intended to identify the angular position of the front wheels of the vehicle during motion, this sensing range is sufficient as the front wheels themselves displace by ± 30 degrees only from the central position [9]. Using suitable conversion gears, this 100-degree operational range can be easily made to read the total of 60 degrees movement of the front wheels from left to right.

values at $G = 11.74$ are almost double to $G = 6.03$ as the selected gain values were not too high that the output voltage V_O was within the slew rate of the IA ($= 1.2 \text{ V}/\mu\text{s}$) [10] at 150 kHz. The sensitivity of the circuit for the two gain values can be identified from the trendline equations presented in Fig. 4 that has been plotted using the values in Table I. For $G = 11.74$, it is equal to $2.2 \text{ mV}/\text{degree}$ while for $G = 6.03$, it is $1.1 \text{ mV}/\text{degree}$ approximately. Although these are not too high values, an ADC like ELVIS whose resolution is in μV can easily identify the corresponding angle from the output values. So, ideally the obtained sensitivity of this new sensor is adequate for the proposed auxiliary SAS. Moreover, the sensitivity can be further improved to $3.2 \text{ mV}/\text{degree}$ by increasing G to 17 which

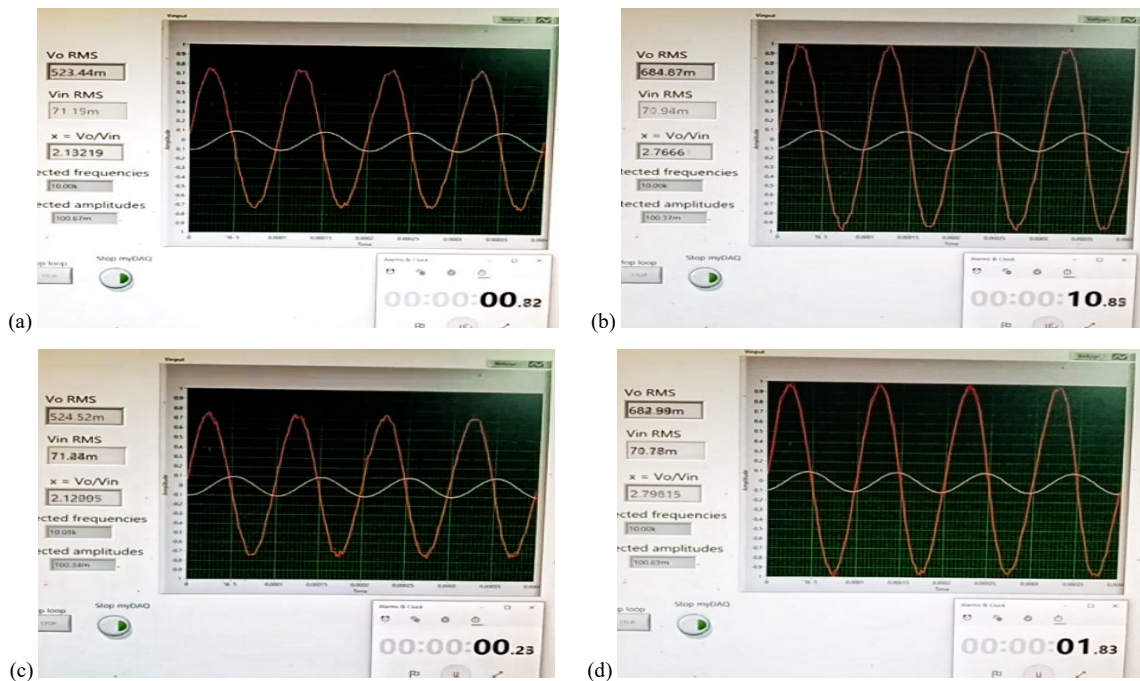

Fig. 6. Evaluating the speed of operation of the new non-contact transducer - (a) & (b) are the initial and final time stamps of the 10 s operation and (c) & (d) are the initial and final time stamps for the 1.5 s operation. In these figures, the red signal is V_O while the white is V_{in} .

b. Sensitivity

The sensitivity of a sensor is the voltage output it produces for unit change in the measurand's value, which is angle in this case. Sensitivity of this sensor (transducer + its signal conditioning circuit) basically depends on the gain of the IA used. The values of the gain resistor R_G used to obtain gains of 6.03 and 11.74 were 9.63 k Ω and 4.60 k Ω respectively. The peak-to-peak (V_{p-p}) values of V_O obtained from the DSO for $V_{in} = 75 \text{ mV}$ amplitude and 150 kHz, for various values of k are shown in Table I. In this table, it can be seen that the output

is the maximum gain possible without affecting the shape of V_O due to the slew rate of the IA when $V_{in} = 75 \text{ mV}$ at 150 kHz.

A point worth noticing in Fig. 4 is that the offset voltage of the sensor denoted by the y-intercepts of the linear trend-line equations is seemed to have reduced when compared to [7]. In [7], the V_{p-p} values of offset voltage obtained during the experimental evaluation should have been 352 mV and 685 mV respectively for $G = 6.03$ and $G = 11.74$ respectively, but these are now 275.2 mV and 541.4 mV respectively. This shows that

the remedial measures suggested earlier have been effective in reducing this nonideality.

c. Repeatability

This is one of the most important attributes of a sensor as it is supposed to produce same outputs for the same magnitude of the measurand irrespective of the direction in which the measurand is varying. The first step in determining repeatability was to set the wiper to 50 degrees and record the obtained output for this position (the features of V_{in} were kept the same as earlier). Then, for every 5 degrees, the wiper was displaced and outputs were collected up to 150 degrees. This can be considered as the forward trend of the measurand. Following this, outputs were collected in the reverse trend from 150 degrees to 50 degrees with the same spacing of 5 degrees. A total of 100 sets of such forward and reverse measurements were taken and their respective averages for each angle were calculated. These averaged values are presented graphically in Fig. 5. As the output values of both trends for each angle are exactly superimposing in this figure, the repeatability of the sensor can be claimed to be very good and therefore, it is very suitable for its intended application. However, an aspect to be noted is the slight deviation in the output values from the dotted trendline provided in this figure. This is due to variation in the value of C along the perimeter of the transducer that was mentioned earlier. Although not easily seen, this aspect is present in Fig. 4 also. In fact, Fig. 4 and Fig. 5 are the same for $G = 6.03$, but in Fig. 4, an additional set of readings has been taken for $G = 11.74$ as the objective there was to identify the best change in output for unit angular displacement in degrees.

d. Precision

Precision is the consistency with which a sensor produces its output for a given magnitude of the measurand. The precision of the new non-contact sensor was also studied while performing the repeatability analysis. The maximum, average and minimum V_{p-p} values obtained for each angle taken in Table I in a set of 200 measurements while $G = 6.03$ are shown in Table II. In this table, the equation for the mean absolute deviation \bar{u} =

$$\bar{u} = \frac{\sum_{i=1}^{200} |V_{p-p-i} - \overline{V_{p-p}}|}{200} \quad (7)$$

Here, V_{p-p-i} is the V_{p-p} value obtained for the i^{th} V_O measurement corresponding to an angle and $\overline{V_{p-p}}$ is the mean V_{p-p} value of these 200 measurements. It can be seen that, although the deviations of the extreme values from $\overline{V_{p-p}}$ are only a few mV, these cannot be considered negligible as the mean absolute deviation \bar{u} is comparable to the difference in

$\overline{V_{p-p}}$ for every 5-degree angle evaluated. This will affect the ability of the sensor to distinguish or resolve angle changes less than 5 degrees which means, the proposed SAS will not be able to sense small changes in front-wheel orientations. Hence, the precision of the sensor needs to be improved for the proposed SAS. The possible reasons for these V_{p-p} variations are ambient noise, quantization noise of the ADC of the DSO (The DSO, Tektronix Model No. 2014C will have a quantization error of 1.56 mV as its 8-bit ADC [11] was operating on a scale of 100 mV/division) and the human error in placing the pointer correctly over a particular angle on the protractor. So, work will be done to improve the precision of the sensor. Although, both repeatability and precision analysis used the same set of (two hundred) V_{p-p} readings, the results of repeatability analysis were presented using $\overline{V_{p-p}}$ values alone. The effects of all the above reasons were minimalized in it due to averaging. Hence $\overline{V_{p-p}}$ values are the most accurate outputs corresponding to the angles evaluated and this is also the reason for the high repeatability obtained earlier. In fact, averaging a good technique to improve the accuracy of the sensor. But for this, the DAQ system has to operate at very high speed as steering angle will change continuously in real-time.

e. Speed of operation

As the intended application of the proposed non-contact transducer was steering angle sensing, the expected speed of operation of the sensor will be in the order of seconds as steering wheels are not abruptly rotated by the driver under normal conditions. Therefore, to investigate if the sensor's output would vary proportionally with angle at these ranges of speed, it was interfaced with a LabVIEW program through NI ELVIS II. The graphical interface of this LabVIEW program would indicate the RMS value of V_O along with a time stamp. Due to technical limitations of ELVIS, the excitation frequency was reduced to 10 kHz and the amplitude of V_{in} was increased to 125 mV. The idea of this test is as follows: If the sensor is able to produce the same outputs that it produced at a lower speed when displaced through its effective operating range at a faster pace later, then it is deemed suitable for the intended application. So initially, its shaft was displaced from 50 degrees to 150 degrees in about 10 s and the outputs (RMS values) corresponding to these limiting values of angles were recorded. These were found to be 524.5 mV and 683.0 mV respectively. Later, the same angular displacement was made in about 1.5 s and the corresponding RMS values were noted. In this attempt, the obtained values were 523.5 mV and 684.7 mV respectively. Similar results were obtained in another 20 more following attempts. As the output values obtained for 10 s and 1.5 s evaluations were very close to each other, it can be said that the

new non-contact sensor is consistent at higher speeds of operation as well. The screenshots of the time stamps of 10 s operation and 1.5 s operation are presented in Fig. 6. In this figure, 6a & 6b show the time stamps corresponding to the initial angular position (50 degrees) & final angular position (150 degrees) of 10 s operation respectively, while 6c & 6d show the corresponding values of 1.5 s operation respectively. As 1.5 s is the quickest time amongst the two, it can be said that the best angular velocity displayed by this transducer is about 67 degrees/s. An angular displacement of 67 degrees in 1 s is a pretty high value for the front-wheels of an automobile and will occur rarely only during an accident. Hence, it can be confirmed that the new sensor has good speed of operation, sufficient enough for its intended application.

Summarizing, the performance analysis of the new non-contact potentiometric angle sensor revealed the following – while it has good repeatability & speed of operation, its sensing range & sensitivity are adequate for steering angle sensing; its precision however needs improvement. So, further work has to be done for improving it. Moreover, if this sensor needs to be used for other applications that require sensing a wider range of angles, then additional work needs to be done for improving this feature too.

V. CONCLUSION

This paper presents the results of performance analysis of a new non-contact potentiometric angle transducer and its signal conditioning circuit designed for the purpose of developing an auxiliary SAS for automobiles. The features that were analyzed were sensing range, sensitivity, repeatability, precision and speed of operation. The sensing range of this angle sensor was observed to be 100 degrees which is adequate for the intended application. But, it can be improved further by minimalizing the effect of its air-gap capacitance if this sensor needs to be used for other applications that require sensing a wider range of angles. Its sensitivity with an amplifier gain of 12 was found to be around 2.2 mV/degree which is also adequate for SAS. From the mean V_{p-p} values obtained from sets of 200 measurements corresponding to different angles, it was identified that this sensor has very good repeatability for both ascending and descending trends of angle. Its speed of operation was found to be about 67 degrees/s, which is also good enough for the intended application. However, due to various reasons, the precision of this sensor was found inadequate. So, further work needs to be done to improve this. Thereafter, the improved sensor will be mounted on the steering column of a test vehicle in the lab and its suitability will be checked in real-time.

TABLE II
RESULTS OF PRECISION ANALYSIS

Identifying Functional and Non-functional Software Requirements From User App Reviews

Dev Dave¹, Vaibhav Anu²
 Department of Computer Science
 Montclair State University
 Montclair, NJ, USA
 {daved2¹ | anuv²}@montclair.edu

Abstract—Mobile app developers are always looking for ways to use the reviews (provided by their app’s users) to improve their application (e.g., adding a new functionality in the app that a user mentioned in their review). Usually, there are thousands of user reviews that are available for each mobile app and isolating software requirements manually from such a big dataset can be difficult and time-consuming. The primary objective of the current research is to automate the process of extracting functional requirements and filtering out non-requirements from user app reviews to help app developers better meet the wants and needs of their users. This paper proposes and evaluates machine learning based models to identify and classify software requirements from both, formal Software Requirements Specifications (SRS) documents and Mobile App Reviews (written by users) using machine learning (ML) algorithms combined with natural language processing (NLP) techniques. Initial evaluation of our ML-based models show that they can help classify user app reviews and software requirements as Functional Requirements (FR), Non-Functional Requirements (NFR), or Non-Requirements (NR).

Keywords— requirements, mining, classification, machine learning, natural language processing

I. INTRODUCTION

The requirements phase in the software development life cycle (SDLC) is one of the most important stages of software development. Incorrect or missing requirements can lead to an incomplete product that does not satisfy customer demand. Requirements are collected from various stakeholders (end-users, client, etc.) and recorded in a formal document called the Software Requirements Specification (SRS). The quality of the SRS document has an immense impact on the quality of the final software product. The SRS document outlines the functional and non-functional capabilities of the software-being-built. Thus, the development team, the end-users, and the client must share the same understanding [1]. The industry is still seeking to establish and apply good practices to identify and classify key software requirements that are often missed by software engineers during the initial releases of the software. Capturing such missing requirements is a key requirement for successful future releases of the software product.

In recent years, the growth of mobile devices has led to an increase in mobile software. App distribution platforms such as the Google Play Store and Apple’s App Store have had 4 million apps as of June 2016 with the number of monthly app downloads hovering around 1 billion per month [2]. Users that download these applications can rate the application and provide textual

feedback relating to the application. User reviews contain important information that can assist a developer in better understanding their users’ needs. Making use of user reviews for app upgrades can lead to an increase in new users and retain existing users. Studies indicated that one-third of users have modified their app ratings after a developer’s response. Mobile applications can receive more than 20 reviews per day and popular mobile applications such as Facebook can receive more than 4000 application user reviews a day [2]. Therefore, user reviews are an important source of feedback for developers to elicit (i.e., identify) requirements so as to provide fixes or updates in their apps. However, it is difficult to sift through vast amounts of user reviews and filter out reviews that do not contain a software requirement. Automatic extraction of software requirements through various approaches and frameworks can enable developers to respond quickly to customer needs and reduce the time spent on eliciting requirements. This paper introduces a *novel hybrid dataset* consisting of Functional Requirements (FR), Non-Functional Requirements (NFR), and Non-Requirements (NR) from Software Requirements Specifications (SRS) document and user app reviews. The hybrid dataset is used to create data models that use machine learning (ML) algorithms such as Support Vector Machine (SVM), Stochastic Gradient Descent (SGD), and Random Forest (RF) combined with natural language processing (NLP) techniques such as term frequency-inverse document frequency (TF-IDF). The data models are then evaluated by using 10 k-fold cross-validation and calculating accuracy metrics such as recall, precision, and the F1 score. Our research addresses the following research questions (RQs):

RQ1: *What is the type and size of data that is required to automate the identification of requirements from user app reviews?*

To answer this research question, we created a novel hybrid dataset. The hybrid dataset consists of formal software requirements from SRS documents from the PROMISE Software Engineering Repository and user app reviews from the dataset prepared by Maleej et. al [3]. The hybrid dataset consists of a total of 1,249 requirements and user app reviews. 507 requirements labeled as functional requirements, 371 labeled as non-functional requirements, and 371 labeled non-requirements.

RQ2: *To what extent can the Machine Learning Algorithms combined with NLP techniques accurately identify and classify Functional and Non-Functional Requirements?*

The results of all three data models using SVM, SGD, and RF combined with TF-IDF are evaluated by using 10 k-fold cross-validations and the performance of each model is evaluated by metrics such as accuracy, precision, recall, and F1 score for Functional and Non-Functional Requirements.

RQ3: *How effective are the data models in isolating Non-requirements from Functional or Non-Functional Requirements?*

To evaluate the effectiveness of the data models in identifying Non-Requirements, the precision, recall and F1 scores are calculated for user app reviews classified as Non-Requirements.

The primary contributions of this paper are:

1. Introducing a novel hybrid dataset with formal software requirements from SRS documents and user app reviews to identify functional and non-functional requirements as well as non-requirements that are unimportant.
2. Introducing and evaluating three data models using various ML algorithms with TF-IDF for the automatic identification and classification of software requirements and user app reviews.

II. BACKGROUND

Identifying and classifying functional requirements from SRS documents and User App reviews is an open research problem. Data related to requirements elicitation may not be well documented by the stakeholders and it is up to the developer to meet the requirements as per their understanding. Ambiguous requirements are a key factor in the failure of software projects. A lot of requirements are not initially captured but are captured during testing by the end-user or client to accept the software project before it is moved on to production [1].

In the rest of this section, we first describe FRs and NFRs, followed by a discussion on existing research on classification of software requirements.

A. Functional Requirements (FRs) and Non-functional Requirements (NFRs)

Software requirements are of two types: Functional requirements (FR) and Non-Functional requirements (NFR). For the purpose of our research, we propose a third type of requirement: a *Non-Requirement (NR)*. A non-requirement (NR) is a statement that contains no information whatsoever about software's features or qualities and thus has no impact on software development.

A functional requirement (FR) describes the required behavior of the software-being-built in terms of required activities, such as reactions to inputs, and the state of each entity before and after an activity occurs. FRs should describe the following [3]: what will the software system do; are there several modes of operation; What kinds of computations or data transformations must be performed; what are the appropriate reactions to possible stimuli?

A Non-Functional requirement describes some quality characteristics that the software solution must possess. It

describes the following [3]: performance; security; reliability and availability; maintainability; usability and human factors.

Thus, it is vital to identify and classify software requirements during the requirements engineering (RE) phase to ensure that the software development project will meet client requirements, is within the budget, and is completed on time.

B. Existing Research on Automatic Identification and Classification of Requirements from Formal Requirements Documents

This section explores the various approaches and tools that have been used to identify and classify software requirements from formal requirements documents (usually referred to as SRS documents).

Machine Learning Based Method: Binkhonain and Zhao [4] give an overview of various machine learning algorithms implemented and their performance to identify and classify non-functional requirements. The performance of 16 machine learning algorithms is evaluated. The 16 algorithms are divided into the following types of algorithms: 4 unsupervised, 5 supervised, and 5 semi-supervised machine learning algorithms [4]. The 4 unsupervised algorithms used are Latent Dirichlet Allocation (LDA), K-means, Hierarchical Agglomerative, and Biterm Topic Modelling (BTM). The five supervised machine learning algorithms used are Support Vector Machines (SVMs), Naïve Bayes (NB), Decision Tree (DT), K-Nearest Neighbors (K-NN), and Multinomial Naïve Bayes (MNB). Lastly, the Semi-Supervised algorithms used are Expectation-Maximization (EM), Self-training, Active learning, Random Subspace Method for Co-training (RAS-CO), and Relevant Random Subspace Method for Co-training (Rel-RASCO). The machine learning approaches had the same data preprocessing steps which included selecting appropriate features and preprocessing the text to be classified. The text was preprocessed by using methods such as stop word removal, stemming, and tokenization. To select the appropriate features, the text was converted into a numeric matrix using Bag-of-Words (BoW) and Term Frequency-Inverse Document Frequency (TF-IDF). The important features are evaluated by using information gain and the Chi-squared test. After preprocessing the text, the machine learning algorithms are implemented and evaluated by metrics such as accuracy, precision, recall, and F1 scores. Overall, ML algorithms achieve an accuracy score of more than 70% when classifying NFRs [4]. Supervised ML algorithms perform better than Unsupervised and Semi-supervised algorithms. SVM and NB algorithms achieved the best performance.

Data Visualization based Method: InfoVis is a tool proposed to identify requirements based on how ambiguous or incomplete a requirement is [5]. The tool combines data visualization and NLP methods to identify requirements. A novel algorithm, Semantic Folding Theory (SFT), takes in user input and then calculates the similarity between two words [5]. The ambiguity score is calculated based on the term and context similarity. Based on the scores, InfoVis generates Venn diagrams to easily visualize and explore requirements.

Template Based Method: An approach to identify security requirements involves the use of templates. Riaz et al. propose

the use of templates that automatically suggest security requirements to aid in the process of requirements gathering [6]. The template serves as a list of important security requirements to be included for the developers as they are eliciting the requirements. The template receives requirements as the input and based on the requirements, it creates a list of security requirements [6]. The template can serve as an assistive tool to be used with other tools to primarily focus on eliciting security requirements and addressing privacy concerns.

Furthermore, there are tools like the PROMIRAR tool that utilizes previous software requirements to create new requirements based on analogy reasoning [7]. The tool uses NLP techniques to identify hidden requirements.

C. Existing Research on Automatic Identification and Classification of Requirements from User App reviews

Lu and Liang et al.'s Approach: Lu and Liang propose four classifications techniques to classify functional requirements and non-functional requirements (NFRs). NFRs are classified into 4 categories which are reliability, usability portability, and performance. Four classification techniques Bag-of-Words (BoW), Term Frequency-Inverse Document Frequency (TF-IDF), Chi-Squared (Chi²) and Augmented User Reviews Bag-of-Words (AUR-BoW) are used in conjunction with three machine learning algorithms Naïve Bayes, J48, and Bagging to classify user reviews [8]. The results of each classification technique are evaluated by the F-measure for each experiment. The classification techniques are defined as follows:

- **Bag-of-Words (BoW):** BoW is a model used to represent textual documents in information retrieval systems. It uses a dictionary that consists of all unique terms of user reviews and uses term frequency (TF) and the number of times a phrase appears in a user review as the weight of the textual features. This is used to train the classifiers.
- **Term Frequency-Inverse Document (TF-IDF):** TF-IDF is like BoW but also uses inverse document frequency (IDF) as the weight of the textual features.
- **CHI2:** A statistical test that is used to select important textual features from user reviews that are acquired from BoW.
- **Augmented User Reviews Bag-of-Words (AUR-BoW):** User reviews are often short and split into sentences that can make classification difficult. AUR-BoW augments short user reviews by the most similar words and uses them as input for BoW.

To evaluate the trained classifiers, the following metrics are used: precision, recall, and F-measure. 10-fold cross-validation was performed on the dataset with each fold consisting of 400 user reviews [8]. The AUR-BoW classifier resulted in the highest F-measure score of 71.7%, a precision score of 71.4%, and a recall score of 72.3%. Augmenting user reviews leads to better results when classifying user reviews.

Chen et al.'s Requirements Mining Framework: Chen et al. proposed a requirements mining framework for mobile app upgrades. A new ranking model is developed to classify customer requirements and rank the importance of each

requirement. The effectiveness of the framework is then evaluated by product quality improvements [9]. The proposed mining framework seeks to transform user reviews into product upgrade requirements. The mining framework has four main components which are context-aware segmentation, opinion target extraction, opinion target grouping, and requirements summarization. To evaluate the effectiveness of the framework, an empirical analysis is conducted to evaluate the effect of requirements mined from customer reviews on app upgrades.

Yang and Liang's Information Retrieval and NLP approach: Yang and Liang propose an approach that utilizes information retrieval and NLP techniques to automatically identify and classify software requirements into functional and non-functional requirements. The approach consists of two components which are User Reviews Extractor and Requirements Identifier and Classifier [10]. The User Reviews Extractor uses an API to collect user reviews of iBooks on the app store. The Requirements Identifier and Classifier are used to automatically identify and classify software requirements into functional and non-functional requirements.

Williams and Mahmoud's Text Classifiers Method: Williams and Mahmoud propose using text classifiers such as Support Vector Machines (SVM) and Naïve Bayes (NB) to mine Twitter feeds to automatically elicit software user requirements. The approach also seeks to summarize common software concerns by making use of algorithms such as TF and hybrid TF-IDF. 4,000 tweets regarding 10 software systems are collected and manually classified. SVM and NB are used to automatically identify and classify the software requirements [11]. The dataset of 4000 tweets is collected by using Twitter's API which utilizes hashtags to search for specific words [11].

III. RESEARCH METHODOLOGY

Previous studies have focused on identifying and classifying functional and non-functional requirements from either requirements artifact such as SRS documents or from user app reviews [9] [11] [12] [13] [4] [2] [10] [5] [8] [6] [1] [7]. This study proposes a hybrid approach to identify and classify requirements from both SRS documents and user app reviews by using machine learning and NLP techniques. Fig. 1 provides an overview of the primary steps. The approach consists of four primary stages as follows:

1. **Data Collection:** A novel hybrid dataset consisting of formal software requirements and user app reviews that have been labeled and will be used as input to the data models.
2. **Data Preprocessing:** NLP techniques such as tokenizing and stop word removal are applied to preprocess the data. The text is then vectorized using TF-IDF.
3. **Model Training:** The preprocessed dataset is used to train the SVM, SGD, and RF ML algorithms.
4. **Model Evaluation:** The performance of the data models is evaluated on the test set by using 10 k-fold cross-validation to calculate the precision, recall, and F1 scores for each category defined as FR, NFRs, and NRs.

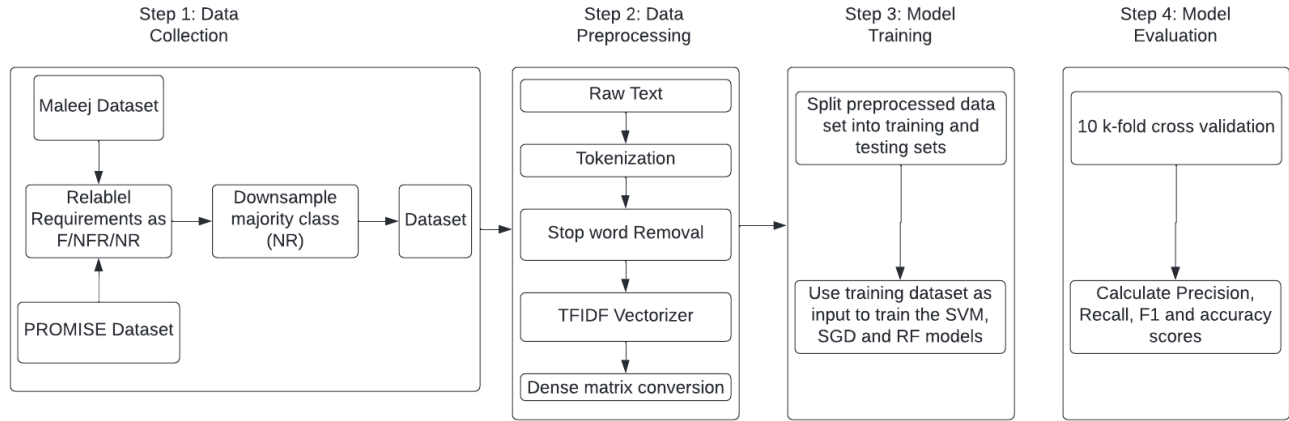

Fig. 1. Classification Process

A. Dataset

A novel hybrid dataset is proposed which consists of formal software requirements from the PROMISE Software Engineering Repository [14] and user app reviews from the dataset prepared by Maleej et al. [15]. The PROMISE dataset consists of 626 software requirements that are classified into FRs and NFRs. The NFRs are further classified into sub-categories: Availability, Legal, Look & Feel, Maintainability, Operational, Performance, Scalability, Security, and Usability. Fault Tolerance and Portability requirements are removed due to having a very small sample size. The user app reviews dataset consists of 3691 reviews from different Google’s apps store and Apple’s app store. The dataset is classified into the following categories: Feature Request, Bug Report, Problem Discovery, User Experience, and Rating. To prepare the dataset for preprocessing and training, the requirements from both datasets had to be labeled as FR, NFR, and NR to form a common set of classes between them. All NFR categories from the Maleej dataset were labeled as NFR and the FR label was unchanged. In the user app reviews dataset, Feature Requests were FRs and were labeled as such. The rest of the requirements were labeled as NRs. Due to the class imbalance of the requirements, the majority class, NRs, had to be downsampled to the count of the minority class, NFR, with 371 observations. The final dataset distribution with relabeling and downsampling is shown in Table I.

TABLE I. DISTRIBUTION OF FUNCTIONAL, NON-FUNCTIONAL AND NON-REQUIREMENTS IN THE FINAL DATASET

Category	Count
Functional Requirement (F)	507
Non-Functional Requirement (NFR)	371
Non-Requirement (NR)	371

B. Data Preprocessing

To have the data ready to be trained by the machine learning models, several NLP techniques were applied to the textual software requirements and user app reviews. The textual dataset is converted into a matrix of TF-IDF features using the TfidfVectorizer function. The TfidfVectorizer function

extracts unigrams and bigrams, splits the words into tokens, ignores terms that appear in less than 1 document, and removes stop words. After the raw text is vectorized with preprocessing, it is converted into a dense matrix.

The terms are defined as follows:

- N-gram: Contiguous sequence of n items from a given sequence of text
- Tokens: An instance of a sequence of characters in some document that are grouped as a useful semantic unit for processing
- Stop words: A set of commonly used words such as “at”, “which”, “the” that do not add a lot of meaning to the text.

C. Model Training and Evaluation

After the data is preprocessed, it is ready to be used as input for the ML algorithms. The dataset is split into train and test sets. The training dataset consists of 80% of the data with 999 observations and the test dataset consists of 20% of the data with 250 observations. The training dataset is used as input for the SVM, SGD, and RF ML algorithms. The algorithms are defined below:

- Stochastic Gradient Descent (SGD) [16]: Method to find the optimal parameter configuration for a machine learning algorithm. It iteratively makes small adjustments to a machine learning network configuration to decrease the error of the network
- Support Vector Machine (SVM) [17]: A classifier that creates a hyperplane in multi-dimensional space to classify observations
- Random Forest (RF): is an ensemble of individual tree predictors [18]

After the models are trained, their performance is validated using the testing dataset. The following metrics are used to evaluate the performance of each model.

- Recall: Calculates the true positives in a class out of all the observations in the class. It is defined as True Positive (TP) / TP + False Positive (FP)
- Precision: Calculates the number of true positives out of all the input classes. It is defined as TP / TP + False Negative (FN)
- F1: Calculated based on the precision and recall scores. It is defined as $2 * \text{Precision (P)} * \text{Recall (R)} / \text{P+R}$
- Accuracy: Calculates the number of true positives out of all the data points. It is defined as TP + True Negative (TN) / TP + TN + FP + FN

In addition to calculating the accuracy metrics, 10 k-fold cross-validation is used to ensure proper model validation by reducing any bias in the training and testing sets that may arise due to the random splitting of the data. In k-fold cross-validation, the data is split into equal-size groups. The number of groups is defined as k. k iterations of model training and testing are performed so that each iteration will have a different train and test set. The average scores of all the 10 groups are calculated to compare the performance of each model.

IV. EXPERIMENT RESULTS AND DISCUSSION

This section provides the results of the experiments to evaluate the performance of each data model. The precision, recall, and F1 and accuracy scores are discussed to answer the research questions.

RQ1: What is the type and size of data is required to automate the classification of requirements from user app reviews?

To answer this question, we proposed a novel approach to create a hybrid dataset consisting of formal software requirements from SRS documents from the PROMISE Software Engineering Repository and user app reviews from the

dataset prepared by Maleej et al. To create a well-balanced hybrid dataset, the requirements were re-labeled to only consist of NFR, FR, and NR. After re-labeling, the issue of class imbalance was resolved by downsampling the majority class, NR, to the minority class count of NFR. The relabeling of requirements and downsampling ensured consistent labels in the final dataset and reduced bias towards the majority class. The final dataset consisted of 507 FRs, 371 NFRs, and 371 NRs. Therefore, the final dataset consisted of a relatively equal count of each type of requirement.

RQ2: To what extent can the Machine Learning Algorithms combined with NLP techniques accurately identify and classify Functional and Non-Functional Requirements?

The precision, recall, and F1 scores of each data model were evaluated to determine their performance. The scores of each model is shown in Fig. 2.

The scores of all 3 machine learning algorithms were compared for each requirement type. In identifying FRs, the RF algorithm had the highest precision score of 0.812 whereas the SGD algorithm had the highest recall score of 0.795, and SGD had the highest F1 score of 0.788. For identifying NFRs, SVM had the highest precision score, and SGD had the highest recall and F1 scores of 0.916 and 0.913 respectively.

RQ3: How effective are the data models in isolating Non-requirements from Functional or Non-Functional Requirements?

The precision, recall, and F1 scores of NRs were evaluated to measure the performance of the algorithms in identifying NRs from FRs and NFRs. NRs are general feedback for an application and do not specify any requirement. For identifying NRs, the SGD and SVM algorithms had the best precision score of 0.783 and the RF algorithm had the highest recall score of 0.839. The SGD algorithm also had the highest F1 score.

Fig. 2. Comparison of the scores for each machine learning algorithm

V. CONCLUSION AND FUTURE WORK

This paper presented the creation of a novel hybrid dataset that addressed the issue of extracting requirements from both, software requirements and user app reviews. Additionally, we proposed the use of NLP techniques such as TF-IDF to preprocess the data combined with using 3 different machine learning algorithms (SVM, SGD, and RF) to identify and classify requirements. Furthermore, we evaluated the performance of each algorithm for each requirement category. The automatic identification and classification of requirements from SRS documents and user app reviews can enable project managers and software engineers to catch any requirements early during the requirements engineering (RE) phase as well as improve the next iteration of their application by being able to quickly sift through vast amounts of user reviews to highlight user wants and needs that may be missed otherwise. In our future work, we intend to incorporate additional datasets consisting of formal software requirements and user app reviews from the various domain. We also plan on using more NLP techniques such as Bag-of-Words (BoW) and Word Embedding to preprocess the raw text data and implement additional machine learning algorithms such as XGBoost and deep learning methods such as Convolutional Neural Networks (CNN) and Recurrent Neural Networks (RNN).

Studying-Alive: A Holistic Wellness Application for College Students

Natasia Fernandez¹, Vaibhav Anu²
 Department of Computer Science
 Montclair State University
 Montclair, NJ, USA
 {fernandezn9¹ | anuv²}@montclair.edu

Abstract—Over the past few years, there has been an increased emphasis on mental health awareness and wellbeing. It is a topic that many do not feel comfortable talking about or acknowledging. Taking care of one’s mental health is important for the individual’s overall wellbeing. College students are a group of individuals who face several pressures that may affect mental health. It can become difficult to juggle their class schedules, assignments, work schedules, and social lives. Struggling to maintain these responsibilities can cause stress and anxiety for the students. Students may be uncomfortable to express their thoughts, as it may be difficult to discuss mental health. With the COVID-19 pandemic there has been an additional stress placed upon college students by taking extra precautions when going out and maintaining their social lives. To alleviate some of the stress and pressures faced by college students, a mobile app called Studying-Alive for holistic wellbeing management is being developed. This wellness app focuses on helping college students reduce stress and organize their schedules while tracking their responsibilities and overall health.

Keywords—mental health, college, students, motivation, anxiety, stress, mobile computing, wellness

I. INTRODUCTION

Mental wellbeing has become more prominent as individuals become more vocal about their mental health. As a college student, there are several responsibilities that one must face. College students have the weight of figuring themselves out while also finding a career path. This can be a great amount of pressure as it may determine the type of job they will be doing for the foreseeable future. In addition, college students have the pressure of maintaining their course load, social lives, internships, and dealing with personal matters. During the COVID-19 pandemic, the stress and anxiety of students increased [1]. They had the pressure of being in a lockdown which may have impacted their social lives. It also decreased the confidence of many college students as they were less active physically and stuck indoors. They also struggled with online classes, as the learning environment completely shifted. In Wang’s study on college students, “among the 2031 participants, 48.14% (n=960) showed a moderate-to-severe level of depression, 38.48% (n=775) showed a moderate-to-severe level of anxiety, and 18.04% (n=366) had suicidal thoughts” [1]. Overall, these are a significant number of students struggling with mental health. The majority also indicated that their stress levels had increased overall during the pandemic.

Several factors need to be addressed to help college students’ declining mental health. There may be several causes for a decline of mental health. Since the pandemic began, the major factors that impact the mental health of college students are fears about one’s physical health and of those around us, difficulty concentration, sleeping problems, decreased sociability, and concerns on academic standings [2]. These factors deteriorate the mental health of college students. Without any help, the students may have difficulty succeeding in school and lack ambitions to keep moving forward in life.

To alleviate some of the issues that students face, a mobile application called Studying-Alive is under development to allow college students to organize their busy schedules, maintain a balance for their social lives, and find ways to de-stress, while remaining safe from COVID-19. Although the app focuses mainly on mental health, it also considers the physical health of the students, as these two are interconnected. If one is not in a good mental state, it makes it difficult to have the motivation to take care of one’s physical health. Similarly, if one is having issues with their physical health they may be stressed out, which will affect their mental health. Therefore, this app helps organize one’s mental and physical and academic record. It also helps the user identify certain routines they may have developed to give them a chance to improve these routines, such as sleep routine. To test the usefulness of the app and gain feedback to improve development, a usability survey was conducted on college students (shown in Section IV). Overall, the app is aimed at improving the mental wellness of college students by providing more time and health management, and methods to de-stress.

II. RELATED WORK

There are several wellness apps that currently exist, but they are not specific to college students. The leading wellness app currently is Calm, which focuses on meditation, improving sleep, relaxing music, stretching, audio classes, and nature sounds. According to Conferroni posthoc tests conducted in Huberty’s study, the app Calm decreased stress, mindfulness, sleep disturbances, and self-compassion significantly with a p-value of less than .001 [3]. This shows that wellness apps are effective, but the app Calm is not specifically helpful to college students during a pandemic. It is more beneficial if students could have an app that is specifically design for their busy schedules and targets their specific stressors, especially during the time of a pandemic.

There are several other mental health applications (MHA), but they have struggled to get interest of college students. When 741 students were surveyed about MHAs, “26.1% of respondents were open to using an MHA yet only 7.3% had used an MHA” [4]. The study shows that there is potential in MHAs to help improve the mental health of college students. However, the students need to be more exposed to the applications as many have not used them. Therefore, a wellness app that is specifically for college students may help students feel more welcomed to using it.

Recently, there was a mobile app that was created for college students, but it faced a low uptake due to the pandemic. This application is called IntelliCare for College Students, which provides “evidence-based cognitive and behavioral skill-building exercises” to decrease depression and anxiety. Some of the features included in the app are mood recording feature, symptom assessment, available resources, and lessons on mental health. It is an app that provided some form of counseling, while also referring the users to more resources. Overall, the app proved to be efficient in decreasing anxiety and stress, but it had a low number of students using it. This may have been due to the pandemic reducing the forms of advertising the app. As this app was created before the pandemic, it may not address certain fears or anxieties that were developed from the pandemic. Studying-Alive will help manage stress, anxiety, and one’s responsibilities rather than help diagnose symptoms of a student. The Studying-Alive app also considers that there is a pandemic occurring. For example, it includes activities that the user may participate in that will help them maintain their social lives while practicing precautions to avoid contracting COVID-19.

III. APPLICATION DESIGN OUTLINE

The Studying-Alive App is being developed to include several features that would help reduce stress and anxiety. The features are Goal Tracker, Schedule, Activities, Routines, Calming Techniques, Recipes, Social Forum, Motivation, and Achievement. Before starting the development of the app, a prototype was created to outline the features that the app would include and the overall design. This prototype was created using a website Proto.io, which facilitates the design process with a drag and drop interface [5]. In this website, each page of the app was outlined, and each feature was created. This created a blueprint of how the app is going to be designed. From this prototype design, information can be gathered on the response of students so that the feedback can be used to enhance the development of the application.

A. Database

The database that it is currently being developed with is Google’s Firebase [6]. This database facilitates authentication of the login page using an email and password. It helps store the information efficiently and easily. For the Studying-Alive app, the Cloud Firestore option for the database is being used as it is a flexible server that syncs the data across apps and allows for support even when there are issues with the Internet connection [9].

B. Login/Starting Survey

The Studying-Alive app will begin with an option to take a personalized survey or sign in (see Fig. 1). The personalized

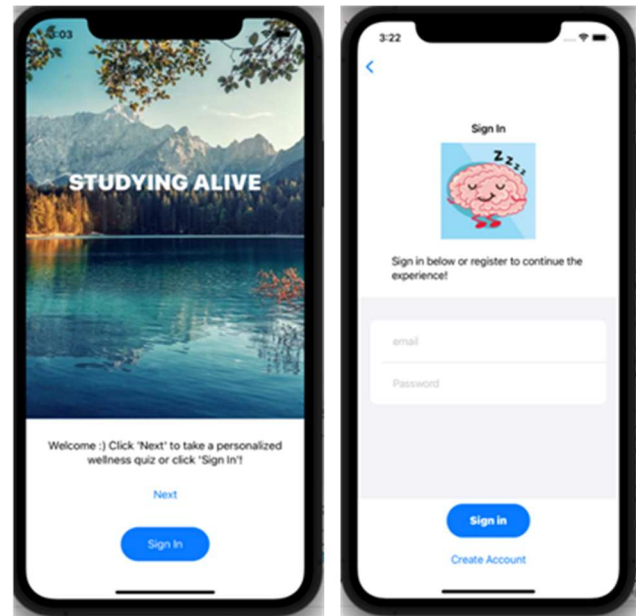

Fig. 1. Studying-Alive App: Initial screen and Sign-in page.

survey helps identify what the user may be struggling with. This may help gain the interest of the user as the app will be specifically focusing on the areas in which they are having difficulties. To sign in, the Studying-Alive app will require the user to enter an email and password. This will then bring them to the home page, which will include the nine features that the Studying-Alive app will provide.

C. Goal Tracker

The Goal Tracker feature will allow users to keep track of the daily, monthly, yearly, and long-term goals while also viewing their progress. When the user adds a new goal, it will be stored in the database, which will add the goal into the lists with an unchecked box. When the goal is completed, the user will mark it as completed, which will increase the percentage of completed goals in the progress ring. In Fig. 2, the current Goal Tracker page is displayed while the app is under development. Overall, this feature will help keep the student motivated, while also helping them to remember that the small daily tasks should be celebrated as well. Students should be proud of their daily accomplishments in addition to keeping their end goals in sight.

D. Schedule

The Schedule features allows the users, which are mainly college students, to organize their classes, assignments, and upcoming events. One of the most stressful parts of being a college student is time management. It is also one of the most essential skills to acquire that is linked to succeeding in one’s academic career [7]. This skill can help decrease procrastination in students as they will learn how to organize their schedules, which can lead to a decrease in stress and anxiety. If students are waiting to complete their assignments when the due dates are closer, they will be more stressed out as they feel like they need to crunch in as much as they can in a short amount of time. This can also help them organize their social lives.

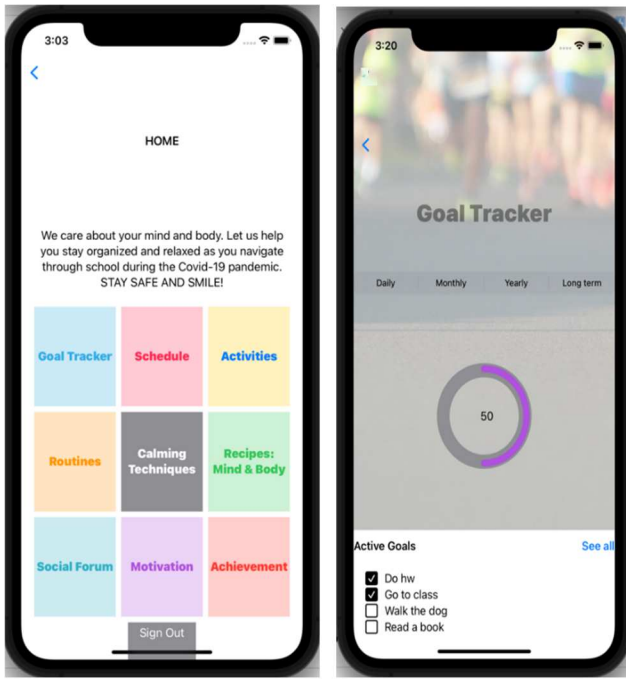

Fig. 2. Current Home screen and the Goal Tracker feature in the app

E. Activities

The Activities feature of the Studying-Alive app offers a variety of activities that the user can do while still taking precaution against COVID-19. It offers activities for solo participants, groups, and outdoor activities. This allows college students to remember that in addition to focusing on their schoolwork, it is also important to take time for themselves to enjoy different activities and hobbies. It is also crucial that “Social support may have indirect effects on health through enhanced mental health, by reducing the impact of stress, or by fostering a sense of meaning and purpose in life. Supportive social ties may trigger physiological sequelae (e.g., reduced blood pressure, heart rate, and stress hormones) [8]. Maintaining a balanced and healthy social life can help improve both mental and physical health. These activities include COVID-friendly places and activities, such as bike riding and rollerblading with friends.

F. Calming Techniques

A crucial part to helping mental health is finding useful techniques to reduce anxiety and try to maintain calm. The Calming Techniques feature offers different techniques that can help reduce stress and anxiety and allows the user to favorite the techniques that work for them. The users can keep these favorited techniques saved so that they can go back to these techniques when needed. Progressive muscle relaxation (PMR) is one of the techniques that help trigger relaxation. It involves the contraction of muscles and slowly relaxing them, which has proven helpful to reduce stress in nursing students [10]. Deep breathing is another technique that helps increase blood oxygen levels and decrease anxiety. In a survey of 4,793 pre-surgical patients, about 40% of the participants showed a decrease in anxiety from using the deep breathing technique [10]. These techniques in the Studying-Alive App will offer students a

healthy, safe, and effective method to decrease anxiety easily and relatively quickly.

G. Recipes: Mind & Body

Physical health and mental health are intertwined. Therefore, eating healthy foods and maintaining a balanced diet can improve mental health. As a college student, one’s diet may be limited to the food on campus, which may include several unhealthy choices. As students navigate more independence on top of academic stress, they may find it difficult to make healthy food choices. In a study of 1956 college students, there was a correlation between anxiety and added sugars intake with a p-value of 0.005, which indicates statistical significance [11]. This shows how what is consumed affects both the body and the mind. Therefore, this Recipes feature in the Studying-Alive app will provide college students with quick and easy recipes to make them feel healthy and provide them with ample energy.

H. Social Forum

The Social Forum allows the students to have a platform in which they may discuss their current mental state and any stresses they may be facing. This can help them acquire feedback from other students that may be experiencing the same events or feelings as them and listen to how others have handled this situation. It can help users that they are not alone and do not need to go through their academic stresses and personal struggles by themselves. This can also be a way to expand the social lives of the users. The users can meet other friends through this application to complete the activities with. It can help the users of the app form a community where they may help each other. This feature can make advice from others and the ability to talk about one’s feelings and thoughts more accessible. Three benefits that social platforms can provide for others are that it “facilitates social interaction”, provides “access to peer support network”, and it “promotes engagement and retention in services” [13]. The accessibility of this social forum can offer these three benefits, while also giving the users an option to not use the feature if they do not feel comfortable.

I. Motivation

College students often need motivation to help them keep persevering and have the determination to complete their degree. The Motivation feature in the Studying-Alive app will have motivational stories and quotes that can resonate with the users and get them to keep moving forward. It will also have quotes that can help push them beyond their comfort zone and set higher goals for themselves.

J. Achievement

The Achievements feature is a reward system that helps the user acquire badges as they use the app. These badges may be given for using different features or for accomplishing a goal. In Platt’s “Evaluating User’s Needs in Wellness Apps,” a survey of 519 participants indicated that one of the features that wellness apps should include to encourage users to interact with the app more frequently is an achievements feature [12]. The users would be getting rewarded for their consistency while also helping them improve their mental health. It will make the app more enjoyable to use as users will want to unlock more badges and it makes the user feel more accomplished. It also makes the

app more interactive as the students are rewarded for using the app.

IV. USABILITY SURVEY

To test the app’s usability, an informal survey was conducted with college students at Montclair State University. A Google form was created with a video of the prototype of the app and nineteen questions to acquire feedback from the students. This helped provide insight into which features, and modifications students may or may not want in a wellness app. The survey received responses from 36 students overall with 2.8% being sophomores, 19.4% being juniors, 63.9% being seniors, and 13.9% being graduate students. Of these students, 72.2% have never used a wellness app, while 27.8% have. Therefore, most of these students have not been exposed to a wellness application before.

A. Interface Design Feedback

An important aspect that needs to be considered during app development is the user interface design. This is the overall style of the app, which the user will interact with. Ideally, an app should be easy to use, interesting to use, and have a style that

attracts the user. It should be pleasing to the eye and motivate the user to keep using it. As shown in Fig.3, according to the survey, about 55.5% of the participants gave the user interface design a four or five rating, which means more than half of the students liked the design. This means that students find the overall look of the application to be pleasing. According to Liew et al.’s survey, the three most important attributes that contribute to the usability of an application are “Satisfaction, Learnability, and Efficiency.” The feedback on the user interface shows that satisfaction can be completed by the Studying-Alive app as the interface feels comfortable and attractive to the user. In other questions, students were allowed to comment more upon the design. Overall, the feedback was positive, but there were several students that believes that the app needed more rounder edges and less colors. When the students were asked for how easy it seems to use the Studying-Alive app, 80.6% of the students gave it a score of four or five, indicating that overall, the Studying-Alive app will be easy to use. This satisfies the second most important attribute, which is Learnability. The students found the app to be easy to use and learn. The app needs to be easy to use to attract users and to accomplish its purpose of alleviating stress.

B. Features Feedback

The Studying-Alive app includes nine features, which are Goal Tracker, Schedule, Activities, Routines, Calming Techniques, Recipes, Social Forum, Motivation, and Achievement. The students who completed the survey were asked for their opinions on these features. The feedback of the students is crucial to ensure that the app will provide features that are useful and are what students feel that they need for their academic success and to improve their mental state. The app offers a great variety of feature, which helps cover different contributors to improving one’s mental health. The students were asked to organize the nine features from 1 to 9, with 1 meaning the best and 9 meaning the worst feature. The stacked bar chart in Fig.4 shows how many students placed each feature under each rating. For example, students voted ‘Schedule’ and ‘Goal Tracker’ the most for the number 1 spot, indicating that these two features are the students’ favorite features, with 13 and 12 votes, respectively. These two features may be the ones that students find the most useful as they are both features that can help in school. Students can use the ‘Schedule’ feature to insert their class schedules and keep track of other events, such as extracurricular and personal events. The feature that came in third place for the number 1 rating was ‘Achievements’. Wellness apps should promote a goal and provide nurturing to lead to “habit formation, self-awareness, and goal attainment” [14]. The ‘Achievements’ feature helps provide small goals within the app by giving badges for using the app and completing certain goals in the app, such as favoriting a calming technique. This will help develop a habit of using techniques to calm oneself and using features for organizations and other habits. The badges are similar to accomplishing small goals within the app, which will further motivate the users. In the second best (2) rating, the most voted were both ‘Goal Tracker’ and ‘Routines’, which nine votes for both. For the third favorite rating (3), the feature ‘Activities’ received the most votes, with nine votes. According to this question, the top five features of the app starting with the highest rated are Schedule, Goal Tracker, Achievements, Routines, and Activities. These are the

Fig. 3. User satisfaction with the interface design of the Studying Alive app prototype

Fig. 4. User ratings of the features with 1 being the best and 9 being the worst.

features that students would be most likely to use and to find the most necessary as a college student. The feature that received the most votes for the worst rating (9) is the Social Forum feature, with six votes. The user may find this feature to be not as useful or may be concerned with how effective it may be.

Some other features that the students recommended are a journal section to keep track of mental state, yoga positions, meditation techniques, an educational feature, brain teasers, music, and daily jokes. These are all features those students believe could be a good addition to the Studying-Alive applications. The students may find that these additions could help them be more engaged with a wellness application or this may be the features that they feel may be missing from other wellness applications. These ideas can be possibly incorporated into the app while development. For example, meditation techniques and yoga positions can be added onto calming techniques and can possibly be created as categories within this feature. “Most common evidence-based strategy was mindfulness-meditation, followed by positive psychology and goal setting” [15]. Therefore, the addition of meditation techniques and positive psychology, such as the addition of jokes in the motivation feature, may help the effectiveness of the application.

C. Organization

The organization of an application can also be a factor in the success of an application. The way an application is organized will determine whether users want to continue to use it. If an application lacks organization, it may frustrate the user. According to the informal survey (shown in Fig. 5), the students found the prototype of the application to be organized overall with 30.6% of the students giving it a five in organization and 50% giving it a four. A rating of five indicated that the app is very organized, while a four indicates it is organized. In the additional comments, students expressed that the colors and text need to be more cohesive throughout the application. The original prototype of the app incorporated a wide variety of colors and different size fonts for each feature. The students found that this made the app slightly less appealing. Consistency with colors and text are more appealing to the eyes. They prefer a simpler theme across the entire application as it helps keep more focus to the features itself rather than to the design. They also found that in some features, such as the stories in Motivation, the font was too small and difficult to read. Therefore, in the implementation of the Studying-Alive application, modifications will be made to make the colors and organization more appealing. The fonts need to be legible in order for the users to be captivated and understand the contents within the features. The colors between text and pictures need to contrast well against each other to make it easy to see. The edges will also be rounded as the users find round edges to portray a cleaner appearance to the application. Overall, the organization is adequate for the application, but it still needs some modifications to make the Studying-Alive application more user-friendly.

D. Effectiveness/Usefulness of the Studying-Alive app

The goal of the Studying-Alive application is to provide students with tools that can help alleviate stress and anxiety while helping them succeed as they navigate through college.

Fig. 5. User responses towards the organization of the Studying Alive application.

Fig. 6. User response for the effectiveness/usefulness of the Studying Alive

Since the Studying-Alive application is still under development, students cannot be asked to use the application to test its effectivity. Instead, students were asked to rate how useful they believe the application would be in improving their mental and physical health. The students were asked to rate the applications usefulness according to a scale from one to five with one being not useful and five indicating that the application is very useful.

According to Fig. 6, about 66.7% of the students rated the effectivity of the Studying-Alive application a four or five indicated that they believe the application would be useful in alleviating their stress and anxiety. Additionally, 27.8% of the students gave a 3-rating indicating that they were not sure how useful it would be. Only 5.6% of the students indicated that they did not think the application would be useful. Therefore, the majoring of the students has found that the application contains at least one feature that can help them in decrease the stress in their personal lives and academic career. An additional study after the application is fully developed could indicate if any of the responses of the students would change once they are able to use the application and apply it to their lives.

E. Frequency of usage

As previously mentioned, the application IntelliCare was a wellness application developed recently for college students, but it failed to grasp the attention of students as it has a low rate of usage. A mobile application needs to be able to attract users so that it can accomplish its purpose. The application’s usefulness

Fig. 7. Frequency-of-Usage Responses

and worthiness are also correlated to how often a user may use the application. In the informal survey, the college students were asked to give an honest opinion on how often they would use the Studying-Alive application. About 52.8% of the students said they would at least use the application occasionally (see Fig. 7). This shows that a majority of college students are willing to use a wellness application, specifically the Studying-Alive application. Only 5.6% of the students, however, said that they would use it very frequently, with the majority claiming they would use it occasionally. Approximately 8.3% of the students said they would never use the application. Therefore, about 91.7% of students would at least use the application once, which is a large number of students. Students may have different ways of dealing with stress that an application may not be able to provide. Therefore, it is expected that some students may not be willing to test out the application or some may not use it as often. However, the Studying-Alive application, has several different

features which means it can appeal to various students with different methods of de-stressing and various students in need of different areas for help. Overall, the initial responses from students indicate that the usage of the application can be relatively high, especially once the students can test the implementation of the Studying-Alive application.

F. Additional Suggestions From Students

At the end of the survey, the students were given open ended questions to allow for more detailed explanations and further suggestions. Several students gave helpful advice that will be considered while completing the development of the application. In Fig. 8, there are a few suggestions that students have included, which may be added into the development or further versions of the application. One that stands out is the fear of the social forum platform because social media can negatively impact students and young adults. However, a great enhancement could be to restrict and filter the comments people post to only allow encouraging comments and motivational comments. This is a valid concern and will need additional modifications.

V. CONCLUSION

This paper has presented a wellness application called Studying-Alive aimed at college students. Overall, the application received positive feedback during the informal survey (responders were college students). In Fig.9, some of the positive responses and comments received have been included.

- “Add a Personal journal feature (deleted daily or saved), fitness and diet/calorie tracker”
- “Better design. Be wise when picking the colors displayed, and make it match. For example, for calming activity, match it with a color that is calming and so on.”
- “a feature I think that should be added should be a habits section. you can track specific habits that a person needs to track, such as medication, skincare, or drinking enough water.”
- “Research visual vs auditorial alarms and consider if it is possible to have the app connect with a google home or Alexa to connect with smart lights to achieve this idea.”
- “College students like apps that are supported by some sort of incentive.”
- “To be honest, the social forum is my least favorite feature. It can be a good addition, but social forums and media can also have a negative affect instead of a positive one. It would have to be moderated.”

Fig. 8. Students’ suggestions for improving the Studying-Alive application

- “I think this app could go a long way. it reminds me of Calm, except it's something a person can personalize and track themselves. the many features available are a great way to help people also start habits, for example, if a person thinks they should start doing physical activities.”
- “App will be helpful to improve mental health and overall health”
- “Can’t wait to try”
- “No dislikes at this time”

Fig. 9. Students’ positive reactions to the Studying-Alive application

The interface design had relatively high ratings, but needs some improvements with the shaping, color, and text sizing. The top 3 features were Schedule, Goal Tracker, and Achievements in the ratings (see Fig. 4). These features seem to be what students mostly want in a wellness application. The organization of the Studying-Alive application was highly rated but may need a few minor adjustments. The students also positively rated the usefulness of the application with most students indicating that the application will be very useful (see Fig. 6). The frequency-of-usage feedback from the college students was also positive as the majority of students claimed they would at least use the Studying-Alive application 2-3 times a week (see Fig. 7). The application may require some marketing by universities so that more students can know about the existence of the application so that more students can benefit from its features.

As the world continues to struggle with the COVID-19 pandemic, college students have endured a large hit to their mental health as they increasingly are struggling with anxiety and depression [1][2]. They are expected to become accustomed to the new methods of online teaching while also maintaining their social lives, dealing with their personal situation, and succeeding academically. The Studying-Alive application offers various features that can help minimize the stress that is accumulating on these college students while allowing them to still take precautions against COVID-19.

As for future works, the application is currently in development as a few of its feature are already being made. The feedback from the survey is being considered in the development of the application. Conducting a larger survey once the development of the application is completed can help give greater insight on the effectivity and usage of the application. The additional features that were suggested by the students will also be considered by adding them into the nine features or keeping them as possible updates for future versions of the application.

Furthermore, after the first iteration of the application development is completed, we intend to identify the features that are found ineffective (i.e., not useful/desirable) by our users. Such features will be replaced by features suggested by students during our survey. In the recent future, the Studying-Alive application will be continuously developed (and refined) and the authors anticipate that this app will bring significant positive change to the lives of college students by improving their mental and physical health.

Abstract—Cognitive dynamic systems are a new field of physical systems inspired by several areas of study such as neuroscience, cognitive science, computer science, mathematics, physics and engineering. Building on Fuster’s paradigm, a system is considered cognitive when it is capable of five fundamental processes to human cognition: the perception-action cycle, memory, attention, intelligence and language. With these capabilities, a cognitive dynamic system can sense its environment, interact with it, and learn from it through continued interactions. The goal of this paper is to provide a thorough review of the cognitive dynamic system framework, along with its theory, applications, and its two special functions: cognitive control and cognitive risk control.

Keywords—cognitive dynamic systems, cognitive control, cognitive risk control, cognitive radio, cognitive radar, cognitive internet of things, smart systems

I. INTRODUCTION

Cognitive dynamics systems (CDS) are a new class of systems which combine knowledge from several disciplines such as neuroscience, cognitive science, computer science, mathematics, physics and engineering [1]. The goal of CDS is to provide a framework for dynamic systems to augment them with cognitive capabilities, allowing them to sense, interact and learn from their environments. A dynamic system is considered to be cognitive when it can carry out five fundamental processes which are critical to human cognition. As defined by Fuster’s paradigm, these processes are the perception-action cycle (PAC), memory, attention, intelligence, and language [2].

Interest in the field of CDS has been growing at an increasing rate in recent years thanks to the seminal work carried out by Haykin on cognitive radio and cognitive radar [3] [4]. These two applications are among the earliest examples of CDS, stoking research into the theory and design of the CDS framework [1]. With cognitive radio, the primary goal is to solve the spectrum scarcity issue by providing the means for radio systems to access underutilized bandwidths. Cognitive radar, on the other hand, has been proposed as a means of providing improved accuracy and reliability in remote-sensing applications [2]- [4].

In essence, the CDS framework can be broken down into two special functions: cognitive control (CC) [5] and cognitive risk control (CRC) [6]. In the former, the limitation of current adaptive controllers and neurocontrollers when faced with

unmodeled dynamics or unstructured environments are addressed. Specifically, CC is additive in nature, meaning that it is augmented to existing system designs by introducing a new state known as the entropic state. The entropic state is based on the notion of an information gap that must be controlled alongside a system model. The second special function, CRC, expands on the CC architecture to account for the risks associated with the uncertainties that are faced by a system, and bring them under control. Such risks may include security threats frequently encountered by physical systems, like cyberattacks on smart grids on jammers acting on radar systems.

The first goal of this paper is to provide a detailed background on the theory and the architecture behind the CDS framework and its two special functions CC and CRC. The second goal is to present a short, structured overview of the current state of the field by reviewing recent literature on applications within the CDS framework. We aim to present a thorough discussion on the methodologies, key findings, experimental results, and limitations of the surveyed literature. Finally, we offer insight into the most promising areas for future research efforts in this field. This paper is organized as follows: Section II of this paper presents a background the CDS framework, theory and architecture. In Section III, cognitive control is introduced as the first special function of the CDS framework, with a review of relevant applications of this architecture. Similarly, Section IV introduces CRC as the second special function of the CDS framework, with a short review of applications and recent advancements. Finally, concluding remarks and suggestions for future researchers are discussed in Section V.

II. COGNITIVE DYNAMIC SYSTEMS

A. Perception-action Cycle

There are two parts to any CDS: the perceptual and the executive. On the right-hand side of Fig. 1, the perceptual component or perceptor is located, whereas the executive or cognitive controller is located on the left-hand side [7]. Depending on the CDS application, the perceptor is in charge of directly observing the system and the environment using appropriate sensors. During perception, for example, a Bayesian estimator might be utilised, which computes the posterior of a system’s state in each PAC and extracts relevant

information from what is experienced. A feedback connection transmits the perceptor's extracted relevant environmental information to the executive, which is then tasked with conducting cognitive or physical actions on the environment or system based on this knowledge [7].

The executive's cognitive efforts are designed to continuously improve the information extracted by the perceptor in following cycles. As a result, the executive indirectly observes the environment through the perceptor and acts on the information obtained, completing the PAC with a global feedback loop. In order to indirectly impact the system's perception, cognitive actions are frequently applied to the surroundings, such as increasing the lights in a dark room [5]. The physical state in this scenario contains the positions of objects that are not changed by light. Other forms of cognitive operations, such as altering the system's own sensors or actuators, can be performed alone on the system. The adaptation of a transmitted waveform in a cognitive radar system is an example of this. Furthermore, by adding a new component to the state controller's cost function called the entropic state, cognitive actions can be used to impact state-control actions [5].

The cognitive controller, as shown in Fig. 1, is in charge of making decisions about the aforementioned cognitive operations in the executive, based on the entropic state established by the perceptor [8]. However, all of the distinct types of cognitive actions are not necessarily present in a given problem. A cognitive radar system, for example, can assess the target's states without being able to physically manipulate them because it only executes cognitive actions on its own actuators and the environment [5]. The application of reinforcement learning (RL) for the cognitive control agent is the mechanism underpinning executive decision-making.

B. Memory

The cognitive process of memory occupies its own physical space in a CDS, as shown in Fig. 1, in three forms: perceptual, executive, and working memory. Both sorts of memories have slightly different functions and responsibilities, but the primary purpose of equipping a CDS with memory is to allow for the acquisition and storage of long and short-term information [2]. A CDS can learn from its past experiences in terms of action

and perception with access to this data, resulting in enhanced performance and resilience.

According to the CDS concept, perceptual memory should have a hierarchical structure with multiple layers [7]. The goal of this setup is to perform perceptual abstraction of incoming inputs or measurements in order to represent the essence of an object, event, or experience, similar to how the human memory system works. Relevant information is kept whereas irrelevant information is eliminated, allowing for long-term memory in the perceptual component of the CDS [9]. In response to feedback information from the perceptor, executive memory serves a dual function with perceptual memory. The executive memory stores long-term cognitive actions made by the cognitive controller based on input from the perceptor and can be utilised as a reference for future cognitive activities. A new policy that considers both long-term and short-term experiences is produced by adding the output of the executive memory to the cognitive controller and incorporating it into future policies [8]. The executive memory effectively keeps track of the cognitive controller's action space in a probabilistic fashion.

The working memory's function is to reciprocally couple the executive and perceptual memories, acting as a short-term memory interface between the two inside the CDS [4]. The cognitive controller may carry out its actions in each PAC in a synchronised manner as a result of this integration, and in summation, memory's general job is to continuously learn from and model the behaviour of the environment and the CDS's action space [8].

C. Attention

Unlike the PAC and memory, which have their own physical locations in the CDS, the cognitive process of attention reveals itself through computational mechanisms inside the framework. There are two types of attention: perceptual and executive attention, which are both based on localised cycles and feedback linkages in their respective sections of the CDS [5]. Their responsibilities include prioritisation of activities and effective resource allocation, and they work closely with and are driven primarily by the presence of memory. This is accomplished in the perceptor, for example, by a variety of strategies that can be utilised to filter out unnecessary input using previously stored characterizations of the environment. On the executive side, attention uses the well-known explore-

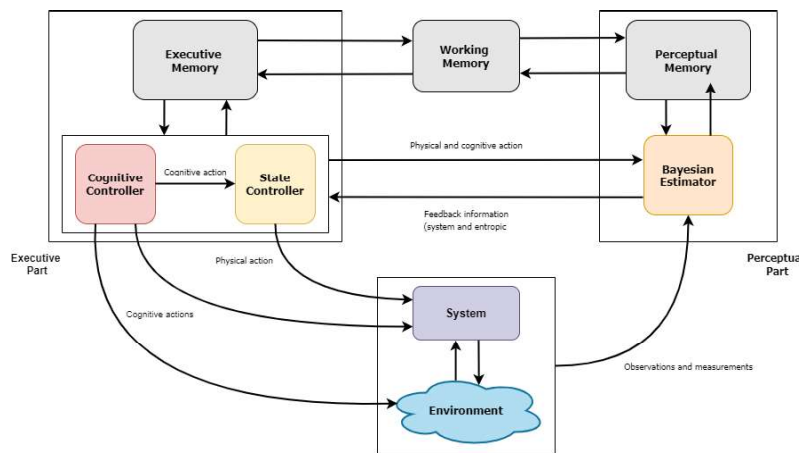

Fig. 1 Block diagram of the basic structure of a cognitive dynamic system and its architecture

exploit tradeoff to help the RL learn from and plan cognitive actions for future cycles, primarily by reducing the action space of the memory for the RL to consider based on the relevance to the perceived information in each cycle [4] [8].

D. Intelligence

Intelligence, like attention, does not have its own physical location in a CDS. It, on the other hand, draws on all prior cognitive processes like memory and attention and integrates them with the PAC to promote computational intelligence through efficient decision-making [2] [10]. Intelligence has an impact over the entire CDS, and its power and effectiveness in information processing are generated from leveraging all of the system's feedback loops, both global and local. As a result, intelligence plays a critical part in the CDS framework in terms of optimal decision-making in terms of the controller's actions on the system or environment of interest [7].

III. COGNITIVE CONTROL

A. Overview of Cognitive Control

Cognitive control is a paradigm that was first introduced in 2012 by Haykin et al. [5] and is additive in nature rather than a replacement system design paradigm. CC can increase the usage of computational resources and lower the correctly defined risk functional for the work at hand by complementing state-control paradigms such as adaptive control and neurocontrol. However, before defining CC, the concept of an information gap must be established, which is related to the risk associated with a policy or action. It is thus possible to define CC with the goal of minimizing the information gap.

The following is a useful summary of the concept of the information gap [5]: From noise-affected data, available information is retrieved and transformed from the measurement space to the information space. The accessible information is then partitioned into useful and redundant information based on the task at hand. In addition, sufficient information must be defined as the information required to complete the task at hand while reducing risk; relevant information is thus the intersection of available information and sufficient information. Furthermore, the information gap can be defined as the difference between sufficient information and relevant information.

Quantifying and reducing the information gap necessitates the development of a task-specific metric – this concept equates to a new state that must be managed. The state of a dynamic system represents the basic information characterising the system's conditions at a given point in time, and the state trajectory, or change in state over time, describes the system's behaviour. The state, on the other hand, can only be obtained through noisy measurements, which necessitates a perception process in order to determine a posterior distribution of the state using a Bayesian generative model. The information gap is the difference between the maximal relevant information in the posterior distribution and the required statistics for a specific job. this quantity is also known as the entropic state, which gets its name from Shannon's entropy [5] [11]. As a result, thinking about a two-state model of a CC system, composed of a state-

space model, which describes the evolution of the system state over time, and an entropic-state model, which quantifies the information gap given the posterior computed by perception, seems intuitive. According to statistical differences in the environment, both models may change from one cycle to the next. It's also worth emphasising that the entropic state is simply the feedback information sent on to the cognitive controller, and that CC is merely a paradigm for minimising the entropic state [5].

The mathematical paradigm of RL is concerned with learning the best possible actions purely through positive and negative reinforcement or rewards. In CC, RL is in charge of ensuring that the entropic state is reduced after each cognitive cycle and establishing a policy in a particular environment that is driven solely by rewards [8]. The entropic reward is defined as the entropic-state decrement after each consecutive cycle. It can be anticipated using a Bayesian filter if the environment is modelled. Thus, learning and planning are two independent ideas in RL for CC, the former using real values of the entropic reward for a particular action and the latter using the predicted entropic reward from the Bayesian filter [8] [12]. It is worth noting that RL can only learn once for each PAC's chosen action; but, RL can prepare for arbitrary number of simulated future cycles and actions [5]. The number of actions that can be performed during planning is limited by considerations such as computing effort and cost, as well as time limits that need planning to be done before a single PAC finishes.

B. Related Works in Cognitive Control

1) Tracking Radar

The authors of [9] create a cognitive radar system and install a cognitive controller within it. The goal of the research is to show how powerful the cognitive controller's information processing capabilities are, as well as the system's potential tracking performance increases as a result. The literature provides details on the parameters of relevance, such as the measurement and system noise covariances, as well as relevant state-space and entropic-state models for the study's applicability. The cubature Kalman filter (CKF) [13] is used to estimate the perceptor's state covariance matrix, which is then utilised to compute the entropic-state.

The system is stated as having 382 distinct cognitive actions (the number of different transmit-waveform library combinations), each of which affects the measurement noise covariance matrix during a cycle of the PAC. Three different scenarios are investigated in the first trials; the first is the absence of CC on the system (fixed radar waveform). In the second situation, the cognitive controller learns but does not plan; the algorithm merely remembers the entropic reward values from the previous step. The third and final scenario introduces planning by using an explore-only method in the planning phase, which means the learning process is repeated for three different cases: the exploration of only one, two, or three random cognitive actions in each cycle of the PAC.

To reduce the impacts of randomness in the author's experimental simulations, 50 cycles were run across 1000 Monte Carlo runs [9]. Because the total number of cycles is substantially fewer than the number of possible cognitive activities (50 vs. 382) [9], performance in entropic-state

reduction in the scenario without planning is not much better than in the absence of CC. However, in the scenario with varying numbers of cognitive actions per cycle, it was discovered that even just one random cognitive action in the planning phase, which is a fraction of the total number of possible cognitive actions, is sufficient to demonstrate a four-order-of-magnitude improvement in entropic-state reduction [9]. In addition, the cases of two or three random cognitive actions showed the same drop in entropy but with faster convergence. In comparison to standard fixed waveform techniques, the planning process in CC was shown to dramatically improve the entropic-state of the model.

Further simulations in the study attempted to see how three distinct CC algorithms, such as dynamic optimization, Q-learning, and the authors' newly suggested algorithm, which combines Q-learning with learning and planning processes, affected the results. The suggested approach, which was configured to plan for three cognitive acts, outperformed both Q-learning and dynamic optimization in terms of minimising the entropic-state while also having a lower computational load [9]. The suggested technique achieved an entropic state value of $10^{0.4}$ in a 250-cycle trial, compared to about $10^{0.7}$ for both Q-learning and dynamic optimization [9]. Finally, the authors point out that while the Q-learning technique is computationally tractable, it can be inefficient in terms of performance. As a result, it may be useful to focus future research on developing algorithms designed specifically for this purpose.

2) Communication-Based Train Control

Communication-based train control (CBTC) systems are automated train control systems that use bidirectional train-ground wireless communications to assure the safe and efficient running of rail vehicles. These solutions aid in the better usage of railway network infrastructure while also improving customer service. However, there are concerns with train-ground communications and train control, which are usually treated as different topics in the literature.

Recent studies have explored combining many concerns into a single problem with the goal of overcoming each challenge using a CC-inspired technique, as in [14]. The authors employ the entropic state to objectively explain the packet delay and drop of information exchanged between the train-ground connection and the train control centre [14]. Wireless local area networks (WLAN) are widely employed in urban rail transit systems around the world as a medium for train-ground communication [15]. The linear-quadratic cost is utilised as a performance metric for train control, and Q-learning is then used to find the best policy based on this metric and the entropic state. In order to characterise high-speed railway and Rayleigh fading, the wireless channels are modelled as finite-state Markov chains with various state transition probability matrices. The CC model is in charge of ensuring that wireless communications and handoffs are reliable and uninterrupted, guaranteeing that the current train receives accurate information about the front train. As a result, the authors believe that adopting CC to increase communication between the train and the control centre will result in a more robust control of CBTC systems in terms of acceleration, deceleration, speed, distance, and emergency brake profiles [14].

With the proposed approach, more reliable velocity management between the system's front and back trains was proved through experimental trials with measurements retrieved from antennas on a train placed within a tunnel and subsequent MATLAB simulations [14]. When compared to alternative control policies like the semi-Markov decision process (SMDP) and greedy policies, which showed tiny disturbances in the difference in front and back train velocities, CC showed completely smooth and significantly safer behaviour. Furthermore, when compared to handoff delays of one second using the SMDP and greedy policies [14], the handoff delay with CC was significantly reduced to 0.2 seconds, half of the train response time parameter. Finally, while looking at the failure rate of the CBTC system under various policies, it is obvious that the CC approach proposed is the most effective due to its 99.78 percent availability. In comparison to the SMDP policy, which has a 10^{-2} unavailability rate, and the greedy policy, which has a 10^{-1} unavailability rate, this figure leads to unavailability rates of the order of 10^{-3} using CC [14]. Overall, the results demonstrate the usefulness of the proposed approach; however, the authors advise that more research is needed to investigate more advanced train-ground communication technologies, such as relaying, in order to increase the performance of CBTC systems.

3) Smart Grid Control

Oozeer and Haykin [16] suggest a CDS as a supervisor for smart grid networks utilising a CC method, as shown in Fig. 2. The authors present a new method for calculating the entropic state that is customised to the smart grid application, and they use it to create a control-sensing mechanism that can recognise and detect incorrect data from sensor measurements in the grid network. Bad measurements caused by erroneous readings, broken hardware components, or power system disruptions can result in a cascade of domino effects that obstruct the state estimation process and can degrade the performance of ordinary control systems [16].

The direct current (DC) state estimator is regarded as the environment in which the CDS acts in the author's suggested framework because it is the recipient of measurements in the network. To classify the observables from the environment, a generative model based on the cumulative sum (CUSUM) is used, followed by a Kalman filter (KF) filter to produce updated estimates for future cycles. The cognitive controller is thus in charge of learning and planning (as illustrated in Fig. 2), as well as providing the network with the ability to prioritise and disregard specific measurements for optimal state estimation by customising the weights assigned to each sensor or metre. By functioning in the opposite direction and independently of the PAC, the shunt cycles facilitate planning. With the use of the memory system in the perceptual and executive sections, this cycle engages both the perceptor and the executive to account for all planned prospective actions in each PAC [16]. The Bayesian Upper Confidence Bounds (Bayes-UCB) algorithm is used to optimise the system's newly tailored entropic state and provide a means for the cognitive controller to learn the best policy of actions, in this case, measurements weights, which are stored in working memory and applied to the system [16].

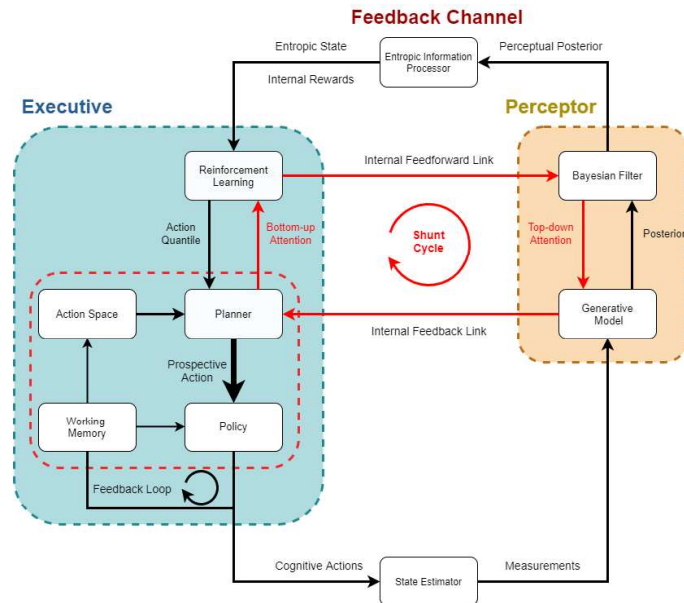

Fig. 2 Structure of a CDS with cognitive control as the supervisor of a smart grid network.

Experimental simulations on a 4-bus network are used to evaluate the suggested CC approach's performance in detecting and correcting erroneous data by changing measurement weights of various metres in the network. With CC, the system was shown to respond dynamically, selecting the optimum collection of metres to obtain readings from at the same time and efficiently assigning the best weight to each measurement for optimal state estimate [16]. Only a few PACs are required when a metre malfunctions in order to learn from the situation and adapt by lowering the weight of the faulty metre.

It is also demonstrated that the cognitive controller's weight assignment to the various measurements is done in such a way that it adapts to the probabilistic characteristics of noisy signals, and that the mean squared error (MSE) of the estimates obtained with the cognitive controller is much lower than without CC [16]. Furthermore, the authors demonstrate that when dealing with cyberattacks such as fake data injection assaults (FDI), the entropic state can be used as a metric to detect such attacks. However, it is noted that the model's structure must be expanded to include CRC in order to effectively deal with and reduce the risk associated with these types of attacks, which the authors address in later works [17] that will be discussed in section IV.

A disadvantage of the suggested framework in dealing with inaccurate measurement data is that it is not scalable to real smart grid networks, which typically have thousands of metres. The rationale provided is that performing an inverse calculation during state estimation is computationally expensive. We believe that machine learning techniques, notably a neural network, might be used to speed up processing and reduce the complexity of the approach. Regardless, the proposed model was more accurate, less prone to false positives, and cost less to compute than existing detection algorithms proposed in [18]. Finally, when scaling up to larger networks, the Bayes-UCB algorithm in the proposed CC model is expected to encounter challenges in terms of response time in determining optimal

configurations in the face of metre malfunctions [16]. In this situation, it may be possible to reduce the algorithm's response time by fine-tuning it and increasing the algorithm's sensitivity.

IV. COGNITIVE RISK CONTROL

A. Overview of Cognitive Risk Control

The CRC model adds a subsystem to the executive side of the CC model to allow for more complex reasoning, which necessitates the coining of a new term, the classifier, as shown in Fig. 3. In this illustration, the subsystem is configured in version II, which entails a disturbed cognitive action to the classifier rather than directly to the physical system. The executive memory, in turn, selects a collection of past acts or experiences for the classifier. There are also two pairs of switches, as indicated in Fig. 3, switches 1 and 2, and switches 3 and 4. Switches 1 and 2 are open in version II, preventing the controller from acting directly on the physical system and providing feedback to the executive memory. Instead, as previously stated, a perturbed cognitive action is delivered to the classifier, which is then in charge of making decisions by selecting a past experience that most closely fits the supplied perturbed cognitive action and then updating executive memory [19]. Switches 1 and 2 are closed, but switches 3 and 4 are opened, when the physical system is working without ambiguity, or under version I. In this case, the controller has direct access to the physical system and can change the executive memory.

The classifier's disrupted cognitive action is of probabilistic origin, and the executive memory's projected past events are similarly probabilistic because they are picked at random from its own action space. The Bayesian paradigm is used as a mechanism of decision-making in recognition of these truths, laying the stage for CRC [19]. For each of the past experiences in the specified set, the probability of the perturbed action's

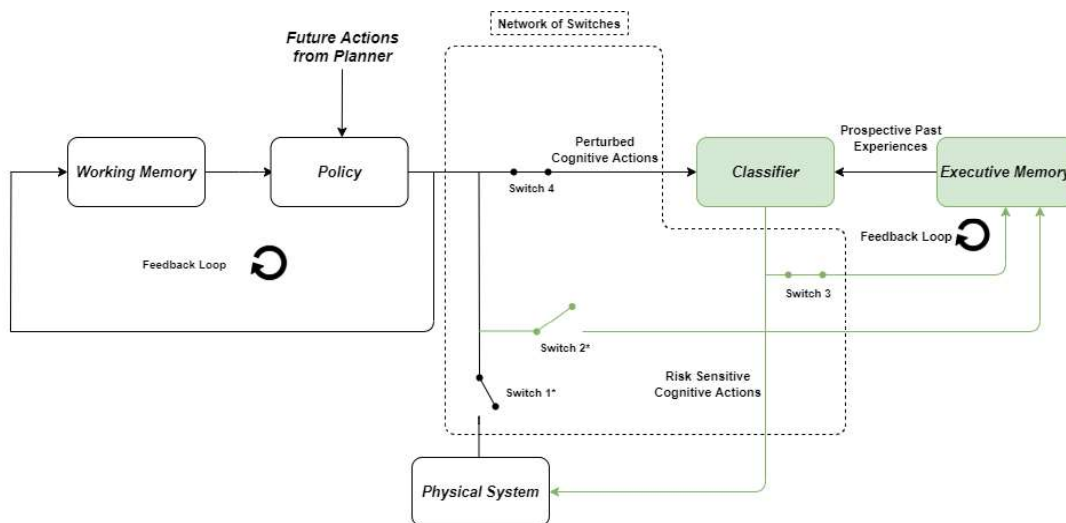

Fig. 3 Structure of the subsystem that is tasked with dealing with risk in the CRC architecture.

posterior given a past experience is determined using Bayes' rule. The risk-sensitive cognitive activity directed to the physical system is then defined as the experience with the highest likelihood [19].

Task-switch control (TSK) is a CRC framework function that exploits the presence of pairs of switches and controls their configuration depending on the presence or absence of uncertainty. The entropic rewards from the feedback channel serve as the foundation for defining TSC methods. The entropic reward in CRC can either be positive or negative, and it can never be zero. These two qualities are crucial in characterising TSC: positive rewards indicate the absence of uncertainty, while negative rewards imply uncertainty [19]. The choice of function to compute the rewards, as well as the tuning of design parameters in the chosen function, are essential considerations when applying CRC to physical systems using this approach. To summarise, when there are no uncertainties, the entropic reward must be positive, so switches 1 and 2 are closed, but switches 3 and 4 are open. When there are uncertainties, the entropic reward must be negative, therefore switches 1 and 2 must be opened and switches 3 and 4 must be closed.

B. Related Works in Cognitive Risk Control

1) Radar and Communications

Feng and Haykin published the first experimental research employing the CRC framework in [20]. The paradigm is studied and used in a cognitive vehicular radar system for self-driving cars by the authors. Recognizing the hazards posed to autonomous vehicles in the presence of uncertainty, the authors attempt to improve the performance of vehicular radar systems in such dangerous situations. The literature discusses the architectural structure of the CRC adapted to the problem of transmit-waveform selection in vehicular radar systems, as well as a simple vehicle-following scenario. A host vehicle is going forward in the stated scenario, and ahead of it is a target vehicle moving in the same direction, both of which are defined by their own velocities and accelerations. Details on state-space dynamics and modelling of the scenario are provided, and we refer the reader directly to the literature in [20] for these specifics. The purpose of the proposed model is to deal with

risky events caused by other physical entities robustly when applied as the supervisor for transmit-waveform selection in the radar system.

The authors remove the Bayesian generative model from the perceptual element of the CDS in their work because, in the case of automotive radars, observables are typically taken in a fashion that can be directly processed by the Bayesian filter [20]. As a result, the Bayesian filter has been relocated to the bottom of the perceptor, and the entropic-information processor has been added to take its place and preserve the feedforward link. Aside from that, the suggested work follows the same structure as Fig. 4. The KF is chosen as the Bayesian filter to represent the vehicle-following scenario, and it is formulated according to the transmit-waveform option, which mixes the linear frequency modulated (LFM) waveform with Gaussian amplitude modulation. Invoking Shannon's information theory [20], the entropic state is determined using the filtered posterior from the KF as input. The entropic state uses a defined function to determine entropic or internal incentives, which it subsequently passes on to the executive. The internal incentives are sent through a defined function in the CRC framework's TSC mechanism, which is then subjected to particular conditions and thresholds formulated in the literature to determine the existence or absence of uncertainty. The rest of the methodology follows the standard CC framework described in earlier sections, which is also depicted in Fig. 4 by the red dashed boundary.

The suggested CRC model with Q-learning for RL was compared to alternative systems, such as a radar with fixed transmit-waveform (FTW), the CC framework, and merely Q-learning on its own for waveform creation, using experimental simulations [20]. The root mean squared error (RMSE) was calculated against each model's five states: the velocity and acceleration of the host vehicle, the longitudinal distance between the host and target vehicle, and finally the velocity and acceleration of the target vehicle. Based on simulation findings, the suggested model has the lowest RMSE for each state in the depicted qualitative graphs, with CC and Q-learning performing similarly [20]. These findings show that regardless of the algorithm used, the executive's learning algorithms will

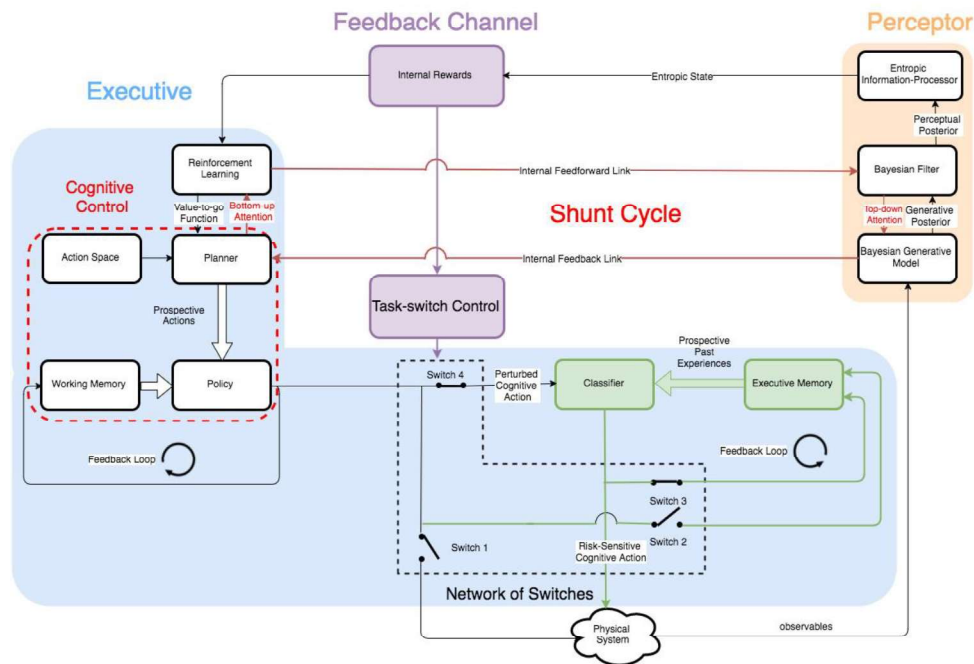

Fig. 4 Structure of the CRC framework. Green coloured elements represent the newly introduced risk-sensitive subsystem.

result in better decision-making and action choices. During the trial, the authors add a structural uncertainty term to the system model to create a dangerous scenario in the experiment, which lasts less than a second. In this circumstance, the Q-learning and CC algorithms were unable to adjust to the uncertainty, resulting in substantial spikes and erratic behaviour in the RMSE, which took upwards of eight seconds to recover from. However, the proposed CRC model relative to the other approaches was only slightly affected in terms of RMSE and recovered within a matter of two or three seconds at most. Overall, the model achieved impressive results and was also deemed a promising alternative to traditional approaches in handling uncertainties and risky events in vehicular radar [20].

These research have culminated in the most current work of Feng and Haykin in [21], in which the authors propose merging cognitive vehicular radar (CVR) and vehicle to vehicle (V2V) communications with a coordinated CRC (C-CRC) model that bridges both systems together. C-CRC investigates the benefits of mutual aid by utilising information emanating from one of the systems that may be useful to the other. In addition, unlike earlier investigations, a nonlinear target-tracking model is used, and the analysis is done with a CKF [21]. The formula for the interference measure in V2V communications in this approach includes tracking findings as well as other practical aspects inferred from those results, such as vehicle motion and channel availability. The CVR also relies on communication system data to determine whether it is operating on a one-vehicle or two-vehicle model, with the latter indicating the presence of a second vehicle engaged in target tracking [21]. Each system in the C-CRC model has its own TSC mechanism and is implemented with a risk-sensitive subsystem. Furthermore, the TSC in each system plays a part in determining what information should be transferred from one system to the next for their dual system.

The authors show that the suggested C-CRC model outperforms previous radar techniques such as FTW and Q-learning in minimising the peak RMSE achieved in tracking longitudinal distance when faced with uncertainty by up to 70% and 67 percent, respectively. Although the typical CRC design in [22] had equivalent performance, it was still 41 percent worse to the C-CRC in terms of RMSE peak reduction. C-performance CRC's is improving across the board, including tracking performance in terms of the utility of power selection in vehicle and jammer communications, total regret from channel selection, and finally, user utility.

However, the ability of V2V communications to keep up with busy networks in specific locations or conditions has been noted in the literature. With less spectrum opportunity, user utility decreases while jammer utility grows, according to further examination of studies relating to the effects of channel availability on power and channel selection [21]. This scenario also leads to a greater regret measure for the host vehicle, a reduced multi-armed bandit (MAB) related reward, and increased channel switching costs. As a result, vehicle networks with several entities sharing available wireless resources in a local area present fascinating and practical V2V performance issues that demand additional research. The authors also highlight that security vulnerabilities in large-scale adversarial CAV networks would be investigated in the future as part of their research efforts.

2) Cybersecurity in Smart Grids

In [17], Oozeer et al. improved on their CC technique for smart grid attack detection from [16] by proposing an upgraded CRC-enabled model capable of also defending against such assaults. The entropic state was utilised as a metric in the initial experiments to detect the existence of FDI attacks, which was signified by the entropic state dropping below a predetermined

threshold, setting the stage for TSC in the extended CRC version of the model. When an FDI assault is detected and TSC is triggered in the extended framework, the cognitive controller is deemed inactive, while CRC is activated to protect against these attacks [17].

The authors note that the action space involved in this scenario involving CRC differs from CC, recognising that FDI attacks try to produce deviation in specific states to trigger a cascade of incorrect control decisions. Unlike the cognitive controller, which has an action space of possible measurement weights, CRC includes picking tuning parameters to be applied to the DC system's configuration matrix [17]. However, if an assault has been discovered, the predictor or classifier must first recognise the states that are at risk. As explained in the literature [17], the affected states are recognised by whether they exceed the maximum deviation allowed by a formulation based on each estimate's mean recorded in the perceptual memory. Following that, once the attacker states have been identified, the planner must carefully pick tuning parameters in the columns of the DC system's configuration matrix corresponding to the impacted states without interrupting the estimation of other states [17]. Each shunt cycle is dedicated to resolving the hazards associated with one of the states at a time during this planning phase of operation, and a new reward connected with a specific action in the cycle is determined. The Bayes-UCB algorithm, as suggested in [16], is then in charge of optimising the policy in such a way that it prioritises actions that will return current attack states to a condition that is closest to past perceptual memories. Similar to CC, the actions that get the highest quantile from the Bayes-UCB algorithm are stored in the working memory and applied once the shunt cycles have expired. Once the impacted states have been restored to acceptable levels, the risk is considered controlled, and no further actions will be taken in those columns of the system configuration matrix. Finally, once the attacks have been determined as having finished, a mechanism is implemented by supplying the TSC with memory and a watchdog timer that restores the system configuration to its original state and marks the end of the current PAC [17].

The experimental simulations used in the author's research are comparable in configuration to those used in their prior investigations [16], which used IEEE 4-bus and 14-bus networks. The literature shows how the cognitive controller and CRC can operate together in the 4-bus network to bring FDI attacks under control once they've been introduced to the system. The network configuration matrix of the system is detailed in the study along with other pertinent parameters, and it is mentioned that the simulations run for a total of 2000 seconds while allowing for 15 shunt cycles in each PAC for learning and planning. The action space for CRC consists of 63 different tuner values, each of which can be tuned with a specific range of values for relevant columns of the network configuration matrix. In the 4-bus network, three states are measured, and an assault is launched on the first two states 1000 seconds into the simulation, lasting 300 seconds. The phase angles of the desired states are shifted by predefined values to imitate FDI attacks [17]. Before the attacks, the CRC only needs 20 cycles to get the estimations or measurements for the impacted states under control and restored to a tolerable

threshold [17]. When the attacks are over, the suggested model continues to run under CRC for another 39 cycles, according to the authors, because the model ensures that conditions for matching current and previous events are met. The altered network configuration matrix is then restored to its original condition before TSC and CRC are triggered.

However, one of the proposed studies' disadvantages is that when other forms of FDI attacks, such as the slowly evolving ramp attack, are used, the detection time can be altered and increased [17]. Furthermore, scaling up the architecture to larger and more realistic networks will necessitate more shunt cycles in each PAC, creating major processing resource and efficiency difficulties. This problem is exacerbated by the fact that other types of FDI attacks, such as developing ramp attacks, necessitate a longer sample time for the DC estimator to overcome them. Another use of this CDS that the author's investigations have not looked into is not just identifying attacked states, but also identifying which sensors or metres have been attacked. Finally, there is a suggestion in the literature that applying a predetermined threshold on the absolute estimated error of the estimated readings might be used to identify the attacked metres in a network [17].

V. CONCLUDING REMARKS

Cognitive dynamic systems, as well as their two particular functions, cognitive control and cognitive risk control, were comprehensively examined in this study. This work is the first attempt to compile data from the voluminous literature published in this young and evolving topic. The goal of this study's methodology was to encourage and facilitate additional research into cognitive dynamic systems. We did so by alerting the reader about advancements in each specialized field, outlining the benefits and limits of the surveyed literature, and providing suggestions and directions for future research. Finally, the contents and outcomes of this survey will serve as a foundation for future research, and will hopefully be useful to other academics working in this fascinating new subject.

Abstract—With the rapid development of Internet of Things, more and more sensing modalities are being integrated into single small devices. The data throughput, however, is always limited due to factors like transmission bandwidth and storage. How to balance the sampling frequencies among different sensing modalities, is little studied. Given a concrete system and its application, the question becomes: 1) how to qualitatively evaluate the loss of information as the sample frequency drops? 2) how to find the optimal sampling frequency ratio and set the multi-modality system according to it? In this paper, we will provide a general workflow to answer these questions. The workflow is evaluated on a self-developed smart-shoe, equipped with one pressure sensing matrix and two Inertial Measurement Units. This workflow could be interesting to both multi-modality IoT system developers and users, support them in finding the best frequency setting and obtaining datasets of higher qualities.

Index Terms—System Optimization, Multi-Modality Sensing, Data Quality, Embedded Systems

I. INTRODUCTION

With the rapid development of sensors and integrated circuits, more and more sensing modalities are being brought into small devices around us. While more sensing modalities enable sensor fusion, they play also a zero-sum game: the overall data throughput is always limited by for example the transmission bandwidth, while all individual sensors want a higher share in the overall throughput to maintain the high-frequency components in its own data.

The Whittaker-Shannon sampling theorem points out that an analog signal can be perfectly recovered as long as the sampling frequency is at least twice as large as the highest-frequency component of the analog signal to be sampled. For systems containing multiple sensing modalities, it is impossible to push at the same time all the sampling frequencies

to their corresponding maxima. It is a common practice to put the sampling frequencies of all the sensors to the same. However, is the 1:1 ratio really the best option for saving the most information? We will show in section IV-B with a concrete example, viz. a smart-shoe, equipped with one textile pressure sensing matrix (TPM) and two Inertial Measurement Units (IMU), that this common practice might not be the optimal: with the 1:1 setting, the overall information loss for IMU is as high as 15% (measured by Cramer-Von Mises test) and for TPM 2%. After frequency balancing, when the frequency ratio is set to 2:1 (IMU over TPM), the information loss of IMU is enhanced to only 2%, while that of TPM remains 2%.

For people who design or use such multi-modality sensing systems, two questions might then come up:

- 1) Do I also need frequency balancing, or not?
- 2) If yes, what is the optimum frequency ratio?

This paper will provide answers to these questions. The contribution lies in:

- 1) We demonstrate with a concrete example that the commonly practiced 1:1 sampling frequency ratio is not optimal if the goal is to keep as much information as possible within limited data throughput.
- 2) We design a general workflow to support multi-modality IoT system developers in finding the optimal ratio and modifying the embedded system's configuration.
- 3) We demonstrate how the workflow works with a concrete example, namely a smart-shoe, featured with two Inertial Measurement Units and a pressure matrix. This is also a typical hardware setting with both discrete multi-channel sensors and a sensing matrix.

This paper could be interesting to both IoT system developers and users, promote their second thought before carrying out large-scale data acquisition, and support them in finding

out the optimal frequency configuration to obtain datasets of higher qualities.

II. RELATED WORK

A. Multi-modality IoT systems

The amount of multi-modality IoT systems are growing together with the need on information. A lot of efforts are given on the sensor level, done by material scientists and hardware developers, including new materials [1], new sensing modalities [2], [3], physical and electronic modeling [4] and better ADCs [5]. The result are IoT systems with more and more sensing modalities. We list a few in Table I, focusing on wearable systems in healthcare applications. There are far more such systems, but the fact is, little thought is given on how to balance the sensing frequencies. The 1:1 ratio is a common practice, because it ensures that data from all sensors are synchronized, which eases the sensor fusion algorithms. Whether this is the optimal ratio, stays with a question mark.

B. Sampling Frequency Considerations

To the best of our knowledge, there was no research on improving information quality by balancing sample frequencies of multiple sensors and/or sensing matrices. We thus go for the most related research category: finding the best frequency of a single sensor/sensing module, mainly for the purpose of reducing power consumption.

Inertial Measurement Unit is widely used in wearable systems. Its sampling frequency is studied for activity recognition applications. Taleb et al. [11] used an entropy-based optimization algorithm to derive the optimal sampling frequencies of the accelerometer in the cell phone for different activities, the conclusion was sitting (10Hz), walking (70Hz), jogging (90Hz). Allik et al. [12] explored the effect of sampling frequency on classification performance. By downsampling triaxial accelerometer data they concluded that there is no

significant difference in classification performance for most activities with sampling frequencies at 50 Hz, 25 Hz and 13 Hz, only that 13 Hz is not sufficient to capture vibrations from outdoor riding. Khan et al. [13] used two-sample K-S test to derive its optimal frequency for activity recognition based on 5 read-to-use public datasets. The conclusion was 45Hz. Anish et al. [14] presented a sensor-classifier co-optimization technique for wearable devices using human activity recognition as a driver application, they dynamically power down the accelerometer and lower the sampling frequency when the user is performing low-intensity activities. Using these optimizations, the proposed approach achieves up to 49% reduction in total platform energy consumption with less than 1% decrease in the accuracy.

Another type of sensing modality that was studied is the Force Myography (FMG). By downsampling the data and analyzing the RMSE (Root Mean Square Error), Xiao et al. [15] suggested that FMG at the forearm and wrist should sample at minimum 54 Hz and 58 Hz for deciphering isometric actions, and 70 Hz and 84 Hz for deciphering dynamic actions. Lei et al. [16] studied 16-channel FMG, and concluded that for recognizing static postures, the frequency can be further reduced to 5 Hz.

While we can borrow the validation methods from these papers, none of them considered multiple sensing modalities in the same system. In such systems, each sensor occupies a part from the overall system resources (CPU time, bandwidth, and etc.), the question changes from how to save system resource given the optimum recognition goal, to how to balance the frequency setting to lose less information with the limited, predefined resource.

III. THE EXAMPLE: A MULTI-MODALITY SMART SHOE

Before going into the general workflow for balancing multi-sensors' frequencies, we first introduce the example system:

TABLE I
MULTI-MODALITY IOT SYSTEM EXAMPLES

Work	Sensing modalities	Application	Note
[6], 2005	Electrocardiogra(ECG) sensors (100Hz) Piezoresistive sensors (16Hz)	A fabric sensing system for monitoring individuals affected by cardiovascular diseases	Arbitrary sampling frequencies
[7], 2009	ECG sensors (200Hz) Accelerometer (200Hz)	A smart shirt for continuous health monitoring	Frequency ratio set to 1:1
[8], 2015	Accelerometer (100Hz) Gyroscope (100Hz) Temperature (1Hz) Humidity (1Hz) Barometric air pressure (5Hz)	A wrist-worn device for recognizing very fine-grained and complex inhome activities of human users	Arbitrary sampling frequencies
[9], 2020	Audio (46.875kHz) Electrical bioimpedance (0.02Hz) Accelerometer (250Hz&100Hz) Gyroscope (100Hz) Temperature (1Hz)	A wearable, multimodal sensor brace for assessing knee joint health	Accelerometer at different sampling frequencies
[10], 2022	Pressure array (30Hz) Accelerometer (30Hz) Gyroscope (30Hz)	A smart shoe for monitoring gait	Frequency ratio set to 1:1

Fig. 1. The smart shoe: driving architecture (left) and sensor configuration (right)

a pair of smart shoes developed by our lab for gait analysis, as shown in Fig. 1. In the later examples, only the right shoe data are used and the system is thus mentioned only as "the shoe". It features two IMU's (we use only accelerometers and gyroscopes in the study, thus 6 channels each, resolution 16 bits) and one pressure sensing matrix (28 × 16 channels, resolution 12bits), all integrated into a single sole and put into the shoe. One IMU is put to the forefoot position and the other to the heel. The pressure sensing matrix covers the whole planta. The data are streamed to a phone or PC via Bluetooth with a maximum bandwidth of 48KB/s, resulting in the sample rate of 68Hz, shall the 1:1 ratio be adopted.

Signals from the shoe are demonstrated in Fig. 2. A health adult wears a pair of smart shoes and walks in a straight line. We first record the data with the TPM turned on and IMUs off, then with the TPM turned off and the IMUs on. This is to push the sampling frequency of each sensing modality to its maxima. It can be seen that the two sensors and the matrix obtain different types of information. While the IMUs are good at capturing the in-air posture, the TPM is good at capture on-ground force distribution. Even the two IMUs demonstrate detailed difference of the forefoot and the heel, as our feet are not as stiff as wood and its shape changes throughout the whole gait cycle. That is to say, we need all sensors for monitoring the gait details. Turning off one IMU means losing quite much information and is not recommended. Also there exist high-frequency components in the signal, demonstrated by the sharp rising and falling edges. That is to say, lower sampling frequency would very likely mean losing more high frequency details.

Here comes the zero-sum game: all sensing modalities want a higher sampling frequency. How to balance the sample frequencies is thus an important question to be answered.

IV. TOWARDS THE BALANCED FREQUENCY SETTING

A. The General Workflow

Given a multi-modality system and its application domain, a pre-experiment on data quality and the corresponding fre-

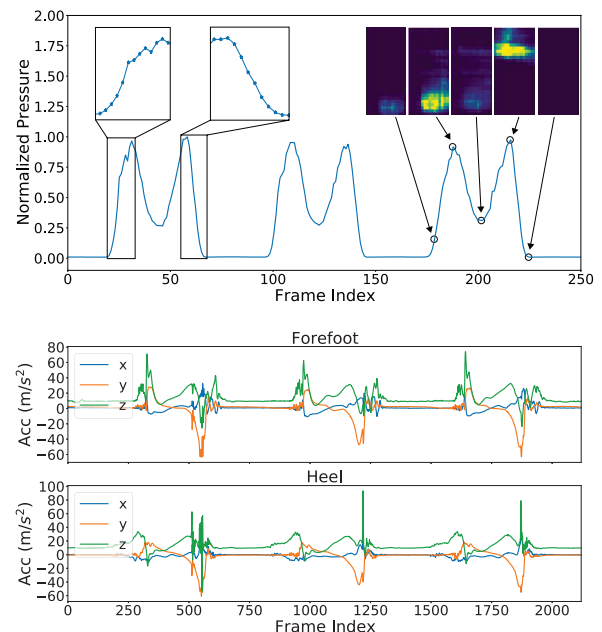

Fig. 2. Smart shoe data from three steps, TPM data (up), two IMU data (down)

quency balancing is recommended before creating the large-scale dataset. Certain amount of information might get lost already during the dataset creation process and the only way to get them back is to repeat the experiment, which normally takes much more efforts, time and human resource than the simple pre-experiment. Below we provide the general workflow and concrete methods, including:

- 1) *Evaluate information quality*: perform a small pre-experiment, with one sensing modality turned on at a time and all the others turned off. The data are then downsampled and compared with the original data to qualify the information loss as frequency drops.
- 2) *Select the optimal frequency ratio*: Given a preset

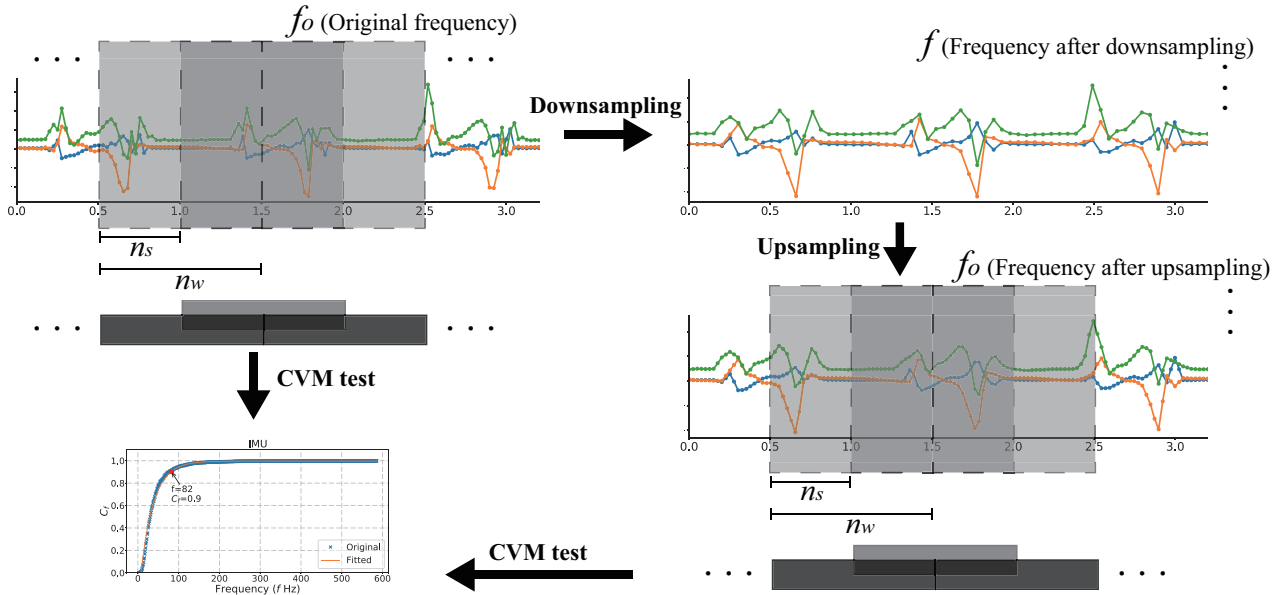

Fig. 3. Data test process (IMU as an example)

frequency ratio, calculate or measure the frequency of each sensing modality. Based on how much information loss can be endured, find the lowest frequency border of each sensing modality. This defines the common space, where the optimal frequency ratio can be found.

- 3) *Configure the embedded system*: Given the found optimal frequency ratio, configure the system. This step is system dependent. We will demonstrate how to do it by modifying the sample process.

This workflow requires no pre-knowledge on signal quality and is not limited to the domain of activity recognition, where the recognition rate can be the measure for information loss.

B. Evaluate Information Quality

Given a multi-modality system, the first step is to find out whether the default frequency ratio (e.g. the commonly practiced 1:1 setting) is good enough for keeping information. We introduce the following approach (also shown in Fig. 3).

The original data are downsampled to frequency f and upsampled back to f_o , using linear interpolation. The original data and the upsampled data are segmented using the sliding window approach. Cramer-Von Mises (CVM) Test [17] is performed on each segments and the results are averaged. The CVM test statistically measures the integral of the squared distance between the empirical cumulative distribution function and the target cumulative distribution function. It is more suitable for demonstrating the overall difference, compared to the K-S test [13], which measures the largest distance between two cumulative distributions. The averaged CVM test result (C_f as defined in Eq. 2) is a value between 0 and 1, where 1 means no information loss. The concrete mathematic expressions are given below, taking IMU data as the example.

First define all the variables:

- N : number of samples;
- d : dimension index, $i \in [1, 12]$;
- j : sample index, $j \in [1, N]$;
- f_o : original sampling frequency;
- f : frequency after downsampling ($f < f_o$);
- n_w : window size;
- n_s : step length;
- W : total number of windows, $W = \lceil (N - n_w) / n_s \rceil$;
- i_w : window index, $i_w \in [0, W - 1]$;
- j_w : $j_w = i_w \times n_s$, each window's starting index.
- $D_o(d, j)$: the dataset, at the original frequency f_o ;
- $D_u(d, j, f)$: the dataset, after downsampling to frequency f , and upsampling back to frequency f_o ;

A two-sample CVM test is performed for each pair of windows, the returned p-value from Python function `scipy.stats.cramervonmises_2samp` is taken as the confidence of CVM test (definition of p-value in [18]):

$$p(d, i_w, f) = \text{cramervonmises_2samp}([D_o(d, j_w), D_o(d, j_w + 1), \dots, D_o(d, j_w + n_w - 1)], [D_u(d, j_w, f), D_u(d, j_w + 1, f), \dots, D_u(d, j_w + n_w - 1, f)]) \quad (1)$$

Finally, the test values of each window are averaged to obtain the CVM test value for one axis of data, and then the 12 axes of data are averaged to obtain the final test value C_f :

$$C_f = \frac{1}{12W} \sum_{d=1}^{12} \sum_{i_w=0}^{W-1} p(d, i_w, f) \quad (2)$$

With $C_f \in [0, 1]$, when $C_f = 0$, it means that the two samples are not similar at all, while when $C_f = 1$, it means

Fig. 4. CVM test result, (a)IMU, (b)TPM

that the samples are identical, and the closer C_f is to 1 the higher the similarity of the two samples' data. The TPM data test process is similar and only requires replacing the 12-axis IMU data with 448-point pressure data.

We performed the CVM test on the smart shoe data with the following strategy:

- *Two IMUs*: All IMU channels are considered equally important, CVM test is performed on each channel and the average is calculated (result given in Fig. 4 a).
- *Pressure matrix*: CVM test is performed on each channel (28×16 in total) and the average is calculated (result given in Fig. 4 b).

Other options remain, for example, calculate the CVM test for the overall acceleration and angular speed ($2 C_f$'s for each IMU), then calculate the average; calculate the CVM test for the overall weight of the TPM. Weight can also be given to certain sensing modalities and/or channel(s) to emphasize its/their importance. For example, for indoor navigation, IMU sampling frequency plays an important role, while the pressure matrix is only an aiding tool, then the IMU can be given to a higher weight; in gait analyses, to emphasize how the foot strikes the ground, a higher weight can be given to the z-axis acceleration of the IMU on the heel.

We use 0.90 and 0.95 as the C_f thresholds to decide where to set the proper sampling frequency (for CVM test, 1 means that the two distributions are identical). To overcome the small glitches (which is more visible on the TPM result in Fig. 4 b)), the curves are fitted. This ends up with 82 Hz and 105Hz for IMUs, and 30Hz and 40Hz for the TPM.

It is specially worthwhile to check the IMU result. While Khan A et al. [13] studied 5 datasets and draw the conclusion

Fig. 5. Comparison of the difference in data between the right forefoot x-axis acceleration of 45hz and 588hz, (1) is the original data (sampled at 588Hz), (2) is the recovered data (downsampled to 45Hz then back to 588Hz)

that 45Hz is proper for activity recognition, our analyze demonstrates that this is definitely not a good choice for obtaining gait details. In Fig. 4 a), the C_f drops to 0.69, indicating significant information loss. To demonstrate the distortion, we provide in Fig. 5 the original data (acceleration on x-axis sampled at 588Hz), the recovered data (downsampled to 45Hz then back to 588Hz) and their difference. The amplitude difference can be as high as 70% of the original signal. As IMU is widely used in IoT systems, it is worthwhile for the developers to take a second thought on its sampling frequency.

If the common practiced 1:1 frequency ratio is taken, then the shoe will sample at 68Hz (detailed analysis in section IV-C). For IMU, C_f drops to 0.85 and for the TPM, C_f drops to 0.98. The IMU data are still seriously distorted. This confirms our assumption, that the commonly practiced 1:1 ratio might not be a good choice. There does exist hope for improvement, as the TPM consumes a large percent of the bandwidth with its 28×16 channels, a small sacrifice of its sampling frequency can already release enough bandwidth to largely increase the IMU's sampling frequency and enhance its information quality.

C. Select the Optimal Frequency Ratio and Configure the Embedded System

Now that it is found out that 1:1 setting is not the optimum, the task is then to find out the optimum ratio. Theoretically, given a fixed bandwidth and a frequency ratio, the frequencies of each sensing modality can be directly deduced. In practice, the data acquisition process is influenced by more factors. Below we will first demonstrate how to estimate the real sampling frequencies, then provide the method to select the optimum ratio.

As IMU data quality is heavily influenced by the 1:1 setting, and the matrix consumes a high percent of the bandwidth, we adopt a slice sampling method. At each interrupt, data are read from the two IMUs and only $\lceil n_{row}/k \rceil$ rows of the TPM, where $n = 28$ is the total number of rows. After k repeats, the whole matrix is sampled for 1 time and the IMUs for k times, resulting in a 1 : k frequency ratio. These data

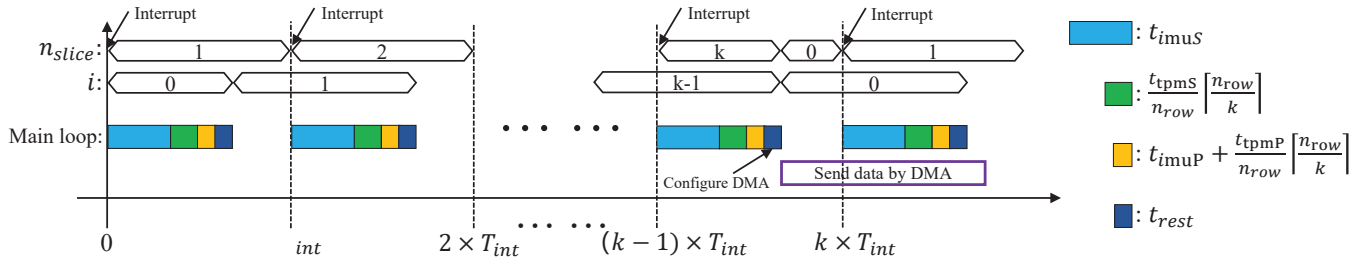

Fig. 6. Slice sampling Gantt chart. Where T_{int} is the set timer interrupt interval, n_{slice} is the current index of the slice to be sampled, and i is the index of the current sampled slice.

are then sent out via DMA through Bluetooth. The general sequence diagram is given in Fig. 6.

The variables are defined as below:

- t_{imuS} : the time needed for sampling the two IMUs;
- t_{imuP} : the time needed for packing the IMUs' data into the final send package;
- t_{tpmS} : the time needed for obtaining data from the entire TPM;
- t_{tpmP} : the time needed for packing the data from the entire TPM;
- n_{row} : the number of TPM rows;
- k : the total number of slices, and also the frequency ratio of the IMUs over the TPM;
- $\lceil n_{row}/k \rceil$: the number of rows sampled each time (at the last round, the rows sampled might be smaller than this value);
- t_{rest} : time consumption of the rest of the codes in a loop (include time spent configuring DMA), which is a constant value.

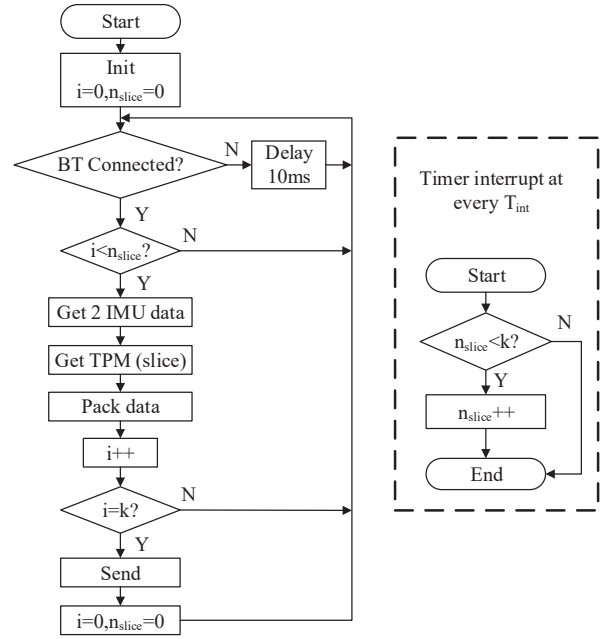

Fig. 7. Slice sampling flow chart

The flow chart for the embedded program is given in Fig. 7.

If the transmission (or storage) bandwidth were not limited, then the time needed for each sample t_{sample} (including two IMUs and part of the matrix) can be estimated as:

$$t_{sample} = t_{imuS} + t_{imuP} + \frac{t_{tpmS} + t_{tpmP}}{n_{row}} \lceil \frac{n_{row}}{k} \rceil + t_{rest} \quad (3)$$

This time is slightly less than the interruption interval (T_{int} in Fig. 7). As the time of interrupt callback is several orders of magnitude less than the existing time, it is not considered here.

The theoretic sampling frequencies of the IMUs and the matrix are then given by:

$$\begin{cases} f_{imu,theory} = 1/t_{sample} \\ f_{tpm,theory} = f_{imu,theory}/k \end{cases} \quad (4)$$

Since the sampling frequency of the TPM is always $1/k$ of the sampling frequency of the IMU, only the equation for the IMU sampling frequency is given below. The sampling

frequency is also limited by the total bandwidth, given as below:

$$f_{imu,limit} = \frac{Bandwidth}{B_{imu} + \lceil n_{row}/k \rceil \times B_{tpm}/n_{row}} \quad (5)$$

The new variables and their values for the smart shoe are given below:

- $Bandwidth$: the bandwidth limit, 48KB/s, due to the usage of Bluetooth transmission;
- B_{tpm} : data size of a whole matrix: 28×16 channels, 12-bit resolution, 672 Bytes/frame;
- B_{imu} : data size of two IMUs per sample: 12 channels, 16-bit resolution, 24 Bytes/sample.

Fig. 8. Sampling frequencies of TPM and IMU at different k's

The real sampling frequency can go beyond neither of the above, thus:

$$\begin{cases} f_{imu} = \min(f_{imu,theory}, f_{imu,limit}) \\ f_{tpm} = f_{imu}/k \end{cases} \quad (6)$$

For the smart shoe, the sample frequencies at different k values can be deduced and measured, the result is provided in Fig. 8. As k grows, the sampling frequency of the IMUs grows and the matrix drops. Already at $k = 2$, $f_{IMU} = 136$, IMUs reach a C_f value of 0.98 (while the C_f of TPM also 0.98). At $k = 12$, $f_{IMU} = 504$, there is almost no information loss for IMUs ($C_f = 0.997$), while the information from the TPM drops to $C_f = 0.95$. It is thus highly recommended to set k to 2 and the embedded program of the smart shoe shall be configured accordingly before gait analyze experiments.

The demonstration of the whole workflow of information quality evaluation, optimal frequency ratio selection and system configuration is finally finished.

V. CONCLUSION AND DISCUSSIONS

The information loss in the digitalization process can not be recovered later by the software. Frequency selection for sensing systems is thus very important. For multi-modality IoT systems, we propose a general workflow, 1) to answer the question whether frequency balancing is needed, 2) to find out the proper frequency ratio and 3) to configure this ratio into the embedded system. We demonstrate how this workflow functions with a concrete example, a smart shoe equipped with two IMUs and a pressure sensing matrix. The sensor configuration of this example system (multiple sensors together with a sensing matrix) and the corresponding workflow are general enough to be expanded also to other multi-modality IoT systems.

We find out that the commonly practiced 1:1 frequency ratio might not be a good choice for multi-modality IoT systems. Specially, IMU frequency might need to be raised to over 100Hz if the goal goes beyond activity recognition. It is highly recommended to follow the frequency balancing workflow before carrying out large-scale data acquisition, so that the most information can be kept, ensuring a sound dataset for information retrieval algorithms and also for future use.

Abstract—Accurate photon detection probability (PDP) modeling is important for the optimized design of single-photon avalanche diodes (SPADs) using modern standard CMOS technologies. To ensure a planar active region of a SPAD, the edge of the depletion region must have a lower electric field, so a lower doping concentration is needed. However, this edge effect may have a negative impact on the total PDP, especially for small-sized SPADs. In this paper, we proposed an enhanced PDP modeling process by combining the Technology Computer-Aided Design (TCAD) simulations with machine learning (ML) techniques. Using this ML-TCAD PDP model, we investigated the influence of the edge effect on the PDP of SPADs by varying the diameter of the SPADs from 1.75 μm to 8.75 μm . After generating the sample simulation data, Gaussian process regression (GPR) and deep neuron network (DNN) are applied to train the model. With the application of principal component analysis (PCA), the accuracy of the trained models was significantly improved. Overall, this ML-TCAD PDP model provides an optimized and accelerated design process for SPADs, thus saving simulation time and reducing the design iterations required in the traditional design process of SPADs.

Keywords—Photon detection probability (PDP), single-photon avalanche diodes (SPADs), edge effect, machine learning (ML), TCAD, principal component analysis (PCA)

I. INTRODUCTION

Single-photon avalanche diodes (SPADs) are p-n junctions that are reversely biased above their breakdown voltages (V_{BD}), thus leading to extremely high electric fields across the depletion regions. In such high electric fields, avalanching can be triggered even by a single photon. Due to the high sensitivity, SPADs are widely used in many optical applications including biomedical imaging [1]–[4], communications [5], and light detection and ranging [6]. With the development of silicon-based fabrication technologies, many SPADs were designed and fabricated using standard complementary metal-oxide-semiconductor (CMOS) technology due to their lower manufacturing cost and the potential to be integrated with other CMOS read-out and signal processing circuits to implement complete imaging systems to achieve a strong overall performance [7]–[11]. However, CMOS SPADs usually suffer from the low photon detection probability (PDP) due to two main reasons [12], [13]. First, the thin

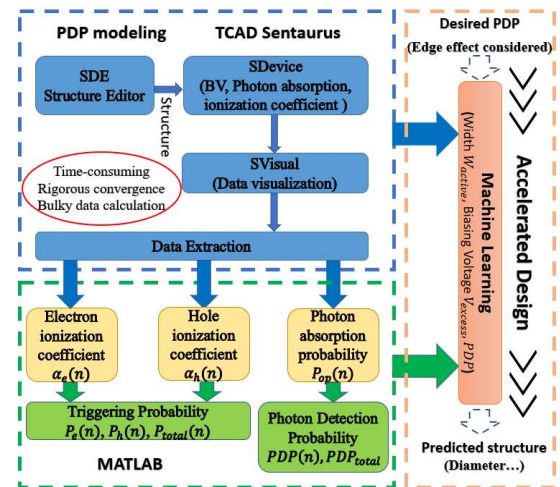

Fig. 1. Design flow of enhanced 2-D PDP simulation with ML-TCAD.

depletion regions of CMOS SPADs lead to a low photon absorption probability. Second, the reflection and absorption of inter-metal dielectric layers and passivation layer result in only a portion of incident photons arriving the active region of SPADs. Traditionally, to optimize the PDP performance, the initial prototype of SPADs needs to be designed, fabricated, and measured. Then, the SPAD designs will be revised based on the initial measured results, then the entire process is repeated, so the final design may need several iterations. This traditional optimization process is costly and time-consuming.

In this paper, to accelerate this optimization process, we developed a PDP model using TCAD simulation tools. With this model, the PDP performance can be easily simulated when varying the SPAD design parameters such as layer doping concentrations, guard ring structure, junction depth, and active region diameter, thus significantly reducing the time and cost for the SPAD PDP optimization. In addition, we investigated the edge effect for SPADs with different diameters and found that the edge effect has more impact on the total PDP in small-sized SPADs. We applied machine learning (ML) techniques, including the Gaussian process regression (GPR) and the deep neural network (DNN), to further improve the PDP modeling. The accuracy of diameter predictions is significantly improved after we introduced the principal component analysis (PCA) into the models. The proposed

ML-TCAD PDP modeling process is shown in Fig 1. The whole process is divided into two parts: PDP modeling and ML. In the PDP modeling part, SPAD’s structure is created and then simulated using TCAD. The data such as photon absorption probability, electron and hole ionization coefficients will be extracted from TCAD directly and processed in MATLAB to calculate the PDP. For the ML part, the diameters and the final PDPs with edge effect of SPADs with different sizes will be used to train ML models to further improve the efficiency and accuracy of the SPAD PDP model.

II. PDP MODELING OF SPAD

The PDP modeling process of the SPADs mainly includes 4 steps: simulating breakdown voltage, simulating triggering probability, simulating photon absorption probability, and calculating the final integration. The simulations were performed using TCAD Synopsys Sentaurus [14], [15] because this tool provides various models for avalanche simulation.

A. Breakdown Voltage

Considering that SPADs are reverse-biased above the breakdown voltage with typical critical electric fields beyond 10^5 V/cm, the avalanche model we applied is the Okuto-Crowell model [15], [16]. The model is implemented as a “local model” so that the ionization coefficients will only be determined by the local electric field. The structure of the SPAD was built using Sentaurus Structure Editor. Fig. 2 shows the cross-sectional view of the general structure of a p⁺/n-Well SPAD with p-Well guard rings. The doping concentrations of the n⁺ and p⁺ regions are set to be 10^{19} cm⁻³ while doping concentrations of the p-Well guard ring and the n-Well are set to be 10^{17} cm⁻³. Shallow trench isolations (STIs) are applied to isolate the n⁺ and p⁺ regions according to the process-related requirements. The Ohmic contacts are tied directly to the highly doped n⁺ or p⁺ regions. With n-type contact tied to the ground, negative sweeping voltages are applied on the p-type contacts to find the avalanche breakdown point. When diodes are reverse-biased above V_{BD} , the reverse current will increase sharply, usually several orders of magnitude [17], [18]. The simulated current-voltage (*I-V*) characteristic is shown in Fig. 3. Upon the breakdown, the reverse current increases almost vertically, from a typical value below 10^{-10} A to around 10^{-6} A. Additional break criteria were added to stop the avalanching process, thus avoiding the convergence problem. In addition to the *I-V* characteristic, we also performed avalanche analysis to calculate the ionization integrals, provided by Sentaurus

Fig. 2. Schematic of the SPAD cross-sectional view.

Fig. 3. Current-voltage (*I-V*) characteristics of the SPAD in Fig. 2. Breakdown voltage $V_{BD}=-13.8$ V obtained.

SDevice. When the ionization integral calculated by TCAD using Eq. 1 and Eq. 2 reaches 1, the V_{BD} is determined.

$$I_E = \int_0^d \alpha_e(x) e^{-\int_x^d (\alpha_e(x') - \alpha_h(x')) dx'} dx \quad (1)$$

$$I_h = \int_0^d \alpha_h(x) e^{-\int_x^d (\alpha_h(x') - \alpha_e(x')) dx'} dx \quad (2)$$

The terms d , α_e and α_h in Eq. 1 and Eq.2 represent the integration path length, electron ionization coefficient and hole ionization coefficient, respectively. Combining the two methods, the accurate V_{BD} of the SPAD was determined to be 13.83 V as shown in Fig. 3.

B. Avalanche Triggering Probability

Avalanche triggering probability is defined to be the probability that carriers induce an avalanching process at specific positions. The widely used McIntyre model is applied in our work as it is easy to be extended in 2-D calculations [19]. The differential equations for calculating the triggering probability are shown in Eq. 3 and Eq. 4.

$$dP_e/dx = (1 - P_e) \times \alpha_e \times (P_e + P_h - P_e P_h) \quad (3)$$

$$dP_h/dx = -(1 - P_h) \times \alpha_e \times (P_e + P_h - P_e P_h) \quad (4)$$

The terms $P_e(x)$ and $P_h(x)$ represent the triggering probabilities of electrons and holes, respectively. The terms α_e and α_h are electron and hole ionization coefficients, respectively. In the previous work, the ionization coefficients are generally either referenced from the literature [20] or calculated through an external MATLAB routine [21]. However, in our work we directly used the simulated results of the ionization coefficients using TCAD. To simulate the 2-D PDP with the edge effect, some researchers chose to use a two-step discrete way [21]. They calculated the triggering probability through the lines following the electric field’s direction first, and then did the integration along the line. However, this method is not convenient and is time-consuming. Therefore, we implemented the simulations of the electric field, ionization coefficients and optical absorption simultaneously in our work, which facilitates the simulation process. Electric field distributions of SPADs with 3 different diameters are shown in Fig 4. SPADs with different diameters are all biased at 1V beyond the V_{BD} (-

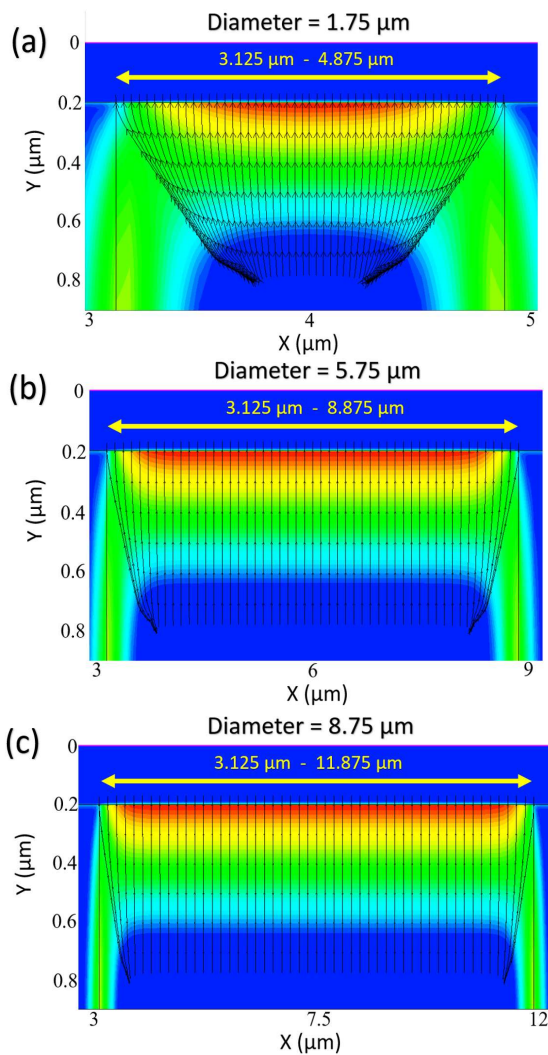

Fig. 4. Electric field distribution of SPAD with diameter of (a) 1.75 μm. (b) 5.75 μm. (c) 8.75 μm, 51 lines along electric force lines are created.

14.83 V). For the SPADs with different diameters, 51 lines following the electric field's direction were generated, and the lengths of each line were specified by applying the boundary conditions of the depletion region. Since the 51 lines were generated through the simulation directly, and no discretization or approximation was applied, our method provided more accurate ionization coefficients and distances for the integration when calculating the avalanche triggering probability. The typical simulated ionization coefficients of electrons and holes of a SPAD with a 5.75 μm diameter are shown in Fig. 5. In Fig. 5, the highest ionization coefficients are in the central part and a decreasing trend of ionization coefficients is shown when the lines are approaching to the edges. After simulation, the coefficients were extracted from TCAD and then imported to MATLAB. These coefficients were used as accurate parameters for solving the differential equations in Eq. 3 and Eq. 4 with the additional boundary conditions in Eq. 5 and Eq. 6.

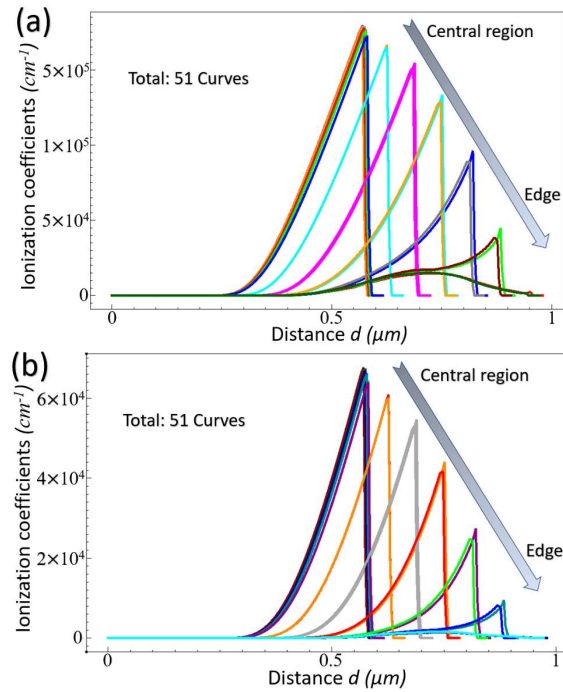

Fig. 5. Ionization coefficients along 51 lines of (a) electrons and (b) holes, based on a SPAD of a 5.75 μm diameter.

$$P_e(0) = 0 \quad (5)$$

$$P_h(d) = 0 \quad (6)$$

The term d is the length of each line. Since the length of each line is determined by specifying the width of the depletion region, additional definitions of the depletion region's length in MATLAB are not needed when solving the differential equations. The triggering probability of each line was calculated using the BVP4C solver in MATLAB. The calculated results show that the lines in the central region have higher triggering probabilities while the lines close to edges show negligible triggering probabilities. For example, the central line (line 26) has a triggering probability of 0.55 while the line closest to edges (line 1 and line 51) has a triggering probability of almost 0. These results clearly show the influence of the edge effect on avalanche triggering probability.

Fig. 6. Absorbed photon density along 51 lines based on a SPAD of 5.75 μm diameter, illuminated by a 500-nm light source

Fig. 7. Simulated photon detection probability of SPADs with diameters ranging from 1.75 μm to 8.75 μm .

C. Photon Absorption Probability

The photon absorption probability (PDP) determines the available number of carriers in the depletion region to possibly trigger avalanche events. Compared to the triggering probability, the photon absorption probability of a fixed material mainly only depends on the depth, following an exponential decay. In this work, the material is silicon. The exact values of the absorbed photon density along the 51 lines we created were first simulated using a vertical illumination of a 500-nm light source, as shown in Fig. 6. Then, the photon absorption probabilities were calculated using Eq. 7, with the intensity $I_{op} = 1 \text{ mW/cm}^2$, Planck constant $h = 6.626 \times 10^{-34} \text{ J}\cdot\text{s}$, speed of light in vacuum $c = 2.998 \times 10^8 \text{ m/s}$, and the virtual thickness $t_v = 1 \mu\text{m}$.

$$P_{op} = \text{Absorbed density} / \frac{I_{op} \times \lambda \times t_v}{hc} \quad (7)$$

D. Photon Detection Probability

The $PDP(n)$ ($n = 1, 2, \dots, 51$) in the depletion region was then calculated according to Eq. 8 with the actual length of each line, where P_{trig} is the total triggering probability defined in Eq. 9.

$$PDP(n) = \int_0^{d_n} P_{op}(x) \times P_{trig}(x) dx \quad (8)$$

$$P_{trig}(x) = P_e(x) + P_h(x) - P_e(x)P_h(x) \quad (9)$$

Next, we varied the diameters of the SPADs to investigate the edge effect on different-sized SPADs. Fig. 7 shows the $PDP(1) - PDP(51)$ of each SPAD with the diameters ranging from 1.75 to 8.75 μm . As expected, a significant edge effect is shown on the PDP for SPADs with smaller diameters. Similar results can be found in [21]. However, the actual PDP modeling or measurement process is time-consuming since it needs careful settings for the simulation conditions, as mentioned in Fig. 1. The simulation of the accurate breakdown voltage, extraction of ionization coefficients, manual operation to generate lines for integration, and the final calculation of $PDP(n)$ require a large amount of time and expertise in optoelectronic device design and programming. One

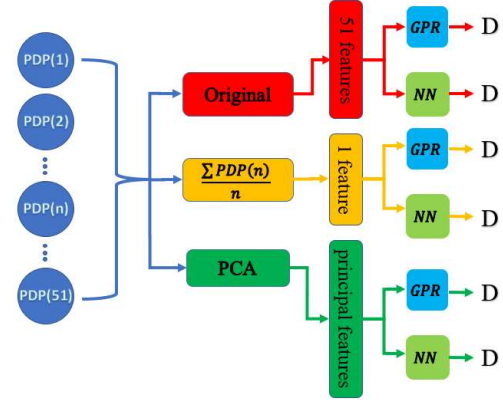

Fig. 8. Proposed process for predicting the diameter D by using the calculated 2-D PDP values.

promising method to improve the efficiency of the optimization process for SPAD design is to combine ML techniques with PDP modeling, which will be discussed in detail in Section III.

III. PREDICTION OF SPADs' DIAMETER

ML was recently applied in the field of TCAD device modeling due to its high efficiency, accuracy, and low cost. Typical applications of the ML-TCAD combined approaches include the prediction of the FinFET defect location [22], process variation analysis of vertical FET [23], breakdown estimation [24], and even circuit design [25].

The effectiveness of the trained model mainly relies on the number of samples, data processing, and algorithms [24]–[27]. However, many works are only based on the basic $I-V$ characteristics of the devices. In our work, we used the complicated input attributes of the PDP of different SPADs to train our model. Our proposed ML route for the diameter predictions is shown in Fig 8. The simulated $PDP(n)$ are preprocessed in three different ways: original values, average value, and PCA applied. After that, processed data will be used to train two different models: Gaussian process regression (GPR) and deep neural network (DNN). The details of each part are stated as follows.

First, GPR and DNN are used to train the model with the inputs $PDP(n)$ and the output diameter D . GPR is believed to be suitable for solving problems with uncertain complexity due to its ability to find the correlation between the samples and the data. The DNN layers are activated using the common rectified linear unit (ReLU) activation function [28]. Fig. 9 shows that GPR trained model gives a good prediction with the root-mean-square error (RMSE) of 0.137 μm while the DNN trained model has presented some unreasonable predictions. This is probably caused by overfitting when using DNN to train the model. Some small variations of the $PDP(n)$ may lead to large differences in the outputs of the model. To alleviate the possible overfitting, we summed up the $PDP(n)$ of each sample and calculated the mean values to train the two models. As expected, the overfitting phenomenon was improved, with RMSE of 0.113 μm and 0.107 μm for the GPR model and the DNN model, respectively.

Fig. 9. Predictions versus actual diameters with original PDP used. (a) gaussian process regression. (b) neural network.

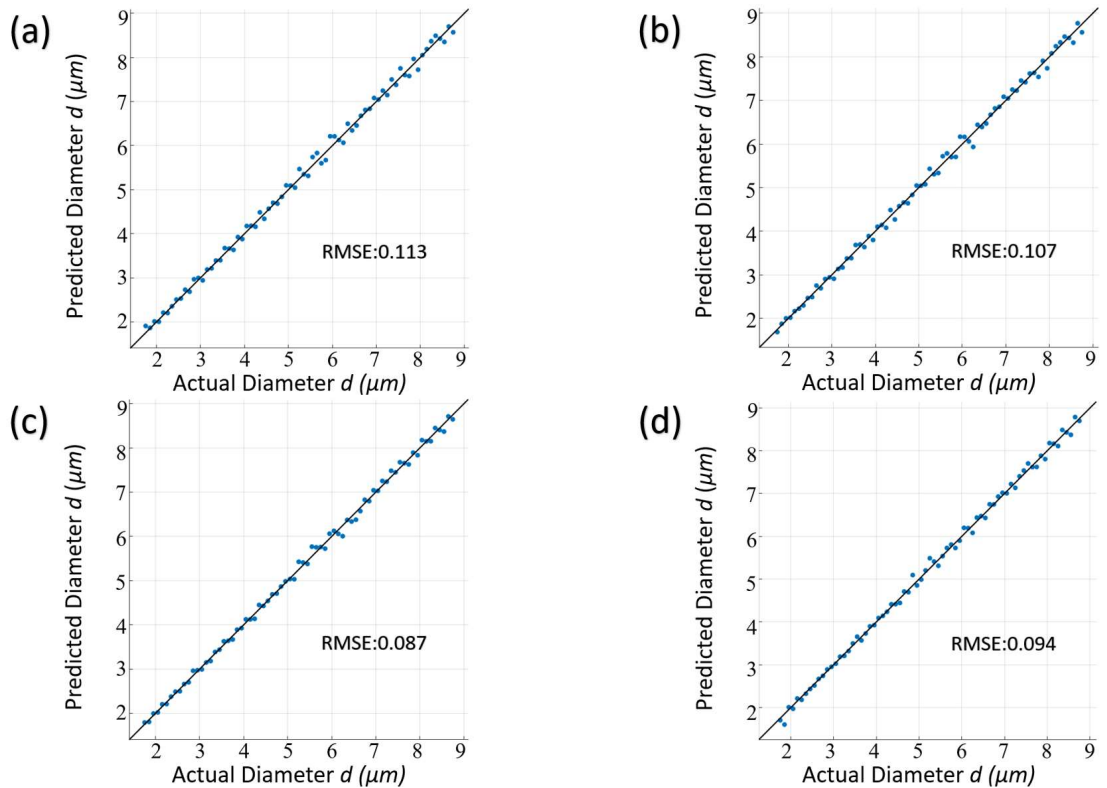

Fig. 10. Predictions versus actual diameters with (a) Gaussian process regression using PDP mean value. (b) Neural network using PDP mean value. (c) Gaussian process regression using PCA. (d) Neural network using PCA

We further improved the effectiveness of the ML-TCAD PDP model by applying the principal component analysis (PCA) to the original PDP(n) along each line. Originally, the input features of each sample are 51. The PCA can help to reduce the dimensions for the training of the model by identifying the most important components. Fig. 10 shows the predictions made by using mean value and PCA, respectively. The models that are combined with the PCA provide the optimal predictions, with RMSE of 0.087 μm for the GPR and 0.094 μm for the DNN model, respectively. The comparison of different models is shown in Table I.

TABLE I. COMPARISON OF MODELS' EFFECTIVENESS

Data Inputs	Features used	Model type	Root-mean-square error (μm)
Original PDP(n) ($n = 1, 2, \dots, 51$)	51	GPR	0.137
		NN	29.424
Mean value of PDP(n)	1	GPR	0.113
		NN	0.107
PCA processed PDP(n)	3	GPR	0.087
		NN	0.094

IV. CONCLUSION AND FUTURE WORK

In conclusion, we proposed a new design process for SPADs that combines the 2-D PDP model that takes edge effects into consideration with the machine learning (ML)

algorithms. We optimized the simulation of 2-D PDP in the depletion region based on simulated results without needing any discrete approximations. Furthermore, the introduction of the principal component analysis (PCA) into the ML model training effectively improves prediction accuracy. To our best knowledge, this work is the first one to improve the accuracy of PDP modeling for SPADs by using ML techniques. The results show that this ML-TCAD PDP model will save the time, cost and effort for the optimization process of the SPAD design. Our future work will include more variables and other physical processes like the biasing voltage, doping concentration and dark count rate to develop a comprehensive SPAD model that can predict all parameters for the SPAD.

Abstract— *This research presents the design of an automated system for obtaining biogas, mainly methane gas, through biodigesters. The anaerobic microorganisms present in the manure generate methane through their digestion, which is the main object of this study, since without this process it would not be possible to obtain natural gas. On the other hand, the system has 5 controlled processes that will complete the anaerobic digestion, namely: evaluation and positioning of manure, transmission belts and actuators that together separate the organic matter and begin with the filling of the biodigesters for the extraction of natural gas; additionally, there will be an adequate temperature control for the development of microorganisms, since at a higher temperature in its ideal environment, the gas will be obtained in less time, so the system will count and turn on heaters or fans based on the results. The objective of this process is to avoid exposure to the contagion of diseases in people and reduce the emission of greenhouse gases.*

Keywords— *Automated system, methane, collection, biodigesters, storage.*

I. INTRODUCTION

Livestock is one of the main polluting activities, since manure is one of the environmental problems that develop in livestock complexes [1], nitrous oxide (N₂O) and methane (CH₄) are important gases involved in the effect greenhouse produced by these animals during the process of manure management and enteric fermentation, the largest amounts of emissions produced are caused by inefficient systems in the rearing, management and production of manure in developing countries due to limited technical and economic resources, for the which the use of mitigation tools is recommended to reduce these gases in the atmosphere [2].

More than 1 million tons of manure is produced in the livestock sector from the digestion of feed in the rumen per

year which has a GHG potential of 21 and 310 times greater than CO₂ by producing methane and N₂O respectively, where burning 1 ton of methane is equivalent to eliminating 24 tons of CO₂ [3]; furthermore, enteric methane accounts for 17% of global CH₄ emissions, which is produced mostly by ruminant animals, and their excretion contributes to 0.4% and 2% of global GHG and methane emissions in that order [4]. Indonesia is committed to reduce 29% of domestic greenhouse gas emissions with its own effort and 41% of international support by 2030, because the anaerobic digester captures CH₄ from manure for use in bioenergy to replace non-renewable energy such as kerosene and LPG, This converts manure into methane-rich biogas, indirectly reducing GHG emissions produced by animals, since the livestock sector contributes between 18% and 51% and the agricultural sector between 10% and 12% of total GHG emissions, digesters produce a concentration of 60% to 80% of methane from pig, poultry and cattle slurry [3].

One of the main facts when considering strategies for methane reduction is methanogens, given that methanogens are the only organisms capable of producing methane, other strategies that are investigated are vaccines and defaunation; other studies take advantage of the potential produced by bioenergy from cow manure in Comarca Lagunera of 21 GW/year and in Mexico of 410 GW/year with a reduction of greenhouse gases of 21 Gg per year in CO₂ equivalent, according to the International Energy Agency the bioenergy potential of cow manure will have an increase of 250% with respect to bioenergy production from biogas, but there is little implementation of the design and operation of biogas plants [6].

An analysis performed on the gas components showed a significant volume of methane in sheep manure with 62.1%

and cow manure with 66.9%, resulting that cow manure is one of the best for obtaining biogas, compared to sheep and pig, since the latter is less productive for biogas, these alternative energy resources obtained will allow us to replace the depletion of fossil fuels [7]. This study aims to optimize time and resources to reduce methane in the environment.

II. MATERIALS AND METHODS

The design proposal aims to reduce greenhouse gas emissions produced in livestock farms, as mentioned above, and reduce the time it takes to obtain biogas. [12] The automated system means that fewer people are exposed to the treatment of waste, thus avoiding diseases. The team used the bio digestion method and the design is called batch biodigester, which is simple and economical unlike other industrial processes [8, 13, 16]. There are 3 main gases that make up the Methane fermentation residue component: and they are nitrogen, phosphorus and potassium which are different according to the manure of each animal and are shown in Table 1. [17].

TABLE 1. The nutrient content in the different manure [17].

Compost	N %	P%	K%
Cow	1	1.4	1.5
Horse	1	1.8	2
Chicken	2.3	2.5	3.4
Food Waste	5.66	1.92	0.52

To estimate a saturation point between methanogens (catalysts) and manure we define that these organisms use H2 and CO2 as substrate for biogas production during their growth, considering also a suitable environment for their development or cultivation of these organisms and having a stable methane production or methanogenesis. The production of CH4 by methanogens requires the consumption of large amounts of sodium formate even for a modest cell growth of these organisms, which is the saturation point in the methanogenesis process, since the large amounts of sodium formate significantly accumulate NaOH (1), modifying the pH of the environment and turning it into an alkaline one, thus causing cell lysis and rapid death of the methanogens [18].

A. Biogas production process

The composition of biogas is mostly methane between 50% to 60% and it is produced thanks to the organic matter through anaerobic digestion, in addition once the natural gas was obtained we also have a residue that can be used as fertilizer, since this residue improves the solubility of mineral compounds in the soil [5, 13, 14].

On the other hand, anaerobic digestion is the interaction of microorganisms in the absence of oxygen, the chemical reaction shown in (2) [15].

Four stages are necessary for the process: hydrolysis, acidogenesis, acetogenesis and methanogenesis, which are consecutive phases and in each one different microorganisms participate; that is, in the first stage these beings decompose the larger wastes and when they are smaller, other types of microorganisms can take charge of their treatment [8].

There are factors that make the development of digestion more feasible and most of them are environmental, methanogens are susceptible to these changes and one of the parameters that has greater influence is the temperature since it alters the activity of enzymes, so a mesophilic temperature of between 30°C to 40°C should be maintained, which accelerates the fermentation process [15].

B. Digester system design

Through the simulation performed in the Factory I/O software we have the inlet of the tanks which we will call biodigesters, there are also the discharge ducts of these, to refer to the mixture of waste and water we use the word affluent, we also find the outlet valve for the biogas.

For the implementation of the biodigesters, the total volume to be housed was considered and is given in (3) where V is the useful volume and Vg is the volume of biogas produced.

$$V_T = V_L + V_G \quad (3)$$

For an optimal retention it is necessary to know the time this variable will be called HRT and are the days required for the organic mass or influent to be consumed by the bacteria, then the design proposes a daily tank filling, so we have an Q_{affluent} (m³/day) then to know the useful volume we use (4).

$$V_D = V_{Useful}(m^3) = TRH \text{ (days)} \cdot Q_{Influent} \left(\frac{m^3}{day} \right) \quad (4)$$

The biodigesters will have a pressure gauge in order to activate the tank discharge process, since the retention time will not always be met, this can be less and will work with a range: if the pressure is very low, the discharge ducts will be opened with a 10-minute advance notice; the same will happen once the pressure of the storage tank and the biodigester are 80% full [14, 15].

On the other hand, it was important to analyze various parameters of the raw material, for which Table 2 was taken as a reference; in addition, it should be noted that the optimum hydraulic retention time is in the range of 25 to 30 days [19].

TABLE 2. Raw material design parameters [19].

Parameter	Value
Average daily generation rate	564 kg/dia
Volumetric feed flow rate	0,4 m3 /dia
Total Solids (TS)	18,9 %
Volatile Solids (VS) (% TS)	80 %
Moisture content	81,1%
In Situ Density	1410kg/m3
Optimum Hydraulic Holding Time (HRT)	25-30 dias
Optimal organic loading rate	5-10 Kg SV/m3

As for the return on investment, the financial viability of biogas to produce biomethane at different scales needs to be looked at, the results are expected to help investors and governments to make decisions. The results obtained show that 'there are 10 potential areas of biomethane produced in Thailand, with a total biogas production capacity of 6,000 m³/day or more, with the condition that the pipeline does not exceed 50 km. Compressed biomethane plants with a capacity of less than 6 tons/day should be financed by the Government with 30% of the total investment capital with a payback period of 5-6 years. Plants producing more than 6 tons/day offer a good return on investment even without public capital [20].

First of all, to establish the development of the process in Fig. 1, it was essential to start the system by evaluating the position of the manure, on which depends the actuation of the pistons and belts, which in turn will move the manure to the extraction zone, thus initiating the methane extraction process; additionally, according to the ideal temperature, the heater or agitator is activated to finally store the manure in the tank.

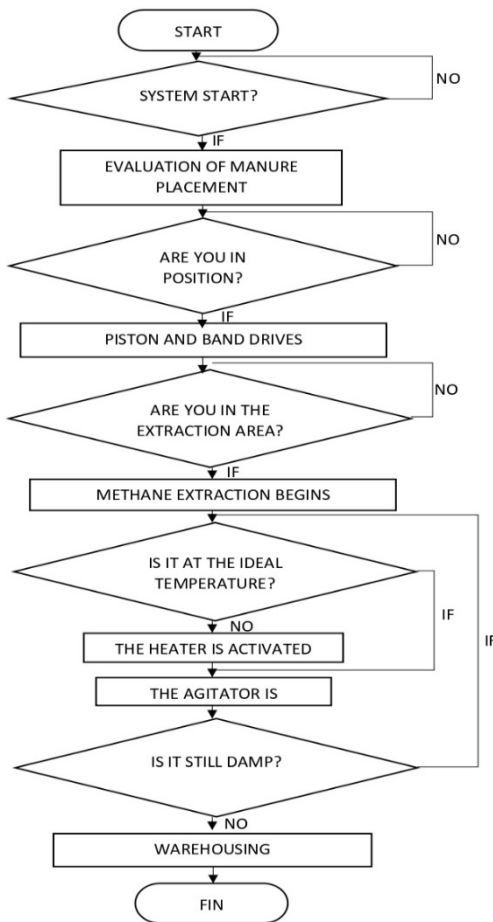

Fig. 1. System flow diagram.

III. RESULTS

Fig. 2 shows in the drivers the sensors and actuators used in the system by means of the Factory IO software; in addition to using the connection to the OPC server and

performing the simulation in the TIA Portal software. On the other hand, infrared sensors, pushbuttons (start and stop), conveyor belts, electric pistons and a 2 GDL robotic arm were used.

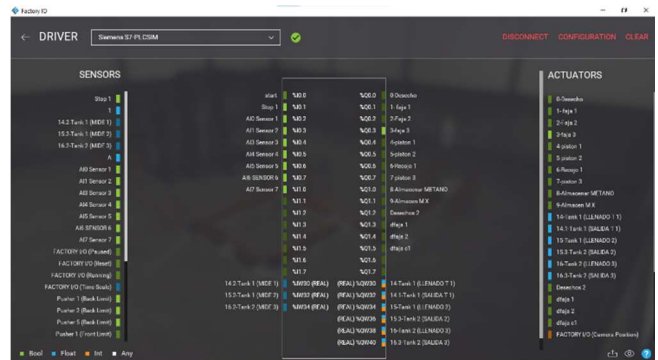

Fig. 2 PLC inputs and outputs in Factory IO software.

In Fig. 3, the programming of the 3 tanks of the system was carried out, which were set within the range of 0 to 10 volts (v); therefore, in the first place, a determined value of 6v was set, which indicates that the input flow rate is 60%. For the second tank, a determined value of 4v was set, which represents 40% of the input flow rate. Finally, the third tank worked with an aggregate value of 2v which revealed that the inlet flow rate is 20%.

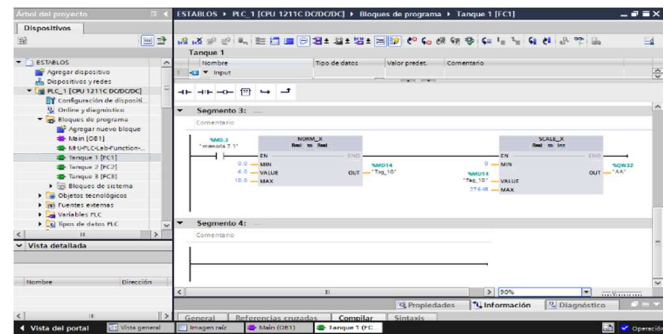

Fig. 3. Block programming of the tanks.

Fig. 4 shows the wet manure store, since it stores the wet feces, which will be detected by the infrared sensor, which will then drive the electric piston to move the feces on the conveyor belt, and the second sensor detects the feces, which generates the drive of the second piston to finally take the feces to the extractor.

Fig. 4. Top view of the wet manure storage area.

Fig. 5 shows the manure detected by the third sensor which actuates the robotic arm, this represents the manure extractor, thus starting the filling of tank 1.

Fig. 5. Isometric view of the manure extractor.

Fig. 6 shows the filling of the tanks with methane in different percentages; for example, in the first process methane was obtained with a mixture of manure. In the second process, a filtering process is carried out to obtain a higher percentage of methane. Finally, in the third tank, a higher proportion of methane gas is obtained through a second filtration.

Fig. 6. Methane tanks.

As shown in the following image, an interface is implemented for a better representation of the automated system, where the process of the second and third tank is represented, for which the first tank stores the manure of livestock animals and through a filter extracts only the liquid to be processed by methanogenic organisms, which as mentioned above are responsible for producing methane [5], in addition these must be in constant movement and in a temperature range of 30° to 40° so that at higher temperature there is an acceleration of methane [15], a motor will be used that can be connected to blades to move the liquid, in addition to having a system to maintain an ideal heat and cooling for methanogenic organisms. Subsequently, as the methane is stored, the percentage of the third tank will be observed, but the pressure sensor will let the methane pass only when the second tank is greater than 90% of its capacity and then the second tank will be emptied. When more than 95% of the capacity of the third

tank is stored, the system stops completely to remove the methane gas.

Fig. 7. Representation of the extraction of tank 2 and tank 3.

Subsequently, the programming for the process is shown, first, for the second tank starts with the filling through the filter, when it is over 40% of its capacity the engine is turned on to mix the liquid, then when it passes 90% of its capacity the filling and filtering is stopped, also oscillating temperatures are programmed to see the heat and cooling system for which a range of 35° to 40° was set so that the organisms produce the methane in less time. Secondly, when the second tank reaches 90% the sensor lets the methane pass to the tank which is stored and is reflected in the indicators of the third tank, once it reaches over 95% the system stops to avoid damage to the tank and the gas can be extracted without any inconvenience for its use.

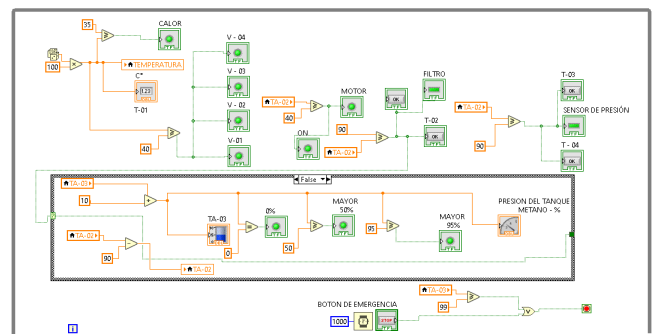

Fig. 8. LabVIEW programming.

In Fig. 9, sensor 4 detects the moisture in the manure, which is directed to the system's feedback belt, where the manure returns to the robotic arm (methane extractor) for extraction. Finally, the dregs are directed to the dregs tank.

Fig. 9. Wet manure feedback.

In Fig. 10, the HMI environment visualizes the emergency start-up and shutdown of the system and the simulated methane extraction at various levels for each tank.

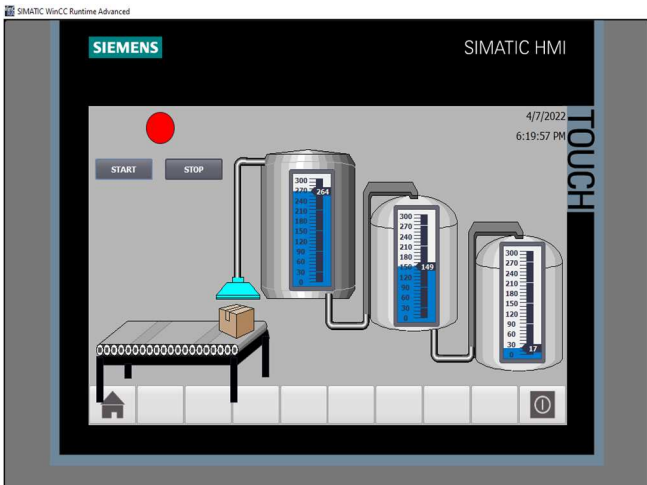

Fig. 10. HMI environment of the system.

Fig. 11 shows the execution of the system programming, where the actuation of the start control and emergency stop control is shown.

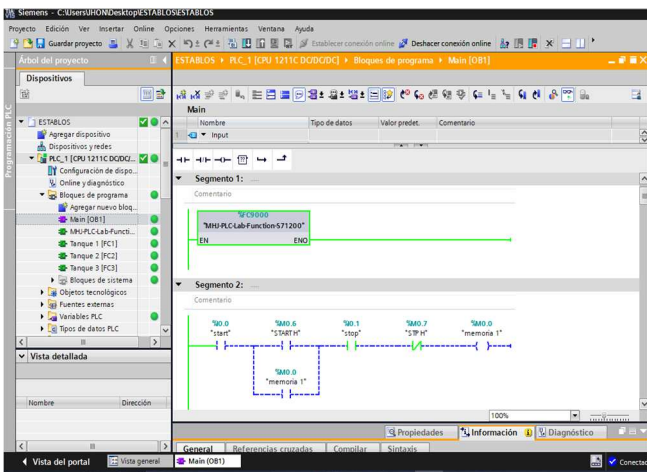

Fig. 11. Compilation of the PLC program in Ladder language.

In Fig. 12, a mushroom button was included on the control panel to interrupt the process or perform an emergency stop. There is also an on/off selector switch for the entire system.

Fig. 12. Control panel design.

IV. DISCUSSIONS

A vacuum depression methane gas enrichment and separation (PSA) system was presented, demonstrating that this type of system can improve the efficiency of methane absorption, separation, and recovery in a coal mine ventilation system. For the development of this system, 2 absorption towers, vacuum pump, sensors and a PLC module were used to process the data from the control, measurement and piping network subsystems and import this data to a computer. A simulation was performed in Aspen Adsim software showing that the proportion of methane decreases with increasing feed concentration with a pressure and adsorption time of 210 kPa and 120 s respectively in the simulation; while in the field experiment, it increased about 30 s the adsorption time and methane concentration by 0.3%. They concluded that this system can reduce the investment cost and energy consumption, significantly improve the adsorption, separation and recovery of methane gas and thus protect the environment [1].

On the other hand, the research "Solution of environmental problems of livestock farming through the intensification of waste treatment processes" developed the design of a bioreactor, introducing bacteria for methane formation. It was carried out in a laboratory using a 50-liter bioreactor and later more components were added to these for improvement. The process starts by introducing microorganisms and manure into the bioreactor with a moisture content between 80 - 85% and continuously recirculating and fermenting for 28 days in mesophilic mode until biogas is formed and repeating the same procedure successively. The results of the research showed that the maximum percentage of methane in the biogas is reached on the seventh day (68%), and a stable mode of biogas formation is established on the 9th-10th day of fermentation. It was concluded and recommended that this bioreactor should be further upgraded to increase productivity and reduce HRT by using a leaching layer and immobilization of microorganisms [8].

When comparing the design presented in this research and the system of enrichment and separation of methane gas by vacuum depression oscillation (PSA) used 2 absorption towers for methane collection which does not have an automated process while the system presented in this research is automated and has 3 tanks that are at different levels, thus separating the processes in each tank for better quality of biogas, including a feedback process to obtain more methane from the manure that has already passed through each tank; This reduces and optimizes the time and amount of methane collected. Consequently, better environmental and economic benefits are obtained. Regarding the bioreactor design on the solutions of environmental problems of livestock farming through the intensification of waste treatment processes this design is not automated and invests considerable time in methane collection, since the research was developed in a laboratory and the bioreactor was not fully developed this would be limited for industrial processes, while the design presented in this article meets these requirements of control processes and automated design.

V CONCLUSIONS

Today it is known that one of the main pollutants is livestock; with which more than 1 million tons of manure is produced per year and having a potential of 21 times with CO₂ producing methane and 310 times more N₂O; furthermore,

enteric methane constitutes 17% of the global emissions produced by these animals. Environmental problems develop due to the manure of livestock animals due to inefficient systems in the respective control and management. This problem, in developing countries, is due to the limitation of economic and technical resources.

In the present investigation, the results obtained showed a control system focused on the collection of manure in cattle stables, since this contributes to avoid diseases and reduces the methane produced by the manure; in addition to optimizing the collection and storage time, it also reduces the percentage of methane gas emission by the fermentation process to the environment generated by the cattle.

The research presents a human-machine interface (HMI) system that makes it reliable and useful for users, from the evaluation process in real time to the identification of a problem or error in the system as a whole. For this, the Factory IO and TIA Portal software were used to simulate the process, which begins with the positioning of the manure to be transferred through a conveyor belt, in order to reach the gas extraction process and then pass by 3 cylinders that are distributed in such a way that the extraction time is accelerated, where the first cylinder will have an inlet flow of 60%, for the second 40% and the last 20%, the connection of the first to the second cylinder will have a filter separating the solids from the liquids, once the liquid is obtained at 40% level, it will be stirred by a motor connected with vanes, at the same time the temperature will be controlled in the range of 35 °C to 40 °C so that the microorganisms work in greater gas production, in an excess of temperature the fans will be activated and otherwise a heater will be activated. Finally, the manure will continue with the help of a conveyor belt to an exit control where it will be stored.

The design presented optimizes manure collection and storage time and automates manpower in the process, since it minimizes the exposure of livestock workers to diseases, since the precision of manure transport is maintained, avoiding spills and human contact.

The motivation for presenting this design was to support farms that produce milk in large quantities; These farms make cheese, yogurt and different products derived from milk. The objective is to avoid the diseases that are generated by exposure to the manure of bovine animals; In addition, given that there is a lack of information on the subject, a collection and storage system was developed based on the problems faced by agricultural workers.

Abstract—Over the years, various activities within the poultry industry have automated their processes to optimize the breeding time of birds; Therefore, this research presents the design of an automated food and beverage system for turkeys in the different stages of its development. To obtain the sequence of the process, a flow chart was developed, the same one that structures the various phases of the system; In addition, to present the nutrients and additives present in the turkey feed, the Factory IO software was used as a simulation tool; on the other hand, the programming of the process was carried out in the TIA Portal software. As a result of the above, three different types of rations were obtained, which will be distributed according to the weights of the turkeys that are within the ranges (0-500) g, (500g-10kg), and (10kg-20kg) respectively; Additionally, each ration contains different Selenium (Se) additives, which is used to enhance the growth of turkeys. Finally, an automated feeding and drinking system for turkeys at different stages of their development was designed by structuring the flow diagram in each phase, which allowed us to optimize the feed supply of turkeys efficiently.

Keywords—Automated system, turkeys, poultry, breeding, optimization.

I. INTRODUCTION

Poultry farming is an economic activity that consists of raising birds such as chickens, ducks, turkeys, and geese to obtain meat and/or obtain eggs for human consumption [1]. However, the conventional poultry rearing system employs traditional free-range rearing; that is, poultry are raised outdoors; therefore, they roam freely during the day. It is evident that such activity requires a higher workload for farmers since the birds need to be fed regularly to be more productive [2]; furthermore, the conventional method is based on a manual feeding system, which requires human labor; therefore, farmers cannot guarantee that all poultry receive similar amounts of feed [3].

On the other hand, the breeding process for turkeys has still been using the conventional method, since it does not delve into automated feeders for this species; on the other hand, turkeys are usually raised on average for up to 18-20 weeks in the case of females and 24 weeks for males, where it is sought to supplement their diet with leaf meal to raise zinc

levels in meat [4]; In addition, as production increases, it is more difficult to maintain clean spaces for birds, therefore they tend to suffer the effects of mycotoxins, especially in the first 6 weeks of life which leads to reduce the performance of animals [5]. Another harmful pollutant for free-range turkeys is *Aspergillus* since it generates a high rate of morbidity and mortality in birds since it produces an acute suppression of the immune system which leads to lower production [6-14].

From another perspective, the integration of automation and new sensory technologies to poultry breeding allows the optimization of time [7] and in turn makes effective the feeding process in which different additives can be added to improve the meat [8].

Faced with this problem, the design of an automated food and drink system for turkeys was proposed at the different stages of its development, this system aims to evaluate by the weight of the turkeys the type of ration that corresponds to it, in this way the various additives are classified, for example, selenium nanospheres (SeNP), organic selenium (Sel-Plex®) and inorganic selenium (Se (IV)), which will be used in their diet [9-15]. In addition, to observe the proper functioning of the system before its implementation in a real environment, its simulation was essential which was carried out through the Factory IO software and TIA Portal.

The distribution of the article is as follows. In section II, the flowchart for the system process was made to order the progress stages of the system, as well as the ingredients, nutrients, and additives of the food on the tables; on the other hand, in section III the results of the simulation are presented using the Factory IO software; in addition to presenting various graphic environments. In Section IV, discussions on the automated system were presented to finally give way to the conclusions of the investigation in Section V.

II. MATERIALS AND METHODS

The process begins by introducing the number of turkeys that will be fed in an HMI graphic environment, in which programming will obtain the respective calculations according to the type of food to be dispensed; therefore, the system was established in the initial, intermediate, or adult stages having as a reference an analog input that converts the

potential differential into grams (g) and kilograms (kg). These references are expressed in ranges (0 -500g), (500g-10kg) and (10kg-20kg) respectively.

According to studies carried out regarding the methodology of feeding and improvement of this process, certain breeds of turkeys undergo a partial amputation of the beak, in which the lower beak is usually left longer than the upper beak, to obtain a better reception of food and avoid possible diseases that may develop throughout the stages of growth of these [10]. On the other hand, to favor the design shown in this article, it was sought that the turkeys obtain a better reception of food which reduces the waste of this in each process to optimize the control of feed rations in daily quantities.

First, to develop the process it was essential to establish the start of the system by identifying the weight of the turkey, which will then go through the second water dispenser process so that it finally goes through the third process of food distribution in rations according to the range established and calculated in the programming as shown in Fig. 1.

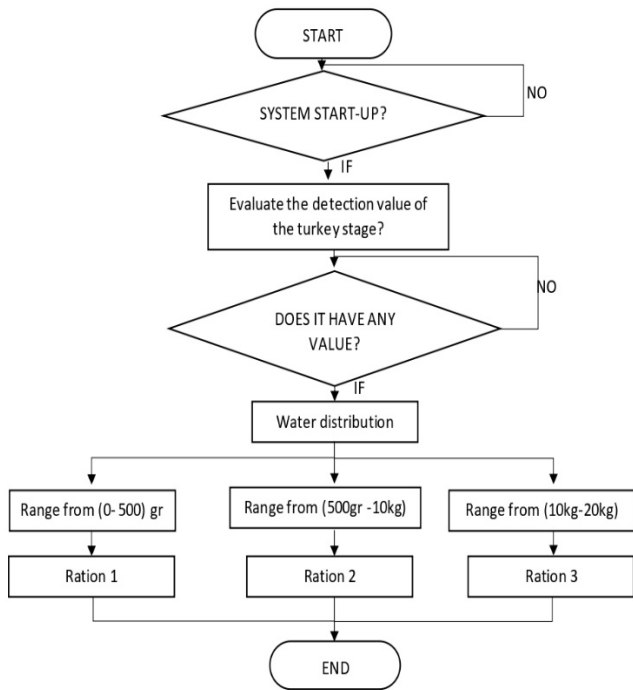

Fig.1 System flowchart.

In automated systems and the representation of these, another study in cattle feeding has used the software (TIA Portal and Factory I / O) in this system the dispensing and transport of food was done in 3 processes, these processes were established according to the amount of feed required by the cattle based on their weights entered, a transformation of a difference in potential to kilograms was made. In this design you could choose 3 portions of feed already balanced with the nutrients that the cattle may require these were 1/2 kg, 1 kg, and 2 kg, leaving three conveyor belts and being mixed later in a single transport belt reaching a scale that through an HMI screen monitored the amount of food based on the weight of each cow and thus ending with the feeding process the Food is transported to feeding points [11]. Developing this design

in a simulation environment with the software makes our research methodology more reliable during the execution of our processes.

Table I is a reference to turkey diets, which were formulated from the recommended nutrient requirements for poultry according to the National Research Council (NRC) was established in 1960 and made constant changes until 1994 [12].

Table I. Ingredients and nutrients were calculated for turkey growth and breeding [9].

Ingredients, %	melancholic 1-2 weeks	growing 2.- 8 weeks
Yellow corn	50	69
Soybean meal, 44% PB	39	20
Pisces, 64%	10	10
PB Dicalcium Phosphate	-	0.3
ground limestone	0.4	0.1
DL-methionine	-	0.3
L-lysine	0.1	0.1
premezclal	0.25	0.1
NaCl	0.25	0.25
Total	100	100
Calculated nutrient levels		
AME, Kcal/Kg	2830	3000
Crude protein, %	27.5	20.87
Extract any, %	3.15	3.72
Crude fiber, %	3.9	2.9
calcium, %	0.79	0.72
Phosphorus available, %	0.43	0.42
Lysine, %	1.8	1.38
Methionine, %	0.78	0.8
Methionine + Cysteine, %	0.9	0.82

Table II shows the effect of different biologically produced forms of Selenium (Se) on growth performance in experimental diets, in which initial body weight, body weight gain, and food consumption are evidenced. This study was developed for 6 weeks with values that express as a measure (±) standard error; In addition, the groups were called: selenium nanospheres (SeNP), and organic selenium (Sel-Plex®), and inorganic selenium (Se (IV)). On the other hand, feed conversion rate (FCR) was also considered [9].

Table 2. The effect of different forms of selenium on the feeding and growth of turkeys [9].

Article	Experimental diets				
	Control	Simple	Selplex	It is (IV)	
Corporate Starting Weight, g	56,79 ± 1,45	57,16 ± 1,25	56,87 ± 1,17	56,97 ± 1,17	0.82
final body, g	4182,35 ± 274,54	4236,90 ± 202,23x	4037,50 ± 261,09	4179,75 ± 290,74	0.153
body weight, g	4125,56 ± 274,63	4179,75 ± 225,61	3980,63 ± 261,47	4122,77 ± 291,10	0.155
feed, g/6 weeks FCR,	14,288,00 ± 16,92un	13,752,00 ± 16,92b	13,483,00 ± 16,92C	13,736,00 ± 16,92b	0.0001
g/g	3,48 ± 0,22un	3,22 ± 0,18b	3,46 ± 0,24un	3,28 ± 0,23b	0.001

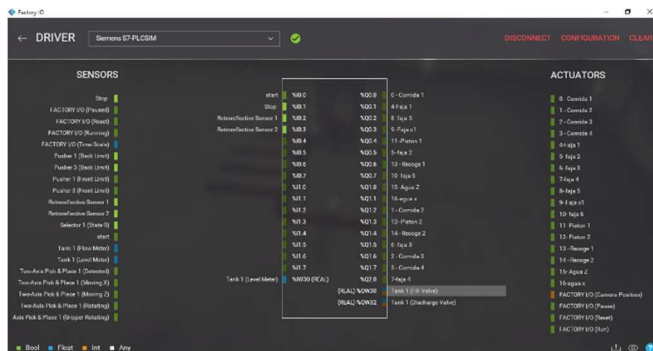

According to the percentage of ingredients and nutrient levels already calculated in Table I; In addition, in conjunction with the sources of selenium in Table II, a

nutritious ration was formed, which stimulates the accelerated metabolism and growth of the turkey.

On the other hand, the automated food and drink system for turkeys at different stages of its development consists of a process for the dispensing of 3 types of food which each attaches various additives, for example, ration 1 contains selenium nanospheres (SeNP), ration 2 includes organic selenium (Sel-Plex®) and ration 3 incorporates the inorganic selenium (Se (IV)) together each serving integrates constant water through the dispenser.

In another order of ideas, in this research, an ON/OFF control system [16] was applied, to monitor the feed distribution in the feed and water dispenser for the turkeys. In addition, when the analog inputs are entered as data to the HMI screen, the programming in Ladder language performs the conversions previously entered to obtain the value in kg of turkeys, consequently, such actuation activates and deactivates the actuators of the system.

Fig. 2 shows the drivers used in the Factory IO software, which will be used for connection through the OPC server; in addition to including the TIA Portal software for the automation of the system, which consists of 6 tapes, infrared sensors, water tank, a 2 GDL arm which simulates a water dispenser, electric piston and an HMI (Human-Machine Interface).

Fig. 6. Representation of the girdles in the Factory IO environment.

To experiment in Fig. 7, an analog input of 13500 was introduced, where weight of 9830g was obtained, which is located within the second established range (500g -10kg).

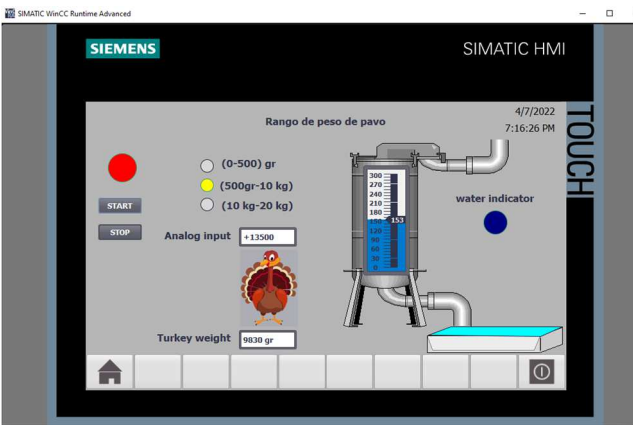

Fig. 7. HMI graphic environment.

In Fig. 8 the process was executed according to the data entered in Fig. 7; in addition, the green box represents the "2nd serving" of turkey food.

Fig. 8. Top view of the girdles in the Factory IO environment.

Finally, to experiment with the last established range, in Fig. 9 an analog input of 26000 was introduced, where a weight of 18932g was obtained, which is located within the third established range (10kg -20kg).

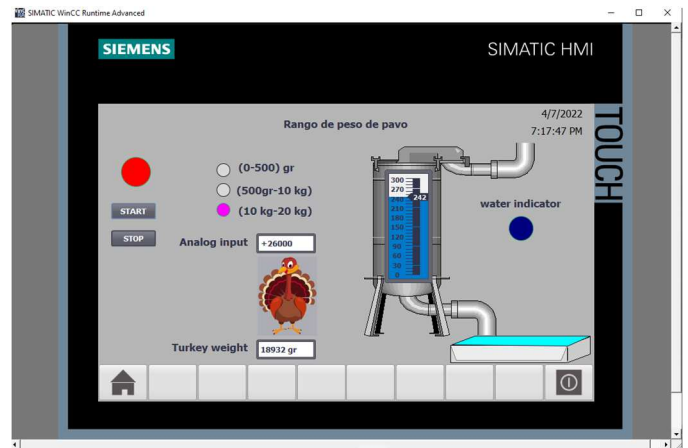

Fig. 9. HMI graphic environment.

Fig. 10 shows the process according to the data entered in Fig. 9; in addition, the gray box represents the "3 servings" of turkey food.

Fig. 10. Upside view of the girdles in the surroundings of Factory IO.

Fig. 11 reflects the virtual environment of the girdles and the water dispensing tank, which is the first to be activated independently of the various analog inputs introduced through the HMI graphic environment since it is indispensable for the diet of poultry (turkeys).

Fig. 11. Graphic representation of the water dispenser.

In Fig. 12 you can see the two environments together since both are related through the data entered in the analog inputs; that is, according to the information entered, the weight of the turkey will be located within the corresponding range and then start the process of water and food supply in the Factory IO environment.

Fig. 12. HMI environment and simulation of the dispensing belts through Factory IO.

Fig. 13 shows the execution of the system programming; where system boot control and emergency control are displayed; in addition, a similar interface was used for each march.

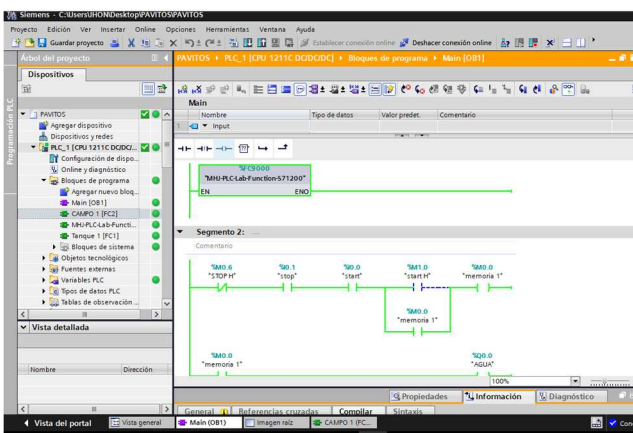

Fig. 13. Compilation of PLC programming in TIA Portal software.

Finally, in case of incidents with the actuation of the sensors or accumulation of the "rations" of food, there is a control box that includes a mushroom button whose purpose is to interrupt the processor also called an emergency stop. On the other hand, there is an on and off selector switch for the entire system as evidenced in Fig. 14.

Fig. 14. Design of the control box of the water and food dispenser.

IV. DISCUSSIONS

According to the research [13], an intelligent system for monitoring the feeding environment of livestock and poultry-based on Bluetooth with minimum energy was designed and implemented where data is monitored and collected with multiple wireless sensor networks. The system was

developed on a pig farm with an effective test time of 276 hours, testing the distance and stability of communication and packet loss rate of the gateway and obtaining a distance of 20.33 m that meets the requirements for monitoring. It was concluded that the gateway design, priority queue, and feedback mechanism are introduced in innovative ways, which effectively solves communication distance problems for Bluetooth devices, the method used is effective in high concurrency data, processing, and response to abnormal environmental changes.

According to the study [2], they developed a feeder system for poultry using a line-following robot to replace humans in feeding poultry by moving along. The development of the system is divided into the bird feeder, the design of the feeder robot, and the alert of notifications by the buzzer. The experiment shows how the feeder robot followed the line and stopped at each intersection to expel the food. During the test, the sensitivity of the IR sensor can be adjusted using the potentiometer to test the efficiency of the IR sensors to detect the lines. It was concluded that the performance of the proposed system has been experienced in a real environment and makes it easier for users to interact with low development costs.

Regarding the design and implementation of an intelligent gateway system for monitoring the feeding environment of livestock and poultry-based on Bluetooth, the design of this research has an automated and selective process through conveyor belts for feeding turkeys which include rations enriched with selenium (Se) and a constant water supply. e, to provide a complete diet; therefore, labor costs in transportation are reduced. Considering the system of a feeder for poultry using a line-following robot this system is the linear movement of the robot and lacks a supply of liquid being this indispensable for the development of the birds, by depending on a battery the activities and efficiency of the robot are reduced according to the level of a load of this, and compared to the design presented which has a constant process of transport, supply of food and drink, this would be more efficient and would reduce the cost considerably.

V. CONCLUSIONS

According to the simulation made with the TIA Portal software, linked to the Factory I/O, our design of an automated feeding and drinking system for turkeys in the different stages of its development shows an optimization in the supply and transfer of these to the feed points correctly and efficiently; Considering these aspects, it is concluded that this design reduces the cost of labor and the time to feed the turkeys according to their stage of development.

In the same way, the human-machine interface HMI facilitates the user's activities in the feeding process and selection of the type of food to be portioned, also avoiding possible errors that may occur in the process or external elements that harm the normal operation of the system.

In addition, this research shows through results a correct dosage of the 3 types of foods enriched with sources of selenium (Se)," using conveyor belts with timers and sensors, making the respective pauses for proper rationing thus avoiding surplus or lack of food.

On the other hand, implementation in the control system with a PID is recommended, since it would optimize the census and control of bird weights, in addition to rationing feed and drink with greater precision. Additionally, algorithms for temperature and humidity monitoring can be added to this type of control to offer a healthier and more comfortable environment for the birds; therefore, consequently, obtaining a better quality of turkey meat and increasing production through the automation of the processes.

Finally, it was concluded that the proposed system not only considerably reduces labor costs and time invested in the turkey feeding process, but also contributes favorably to industrialized processes, where parameters such as the individual weight gain of each turkey and the consumption of food, the periods desired by the poultry industry are estimated; since with this design, daily quantities of 3 types of food can be estimated with more precise rationing, avoiding surpluses that could cause possible monetary losses. That said, the system can compete in a national or international market in the poultry industry.

Abstract— Guinea pig breeding is an important livestock activity in Peru, since its consumption provides great nutritional value to humans; however, its production has been affected mainly by two factors: first, the lack of hygiene in the guinea pig sheds generates salmonella, which enters the guinea pig's body through the consumption of contaminated food and generates a rate of mortality from 15% to 18%; secondly, the excesses of temperature in the environment generate stress in the guinea pigs, where they end up dying and therefore the offspring are affected. For these two reasons, the automated design of a cleaning machine and an environmental temperature controller for guinea pig sheds was proposed, with the aim of optimizing the time of farmers and obtaining an ideal habitat for raising guinea pigs. The results obtained from the system are the programming and simulation of the cleaning machine through the Factory IO software, where the process ends with the storage of its excrement, which can then be used as fertilizer; On the other hand, a temperature controller was established that ranges between 24°C and 26°C, which were determined as ideal temperatures of the environment in which guinea pigs should be raised, said implementation was carried out through programming and simulation in the LabVIEW software.. Then, this research presents a novel solution to the various problems mentioned above.

Keywords— Guinea pigs, sheds, optimization, cleaning machine, temperature, humidity.

I. INTRODUCTION

The guinea pig is a hybrid rodent species that provides great nutritional value to the body if ingested as a food source. It is also a species with a higher productive efficiency in feed conversion compared to other animals in the livestock sector such as cows, horses and pigs [1]. For people involved in livestock farming, the raising of this species is very important, since it is being developed with great success, since its meat is export-oriented [2].

On the other hand, the young of the guinea pig are neonatal animals that are born in an advanced state of maturation; however, their mortality rate can reach 38% to 56% in family farms and in technified farms it can reach 23% [3], [4], the causes can be diverse; However, there is not enough research that analyzes the guinea pig breeding environment, since not frequently cleaning the sheds where they are raised is a reason

for the generation of various diseases that attack them and therefore the breeding of this species is affected [5].

Due to this context, it is important to study this problem, since there are very few studies oriented to these situations. For example, salmonella is a frequent infection due to inadequate house hygiene. A particular case is evident in Peru, where the mortality rate of this species is between 15% and 18%, which generates economic losses of up to 53% due to morbidity and 95% due to mortality [6], [7]. On the other hand, it is known that most mammals have homeothermy as a characteristic [8], [9]; however, in the case of guinea pigs, temperature is a factor that affects breeding, since they experience increases in body temperature when stressed [10], which is another of the most frequent causes of mortality in this species.

From another perspective, the research [11] presents a patent of a scraper type manure cleaning machine for livestock, which is connected with 2 support rods at the ends; On the other hand, this research aims to propose an automated design of a cleaning machine and an environmental temperature controller for guinea pig sheds, in order to optimize the time of farmers and obtain a better production through the breeding of these animals, also emphasis was given to the main causes of mortality of guinea pigs; finally the machine will move the excrement of the guinea pigs so that it can be stored and used as fertilizer later.

The structure of the research is as follows: in section II, the flow diagram of the various processes of the system was made, in addition to showing the percentage of bacterial species in the sheds. On the other hand, section III presents the results obtained; firstly, the results of the house cleaning machine are shown, and secondly, the results of the environmental temperature controller are visualized, and the simulations were carried out using Factory IO and LabVIEW software, respectively. Section IV presents the discussions regarding the research proposal proposed in this study and finally the conclusions in Section V.

II. MATERIALS AND METHODS

First, to establish the development of the process in Fig. 1, it was essential to start up the system which first evaluates the position of the guinea pig manure, on which depends the drive of the pistons and the conveyor belt, which in turn will

move the manure to the storage area where the robotic arm of 2GDL is located, which is programmed to deposit the manure from the conveyor belt to the storage box; in addition, as a result, an ideal habitat is obtained as shown in Fig. 1.

On the other hand, since the aim is to control the temperature, it is important to detect the humidity in the environment; if an excess of humidity is detected, the fan is activated; otherwise, if low humidity levels are detected, the heater is activated to obtain an ideal habitat.

Finally, the temperature levels are detected; if there is an excess of high temperature in the environment, the fan is activated; on the other hand, if there are low temperature levels, the heater is activated in order to obtain an ideal habitat.

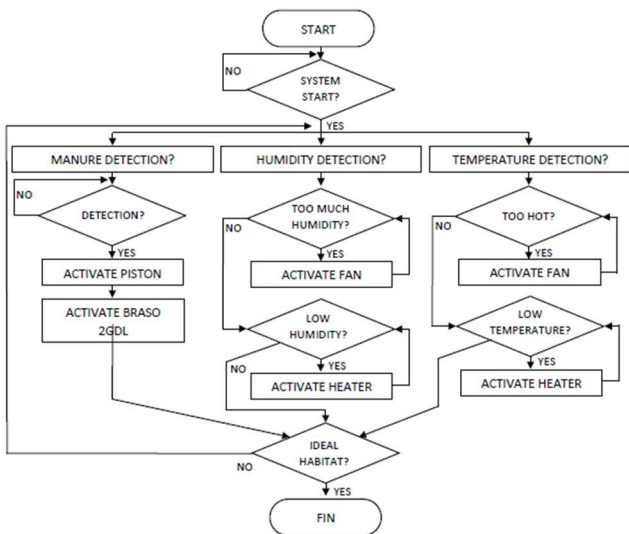

Fig.1 System flow diagram.

On the other hand, the design presented aims to reduce mortality of guinea pigs, either by the bacterial disease "salmonellosis" which most frequently affects their production in Peru, so it is mentioned that the causes of death of guinea pigs during the first week of lactation are 46.7%. Salmonellosis is transmitted through the digestive tract, that is, by ingesting contaminated water or food, which mainly affects young guinea pigs and old of them. Table 1 shows the percentages of bacterial species identified from the liver, spleen, lung and intestine of the guinea pigs that were affected by salmonellosis [3].

Table 1. Percentages of bacterial species [3].

Bacterial species	Positives		Negatives	
	N° of animals	Percentage (%)	N° of animals	Percentage (%)
<i>Escherichia coli</i>	78	40.84	113	59.16
<i>Salmonella spp.</i>	75	39.27	116	60.73
<i>Citrobacter freundii</i>	35	18.32	156	81.68
<i>Citrobacter diversus</i>	27	14.14	164	85.86
<i>Enterobacter aerogenes</i>	21	10.99	170	89.01
<i>Serratia liquefaciens</i>	21	10.99	170	89.01
<i>Proteus vulgaris</i>	14	7.33	177	92.67
<i>Citrobacter amalonaticus</i>	5	2.62	186	97.38
<i>Providencia alcalifaciens</i>	5	2.62	186	97.38
<i>Providencia stuartii</i>	5	2.62	186	97.38

<i>Serratia marcescens</i>	5	2.62	186	97.38
<i>Hafnia alvei</i>	3	1.57	188	98.43
<i>Proteus mirabilis</i>	3	1.57	188	98.43
<i>Edwardsiella tarda</i>	2	1.05	189	98.95
<i>Morganella morganii</i>	2	1.05	189	98.95
<i>Klebsiella pneumonia</i>	1	0.52	190	99.48
<i>Providencia rettgeri</i>	1	0.52	190	99.48

In another order of ideas, a temperature and humidity control were implemented in the cleaning machine, since high temperature levels are another factor that increased the mortality rate of guinea pigs [5].

Fig. 2 shows in the controllers the sensors and actuators used in the system using the Factory IO software; in addition to using the connection to the OPC server and performing the simulation in the TIA Portal software. On the other hand, various inputs and outputs were used for the system, for example: the fuzzy sensor, push buttons (start, stop and emergency), conveyor belt, electric pistons and a 2 GDL robotic arm.

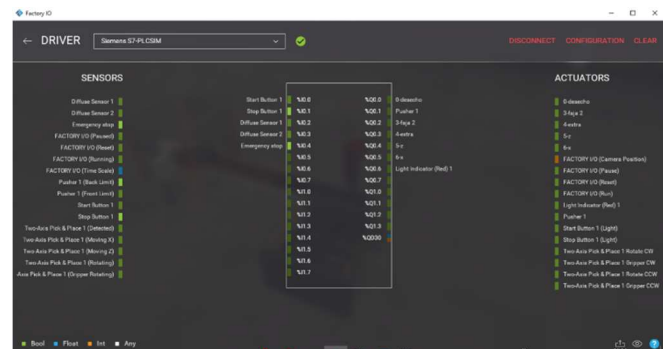

Fig. 2 System conformation controllers in Factory IO software.

In Fig. 3, the 2 GDL robotic arm was programmed to simulate the storage of guinea pig manure, a fuzzy sensor 2 was used to detect the manure and subsequently activate the robotic arm, on the other hand, different timers such as TP and TOM were added for the activation of each degree of freedom and the arm's aspirator.

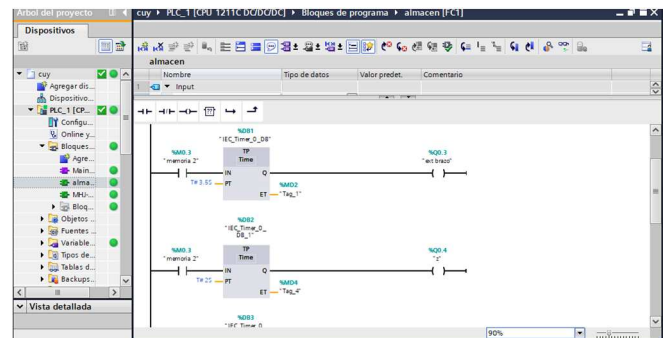

Fig.3 Programming of manure storage in the PLC.

III. RESULTS

A. Cleaning machine for guinea pig houses

Fig. 4 shows the control box, where there is a green button (on), a red button (off), a mushroom-shaped button (emergency stop) and a red pilot light, which lights up when the system is started.

Fig. 4. System control box.

Fig. 5 shows the fuzzy sensor 1, which detects the manure (green boxes) to then activate the electric piston to then send the manure to the belt where it will go to storage, the objective of the research is to obtain a constant cleaning as it is a very important factor for the guinea pigs to feed healthily and not to be in contact with their own excrement.

Fig. 5. Representation of manure output in the Factory IO environment.

In Fig. 6 we can see on the fuzzy sensor 2 where it activates the robotic arm to send the guinea pig manure to the warehouse, the purpose of this is to obtain organic fertilizer in x amount of time.

Fig. 6. Robotic arm interaction.

Fig. 7 shows that after some time the warehouse is gradually filling up, which indicates that the project is constantly being worked on in order to observe the potential of what is proposed.

Fig. 7. Manure storage environment.

Fig. 8 shows the execution of the ladder programming of the system, where the optimal operation of the start-up control and the emergency control is shown.

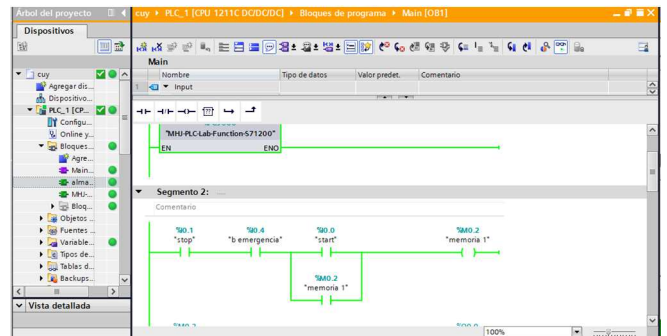

Fig. 8. Compilation of PLC programming in TIA Portal software.

B. Environmental temperature controller for guinea pig houses.

LabVIEW software was used to represent the automation process to control the temperature and humidity in the guinea pig houses; in addition, with the help of sensors and respective actuators, we have the appropriate measurement to control these two factors and thus have an ideal habitat for these animals. Additionally, being an automated process, each factor is controlled independently to avoid conflicts according to the environmental measurements taken by the sensors, in which it was determined that at higher values of the ideal standard the fans will be turned on and at lower values the heaters will be turned on, as shown in Fig. 9.

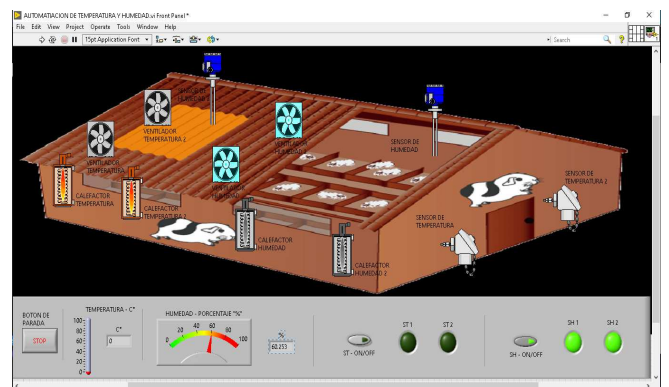

Fig. 9. Graphical representation of the automation of the temperature and environment of the sheds.

In order to have an adequate programming, a temperature range of 23C° to 26C° was used in the case of humidity in the environment, for which a range of 40% to 50% was used in order to have an ideal habitat in the sheds [5]. On the other hand, Fig. 10 shows the start of the process, where the actuators will respond once the sensors are sensed or are

turned on to prevent errors in the process, meanwhile the value of 0C°; in addition, random values were set to visualize the reaction of the actuators and indicators in the control table and thus activate or deactivate the actuators and indicators in the control table.

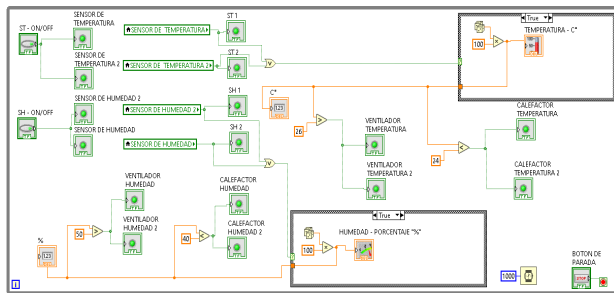

Fig. 10. Compilation of the programming in the LabVIEW software.

IV. DISCUSSIONS

Over the years some machine designs were made to have a space cleaning control in order to automate and facilitate such process, in which one of them focuses on sheep cleaning and is composed of upper and lower blades and with a rail provided at the top that allows moving the blades from one side to another to perform effective work, whereby it is also composed of gears, bearings, gear wheel and rack and pinion coupling [12]. Other designs include a water tank, manure scraping device and a controller, the bottom of the water tank is provided with a driving wheel is electrically connected with the controller, the bottom section is grooved on the front side the water tank; in addition, two vertical motorized rails are installed, these are electrically connected with the controller and the manure scraping device is provided with the front of the motorized rails in the groove; therefore, this model is more related to the field of chicken breeding equipment thus helping in farms [13].

Among all these designs a machine that covers more generally manure cleaning for livestock is characterized by having a shovel at the front of the self-propelled equipment for cleaning excrement behind a support beater that are installed as a helical blade to the groove of the shovel this is connected to the main shaft to the power system with a driving mechanism, therefore, this design is intended to facilitate this tedious, dirty and painful activity [14], other cleaning machines focus on mixing the supplies in the receiving device and transporting them along a filter to a conveyor unit; whereby, this is separated from the manure by shaking / sliding the filter element, so that the manure is shaken, pressed and slid through the orifices, dropping into a sand collecting container or onto a stable outlet and/or base, a separate claim is also included for a mobile cleaning device, with the object of separating litter from manure in horse stables [15].

Sends along the plate from one direction of plate movement and barbed wires. The device allows the manure removal to be gentle and plays a good protective role for livestock, in addition, it is simple and easy to manufacture, with low production cost [8]; however, all these machines focus only on cleaning for which is a very important but not the only feature to have an ideal environment for animals. For this reason, the present research presented an automated design of a cleaning machine for guinea pig houses, as well as a control system for air conditioning the environment through a range of ideal temperature and humidity

determined in the guinea pig houses to optimize production and reduce mortality rates.

V. CONCLUSIONS

From the research carried out, it is concluded that the present work will allow an optimal cleaning of the sheds that will prevent the guinea pigs from contracting diseases such as salmonellosis, which affected 46%; the latter, in turn, affects the owners of these animals due to the economic loss of 53% due to morbidity and 95% due to mortality. In addition, with this project the temperature and humidity of the environment will also be controlled, since cases of guinea pig mortality due to excessive amounts of these factors were found. In this way, the temperature and humidity were regulated by sensors allowing a range of 24C° to 26C° and 40% to 50% respectively.

For a detection of lower temperature and humidity, the heaters will be activated to control both factors and in case of excess, the turbines will be activated to cool the environment and lower the humidity in the sheds; on the other hand, in the case of cleaning, once the guinea pig manure is detected, the pistons will be activated and in turn will work in parallel with the activation of a 2GDL arm, as shown in Fig. 1. Finally, to complete the process, all the factors mentioned will be evaluated and the process will be completed until returning to the beginning of the system. With this project, it is possible to have an ideal environment for the guinea pigs, at the same time reducing economic expenses in the loss of production and/or bad control of temperature and humidity and even in the worst of the scenarios to lose the breeding of these animals for not having the respective care.

Abstract— Coronavirus disease (Covid-19) is an infectious disease that attacks the respiratory area caused by the severe acute respiratory syndrome (SARS-CoV-2) virus. According to the World Health Organization (WHO) as of April 2022, there were more than 500 million cases of Covid-19, and 6 million of them died. One of the tools to detect Covid-19 disease is using X-ray images. Digital X-ray images implementation can be developed classification method using machine learning. By using machine learning, the diagnosis of this disease can be faster. This study applied a features extraction method using the Histogram of Oriented Gradients (HOG) algorithm and the Linear Support Vector Machine (SVM), K-Nearest Neighbor (KNN) Medium and Decision Tree (DT) Coarse Tree classification methods. The study can be used in the diagnosis of Covid-19 disease. The best method among the classification methods is features extraction from HOG algorithm and DT Coarse Tree. The highest values of accuracy, precision, recall, specificity, and F-score were 83.67%, 96.30%, 78.79%, 98.25, and 76.48%.

Keywords—Covid-19, Histogram of Oriented Gradients, Support Vector Machine, K-Nearest Neighbor, Decision Tree.

I. INTRODUCTION

In the last three years, the world has been hit by a global pandemic that has affected the entire world community. Coronavirus disease (Covid-19) is an infectious disease that attacks the respiratory area caused by the Severe Acute Respiratory Syndrome (SARS-CoV-2) virus [1]. According to data from the World Health Organization (WHO) as of April 2022, there were more than 500 million cases due to Covid-19, and 6 million of them died [2].

This Covid-19 disease is quite dangerous apart from being deadly because the transmission of Covid-19 is very fast. With its rapid spread and very easy transmission, fast

and accurate detection is needed to prevent its spread. There are several methods of detecting Covid-19 disease, one of which is detection using x-ray images [3]. Although diagnosis using Polymerase Chain Reaction (PCR) is more widely used, detection with x-ray images is cheaper because it can detect a large number of patients and is not limited by test equipment [4]. However, the diagnosis of Covid-19 disease using x-ray images can only be carried out by the relevant expert or doctor. So it takes quite a long time and is limited to the number of experts or doctors available [5] [6].

To speed up the diagnosis of Covid-19 disease, it is carried out on a computer-based basis. The development of computer-based Covid-19 disease detection is one of the studies that has been widely developed. In recent years, studies [7] [8] have used computers to help in the early diagnosis of Covid-19.

Machine Learning (ML) is well known for its high-performance image processing and its application in certain image classifications. Thus, ML is an alternative for automatic detection of Covid-19 disease using x-ray images. The use of ML in the diagnosis of Covid-19 disease has been carried out by several studies [9] [10].

Image processing is an important aspect in the ML process. For an image to be analyzed using the ML method, the image must be extracted (feature). One feature extraction method that is quite often used is the Histogram of Oriented Gradients (HOG). HOG feature extraction focuses on the shape and angle of the feature gradient. Several related studies that use HOG as a feature extraction method in detecting Covid-19 images are. [5][11][12] yielded the highest accuracy values of 98.66%, 98.11%, and 98.5%.

To determine the image of Covid-19 and not the image of Covid-19, a classification method is used. Several image classification methods include Support Vector Machine (SVM), K-Nearest Neighbor (KNN) and Decision Tree (DT). Several studies related to the diagnosis of Covid-19 disease using the SVM, KNN, and DT classification methods include [13] [12]. Several studies use other methods to be applied in the detection of Covid-19 disease [14].

With only a few studies on Covid-19 images combined with the HOG feature extraction method with the SVM, KNN, and DT classification methods. Therefore, in this study the HOG method, with the classification of SVM, KNN, DT is used in the diagnosis of Covid-19 disease with x-ray images.

II. METHOD

A. Data Collection

The image data used in this study is Covid-19 images obtained from open datasets and Machine Learning Projects Kaggle website with the type of lung X-ray images. The number of Covid-19 images used is 1184 images, which are divided into three types of images, namely Covid-19 images (class 1), Pneumonia images (class 2), and Normal lung images (class 3). The number of images for each class is 404 images for class 1, 390 images for class 2 and for 390 images for class 3. The data is divided into 2 types of data sets, namely training and testing. The amount of training data is 90% of the total image data, which is 1065 images, and for data set testing is 10% of the total image data, which is 119 images.

B. System Design

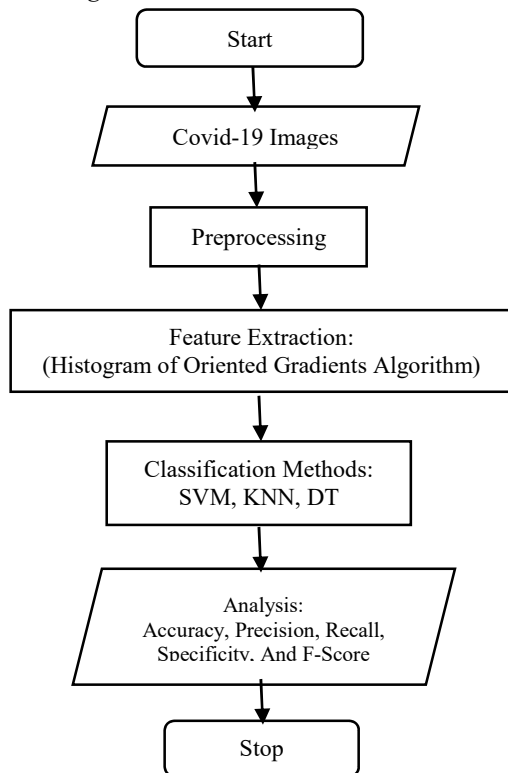

Fig. 1. System Design Flowchart

In this study, the analysis was carried out using the MATLAB software version R2020a. The computer specifications used during the Covid-19 image processing process are shown in Table 1.

TABLE I. COMPUTER SPESIFICATIONS

Hardware	Specification
Processor	Intel® Core i5 9400f
RAM Memory	16GB
GPU	Nvidia RTX 2060 6GB

This COVID-19 image classification goes through several steps, including pre-processing, feature extraction, classification, and analysis. The feature extraction used for this study is the Histogram of Oriented Gradients (HOG) algorithm. The classification method used is Linear Support Vector Machine (SVM), K-Nearest Neighbor (KNN) Medium and Decision Tree (DT) Coarse Tree. The whole system design is shown in Figure 1.

C. Pre-pocessing

This Covid-19 image is divided into a training dataset and a testing data set. The next process is preprocessing for the two datasets. The original image with the 2 datasets was flipped vertically as an effort to reproduce the image. To be able to perform feature extraction using the HOG algorithm of the image must be changed from an RGB image to a Grayscale. The image that has been converted to grayscale is converted to histogram to equalize the contrast value of the image.

D. Feature Extraction

The testing and training datasets are processed to obtain feature extraction. This feature extraction stage is carried out after the image has been pre-processed. In this study, the feature extraction used is the HOG algorithm, with the extraction results totaling 36 features.

E. Classification

At this stage, classification is carried out with the extracted data using HOG algorithm. Classification is carried out using 3 different methods, the classification methods used include Linear Support Vector Machine (SVM), K-Nearest Neighbor (KNN) Medium and Decision Tree (DT) Coarse Tree. These three methods were tested ten times running with 10% data validation of the training data. The results of the classification are analyzed based on the training computation time and training accuracy. These results are displayed on the Receiver Operating Characteristic (ROC) graph.

F. Analysis

The results of the Covid-19 image classification were analyzed using a performance matrix. The image dataset used in this analysis is a testing dataset. The performance matrix analysis used includes accuracy, precision, recall, specificity, and f-score. The results of the performance matrix analysis are compared to get the best method.

III. RESULTS AND DISCUSSIONS

A. Feature Extraction Result

The testing and training dataset images are feature extraction using HOG algorithm and produce a total of 36 features for each image, with different extraction values. The results of feature extraction with HOG algorithm are shown in Table 2. Table 2 shows the average extraction results of 10 images in each class.

TABLE II. FEATURE EXTRACTION RESULTS

Images	Histogram of Oriented Gradients		
	Class 1	Class 2	Class 3
1	0.142	0.144	0.149
2	0.149	0.145	0.149
3	0.144	0.146	0.139
4	0.149	0.136	0.154
5	0.143	0.125	0.143
6	0.150	0.135	0.137
7	0.144	0.127	0.141
8	0.147	0.133	0.145
9	0.145	0.133	0.142
10	0.151	0.139	0.146
Mean	0.147 ± 0.003	0.136 ± 0.007	0.144 ± 0.005

B. Classification Result

The extracted data obtained were used for classification using the Linear SVM, KNN Medium, and DT Coarse Tree methods. Classification was carried out 10 times running for each method. From the classification with these methods, the value of training accuracy and training time is obtained. The results of the classification, namely training accuracy and computational time are shown in Table 3 and the results of the Receiver Operating Characteristic (ROC) graph. The best ROC graph is shown in Figure 2.

TABLE III. CLASSIFICATION RESULTS

Run	SVM Linear		KNN Medium		DT Coarse Tree	
	Accuracy (%)	Time (s)	Accuracy (%)	Time (s)	Accuracy (%)	Time(s)
1	69.40%	1.21	69.80%	0.79	63.70%	1.28
2	69.30%	1.23	69.50%	0.81	62.50%	0.80
3	69.30%	1.22	70.50%	0.76	63.20%	0.80
4	68.80%	1.23	69.90%	0.82	63.20%	0.83
5	68.50%	1.21	70.00%	0.77	62.70%	0.82
6	68.20%	1.22	70.00%	0.75	62.60%	0.82
7	68.70%	1.24	69.30%	0.76	63.00%	0.82
8	68.20%	1.28	70.00%	0.72	62.90%	0.86
9	68.80%	1.33	70.30%	0.81	63.60%	0.85
10	69.10%	1.30	69.80%	0.79	62.40%	0.84
Mean	68.83% ± 0.42%	1.25 ± 0.04	69.91% ± 0.33%	0.78 ± 0.03	63.05% ± 0.47%	0.88 ± 0.13

Based on the results of image classification in Table 3, the best training accuracy was obtained by KNN Medium with the highest accuracy value of 70.50% and the fastest time of 0.72 second. The average value of training accuracy obtained by KNN Medium is 69.91% ± 0.33% and the average computation time is 0.78 ± 0.03. In contrast to KNN Medium, the DT Coarse Tree method gets the lowest training accuracy value, which is 62.40% with a time of 0.84 seconds. The average training accuracy of the DT Coarse Tree method is 63.05% ± 0.47% and time 0.88 ± 0.13.

C. Analysis Result

At this stage, a testing dataset that has been extracted has been used as input. Testing data is tested using the best training classification results from each method. The analysis was carried out using a performance matrix comparison for each method to find out the best method for classifying Covid-19 images. The results of the performance matrix for testing are shown in Table 4. The results of the best confusion matrix of the three methods are shown in Figure 3, the best confusion matrix for SVM Linear is 1st running, KNN Medium is 3rd running, and DT Coarse Tree is 5th running.

Based on the data shown in Table 4, the best performance matrix in the classification of Covid-19 images is the DT Coarse Tree method. The accuracy values obtained by the DT Coarse Tree method are 78.10% for class 1, 83.67% for class 2, and 70.09% for class 3. The precision values are 76.48% for class 1, 96.30% for class 2, and 48.15% for class 3. The recall obtained were 63.41% for class 1, 63.41% for class 2, and 78.79% for class 3. The specificity results obtained were 87.54% for class 1, 98.25% for class 2, 66.67% for class 4. Results F- the score obtained is 69.33% for class 1, 76.48% for class 2, and class 3 is 59.78%. The results of the comparison of these three methods can be seen in the graph shown in Figure 4. From the graph, the performance of DT Coarse Tree tends to be higher than the other methods.

Fig. 2. Best of Receiver Operating Characteristic Graph (a) SVM, (b) KNN, (c) DT

TABLE IV. ANALYSIS PERFORMANCE MATRIX RESULT

Results	SVM Linear			KNN Medium			DT Coarse Tree		
	Class 1	Class 2	Class 3	Class 1	Class 2	Class 3	Class 1	Class 2	Class 3
Accuracy	70.37%	83.52%	66.09%	70.37%	81.72%	67.26%	78.10%	83.67%	70.09%
Precision	59.57%	96.55%	54.90%	58.18%	76.19%	76.19%	76.48%	96.30%	48.15%
Recall	68.30%	66.67%	63.64%	78.05%	82.05%	54.24%	63.41%	63.41%	78.79%
Specificity	71.64%	97.96%	67.61%	65.67%	81.48%	81.48%	87.54%	98.25%	66.67%
F-score	63.64%	78.87%	58.95%	66.67%	79.01%	63.37%	69.33%	76.48%	59.78%

Fig. 4. Comparison Graph of Classification Models

IV. CONCLUSION

Covid-19 image classification using Linear Support Vector Machine (SVM), K-Nearest Neighbor (KNN) Medium and Decision Tree (DT) Coarse Tree with feature extraction by using Histogram of Oriented Gradients (HOG) algorithm can be developed to help to classify the Covid-19 disease based on X-ray images. It can be concluded that the DT Coarse Tree method is the method that produces the best performance in the classification of Covid-19 images. The results of the DT Coarse Tree produce accuracy values for class 1, class 2, and class 3 of 78.10%, 83.67%, 70.09%. The

precision values for class 1, class 2, and class 3 are 76.48%, 96.30%, and 48.15%. The recall scores for class 1, class 2, and class 3 were 63.41%, 63.41%, and 78.79%. The specificity results for class 1, class 2, class3 were 87.54%, 98.25, and 66.67%. The F-score results for class 1, class 2, and class 3 were 69.33%, 76.48%, and 59.78%. Based on these results, it is necessary to test using feature extraction and other classification methods as a comparison reference for the automatic detection method for Covid-19 disease.

Abstract—Multilayer aperture coupled patch resonator antenna (M-ACRA) introduced to achieve single band second order frequency response. L shaped truncated patch at 12GHz designed to achieve circular polarization and minimize cross polarization at the receiver section. A theoretical approach for demonstrating floquet excitation are explained, furthermore, current distribution of proposed design are demonstrated. Based on analysis mode, the operation principle for equivalent circuit model about proposed designed also discussed. The simulated results and antenna parameters are to be consider for aperture coupled based frequency selective surfaces, reconfigurable frequency selective surfaces, reconfigurable intelligent surface, etc.

Index Terms—Aperture-coupled patch resonator, single-mode, dual order frequency

I. INTRODUCTION

Multilayer Aperture Coupled Resonator Antenna (M-ACRA) electrically compact size, low profile and low noise RF antenna. Aperture coupled based Frequency Selective surfaces (A-FSS) deals by various authors [1] [2]–[6], this type of aperture coupled resonator are applied to achieve higher order bandpass responses [3], [7], [8]. M-ACRAs maintain beam polarization stable, used to absorb transmitted EM waves in metamaterials based FSS structures, to minimize cross polarization and improve co-polarization towards receiver. A multilayer aperture coupled patch resonator introduced in 2D planar pattern on dielectric substrate, the approached design electrically small size when compared to aperture coupled dielectric resonator antennas. This type of design proposes single and dual bandpass responses in-terms of periodic structure implementation in [3], [9]. Various authors in the last decade used this types of structure to achieve higher order bandpass responses and transmission zero characteristics [2], [4], [8].

Aperture coupled mounted between two substrate acts like coupled resonator theory in filters [3]. Transmitted wave from the free space will be absorbed by aperture coupled layer and the waves are reflected back by ground patch. The ground patch similar geometry structure of top patch which is shown in Fig. 1. Given antenna excites by floquet excitation techniques which is discussed in [10], [11]. The primary sweep of reflection coefficient and insertion loss are shown in Fig. 2. Aperture coupled as non-resonant and it have

strong magneticfield in it. The field distribution towards top and bottom patches to achieve higher order bands.

In this article proposed L shaped truncated multilayer aperture coupled patch resonator to achieve second order transmission zero filter response, where two transmission zeros are produced near to the passband and enhancing the frequency selectivity. So, this model can be consider for unit cell element model for Aperture coupled frequency selective surfaces. The resonant frequency at 12GHz, the bandwidth maintained by 2.2GHz from 12.01GHz to 14.8GHz. The L shaped truncated patch helped to achieve circular polarization towards receiver and all the antenna parameters like, axial ratio for circular polarization, returnloss for showing transmission zero characteristics, maximum gain towards desired direction are discussed. This type of aperture coupled resonator antennas can be useful in high frequency wireless applications like IOT devices, metamaterials based frequency selective surfaces, metasurfaces for Reconfigurable intelligent system, etc.

II. MULTILAYER APERTURE COUPLED RESONATOR

Multilayer aperture coupled resonator antenna shown in Fig. 1, the fundamental square patch for 12GHZ designed. L shaped truncated edges in both side to achieve circular polarization towards receiver and transmitter, the design equation for square patch referred in [12], the resonance mode equations are referred from same [12]. Rogers 4003 substrate with $\epsilon_r = 3.55$, $h = 0.813mm$ and $f_o = 12GHz$ to 14GHz used. As discussed, multilayer aperture coupled approached in this article, so h_1 and h_2 multi substrate with same properties are placed in between top and bottom of patches. The geometrical values are mentioned in Fig.1 and its corresponding returnloss shown in Fig.2. The excited \vec{E} and \vec{H} field intensities between top and bottom layer, which is leading to the cavity modes [12]. The reflection coefficient obtained from L shaped truncated patch from the bottom.

To understand the operation of mechanism, the incident Efield \vec{E}_x and \vec{E}_y along diagonal line from Fig. 1. The reflected \vec{E}_x and \vec{E}_y can be written as

$$\vec{E}_x^r = \frac{1}{2}(\vec{e}_y - \vec{e}_x) | \vec{E}_y^i | (S_{11})_x \quad (1)$$

(a)

(b)

Fig. 1: (a) Dimension of approached aperture coupled patch resonator, (b) multilayer substrate $h_1 = h_2 = 0.813mm$ with $\epsilon_r = 3.55$ and thickness of patch and aperture $t = 0.01mm$

Fig. 2: Reflection coefficient S11 and Insertion loss s22 in dB for $L = 8mm, D = 5.3mm, l_1 = 2.8mm, w_1 = w_2 = 0.3mm, l_2 = 2mm, l_3 = 1.3mm, w_3 = 1.3mm$

$$\vec{E}_{\bar{y}}^r = \frac{1}{2}(\vec{e}_{\bar{y}} + \vec{e}_{\bar{x}}) | \vec{E}_{\bar{y}}^i | (S_{11})_{\bar{y}} \quad (2)$$

Here $(S_{11})_{\bar{x}} = | S_{11} |_{\bar{x}} e^{j(\beta_{11})_{\bar{x}}}$ and $(S_{11})_{\bar{y}} = | S_{11} |_{\bar{y}} e^{j(\beta_{11})_{\bar{y}}}$ are reflected coefficients of whole resonator in terms of $\vec{E}_{\bar{x}}^i$ and $\vec{E}_{\bar{y}}^i$ incident polarization respectively. So the total E-field vector \vec{E}^r can be written as,

$$\vec{E}^r = \vec{E}_{\bar{x}}^r + E_{\bar{y}}^r \quad (3)$$

Referred from 1 and 2 we can obtain $(S_{11})_y$ and $(S_{11})_x$. can be written as

Fig. 3: Current distribution at 12GHz

$$(S_{11})_y = \frac{1}{2}((S_{11})_{\bar{y}} + (S_{11})_{\bar{x}}) \quad (4)$$

$$(S_{11})_x = \frac{1}{2}((S_{11})_{\bar{y}} - (S_{11})_{\bar{x}}) \quad (5)$$

Eq.4 and Eq. 5 are cross polarized $((S_{11})_y)$ and co polarized $((S_{11})_x)$ respectively.

III. SINGLE BAND SECOND ORDER RESONANCE

The equivalent circuit model shown in Fig.4 the designed equations are follows,

$$f_o = \frac{1}{2\pi\sqrt{LC}} \quad (6)$$

Here, $L = L + 2L_m$ and $C = C + 2C_m$ corresponding to [7], so the Eq. 6 becomes,

$$f_o = \frac{1}{2\pi\sqrt{(L + 2L_m)(C + 2C_m)}} \quad (7)$$

In Fig.4 introduced inductances and capacitances to achieve single band second order resonance frequency with respect to Fig.1 the corresponding S11 and S21 shown in Fig. 5. The Fig.5. shows the dual transmission zero in single mode frequency response. The inband maximum and minimum insertion loss also shown in the same figure.

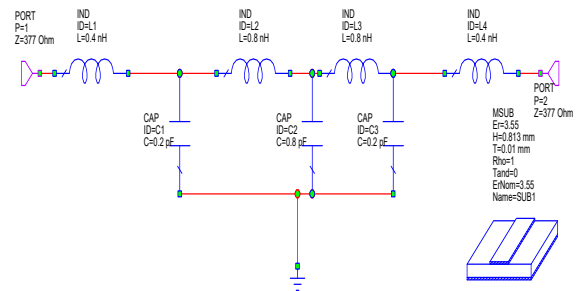

Fig. 4: Lumped circuit model for single band dual order, $L = 0.2pH, C = 0.205pF$ at free space impedance $Z_{in} = Z_O = 377\Omega$

Parameters	Bo Li <i>et al.</i> [13]	Abbaspour-Tamijani <i>et al.</i> [14]	Li <i>et al.</i> [15]	Xie <i>et al.</i> [7]	In this work

IV. RESULTS AND DISCUSSION

Fig.2 illustrate reflection coefficient with two transmission zero between $12.14GHz$ and $14.8GHz$ in single band S22 shown in same Fig. 2.

The radiation pattern for approached design refer from Fig. 6. shown in Fig. carries $12dB$, the axial ratio for proposed design shown in Fig. 7. for circular polarization. The axial ratio maintained $2dB$ to $0dB$ for circular polarization, the maximum gain at desired direction have $12dB$. For single band response, the techniques [14] also proposed with second order and fourth order bandpass filter responses. The structures have polarization sensitive and angular range of operation.

Fig. 6: Gain at $\phi = 90^\circ$, $\theta = -180^\circ$ to 180° at $f_o = 12GHz$

The wave ratio of proposed structure is ≤ 2 , the antenna parameters comparison Table 1 shows the previous works on higher order bandpass resonators, from the literature comparison, this work have key parameters characteristics to be consider for frequency selective surfaces.

Fig. 7: Axial ratio Vs Freq in GHz at $f_o = 12GHz$

V. CONCLUSION

L shaped truncated unitcell patch along with aperture coupled multilayer resonator antenna proposed to achieve higher order frequency response. Here single band second order response discussed on details and equivalent circuit with analysis also explained. The proposed structure achieved higher order frequency response without introducing number of elements and size. The proposed design resonance at $12GHz$ to $14GHz$. Aperture truncated patch antenna can be used for high frequency applications like IOT based wireless devices, radar receiver where circular polarization on demand and higher order frequency selective surfaces.

Abstract—In this document, a prototype of an explosive deactivator robot called JVC 0.1 was analyzed, based on the minimum requirements of the UDEX- Arequipa and the international standards given by the ASTM and NIST organizations, then it was evaluated using the Failure Modes and Effects Analysis (FMEA) matrix. In this way, design parameters are proposed for a next version of this prototype. It was obtained that the robot is oversized in material, dimensions and motors, has a reduced working space for the manipulator with low drive speeds and an inadequate gripper. Therefore, a redesign is necessary.

Index Terms—EOD Robot; Performance testing; FMEA; Overdimensioned.

I. INTRODUCTION

EOD (Explosive Ordnance Disposal) robots are used in many police units that deal with explosives disposal.

In the Arequipa region, the Unit for the Deactivation of Explosives (UDEX-Arequipa) emerged in the 1980s, where several subversive groups used explosive devices to carry out attacks in different parts of Peru [1].

In recent years, EOD robots have been designed with specific characteristics depending on the use that will be given to them, such as the degrees of freedom to access small spaces, the range of the actuator, the type of locomotion to adapt to the type of terrain, the light weight to be transported quickly, and so forth [2]–[4].

For the evaluation of robots, standardized tests established

by both the NIST (National Institute of Standards and Technology) and the ASTM (American Society for Testing and Materials) are used. NIST promotes innovation and industry competition through advances in metrology, standards, and technology [5], while ASTM is an international standards organization that develops and publishes voluntary technical standards agreements for a wide range of materials, products, systems, and services [6].

The proposed tests evaluate mobility, manipulation, human interaction, energy, sensors, radio communication, safety, and durability [7]. And they are used by world-class competitors like the Robocup, where robots are tested in their different configurations and the capabilities of the participants can be objectively compared. In this work, only some representative tests will be taken, since the prototype still has deficiencies that prevent complex tests.

In 2021, UDEX-Arequipa built an EOD robot prototype (Fig. 1), which has a chassis that resembles that of a tank and a robotic arm that has 4 degrees of freedom and a 3-finger claw. This robot was built empirically, so it has many shortcomings when performing operations. In the study carried out at UDEX-Arequipa as part of the project "Design and development of the prototype of a bomb disposal robot equipped with a tele-operated precision actuator" the data of the incidents presented with explosive devices in a period from 2013 to 2020 were analyzed. and the main requirements for the design of an EOD robot in Arequipa were compiled [1]. Currently, a series of advances are being made to obtain an improvement in the user experience regarding the control of

Fig. 1. Robot JVC 0.1

Fig. 3. Robot JVC 0.1

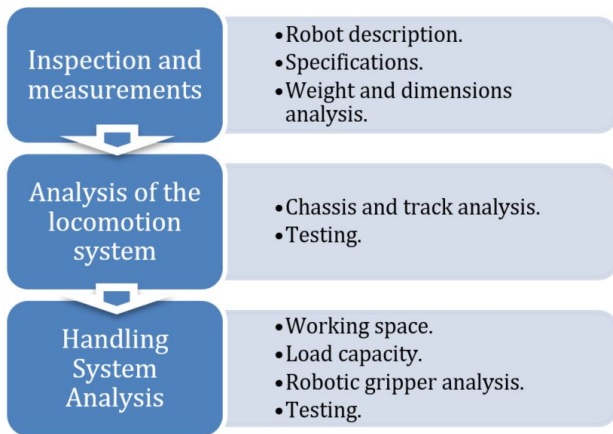

Fig. 2. Methodology

the robot [8] [9] [10] [11] .

II. METHODOLOGY

The objective of this study is to analyze the JVC 0.1 considering some international standards of NIST and ASTM, and specific requirements of UDEX-Arequipa through field tests and digital simulation.

The analysis and evaluation have been divided into 3 parts (Fig 2): First, we will proceed with the general inspection and measurement taking for the 3D modeling by means of SolidWorks computer-aided design. Then, the analysis of the locomotion system will be carried out and later the handling system. The manipulator tests and the locomotion tests will be guided considering the ASTM and the NIST, to see the effectiveness of the robot. Finally, the design parameters will be defined by using the FMEA matrix [12].

III. ANALYSIS OF THE ROBOT JVC 0.1

A. Inspections and measurements of the robot JVC 0.1

The JVC 0.1 robot (Fig. 3) is a hybrid robot, it means that it consists of a mobile platform and a manipulator arm. It has the following characteristics:

- 1) It has a system of caterpillars with independent motors, to move in unstructured terrain, this system allows turning on its own axis and climbing stairs with an inclination of up to 45 degrees.
- 2) It has DC servomotors with reductive gearboxes to control the speed, provide high torque, and maintain the position of the arm, even without power.
- 3) Anthropomorphic manipulator arm, with 4 degrees of freedom, with a three-finger gripper for handling and grasping objects.

When measuring the total mass of the JVC 0.1, a value of 155.20 kg was obtained. According to the ASTM E-2592-07 packaging weight and volume evaluation standard for emergency robots [13], the weight of a robot in emergency scenarios must be up to 90 kg so that two people can move it; however, in this case the robot exceeds this limit by 73%, requiring a minimum of four people to transport it.

TABLE I
WEIGHT DISTRIBUTION OF THE JVC 0.1.

Components of robot JVC 0.1	Weight(Kg) / Percentage
Motors	32.92 / 21%
Battery	18.624 / 12%
Chassis	68.288 / 44%
Robotic arm	35.696 / 23%

From table I, we deduce that the construction material of the chassis as well as the robotic arm can be changed for one of lower density, considerably reducing the weight dramatically. Nevertheless, motors and the battery are elements that correspond to an important part of the total weight, because even if the weight were reduced due to a possible change of the construction material, these elements will continue to represent an important weight. In the case of the battery, by changing it for a lighter lithium alloy one to reduce weight and space by taking advantage of its high energy density, and in the case of motors, by using lower power motors.

Regarding dimensions, the Allen Vanguard MK2 [14] was considered as a reference to compare it with the JVC 0.1,

Fig. 4. Chassis JVC 0.1

because it is a model that can be easily moved by the agents in the UDEX-Arequipa patrols, it can go through doors and be transported in small spaces without many complications. Table 2 shows a comparison between the dimensions of the MK2 robot and the JVC 0.1.

The general dimensions required for a packaging of the robots are considered; however, in the case of the height of the JVC 0.1, two height measurements were taken to appreciate to what extent the robotic arm influences the volume, which in the MK2 is negligible because it has a folding arm, which is much more convenient. by requiring less space moved and lowering the center of gravity to achieve greater stability. From table 2 we can deduce that the cubic volume required to transport the JVC 0.1 is more than 4 times that of the MK2, so it is convenient to reduce dimensions and have a folding arm in the next version.

TABLE II
DIMENSIONS MK2 VS. JVC 0.1

	Length (m)	Width (m)	height (m)	Cubic volume (m ³)
MK2	0.915	0.435	0.405 with arm	0.161
JVC 0.1	1.00	0.70	0.97 with arm 0.30 without arm	0.679

B. Analysis of the Locomotion System

The JVC 0.1 chassis (Fig. 4) has a box-shaped architecture, is made of 6mm thick steel sheet, and houses the electronic control systems, batteries and serves as a support for the caterpillar-type traction system.

It consists of two motors with 12V DC reductive gearboxes wound in series with an output of 1.2KW each for a total of 2.4 KW, with independent movement. Each motor is coupled to a gearbox and later to an output shaft which is coupled to the tracks for movement, this allows it to support up to 400 Kg of additional weight on the chassis and the towing capacity of a vehicle of up to 1361 Kg on flat surface (Fig. 3) Its weight of 155.20 kg, allows greater load capacity and stability; however, at UDEX-Arequipa such capacities are not

Fig. 5. JVC 0.1 robot towing a UDEX vehicle

Fig. 6. Assignment of parameters following the DH algorithm

required and reducing the power of these motors is convenient. The traction system allows it to travel at a speed of 0.70 km/h, providing a low degree of maneuverability in closed spaces.

C. Handling System Analysis

The dimensions of the robot were considered to carry out the study of the position. Analysis was performed using the Denavit-Hartenberg (DH) algorithm [15]. In (Fig. 6) the assignment of the DH parameters is shown and their values in Table 3.

TABLE III
PARAMETROS DH

Articulation	θ	D	A	a
1	θ_1	d1	0	90
2	θ_2	0	a2	0
3	θ_3	0	a3	0
4	θ_4	0	a4	90

The use of DH parameters allows us to find the orientation and position of each joint in space with respect to a defined coordinate system. From Table 3, by means of transformation and translation matrices, we found the working space of the manipulator. The results obtained are shown in (Fig. 7) The workspace of the JVC 0.1 compared to commercial robots like the MK2 is noticeably smaller. In addition, considering that the dimensions of its links are larger, it is not able to take advantage of its linear drive system and its joints are limited.

Fig. 7. Work area of the manipulator. (a) Projection on the floor of the Work Area. (b) Side view workspace projection. (c) Workload

Fig. 8. Robot JVC 0.1 at test bench

At ground level (Fig 7a) the work area is not optimal, since it has difficulties with the actuator when approaching the chassis. So as the arm is raised in the side view (Fig 7b) the space is reduced. In (Fig 7c) the size of the robot and its volume of work can be seen, which barely becomes a ring around the robot.

D. Test result

Tests were performed according to ASTM and NIST standards by performing the test bench with the given specifications [13]. In (Fig. 8) it can be seen how the robot picks up the targets of the omnidirectional device.

The results obtained from these tests led us to understand that the robot is too slow to perform these tests, because the actuators limit the movement of the arm joints, obtaining average speeds of 0.12 rpm at the shoulder and 0.28 rpm at the elbow.

Fig. 9. Robotic Gripper of the JVC 0.1

Fig. 10. Gripper holding a pineapple-type grenade

E. Robotic Gripper

The robotic gripper (Fig. 9) belonging to the JVC 0.1 presents three fingers separated by 120° that are activated simultaneously by a power screw mechanism located in the central axis of the gripper.

The manipulator can lift different shapes of objects. In tests carried out at UDEX-Arequipa, it was found that due to their geometry and with proper positioning, the grippers are capable of lifting objects such as grenades, dynamite, among others.

For a weight of 15Kg (maximum load) a Clamping Force of 163N is obtained, being more than necessary (147 N) to hold the object firmly. The main problem is the lack of rotation of the gripper, since the JVC 0.1 is forced to perform a large number of maneuvers to pick up or deposit an object to align the jaws accordingly the shape of the object.

Therefore, the last link in the arm requires an additional degree of freedom. Being a 3-finger gripper, it has a greater grip when grasping an object, the main shapes it could capture are spherical (Fig. 10), in the case of cylinders and prisms, it can easily grasp them only if they are vertical. A 2-finger gripper could easier grasp a dynamite (cylindrical object) and in the same way prismatic objects, it would also adapt to spherical objects if the fingers were aligned to the center of gravity of the object; thus, it is concluded to use a 2-finger gripper in the redesign.

F. Robotic Arm Load Capacity

When gathering the requirements of the UDEX-Arequipa, (2013 - 2020), they indicate that a load of 10Kg is enough to cover 97% of all incidents with explosive devices [1]. So, we

Fig. 11. Load capacity test

would have a 50% margin that would be wasted by increasing weight and power consumption unnecessarily. For the JVC 0.1 loading test, 3 explosive devices were selected at UDEX-Arequipa as shown in (Fig.11), grenade, mortar and tank shell. The targets were picked up from the ground and maneuvered in extended arm position. Sequences of 10 operations were performed for each object and the results of effectiveness were obtained in the following table.

TABLE IV
ROBOT LOADING EFFECTIVENESS WITH RESPECT TO DIFFERENT EXPLOSIVES.

Explosive Device	Mass (kg)	Effective percentage
Grenade (0.6kg)	0.6	100
Mortar (13.5kg)	13.5	100
Tank bullet (15.3kg)	15.2	80

According to the recommendations of the ASTM for carrying out these tests, we must reach a success rate of over 80% [6]. The results in Table 4 reflect that the JVC 0.1 had no inconveniences with the first two artifacts, but with the tank bullet it barely achieved 80%.

The tank bullet load shows enough capacity in actuators, but at this point the chassis begins to lose stability. Despite the high weight of the design, the incorrect distribution of mass in the chassis decreases the load levels, making it unstable in the position of extended arm. For this reason, 15.2 kg was considered as the maximum load.

IV. FMEA MATRIX

The FMEA matrix is a method that is used to analyze a product or process in its design phase, in this case we will analyze the JVC 0.1 bomb disposal robot. The main objective with the FMEA matrix will be to highlight the critical points to eliminate them or establish actions to be taken to avoid their appearance in the next version of the robot [12].

Fig. 12. RPI matrix FMEA

As seen in table 5, the failure modes were divided into the three stages mentioned above, their causes and effects are described as well as the actions to be taken that would become our redesign parameters for a latter version.

In (Fig. 12) the Risk Priority Index (RPI) found for each analyzed aspect is plotted. An RPI of less than 100, an adequate one, which does not require any intervention; however, we have higher values, that is, the JVC 0.1 prototype is far from optimal for UDEX-Arequipa. The most critical aspects will be regarding the robotic gripper and the workspace, where the increase of one degree of freedom for the gripper rotation, the redesign of the two-finger gripper and the change of the drive system will be extremely essential. With a little less criticality, we have to reduce the weight of the robot, adjust the load capacity without oversizing motors and structure, as well as increase the drive speed.

V. CONCLUSIONS

In this work, the JVC 0.1 explosive deactivation robot prototype was analyzed through performance tests and digital simulation, where it was found that this design was not the most suitable for the tasks at UDEX-Arequipa, mainly because it was very difficult to transport, it had a reduced workspace, the actuators were oversized and it had low speed in the robotic arm drive. According to the studies carried out on the JVC 0.1 robot, its redesign with the following parameters is of vital importance:

- 1) Aluminum main construction material.
- 2) The last link in the robotic arm requires one degree of freedom to rotate the robotic gripper.
- 3) Increase speeds, to improve the user experience of a conventional EOD robot.
- 4) Reducing the size of the robot
- 5) Use a two-finger robotic gripper.
- 6) Change the linear drive system to worm-crown gear-boxes.

The JVC 0.1 prototype, in addition to having the difficulty of being the first of the EOD robots manufactured in the city of Arequipa, had a short time for its development. This factor did not allow the complete definition of client traits; therefore, the specifications of JVC 0.1 were not the best. The new JVC 0.2 version will be designed based on the mentioned parameters. First, modeling, simulation and analysis will be

Abstract In this paper, we study the problem of forecasting the energy consumption of real estate objects. The purpose of the work is to increase the efficiency of distribution companies by improving the mechanism for determining planned consumption volumes. The task of the work is to construct a mathematical model based on existing data and further forecast on its basis. To achieve the goal of the work, 2 approaches are used: forecasting energy consumption based on time series (regression task) and forecasting the energy consumption profile for each object (classification task). Various methods of machine learning, as well as clustering, were used in the work. We compared machine learning methods that solve different problems with each other, and selected the best ones. As a result, the ARIMA and Support Vector Machine methods are compared for predicting energy consumption. The choice of a particular algorithm will depend on the goals of the companies that produce and distribute energy.

Keywords— Energy consumption, mathematical model, machine learning, ARIMA, SVM method

I. INTRODUCTION

Currently, the European Union has the Treaty on the European Union and the Treaty on the Establishment of the European Community of December 13, 2007 (entered into force on December 1, 2009), which refers to the following main goals in the development of energy:

- Ensuring the functioning of the energy market;
- Ensuring energy security;
- Promoting energy efficiency and energy conservation, including the use of renewable energy sources (RES) and the development of new types of energy;
- Facilitate interconnection of energy networks.

To implement these goals, acts are adopted that are binding on all countries that are members of the European Union. One of these documents are the decisions and directives of the European Parliament and the Council of the European Union. Until recently, Directive 2009/72/EC of the European Parliament and of the Council of July 13, 2009 on general rules for the internal electricity market and the repeal of Directive 2003/54/EC [1], which establishes the basic rules for the production of , transmission, distribution and sale of electricity, taking into account the protection of consumer rights, as well as the principles of organization and functioning of the electricity industry to increase competitiveness and integrate electricity markets between the countries of the European Union. In particular:

- Separation of natural monopoly (transfer, transportation) activities from competitive ones (production, sales);
- Increasing the share of renewable energy use from 20% to at least 27% by the end of the 2030s;

- Limiting the monopoly of electricity suppliers that block the supply of electricity from competing energy companies through ownership of delivery networks to end consumers (power lines).

One of the main regulators in the electric power industry is the Directive of the European Parliament and of the Council No. 2019/944 of 06/05/2019 on the general rules of the internal electricity market and amending Directive 2012/27/EU [2].

The main provisions of the fourth energy package:

- Separation of natural monopoly (transfer, transportation) activities from competitive ones (production, sales). Despite the fact that this was also indicated under the third energy package, in many countries of the European Union there is still a share of regulated electricity supplies;
- Decentralization of electricity consumption and generation;
- Increasing the share of renewable energy use from 20% to at least 32% by the end of the 2030s [3].

The fourth energy package is aimed at improving the energy efficiency of the European economy, providing maximum freedom to consumers, and achieving the global leadership of the European Union in renewable energy.

In the European Union, much attention is paid to RES, in the field of energy a new set of rules has been developed, which is called the Clean Energy for all Europeans package, adopted in May 2019 [8]. In this package the Commission considered five main aspects of development:

- Energy efficiency - the use of energy-saving technologies in industrial and commercial buildings that consume a large amount of energy.
- The use of renewable energy sources - reaching the mark of 32% of the share in the use of renewable energy sources from the total number of energy sources used by 2030.
- Better governance in the Energy Union – each member state of the European Union is required to develop National Energy and Climate Plans (National Energy and Climate Plans) for 2021-2030, which will describe exactly how the state plans to achieve the goals set by the Energy Union, in particular in energy efficiency and the use of renewable energy sources. These projects must be reviewed and approved by the European Commission.
- More rights for consumers - individuals will be able to produce, store and sell their own energy, as well as keep track of generated electricity bills and be

able to change the distribution company at their own discretion.

A more efficient electricity market - the new energy package will improve the security of supply, integrate renewable energy into the power grid, and effectively organize cross-border cooperation [5].

Thus, we can conclude that Europe is aimed at changing the structure of the energy market and making the transition to unregulated management of the electricity market, and in the European Union, much attention is paid to the environmental situation and the use of renewable energy [6].

With the advent of a competitive unregulated electricity market, there is a separation of energy suppliers from network operators and the creation of Distribution System Operator (DSO) as a separate operating entity, as well as a separation between supply and network operations, both in terms of operations, and in terms of access to operational data and ownership. This means that the energy supplier will continue to use its system for end-user billing, while the PDM will need to implement a comprehensive meter data management (MDM) system to collect and store metering and customer data for all consumers (and manufacturers associated with distribution) of a country or region, while suppliers will only have access to their own customer data

Thus, for PDM there is a need (within the framework of the third and fourth energy packages) to forecast the consumption of electricity for each of the sales companies so that the PDM can effectively distribute the volume of generated electricity between the sales companies according to their needs. Due to the fact that the number of consumers for each supplier will be quite large, the consumption of consumers will be different, and it is labor-intensive and unproductive to build forecasts for each consumer separately, it makes sense to divide all consumers into classes with certain similar characteristics, and the nature of subscriber consumption in class should be approximately the same for the same reporting period. At the same time, it is also necessary to take into account the historical consumption of subscribers, since seasonal factors can also affect the nature of consumption.

At present, an important research task is to predict the magnitude of energy consumption. It is relevant for such areas as the economy, industrial production, environmental protection, etc. But for companies producing and distributing energy, this task plays an important role, since accurate forecasting provides more profit and minimizes the risks associated with incorrect calculation energy consumed by objects, as well as the optimal distribution of energy [7]. However, due to the large number of types of consumers and factors affecting the consumption profile, forecasting is a difficult research task.

II. PROBLEM STATEMENT

The purpose of the work is to increase the efficiency of energy distribution companies by improving the mechanism for determining planned consumption volumes.

To achieve the goal of the work, namely to improve the efficiency of distribution companies, it is necessary to develop

an algorithm that solves the problem of consumption forecasting. There are many methods that solve the forecasting problem, in this paper supervised machine learning methods are used, which are divided into two large types depending on the task: solving the regression problem and solving the classification problem. One of the tasks of the work is to determine how the type of supervised MMO is best suited to achieve the goal.

Thus, the paper considers two ways to solve the problem of predicting the energy consumption of real estate objects: based on historical data on energy consumption and based on the belonging of a real estate object to a certain consumption profile. The consumption profile of each object is determined using clustering.

Main tasks have been:

- Analysis of energy consumption data;
 - Building a mathematical model based on consumer parameters;
 - Clustering of real estate objects by consumption profile;
- Solution of the energy consumption forecasting problem in two ways: through the regression task using historical data, and through the classification task using the results of clustering.

III. METODOLOGY

A. Data Preprocessing

Data for analysis was exported from the Oracle MDMS database using Oracle SQL. Oracle MDMS is a consumption calculation tool that uses special calculation algorithms and takes into account the metering device type of appliance and the client's metering point. Since the data was extracted from different databases, the data was then combined into one dataset and processed to extract empty and anomalous values. One of the important advantages of MDMS is the support of the meter-to-cash process - the provision of calculated values at the request of an external system [8, 9]. The external system is CC&B, which queries MDMS for meter readings at the time of billing. Figure 1 shows a graph of daily electricity consumption, built on the basis of data from MDMS.

Fig. 1. CHART OF THE DAILY ELECTRICITY CONSUMPTION

To conduct cluster analysis, it is necessary to prepare the initial data. To determine which data and characteristics influence consumption volumes, it is necessary to put forward

a number of hypotheses. A hypothesis is an assumption about the influence of certain features on the formation of clusters.

It is necessary to analyze and display all the signs, and then evaluate them. Thus create a feature space. Feature selection is based on available data. Therefore, to determine the features, the existing data sample should be examined and cleared of anomalous values. After that, it is necessary to check the signs for correlation. If a correlation is found, regularization should be performed.

In the process of data research and analysis of current trends in the development of the electricity market, the following hypotheses were put forward:

1) The type of device affects the algorithm for calculating the consumed energy.

2) Metering Equipment type affects the algorithm for calculating the consumed energy

3) The process of electricity consumption is characterized by cyclicity and seasonality, which makes it possible to single out such features as seasonality and peak values of consumption for each consumer during the month. Just as important is the overall level of consumption.

The data includes information on the energy consumption of 240 commercial properties on a monthly basis from 2018 to 2021 in kW.

Each object is characterized by several parameters:

- SP Type (service point of consumption type), for example, WPUMP – Water pumping,
- Premise Type, for example, Building
- Region, for example, Nicosia
- Meter Type, for example, Low voltage single.

We consider properties belonging to the following types of industries (according to SIC- Standard Industrial Classification):

- Residential Rural
- Growing of crops
- Dairy products
- Bakery
- Beverage
- Tobacco products
- Wear and accessories
- Souvenirs
- Fishing and aquaculture

All consumers of electricity should be divided into classes according to similar consumer characteristics (for example, individuals, industrial, commercial consumers, etc.). It is assumed that consumers of the same class have a similar consumption pattern, taking into account the influence of seasonal factors. In the current context, a consumer is understood as a service metering point from which readings are taken. The nature of consumption at these points may differ depending on the technical characteristics of the connection, the connected devices, the seasonality of the use of the connected devices (for example, a warehouse heater), the nature of the subscriber's agreement with the power supply company, the tariffs used, the region of consumption, and

even proximity / remoteness from the central regions, which is determined by the postal code.

Thus, in order to separate consumers by trend regions, it is necessary to identify significant criteria (factors) that affect the volume of consumption.

In order to divide objects into clusters according to the consumption profile, clustering must be carried out according to criteria directly related to energy consumption. Therefore, the average values of energy consumption of real estate objects for the 2nd, 3rd and 4th quarters of 2021 were taken as criteria:

- o April 2021 – June 2021
- o July 2021 – September 2021
- o October 2021 – December 2021

Thus, for clustering the studied data, the k-means method is used with the join rule for clusters "single connection" and the parameters for clustering - the last 9 months of 2021 - 2,3,4 quarters with an average value of energy consumption.

B. Machine Learning Methods

As part of the problem of forecasting energy consumption, the regression problem is interesting in that a mathematical model is built for each property based on historical data on the energy consumption of this object, and for each object its own approximating function is built, taking into account the behavior of the object as an energy consumer. Accordingly, the better the regressor works, the better the amount of energy that will be spent in the future is predicted.

As part of the energy consumption forecasting problem, the classification problem is interesting in that it can be used to divide real estate objects into classes based on their electricity consumption profile, and predict for future periods not the amount of electricity that will be spent, but the consumption profile for a particular object. Such a task may be of interest to the company, since it is not always necessary to predict the total amount of electricity; more often, more detailed information about the behavior of real estate as consumers of electricity is of interest.

IV. COMPUTER SIMULATION RESULTS

To train the models, the data under study were divided into training and test sets. 240 real estate objects were divided in the ratio of objects in the samples - 80% and 20%, respectively. For each object, its time series is investigated - the values of energy consumption in the period from 2018 to 2021. Objects are serial numbers of the months, answers are energy consumption values.

The following methods were used to solve the regression problem [10, 11, 12]:

- Linear regression
- Support Vector Machine (SVM)
- ARIMA
- SARIMA

Python and libraries: scikit-learn, Statsmodels were used for computer simulation.

For each model, a graph of the dependence of the object number and the error percentage for this object was presented (Fig. 2 - Fig. 4).

Fig. 2. GRAPH FOR LINEAR REGRESSION

Fig. 3. GRAPH FOR ARIMA

Fig. 4. GRAF FOR SARIMA

To assess the quality of forecasting, the MAPE (mean absolute percentage error) metric was used - the average absolute error in percent. It is given by the formula

$$MAPE = \frac{100}{n} \sum_{i=1}^n \left| \frac{A_t - F_t}{A_t} \right|, (1)$$

where n is the number of objects, A_t is the actual responses, F_t is the predicted responses. The results of assessing the quality of forecasting are presented in Table 1.

TABLE I. MAPE METRIC FOR MODELS SOLVING THE REGRESSION

Method	MAPE
Linear Regression	3.0106
ARIMA	0.9023
SARIMA	1.8186

For the clustering of 240 properties, the k-means method was used with the metric "single link" combined based on historical data for the last 3 quarters of 2019 - average values of energy consumption of properties for 2, 3 and 4 quarters of 2019.

For clustering, a similarity metric was chosen - the "distance" metric - the Euclidean distance, since when using the "squared Euclidean distance" and "Manhattan distance" metrics, the composition of the clusters practically did not change, and when using the "Chebyshev distance", the objects were practically not divided into clusters (Fig.5).

Fig. 5. REAL ESTATE CLUSTERING WHEN USING THE "CHEBYSHEV DISTANCE" METRIC

The standard k-means algorithm takes the parameter k - the number of clusters, that is, the number of final clusters is not determined automatically, and additional analysis is required to determine the optimal value of the parameter k for the data under study [11, 12].

Dividing the objects under study into 2 clusters will not give good results in predicting, therefore, you need to start analyzing possible options for the parameter k, you need to start with 2. Figure 6 shows the clustering of the objects under study with the parameter k=3, that is, with the number of final clusters 3.

Fig. 6. REAL ESTATE CLUSTERING WHEN USING "EUCLIDEAN DISTANCE" METRIC WITH PARAMETER K=3

Fig. 7 Fig. 8 shows the clustering of the studied objects with parameters k=4 and k=5.

Fig. 7. REAL ESTATE CLUSTERING WHEN USING “EUCLIDEAN DISTANCE” METRIC WITH PARAMETER K=4

Fig. 8. REAL ESTATE CLUSTERING WHEN USING “EUCLIDEAN DISTANCE” METRIC WITH PARAMETER K=5

As can be seen from the graphs, with an increase in the number of clusters, the composition of clusters does not change much, large clusters are detailed, and the number of objects in clusters becomes disproportionate. For a given set of objects, namely 240 objects, it is sufficient to use k=3.

An example of the Python code for the clustering algorithm is shown in Fig. 9

Fig. 9. PYTHON CODE FOR THE CLUSTERING ALGORITHM

```
def clustering(d, k):
    q = queue.PriorityQueue()
    sets = [set([i]) for i in range(len(d))]
    nb_sets = len(d)
    for i in range(len(d)):
        for j in range(i+1, len(d)):
            q.put((distance((d[i][1],d[i][2],d[i][3]), (d[j][1], d[j][2], d[j][3])), (i, j)))
    dis = 0
    #print(q.get())
    while not q.empty() and nb_sets >= k:
        e = q.get()
        u = e[1][0]
        v = e[1][1]
        dis = e[0]
        set_uv = [s for s in sets if u in s or v in s]
        if len(set_uv) > 1 and set_uv[0].isdisjoint(set_uv[1]):
            unionset = set_uv[0].union(set_uv[1])
            sets_c = copy.copy(sets)
            sets.remove(set_uv[0])
            sets.remove(set_uv[1])
            sets.append(unionset)
            nb_sets -= 1
    return sets_c
```

```
d = {}
for i in range(len(data_for_clust)):
    x = x_list[i]
    y = y_list[i]
    z = z_list[i]
    d[i] = (i, x, y, z)
```

```
k = 3
cl = clustering(d, k)
```

```
color_list = np.zeros(len(d))
```

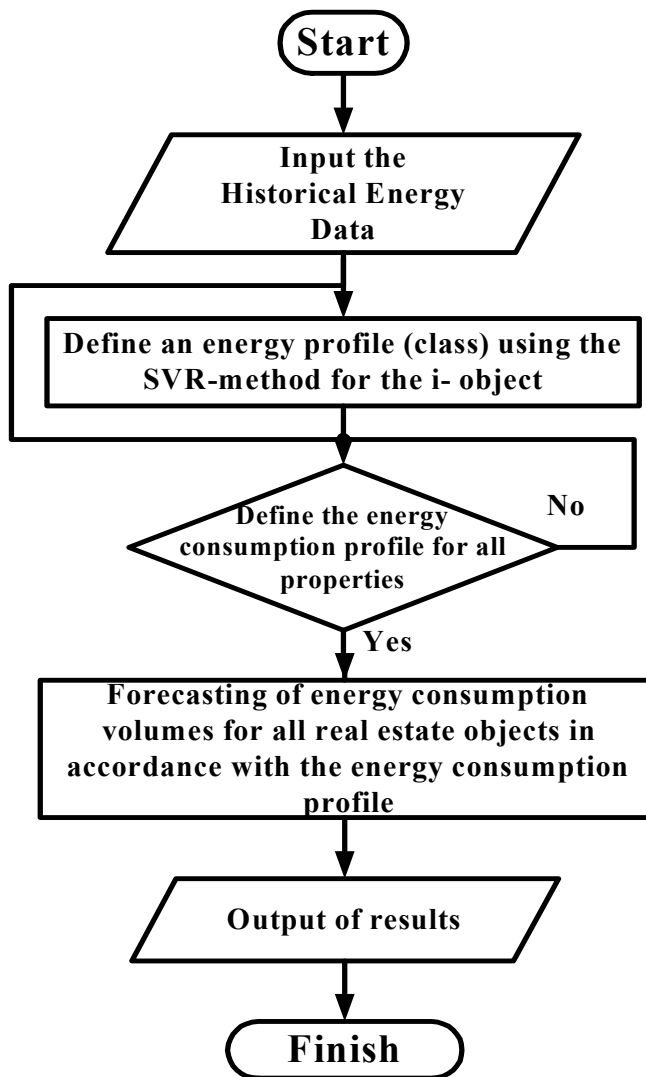

```
for i in range(len(cl)):
    for item in cl[i]:
        color_list[item] = i
```

```
d = {}
for i in range(len(data_for_clust)):
    x = x_list[i]
    y = y_list[i]
    z = z_list[i]
    d[i] = (i, x, y, z)
```

The proposed algorithms for clustering and forecasting energy consumption will be used to implement the energy management system for real estate objects.

Fig. 10 shows the profiling algorithm for electricity consumers, which will be used in the energy management system.

Fig. 10. BLOCK DIAGRAM OF THE ENERGY PROFILING SYSTEM

V. CONCLUSION

The paper analyzes the data provided by the energy company of one of the European countries. The following are applied to the data: clustering, which determines the object's consumption profile; mathematical models suitable for describing the data under study; machine learning methods that solve regression and classification problems. In addition, the evaluation of the work of applied machine learning algorithms with the data under study was carried out.

Using the Python programming language, machine learning methods and clustering methods were implemented. Methods for assessing the quality of algorithms are also implemented [13, 14, 15].

To assess the quality of methods that solve the regression problem, the MAPE metric was chosen. According to the results of such an assessment, ARIMA best describes the data.

The F-measure was chosen to assess the quality of methods that solve the classification problem. According to the results of such an assessment, the support vector machine with kernel = linear best describes the data.

Abstract—In order to satisfy the current needs of urban grassroots governance, a novel city hotline service ontology is constructed to improve the efficiency and effectiveness of city hotline service in this paper. Firstly, the TOVE method is applied to construct government hotline service ontology for urban grassroots governance based on the cases of city hotline service. Secondly, the necessary concepts are defined, including the hierarchical relationships, attributes, and constraints among the seven modules of the city, personnel, organization, government, hotline appeal, hotline complaint object, and hotline processing results. Finally, the city hotline service ontology is built with the protégé ontology development tool and then tested in hotline scenarios of different urban grassroots governance. The testing results verify the validity and practicability of the proposed ontology so that the needs of hotline service are met in urban grassroots governance.

Keywords—city hotline service, urban grassroots governance, TOVE method, ontology, protégé

I. INTRODUCTION

Ontology plays an essential role in the standardized description and sharing of domain knowledge with the wide application of ontology. It can extract and integrate massive intelligence information to build a knowledge framework in the field of urban grassroots governance and then the intelligent governance of urban grassroots is realized [1]. With the increase of city hotline service data, it is necessary for the city hotline service ontology to standardize the city hotline data. As one of the essential styles of urban grassroots governance, the urban hotline service can be applied to accurately understand the needs of the public [2]. The problems that existed in the operation of the city can be fully mined and the hidden value behind its massive consultation, complaint data and other information data are able to improve the level of the urban grassroots governance and the processing efficiency of city hotlines [2].

Currently, many urban government performance management systems have been developed in a variety of cities all over the world, such as CitiStat, CompStat, and GMAP based on the 311 system [3]. Meanwhile, the 311 system has become the primary basis for the assessment and accountability of city government departments [3]. One of the main goals of the 311 system is to increase the accessibility of urban services. At the same time, the efficiency of the city's response to public inquiries is improved. The hotline information in the city has been summarized and the needs and problems of the public are organized in the 311 system.

In China, the “12345” citizen service hotline system is mainly used in the performance management system of the city government. In the Beijing “12345” citizen service hotline system, “public complaints have been processed without delay” has played a critical role as one working mechanism in the government’s performance appraisal [4]. Additionally, the “12345” citizen service hotline system can efficiently solve residents’ timely worries, and the improvement of governmental service performance is realized continuously [4]. There are a series of advantages for the “12345” citizen service hotline such as fast acceptance, quick transfer, and efficient settlement. Meanwhile, the “12345” citizen service hotline reduces the administrative cost of government departments and also satisfies the demands of the masses [5].

In order to strengthen the construction of city hotline services in China and other countries, it is necessary to simplify and speed up the communication process between governments and citizens so that many relevant problems can be solved or improved [2]. Compared to the 311 system with the “12345” citizen service hotline system, it is obvious that both are evaluations to handle efficiency of hotline service cases for urban grassroots governance. Hence, by completing the construction of the city hotline

service ontology, the processing efficiency of the city hotline can be significantly accelerated. At the same time, it can improve the performance appraisal of governments at all levels and the level of urban grassroots governance.

Currently, the government can only implement simple statistics on the city hotline data because of the complexity of the data in the city hotline system [2]. Correspondingly, the efficiency of the government in both solving citizens' problems and the level of urban grassroots governance are reduced. Hence, it is a challenging problem to conduct in-depth analysis in the information processing for the city hotline system. Based on the hotline service case of urban grassroots governance, the protégé tool is applied to construct the hotline service ontology for urban grassroots governance in this paper. A knowledge framework is proposed for efficient processing of urban hotlines for the low efficiency of existing urban hotlines. The city hotline service can provide the hotline staff with efficient processing methods so as to find out the critical information in the case, then the efficiency of handling the case will be improved, thereby the government's execution efficiency and citizens' satisfaction with the government can be increased finally.

II. PRELIMINARY KNOWLEDGE

A. Ontology Concept

Ontology is a distinct normative description and knowledge representation about a domain's hierarchical structure. And it is a system for people to understand the unified nature of concepts in a particular domain. The ontology conceptualizes the description objects and provides a uniform set for terms and relations in the domain [6]. The main target of ontology is to acquire knowledge in relevant fields, so that the general concepts are recognized and understood for the knowledge in this field and the relationship between these concepts is defined well. Finally, the semantics of concepts can be represented to clarify the interrelationships between these concepts [7].

B. Ontology Construction

The TOVE enterprise modeling method was proposed by Fox to construct a hotline service ontology for smart cities in 1994 [8] and it is firstly employed to the city hotline service systems by authors' team in this paper. The TOVE enterprise modeling method was not only constructed directly through the knowledge logic model in the form of ontology but also first used to establish the informal description [9]. Generally, the TOVE enterprise modeling procedure included the following steps: [10-11]

- Acquisition of motivational plots;
- The explicit expression of formal competency questions, the competency questions are based on

use cases requirements to test the capabilities of ontology information retrieval and question answering;

- Normalization of terms;
- Explicit description of formal competency questions;
- Formalization for the rules into axioms;
- Adjust the conditions for the solutions of the ability problem so that the ontology of knowledge tends to be complete.

Based on the above steps the modeling structure is shown in Fig. 1.

Fig. 1. TOVE enterprise modeling method flowchart.

Ontology Building Tool

Protégé is an open-source application tool based on the Java environment developed by Stanford University [6]. The ontology structure in Protégé is displayed in a tree-like hierarchy under which the classes, subclasses, attributes, instances, and relationships of the ontology can be either edited or extended, even deleted. There also exist a variety of plug-ins that can provide extensible markup languages (XML), resource description framework (RDF), web ontology language (OWL) and other storage formats [12].

III. CITY HOTLINE SERVICE CASES AND COMPETENCY QUESTIONS

The following four types are the major items accepted by the government hotline, which almost covered the main issues in urban grassroots governance. The city hotline service center will report the following problems mentioned to the relevant departments respectively, and the relevant departments will take actions to deal with them according to the follow-up investigation and then reply to the public one by one.

A. Transportation

The city hotline service center receives varieties of reports and complaints from citizens, mainly including traffic facility, traffic order, motor vehicle, and driver management, bus operation, rental management, operation

vehicle management, logistics management, and railway transportation, etc.

Competency questions:

- As of time t , how many complaints are related to transportation in city c ?
- From time a to time t , which one receives the most complaints hotline among the traffic facilities, traffic order, motor vehicle and driver management, rental management, operating vehicle management, logistics management, railway management, port and shipping and highway administration in the transportation of the city c ?
- From time a to time t , what problem does the citizen p reflect in the transportation of the city c ?
- On the moment t , what is the result of the city c accepting the citizen p 's handling of the taxi detour problem?

B. Social Security

The city hotline service center has received hotlines from citizens about urban social security, including public security management, case handling, fire management, household registration management, entry and exit management, network security, and mountain quarrying, etc.

Competency questions:

- From time a to time t , which have received the most complaints about dog raising, living noise, explosives, official seal engraving, and mass gatherings in city c ?
- On the moment t , what is the contact information of citizen p who complained about fighting and gambling in the city c ?
- As of time t , which district or county in the city c has received the most complaints about social security?
- On the moment t , what is the processing result after citizen p in the city c reports that the fire escape is blocked?

C. City Management

The city hotline service center has recently received hotlines from citizens about the urban appearance and environment, including municipal environment, landscape lighting, energy-saving insulation, and building enclosures.

Competency questions :

- On the moment t , what is the contact information of the citizen p who has built privately or arbitrarily in the cityscape environment of city c ?

- From time a to time t , which one received the most complaints of the city c 's city appearance environment, landscape lighting, energy-saving thermal insulation and building enclosure?
- As of time t , the city c receives comments from citizen p on energy conservation renovation and old residential areas. What is the result of the subsequent treatment?
- As of time t , has the relevant departments implemented the suggestion of citizen p to improve the brightness of landscape lights in the urban management of the city c ?

D. Urban Management Law Enforcement

The city hotline service center receives hotlines about the needs for urban management to enforce the law, mainly in municipal engineering, greening management, urban planning, civil air defense, and environmental protection management.

Competency questions:

- From time a to time t , which hotline has the most complaints about municipal engineering, greening management, environmental protection management, urban planning and civil air defense in urban management law enforcement in the city c ?
- As of time t , which have received the most complaints among the uncivilized road construction, unlicensed road excavation, unauthorized occupation of urban roads, and unauthorized establishment of gas storage stations in the municipal engineering of the city c ?
- On the moment t , citizen p reports illegal construction in urban planning and civil air defense in city c . Will the relevant departments handle it afterward?
- On the moment t , city q reflects the behavior of cutting down trees without authorization in city c . What is the contact information of the citizen p ?

IV. ONTOLOGY CONSTRUCTION OF CITY HOTLINE FIELD

ISO/IEC 5087 is a family of standards that define city data model. This standard defines the foundation level of the core concept model. It also addresses some of the core concept and cuts across the domain knowledge models. It will also define knowledge models for the services of citizen livelihood, urban management, and smart transportation illustrated [13-14].

The city hotline service ontology mainly adopted ISO/IEC 5087-1 and ISO/IEC 5087-2 city data models. The namespace prefixes used in the city hotline service ontology is shown in TABLE I.

Pattern Introduction of City Hotline Service Ontology

A pattern is a set of concepts that are related to the topic and inter-connected by properties, thereby forming a graph. The city hotline service ontology is mainly composed of seven patterns: city, person, government, organization, complaint object, hotline appeal, and hotline processing result.

The city pattern mainly involves the name of the city, the administrative area, and the community under its jurisdiction.

The person pattern mainly covers all personnel information and geographic location information in the city.

Some of the objects that citizens call the hotline are shops and organizations, and the organization pattern systematically classifies these objects. The organization pattern mainly covers all the shops and some institutions in the city. Organizations are mainly divided into three categories, namely government organizations, for-profit organizations, and non-profit organizations. Government organizations are government units, for-profit organizations are some businesses and shops, and nonprofit organizations are mainly public welfare organizations such as the Red Cross.

The government pattern mainly contains implementing the public's complex problems and the release of some government announcements and suggestions during the epidemic management stage. The government mainly covers many functional departments, among which the city government mainly contains two parts, one is the municipal government, and the other is the district government.

The hotline appeal pattern mainly refers to whether the hotline calls made by citizens to the government about

complaints, suggestions, help, and inquiries are implemented and whether the citizens are satisfied.

The hotline complaint object pattern mainly introduces hotline complaint objects, including the person, organization, or phenomenon that the hotline complained about.

The functional departments of the government mainly apply the hotline processing result pattern to cope with the content of the hotline calls made by the citizens to make the citizens feel satisfied with the handling of the government, to avoid the problem of social security. After the city hotline service center is received from the citizens, the government department will implement specific measures, and there are also specific implementation situations. After the implementation, the city hotline service center also needs to reply to the citizens who call the hotline, give the government's solutions and then get the reply about whether they are satisfied with the implementation.

The overall pattern structure diagram of urban hotline service ontology is shown in Fig. 2 in the Appendix.

A. City Pattern

The city pattern of the city hotline service ontology mainly employs the city pattern in 5087, and the city pattern mainly contains “class city: City”, “class District” and “class Community” [13-14].

B. Person Pattern

The person pattern mainly utilizes the person pattern in 5087. The person pattern mainly contains “class person: Person”, “class contact: Address”, “class contact: AddressType”, “class contact: PhoneType” and “class person: Sex”. In order to meet the needs of hotline application scenarios, the city hotline service ontology adds *hasRoad* and *hasBridge* to the “class contact: Address” [13-14].

Address: The following properties have been added.

- *hasRoad*: The address specifies the name of the road.
- *hasBridge*: The address specifies the name of the bridge.

C. Organization Pattern

The organization pattern mainly reuses the organization pattern in 5087, and the organization pattern mainly contains the “class org: Organization”, “class org: ForProfitOrganization”, “class org: NonProfitOrganization” and “class org: GovernmentOrganization” [13-14].

D. Government Pattern

The government is a special kind of organization, and the government pattern mainly contains “class MunicipalGovernment” and “class DistrictGovernment”. The “class MunicipalGovernment” and “class

DistrictGovernment” are subclasses of the class “org: Organization”, corresponding to municipal and district governments, respectively. Since the government is the main party of the city hotline service, a separate pattern is set up [13-14].

MunicipalGovernment: The following properties have been added.

- Schema: name: The name of the municipal government.
- Spatialloc: hasLocation: The city where the municipal government unit is located.
- Mereology: hasProperPart: Districts and counties under the jurisdiction of the city government.

DistrictGovernment: The following properties have been added

- Schema: name: The name of the district and county government.
- Spatialloc: hasLocation: The district and county of the city where the district government is located.

The key classes, attributes and constraints in the government pattern of city hotline service ontology are shown in TABLE II.

TABLE II. GOVERNMENT PATTERN

Class	Property	Value Restriction
MunicipalGovernment	rdfs: subclassOf	org: Organization
	schema: name	exactly 1 xsd: string
	spatialloc: hasLocation	exactly 1 geo: Feature
	mereology: hasProperPart	some DistrictGovernment
	rdfs: subclassOf	org: Organization
DistrictGovernment	schema: name	exactly 1 xsd: string
	spatialloc: hasLocation	exactly 1 geo: Feature
	rdfs: subclassOf	org: Organization

Hotline Appeal Pattern

The hotline appeal pattern mainly contains “class HotlineEvent” and “class Complainant”. Among them, the “class HotlineEvent” describes the specific questions and difficulties encountered by the questioning masses. The “class Complainant” is a hotline appeals officer [13-14].

HotlineEvent: The following properties have been added.

- hasOccurDate: When the event occurred in the citizen dialing the hotline.
- hasCallDate: The time when the citizen called.
- hasComplainant: The citizen who called the hotline.
- hasOccurLocation: The location of the incident in the hotline that the citizen calls.
- hasHotlineEventType: The type of incident that the citizen calls the hotline to complain about.

- hasContent: The event's content is mentioned in the citizen's call to the hotline.
- asComplainedObject: The object that the citizen calls the hotline to complain about.
- associatedHotlineProcess: The associated hotline processing process.
- hasComplaintTelephone: The telephone number for citizens to call the hotline.

Complainant: The following properties have been added.

- associatedHotlineEvent: The associated hotline appeal event.
- hasComplainantName: The name of the citizen who called the hotline.
- hasComplainantSex: The gender of the citizen calling the hotline.

The hotline apple pattern structure diagram is shown in Fig. 3 in the Appendix. The key classes, attributes and constraints in the hotline appeal pattern of city hotline service ontology are shown in the following TABLE III.

TABLE III. HOTLINE APPEAL PATTERN

Class	Property	Value Restriction
HotlineEvent	rdfs: subclassOf	activity: Activity
	hasOccurDate	exactly 1 time: Instant
	hasCallDate	exactly 1 time: Instant
	hasComplainant	only Complainant
	hasOccurLocation	only loc: Feature
	HotlineEventType	exactly 1 xsd: string
	hasContent	exactly 1 xsd: string
	hasComplainedObject	some ComplainedObject
	associatedHotlineProcess	only HotlineProcess
	hasComplaintTelephone	only xsd: string
Complainant	rdfs: subclassOf	orgs: Role
	associatedHotlineEvent	only HotlineEvent
	ComplainantName	exactly 1 xsd: string
	ComplainantSex	exactly 1 Sex

Hotline Complaint Object Pattern

The hotline complaint object pattern mainly contains “class ComplainedObject”, “class ComplainedPerson”, “class ComplainedOrganization”, and “class Complained-Phenomenon”. The “class ComplainedPerson”, “class ComplainedOrganization”, and “class ComplainedPhenomenon” are subclasses of the “class ComplainedObject”. The “class ComplainedPerson” indicates that the complained object is a person; the “class Complained-Organization” denotes that the complained object is an organization; and the “class ComplainedPhenomenon” represents that the complained object is a phenomenon [13-14].

ComplainedObject: The following properties have been added.

- associatedHotlineEvent: the associated hotline appeal event.
- hasComplainedObjectAddress: The address of the complained object

ComplainedPerson: The following properties have been added.

- hasComplainedPersonName: The name of the complainant.
- hasComplainedPersonTelephone: The phone number of the complainant.
- hasComplainedPersonSex: The gender of the complainant.

ComplainedOrganization: The following properties have been added.

- hasComplainedOrganizationName: The name of the organization being complained about.
- hasComplainedOrganizationTelephone: The phone number of the complained organization.

ComplainedPhenomenon: The following properties have been added.

- hasComplainedPhenomenonName: The name of the phenomenon being complained about.

The Hotline complaint object pattern structure diagram is shown in Fig. 4 in the Appendix.

The key classes, attributes and constraints in the complaint object pattern of city hotline service ontology are shown in the following TABLE IV.

TABLE IV. COMPLAINT OBJECT PATTERN

Class	Property	Value Restriction
ComplainedObject	associatedHotlineEvent	HotlineEvent
	contact:hasAddress	only contact: Address
ComplainedPerson	rdfs: subclassOf	orgs: Role
	rdfs: subclassOf	ComplainedObject
	hasComplainedPersonName	exactly 1 xsd: string
	hasComplainedPersonTelephone	only xsd: string
	hasComplainedPersonSex	exactly 1 Sex
ComplainedOrganization	rdfs: subclassOf	org: Organization
	rdfs: subclassOf	ComplainedObject
	hasComplainedOrganizationName	exactly 1 xsd: string
	hasComplainedOrganizationTelephone	only xsd: string
ComplainedPhenomenon	rdfs: subclassOf	activity: Activity
	rdfs: subclassOf	ComplainedObject

	hasComplainedPhenomenon	exactly 1 xsd: string
--	-------------------------	-----------------------

E. Hotline Processing Result Pattern

The hotline processing result pattern mainly contains “class HotlineProcess”, “class HotlineServiceStaff”, and “class Hotline-Replier”. Among them, the “class HotlineProcess” is the process content of the relevant departments to solve the problems raised by the masses. The “class HotlineServiceStaff” is the hotline operator, and the “class HotlineReplier” is the responder after processing the hotline event [13-14].

HotlineProcess: The following properties have been added

- hasStartDate: The time the hotline event started processing.
- hasFinishDate: The event that the hotline event processing ends.
- hasWay: The way the hotline event is handled.
- hasResult: The result of the hotline event processing.
- hasFeedbackTelephone: The telephone number of the hotline processing result feedback.
- associatedHotlineEvent: The associated hotline appeal event.
- hasHotlineServiceStaff: The operator for hotline handling.
- hasHotlineReplier: The responder of the hotline processing result.
- hasEventHandler: The handler of the hotline event.

HotlineServiceStaff: The following properties have been added

- associatedProcess: The process of the associated hotline handling.
- associatedHotlineEvent: The associated hotline appeal event.
- worksAt: The organization the operator works for.

HotlineReplier: The following properties have been added

- associatedProcess: The process of the associated hotline processing.
- associatedHotlineEvent: The associated hotline appeal event.
- hasPost: The hotline responds to the person's post.
- worksAt: The organization the hotline responder works for.

The hotline complaint processing result pattern structure is shown in Fig. 5 in the Appendix. The key classes, attributes and constraints in the hotline processing result pattern of city hotline service ontology are shown in the following TABLE V under the next page.

V. VERIFICATION OF CITY HOTLINE SERVICE ONTOLOGY

The verification procedure of the city hotline service ontology focuses three major steps: instantiate the ontology in the protégé; store the instantiated data in the GraphDB database; and verify the accuracy and feasibility of the ontology through the SPARQL statement. As an example, the main functions based on the city hotline service data during the epidemic and the corresponding cases are selected as follows for verification in combination with the four directions in Section III.

Class	Property	Value Restriction
HotlineProcess	rdfs: subclassOf	activity: Activity
	hasStratDate	exactly 1 time: Instant
	hasFinishDate	exactly 1 time: Instant
	hasWay	exactly 1 xsd: string
	hasResult	exactly 1 xsd: string
	hasFeedbackTelephone	only xsd: string
	associatedHotlineEvent	only HotlineEvent
	hasHotlineServiceStaff	only HotlineServiceStaff
	hasHotlineReplier	only HotlineReplier
hasEventHandler	some (org: GovernmentOrganization or org: ForProfitOrganization or org: NonProfitOrganization)	
HotlineServiceStaff	rdfs: subclassOf	org: Employee
	associatedHotlineProcess	only HotlineProcess
	worksAt	some Organization
HotlineReplier	rdfs: subclassOf	orgs: Role
	associatedHotlineProcess	only HotlineProcess
	org: hasPost	only Post
	worksAt	some Organization

A. Follow Closely

The city hotline service center received a call from one citizen who found a Hubei-registered vehicle in the city, and requested the relevant departments to investigate the vehicle's itinerary and the owner information. The city hotline service center reported the citizen's questions and suggestions to the relevant departments for implementation and gave a personnel reply by phone.

Competency question:

- From 13th to 18th in January, how many citizens in the city Jinan reported the discovery of Hubei-registered vehicles through the hotline?

Answer:

2314.

B. Government Epidemic Prevention Consultation

The city hotline service center received complaints from citizens that the publicity of epidemic prevention and control near their communities was not adequate, and that outsiders encountered problems when they came to the city. The city hotline service center will report the above-mentioned problems to the relevant departments, and the relevant departments will deal with them according to the investigation and reply the results to the citizens.

Competency question:

- From 17th to 24th in January, how many people come to the city Jinan?

Answer:

2658.

C. Return to Work and School

The city hotline service center received a request to delay the start of work from citizens because in Jinan there are new patients increased recently. At the same time, another request is to ask students when school can start normally. In addition, there are some off-campus remedial classes to be arranged to start school early, but it is also hoped to delay the starting of the school because of the current serious epidemic. On the other hand, there is no protective measure to be provided after the company starts work, and there are many people who start work but not comply with the epidemic control policy. The city hotline service center will report these problems to the relevant departments, and the relevant departments will implement them after investigation and reply the results to the citizens.

Competency question:

- From 22nd to 26th in January, how many citizens in city Jinan want to delay the start of construction?

Answer:

1497.

D. Market Supervision

The city hotline service center received complaints from citizens about the short supply of masks. Currently, almost every pharmacy has no masks to sell while problems appeared in some private stores such as driving up the price of masks arbitrarily, and so on. At the same time, some vegetable markets and supermarkets are driving up some necessities of life. The city hotline service center will report these problems to the relevant departments, and the relevant departments will immediately investigate the problems and implement them, and then reply to the public on the implementation situation.

Competency question:

- From 23rd to 25th in January, how many people are calling to complain about the shortage of masks in city Jinan?

Answer:

4896.

VI. CONCLUSION

The modelling tools protégé and the TOVE enterprise modelling method are applied to construct a hotline service ontology for urban grassroots governance in this work, and the ontology is firstly stored in the GraphDB graph database by instantiating the urban hotline data in different scenarios. Then, the SPQRQL statements are used to verify the validity and practicality of the ontology. Finally, the urban grassroots governance level and the processing efficiency of urban hotline are improved by the hotline service body of urban grassroots governance with increasingly the processing efficiency of urban hotline data.

Abstract— Various researchers have studied how to increase the performance of thermoelectric cooling devices by optimizing their module design. In the present study, the researchers investigate whether a truncated square pyramid leg geometry results to a higher COP than a symmetrical rectangular leg by varying the middle and contact areas. The values of the input parameters for the thermal-electric analysis were generated using a sphere packing design. Then, the different leg geometries were modelled in FUSION 360 and simulated in ANSYS to determine the COP from the resulting hot and cold side temperatures. Afterward, a mathematical model was generated using Gaussian Process modelling to model COP as a function of the middle and contact areas. By maximizing the desirability function of the model, results show that for the experimental design space considered for this study (contact area: $0.108 \text{ mm}^2 < AC < 1.000 \text{ mm}^2$; middle area: $1.150 \text{ mm}^2 < AM < 2.560 \text{ mm}^2$), the highest COP was attained at $AC = 1.000 \text{ mm}^2$ and $AM = 1.150 \text{ mm}^2$. The researchers therefore conclude that an asymmetrical truncated square pyramid leg geometry yields a higher COP compared to a symmetrical rectangular leg geometry, which is consistent with the results of past studies.

Keywords— *thermoelectric cooling, space-filling design, Gaussian process modelling, optimization*

I. INTRODUCTION

Significant consensus has already been established within the scientific community regarding the degree of impact that anthropogenic carbon emissions have on global warming and climate change. A significant step towards decarbonization was the adoption of the Montreal Protocol in 1987 in which signatory nations pledge to phase out the manufacture of chlorofluorocarbons (CFCs) and hydrochlorofluorocarbons (HCFCs) and to phase down the use of hydrofluorocarbons (HFCs). These chemicals are widely used in refrigeration and air-conditioning systems. Although HFCs have a lower ozone depleting potential compared to CFCs and HCFCs, they still unfortunately have a considerably high global warming potential. Therefore, efforts must be made to make cooling systems that are free from emissions which harm the environment and the ecosystem.

Thermoelectric cooling (TEC) systems are a viable substitute to cooling systems that run on vapor compression cycles. TEC devices operate on the principle of Peltier effect. This refers to the phenomenon in which a temperature differential is induced between two ends of a thermocouple wire, consisting of two different semiconductor materials, when electrical current is allowed to pass through it [1].

Benefits of using TEC systems over the conventional cooling systems include its compactness, high reliability, and the absence of moving parts and working fluids. In addition, these can also be powered by direct current sources and can easily be switched from cooling to heating modes. However, its major drawbacks are its high cost and low energy conversion efficiency. These limitations restrict the use of TEC devices in aerospace, waste heat recovery, and electronic cooling applications [2], where reliable and quiet operation is more important than affordability and high efficiency [3].

Various studies have been published in the recent decades with the objective of improving the performance of TEC devices. Attempts to increase the coefficient of performance of TEC devices revolve around discovering novel materials for Peltier modules, optimizing the module design and fabrication, and analyzing the overall Peltier cooling system and heat exchange efficiency [4].

Pourkiaei et al. [5] produced a comprehensive review of materials that are currently used in the manufacture of thermoelectric modules. They grouped these materials into semiconductors, ceramics, and polymers, then characterized these materials based on important thermoelectric properties such as Seebeck coefficient, electrical resistance, and thermal conductivity. This review study was able to provide a list of promising materials for thermoelectric module fabrication with their corresponding figures of merit for certain values of operating temperatures.

In addition to the TEC material, the thermoelectric module geometry was also the subject of improvement in various studies. Shittu et al.'s work [6] presents the most current review of the studies that have been published so far that are related to thermoelectric geometry and structure optimization.

Based on this comprehensive review, the four main geometrical parameters that are the subject of most optimization studies are leg length or height, cross-sectional area, number of legs, and leg shape. In addition, several optimization methods, such as three-dimensional finite optimization and multi-objective optimization, were cited as the main optimization routines used to improve TEC efficiency with respect to the module geometry.

This research intends to add to the growing body of literature that attempts to address the question on how to determine the optimum thermoelectric leg shape and geometry to attain the maximum possible COP. For context, several studies have already been published in this regard. Lamba et al. [7] used genetic algorithm to optimize the cooling capacity and coefficient of performance (COP) of a trapezoidal thermoelectric leg. The choice of trapezoidal leg geometry was anchored on the study of Sahin and Yilbas [8] which found that the COP increases with increase in the shape parameter (ratio of the cross-sectional area at the cold side to that at the hot side). The variable parameters considered in the optimization were the temperature dependent thermoelectric properties, shape parameter, and the temperature ratio (ratio of the hot side temperature to the cold side temperature). In addition, Lin and Yu's [9] study proved using numerical simulation that the trapezoid-type two-stage Peltier couple reduced the thermal resistance compared to the standard geometry of TEC, increases heat rejection on the hot side due to the larger cross-sectional area of the trapezoid-shaped thermoelectric legs, and enables Joule heat conduction to lean towards the hot side due to the asymmetrical thermal resistance. The results of these studies are consistent with the findings of Fabian-Mijangos et al.'s research [10] on the performance of thermoelectric modules with asymmetrical legs. This is one of the first studies that provided experimental validation confirming that pyramidal legs aid in decreasing the overall thermal conductance of a TEC device, thereby increasing the thermal gradient in the legs and harnessing the Thomson effect, which is generally neglected in symmetrical rectangular thermoelectric legs.

The main objective of this study is to optimize the leg geometry of a semiconductor thermoelectric cooling Peltier module with respect to the cross-sectional areas at the contacts (A_C) and at the middle (A_M) to maximize the coefficient of performance. The following are the sub-objectives of this study:

- To determine the allowable range of working current for a proposed TEC module with truncated square pyramid leg geometry using ANSYS
- To generate the values of the input parameters using sphere packing design
- To perform thermal-electric analysis of the truncated square pyramid leg geometries and conventional TEC geometry
- To determine the values of the hot and cold side temperatures for all modelled leg geometries and compute the corresponding COP

- To generate a Gaussian Process model to fit the response variable (COP) as a function of the contact area and middle area
- To confirm the goodness-of-fit of a Gaussian Process model by analyzing model diagnostics in JMP®
- To determine the optimal cross-sectional area of the middle and contact areas of the proposed truncated square pyramid geometries and the corresponding maximized COP value
- To determine whether the optimized truncated square pyramid leg geometry has an increase in COP compared to a conventional TEC-12706 module.

The optimization of the TEC module will be focused on the semiconductor leg geometry. For this study, Bismuth Telluride (Bi_2Te_3) will be used as the semiconductor material due to its applications in various thermoelectric modules [11][12]. Material properties such as the Seebeck coefficient, thermal conductivity, electrical resistivity, and current range will be set as control variables of the study to focus on the optimization of the modified leg cross-sectional areas to maximize the COP. Moreover, a single thermoelectric thermocouple will be modelled in the simulation. The truncated square pyramid leg design will be tested using thermal-electric heat analysis through ANSYS 2021 Software. The final optimized model was not fabricated during this study.

A segmented single thermocouple analysis was performed on the thermoelectric leg after the material's dimensions had been determined. The areas of the leg were assigned as A_C and A_M . The contact surfaces of the semiconductor legs to the copper plate were denoted as A_C , and the middle area of the legs was denoted as A_M . The dimensions of the contact areas of the top and bottom parts of the legs were set as equal. Furthermore, the same geometry configuration was used for both the p-type and n-type semiconductor legs.

Fig. 1. Truncated square pyramid leg design with its indicated cross-sectional area assignments.

II. METHODOLOGY

The study consisted of six phases: space filling design, determination of the working current range, FUSION 360 modelling, ANSYS thermal-electric analysis, COP computation, and statistical analysis. Figure 2 represents the research procedure performed in the study.

The first step of the study was establishing a design space for A_C and A_M to be investigated. The working current was determined for all the samples using the minimum and maximum values of the design space through limit testing of simulated TEC working temperatures. A range of working current was established to ensure that the simulation results were consistent and ensure that the parameters do not exceed the suitable operating conditions of the thermoelectric leg. Simultaneously, Sphere Packing was used as the space filling design method using JMP software to obtain the working sample dimensions. The generated dimensions from the Sphere Packing were modeled in the Autodesk FUSION 360 software, which was used as the model for the simulation. The thermal and electrical properties of the thermoelectric pair together with its physical model were simulated in ANSYS using the finite element approach. A thermal-electric simulation system was used to simulate the thermoelectric conditions for the different samples. After the simulation, the highest COP gathered from the different samples was used for Gaussian Process modeling in the JMP software to define the COP characteristics of the design space with respect to the change in cross-sectional areas of the modelled legs and obtain the optimized truncated square pyramid leg geometry. Only one Gaussian process model was generated during the research. Afterward, the TEC-12706 was simulated with the same current range, and its highest COP will be compared to the maximized COP of the modified TEC.

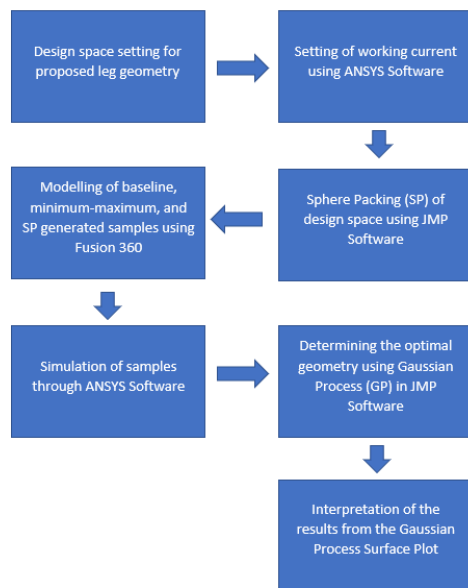

Fig. 2. Research procedure employed during the study.

A. Current range

The allowable working current range was determined by testing the minimum and maximum contact and middle areas through ANSYS thermal-electric analysis. The allowable working current range for all runs was based on the current range that would not result to an operating temperature of 250 °C. This was set as the allowable operating temperature

because bismuth telluride undergoes phase change upon reaching temperatures of 250 to 300°C [13].

The assumed material properties used for the simulation are presented in Table 1. Current was induced in the n-type copper plate, and a ground voltage was set in the p-type copper plate. The assumed values of the other simulation parameters are given in Table 2.

TABLE I. MATERIAL PROPERTIES FOR ANSYS SIMULATION

	Seebeck Coefficient $\frac{V}{K}$	Thermal Conductivity $\left(\frac{W}{m \cdot K}\right)$	Resistivity (Ωm)
Copper alloy	-	401	ANSYS table values
n-type Bi ₂ Te ₃	-1.65x10 ⁻⁴	1.285	1.05x10 ⁻⁵
p-type Bi ₂ Te ₃	2.1x10 ⁻⁴	1.285	9.8x10 ⁻⁶
Ceramic plate	-	13.74	3.162x10 ¹³

TABLE II. VALUES OF PARAMETERS FOR ANSYS SIMULATION

Convection film coefficient	1x10 ⁻⁸ $\frac{W}{m^2 \cdot ^\circ C}$
Ambient temperature	32°C
Cold side temperature	20°C
Current	0A (ramped)
Ground voltage	0V

The working current range was then ramped from 0A to the highest allowable current in the ANSYS software.

B. Sphere packing space filling

Space filling designs are often used in computer-generated experiments due to its ability to spread design points evenly across the design space [14]. For this study, a sphere packing space filling design using JMP® statistical analysis software was used to determine the values of the variable input parameters. Sphere packing maximizes the minimum distance between pairs of design points in the experimental region. Sphere packing also favors areas near the edge of the design space, then plots points within the middle to maximize the minimum distance between points.

TABLE III. INPUT PARAMETERS OF A_C AND A_M IN SPHERE PACKING.

	A_C (mm ²)	A_M (mm ²)
Minimum	0.108	1.150
Maximum	1.000	2.560

The minimum and maximum values of the contact cross-sectional area (A_C) and the middle cross-sectional area (A_M) represents the design space used in the study. These values were used for the sphere packing model, for a total of 10 runs. The values inputted in the JMP software for sphere packing design was summarized in Table 3.

C. FUSION 360 model

FUSION 360 was used as the 3D-modelling software in the design of the thermoelectric leg segments. The dimensions of the model were based on the actual TEC-12706 thermoelectric module and were equally segmented to show a per pair measurement. Table 4 shows the measured dimensions for the segmented thermoelectric pair.

TABLE IV. DIMENSIONS OF THE SEGMENTED THERMOELECTRIC PAIR.

	Dimensions (L × W × H)
Ceramic Plate	40.1 mm × 40.02 mm × 1mm
Copper Plate (Larger)	4 mm × 1.6 mm × 1mm
Copper Plate (Smaller)	2mm × 1.6mm × 0.33mm
Leg Length	1.7mm

D. ANSYS thermal-electric analysis

The modelled thermoelectric leg segments from FUSION 360 were exported to ANSYS for thermal-electric analysis. Similarly, the material properties and simulation parameters in Tables 1 and 2 were used in the simulation. Each thermoelectric leg was tested separately, where the hot side and cold side temperatures across the working current were used for the computation of the COP.

E. COP calculation

The COP of the segmented thermoelectric device is derived from its cooling load, Q_c , and the electrical power required, P , which was determined by using the COP equation 1:

$$COP = \frac{Q_c}{P} = \frac{(\alpha_p - \alpha_n)T_c I - 0.5I^2(R_p + R_n) - (K_p + K_n)(T_h - T_c)}{(\alpha_p - \alpha_n)I(T_h - T_c) + I^2(R_p + R_n)} \quad (1)$$

where, α is the Seebeck coefficient (α_p for p-type, α_n for n-type), T is the temperature of the thermoelectric pair (T_c for cold-side temperature, T_h for hot-side temperature), R is the resistivity of the material (R_p for p-type, R_n for n-type), and K is the conductance of the material (K_p for p-type, K_n for n-type).

The resistivity was computed using the equation 2:

$$R = \rho \frac{L}{A_{ave}} \quad (2)$$

and the conductance was computed using the equation 3:

$$K = \sigma \frac{A_{ave}}{L} \quad (3)$$

The COP for the TEC-12706 was determined through equation 4.

$$COP_{TEC12706} = \frac{ZT_c^2(T_h - T_c)}{ZT_h T_c} \quad (4)$$

Z in equation 4 can be found using equation 5.

$$Z = \frac{(\alpha_p - \alpha_n)^2}{\{(K_p + K_n)(R_p + R_n)\}} \quad (5)$$

COP formulas used in the study were gathered from [1].

F. Statistical Analysis

JMP® statistical analysis software was used for the data analysis of the study. JMP is a statistical tool used to analyze data tables in design of experiments (DOE). A specialized model through Gaussian process modelling was performed to model the results and was used for optimization.

1) Model validation

An actual by predicted plot was used for regression analysis to determine the fit of the modelled data. The actual by predicted plot shows the data points of the actual response COP in the x-axis to the jackknife predicted values of the y-axis. Points lying closer to the 45° regression line indicate better fit model.

2) Gaussian process modelling

Gaussian process models are commonly used to model the response of computer-generated experiments [14]. Moreover, the Gaussian process is a simple and effective method to observe the behavior of different parameters while effectively measure the prediction uncertainty of the model [15].

The highest COP for each run was used to model the results through the Gaussian process model. A marginal model plot was generated to visualize the relationship of each factor to the response. Each factor has a marginal model plot that visualizes the predicted values [16][17]. Furthermore, a model report table that describes the main effect and interaction between each variable was generated. Lastly, a surface plot for the relationship of the response COP to the changes in A_C and A_M was generated.

3) Desirability factor

The optimal cross-sectional areas A_C and A_M that yield the maximum COP were determined by maximizing the desirability function of the response COP in the prediction profiler of the JMP software. Desirability is the estimated response value that lies between 0 to 1, where values closer to one indicate the optimal performance of factors within the design space [18].

4) COP comparison

The determined COP through the desirability function was compared to the COP of the TEC-12706 simulated model. The leg geometry parameters A_C and A_M were also compared to each other.

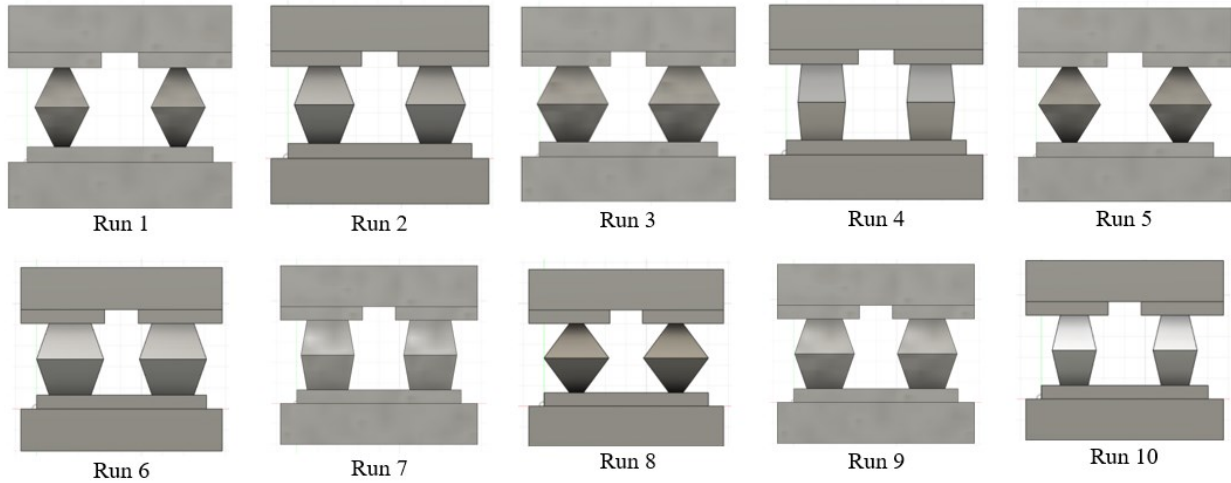

Fig. 3. Leg geometry designs of the 10 sphere packing runs.

Fig. 4. Sphere packing space filling A_C vs A_M bubble plot.

7	1.000	1.683
8	0.117	2.560
9	0.747	2.121
10	0.458	1.150

Data gathered from the sphere packing design was summarized in Table 5. Figure 3 shows the visualization of the data points across the design space generated from the sphere packing design. As mentioned in section 2.2, sphere packing favors values lying at the edges of the design space before plotting points at the middle.

III. RESULTS AND DISCUSSION

A. Sphere packing runs

TABLE V. A_C AND A_M VALUES FROM SPHERE PACKING.

	A_C (mm ²)	A_M (mm ²)
1	0.108	1.370
2	0.456	1.744
3	0.493	2.560
4	0.834	1.150
5	0.108	1.966
6	1.000	2.560

B. Current range

TABLE VI. DETERMINATION OF ALLOWABLE CURRENT RANGE.

Current (A)	Highest Temperature (°C)	Valid or Invalid
0	20	VALID
0.1	45.778	VALID
0.2	78.93	VALID
0.3	121.67	VALID
0.4	177.05	VALID
0.5	250.17	VALID
0.6	348.83	INVALID

Initial tests performed on the modelled thermoelectric leg using the minimum and maximum A_C and A_M values showed that the operating temperature reached 250.17°C when the current was set at 0.5A. Therefore, the researchers used 0.5A

as the maximum operating current during the runs since the operating temperature was still within 250 to 300°C range.

C. FUSION 360 models

The values of A_c and A_m in the sphere packing runs and the measured dimensions from the TEC-12706 module were used in modelling the segmented thermoelectric pairs. Using FUSION 360, the segmented thermoelectric pairs were modelled using the loft feature to create a loft between the contact cross-sectional area and the middle cross-sectional area. A total of 10 models were produced in the software and was exported in IGES format to enable cross-software compatibility between FUSION 360 and ANSYS. The models are shown in Figure 4.

D. Temperature profile

The corresponding temperature profiles for each run during ANSYS thermal-electric analysis are shown in Figure 5. The hot side and cold side temperatures across the current range were collected to determine the COP for each current increment per run.

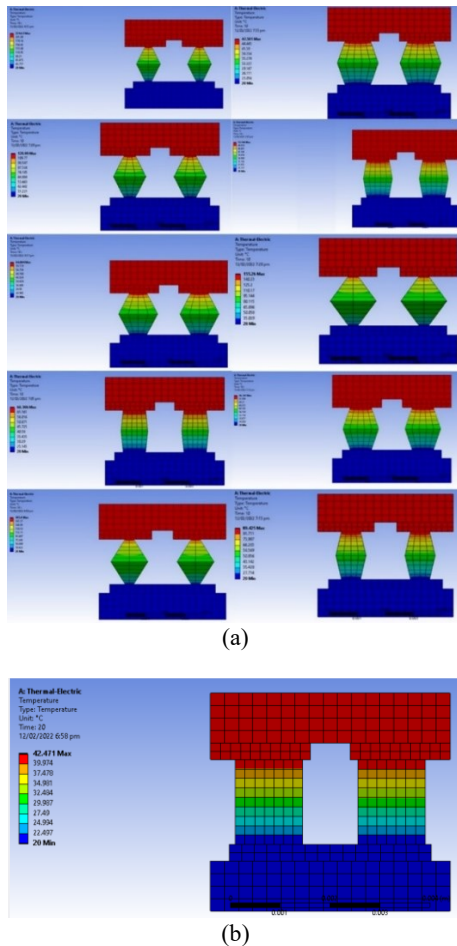

Fig. 5. Temperature profile of the leg geometry designs from ANSYS thermal-electric analysis (a) sphere packing runs (b) TEC-12706.

E. Determination of highest COP

TABLE VII. HIGHEST COP VALUES PER RUN.

Runs	Ac (mm ²)	Am (mm ²)	COP
TEC-12706	1.823	1.823	0.486
1	0.108	1.370	-2.244
2	0.456	1.744	-1.254
3	0.493	2.560	-1.911
4	0.834	1.150	0.037
5	0.108	1.966	-3.313
6	1.000	2.560	-1.028
7	1.000	1.683	0.466
8	0.117	2.560	-4.366
9	0.747	2.121	-1.070
10	0.458	1.150	-0.465

The highest COP for each run is listed in Table 7. Negative COP for runs 1, 2, 3, 5, 6, 8, 9, and 10 indicated that Peltier cooling did not overcome both heat conduction and Joule heating when current was induced in the device. Peltier cooling of thermoelectric coolers should overcome these heating mechanisms to produce a cooling effect [1]. Meanwhile, runs 4 and 7 overcame both heat conduction and Joule heating, which led to positive COP values of 0.037 and 0.466, respectively. It was observed that the positive COP from the runs was lower than the COP of TEC-12706.

F. Gaussian process model

1) Actual by predicted plot

Regression analysis using the actual by predicted plot of COP shows that the COP values were close to the regressed diagonal line, which means that the predicted COP values were close to the actual COP values. Figure 6 shows that data is scattered almost symmetrically above and below the 45° line. Therefore, the predicted values generated by the Gaussian process model were not underestimating or overestimating.

Fig. 6. Actual COP by COP Jackknife Predicted.

2) Gaussian process model report

Figure 7 presented that the COP increases as A_C increases. The relationship was seen to exhibit an increasing periodic function. Meanwhile, COP decreases as A_M increases. This relationship between A_M and the COP was observed to be linear.

The main effect is the integrated total variation by the individual factor to the response, which is computed by the ratio of the functional effect and the total variation. Similarly, the functional interaction effects describe the effects of the factors on the response. Lastly, the total sensitivity measures the influence of each factor and its two-way interaction on the response variable [19].

TABLE VIII. MODEL REPORT FROM THE GAUSSIAN PROCESS MODEL.

Column	Theta	Total Sensitivity	Main Effect	Ac Interaction	Am Interaction
Ac	1.098	0.742	0.720	-	0.0212
Am	0.191	0.280	0.258	0.0212	-
μ	σ^2	$-2*\text{LogLikelihood}$			
-1.568	3.076	24.544			

From the model report in Table 8, A_C showed a higher main effect value of 0.720 compared to A_M at 0.258. This means that A_C has a larger effect compared to A_M in the behavior of the response COP. Meanwhile, A_C and A_M interactions had a value of 0.0212. This value describes the changes of the response COP to the effect of A_M depending on A_C , and vice versa. Lastly, the total sensitivity of A_C and A_M variable were 0.742 and 0.280, respectively. The $-2*\text{LogLikelihood}$ is the negative of the log-likelihood function. The log-likelihood describes the deviance of the model. A higher log-likelihood indicates better parameter estimate. In contrast, smaller $-2LL$ values indicate better model fits. This value is usually used to compare different models to determine the better fit model [20]. Since the study did not compare two different models, the $-2LL$ was not used for data interpretation. However, the $-2LL$ may serve for future model comparisons.

Meanwhile, the Gaussian process surface plot in Figure 8 shows that the COP was influenced by the change in A_C and A_M . It was observed that as the value of A_C increases, the value of the COP increases. Inversely, as A_M increases, the COP decreases. The Gaussian process modelled surface plot for both factors can be seen in the figure, which represents the combined influence of A_C and A_M to the COP.

(a)

(b)

Fig. 7. Marginal model plot of COP with respect to (a) A_C and (b) A_M .

3) Prediction profiler

Figure 9 shows the prediction profiler generated through JMP software. The maximized COP within the experimental design space was determined to be 0.881, with a desirability of 0.996. The COP was achieved when the cross-sectional areas lie on the edges of the design space, where A_C was at maximum with a value of 1.000mm², and A_M was at minimum, with a value of 1.150mm².

TABLE IX. VALUES OF A_C , A_M , AND COP WITH THE HIGHEST DESIRABILITY FUNCTION

Desirability	A_C (mm ²)	A_M (mm ²)	COP
0.996	1.000	1.150	0.881

A desirability value close to 1 was expected due to only having one response variable in the study. Furthermore, the behavior of the factors to the response as presented in Figures 7 and 8 explain why the maximum A_C and the minimum A_M were the critical points of the COP response. Figure 7 shows that A_C and A_M have opposite effects to the COP, where the COP increases in relation to an increase in A_C and a decrease in A_M .

Fig. 8. Gaussian process surface plot of the COP in response to A_C and A_M (a) A_C and COP Predicted (b) A_M and COP Predicted (c) A_C , A_M , and COP.

Fig. 9. Prediction profiler of the response COP.

4) COP comparison

TABLE X. COMPARISON OF RESULTS FOR MAXIMUM COP.

Parameter	Optimized Model	TEC-12706
A_C (mm ²)	1.000	1.823
A_M (mm ²)	1.150	1.823
COP	0.881	0.486

The optimized leg geometry from the Gaussian process model has a higher COP than the TEC-12706. Table 10 summarizes the COP and cross-sectional areas of each model. The design parameter A_C was set to be lower than that of the TEC-12706 model to achieve a truncated square leg geometry, which explains the lower value of this cross-sectional area compared to that of the baseline model.

IV. CONCLUSION

In this study, the research was able to optimize the leg geometry of the semiconductor thermoelectric cooler A_C and A_M through Gaussian process modelling. Results from the experiment showed that through the Gaussian process model, the COP of the optimized TEC was greater than the

conventional TEC-12706. During the study, it was determined that the allowable working current for the established design space was 0 to 0.5A. Through the Gaussian model, the researchers were able to determine the relationship of the middle and contact cross-sectional areas to the COP. The Gaussian model showed that A_C had a greater effect to the COP than A_M .

Moreover, the optimal cross-sectional areas for A_C and A_M were within the edges of the design space, with A_C equal to the maximum contact cross-sectional area and A_M equal to the minimum middle cross-sectional area. Following this study, future research could investigate different values of the contact and middle cross-sectional areas of the TEC leg. The behavior of the COP in response to the changes in these cross-sectional areas indicates that decreasing the middle area may result in higher COP values. Thus, it is recommended that future research investigate the effects of the leg geometry with a large middle cross-sectional area than the contact area. Moreover, optimizing other properties of the thermoelectric cooler such as the Seebeck coefficient, thermal conductivity, and electrical resistivity using the Gaussian process model could also be investigated. Lastly, fabricating an actual model with the optimized dimensions and running physical experiments utilizing statistical design of experiment (DOE) principles could be performed to validate the results of this study.

A Sliding Mode based Finite-Time Consensus Protocol for Heterogeneous Multi Agent UAS

Madhumita Pal

Institute of Engineering & Management
madhumita.pal@iemcal.com

Abstract—This paper presents a finite-time consensus for a connected network of heterogeneous unmanned aerial vehicles subjected to wind disturbances. A sliding mode control and graph algebraic theory based strategy is developed for consensus while independent tracking controller ensures robust trajectory following of an agent. Stability of the agents are decoupled from distributed consensus algorithm. Finite time convergence of the measurement vectors of heterogeneous agents to the agreement value are proved. Comparison results with the recent work show the superior performance of the proposed algorithm.

Index Terms—Consensus, sliding mode control, heterogeneous, multi agent systems

I. INTRODUCTION

Various distributed consensus protocols for multi-agent systems have proved to be useful in many applications scenarios, such as formation control of ground and aerial vehicles, consensus control of quad rotors for payload transportation, etc[1].

A typical consensus problem demands some or all of the states of the cooperating agents, which can be considered as general dynamical systems, reach to a common agreement based on their local information exchange. Such information exchange between these agents can be represented using a directed or an un-directed graph and various graph theoretic methods [2], [3], have been used to treat the consensus problem. Traditional control theory knowledge such as the Lyapunov direct method [4] [5], or the frequency domain analysis method [6], [7], etc, have also been used to solve the consensus problems of MASs. For the first-order, second-order, and high-order MASs, a lot of consensus protocols have been proposed. However, these algorithms are mostly proposed for homogeneous multi-agent systems and in particular systems having simple and double integrator dynamics, see [8]; [9]. However, in practical scenarios, the dynamics of various MASs are far from such conservative assumptions.

The consensus problems of the heterogeneous MASs which consist of agents with different dynamical properties have not been studied enough in past. This paper considers finite time consensus for heterogeneous multi-agent systems. Only a few papers consider heterogeneous cases of consensus problem. In particular, among many [10], [11] solved

the output consensus problem with a non-linear approach. Recently, [12] consider output consensus for heterogeneous multi-agent systems with linear dynamics. In other works, [13], [14] the problem of heterogeneous consensus is addressed where agents are considered as linear dynamical systems. Consensus for heterogeneous multi-agent systems composed of simple and double integrator are presented in [13] while [15] focused into a formation control problem. However, most consensus algorithms based on this technique assure consensus amongst the agents only asymptotically.

In most literature, consensus for MASs are achieved asymptotically. However, it is usually necessary to reach consensus in a finite time. The systems in such cases, show better disturbance rejection properties under a finite-time control. In recent years, focus is on obtaining the state consensus in homogeneous networks, that is, networks with identical agent dynamics. Many results of homogeneous finite-time consensus based on sliding mode are reported in the literature [16], [17], [18], [19]. The major advantage of sliding mode control is in its robustness against matched uncertainties, that is, when uncertainties are manifested through the input channel.

Because the dynamics of many mechanical systems can be modeled as double integrator, the MAS with double-integrator dynamics have gained great attention in recent years [16], [17]. Recently, MAS with general high-dimensional linear dynamics have attracted much attention of researchers in the control field [20], [21]. However, designing consensus algorithms using sliding mode for higher order MAS remains challenging.

This article proposes a sliding mode based control strategy for consensus on measurement variable of heterogeneous agents. The heterogeneous agents outputs are directed to follow reference trajectories generated by same number of ideal agents based on the idea of model reference control protocol. Ideal agents have simple first order dynamics and are connected with same directed graph as the original agents are. Reference trajectories are designed based on sliding mode based finite time consensus protocol. A finite time sliding mode based model reference tracking control is then designed for the practical heterogeneous agents to meet the

reference trajectories. The stability of the close loop for each agent is assured and decoupled from the outer loop sliding mode based tracking controller.

II. PROBLEM STATEMENT

In this section, we are going to study finite time consensus algorithms for a set of heterogeneous linear systems. Consensus control for heterogeneous agents with finite time convergence are not much explored in recent past. Although some results for such problem have been proposed in literature, most of them presents major drawbacks such as asymptotic convergence, computational effort, complexity or accuracy of the solution. Therefore, in this article a simple control design is proposed addressing the above drawbacks.

A. System Description

Consider the multi-agent linear systems

$$\begin{aligned} \dot{x}_i &= \bar{A}_i x_i + B_i u_i \\ y_i &= x_i \quad \forall i \in \mathcal{N} = 1, \dots, N \end{aligned} \quad (1)$$

$$z_i = C_i x_i \quad (2)$$

where $x_i \in \mathcal{R}^{n_i}$, $y_i \in \mathcal{R}^{n_i}$, $z_i \in \mathcal{R}^m$ and $u_i \in \mathcal{R}^m$ are the states, outputs, measurements and input vectors respectively. For all $i \in \mathcal{N}$, the matrices $\bar{A}_i \in \mathbb{R}^{n_i \times n_i}$, $B_i \in \mathbb{R}^{n_i \times m}$ and $C_i \in \mathbb{R}^{m \times n_i}$ with $m < \min n_i$ and $n_i > m$ are assumed to be constant and known.

The objective is to design an inner-loop controller which ensures stability for each subsystem and an outer-loop controller which achieves consensus on measurement vectors of each agent.

Assumption 1. *The N systems are considered to be heterogeneous, i.e., the matrices defining the systems may differ from one agent to another one and the vectors x_i may have different dimensions.*

Assumption 2. *The measurement vectors z_i represents the same quantity of interests for all agents. Therefore, the measurement vectors have the same dimension, $z_i \in \mathbb{R}^m \forall i \in \mathcal{N}$, where $m < \min\{n_i\}$.*

Assumption 3. *$\forall i \in \mathcal{N}$, the condition $\text{rank}(C_i B_i) = m$ holds. Therefore, the input vectors directly affects the measurement vector*

Assumption 4. *To design the controller for stability of each agent, each pair (A_i, B_i) is assumed to be controllable.*

It is natural to model information exchange between agents in a cooperative team by directed/ undirected graphs.

Assumption 5. *In this paper, it is assumed that communication graph is represented by directed spanning tree.*

Denoting for any agent $i \in \mathcal{N}$, \mathcal{N}_i as the subset of \mathcal{N} including all neighbors of agent i , i.e., all nodes that agent

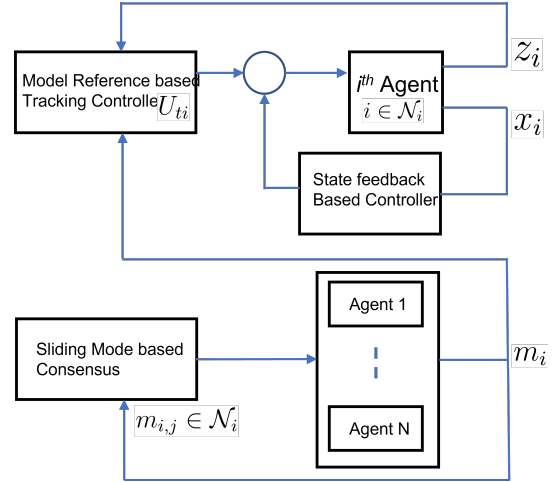

Fig. 1: Control Architecture

i can communicate. For the graph \mathcal{G} with N vertices and an edge set given by $E = \{(i, j) : j \in \mathcal{N}_i\}$ the adjacency matrix $A(\mathcal{G}) = (a_{ij})$ is a $N \times N$ matrix given by $a_{ij} = 1$, if $(i, j) \in E$ and $a_{ij} = 0$, otherwise. If there is an edge joining vertices i, j , i.e., $(i, j) \in E$, then i, j are adjacent. The degree d_i of a vertex i is defined as the number of its neighboring vertices, i.e., $d_i = \#j : (i, j) \in E$. Denote also $d_{max} = \max d_i$. Let Δ be the $N \times N$ diagonal matrix of d_i 's. The Laplacian of \mathcal{G} is the matrix $L(\mathcal{G}) = \Delta - A$.

III. CONTROLLER ARCHITECTURE

In order to achieve finite time consensus for MASs, a controller composing two parts, one for local stability and other for tracking an ideal trajectory leading to consensus is proposed, as shown in Fig.1 . Therefore, the control law for each agent is represented by

$$u_i(t) = u_{s_i}(t) + u_{t_i}(t), \quad i \in \mathcal{N} \quad (3)$$

where u_{s_i} is the local controller to assure stability for each agent and u_{t_i} is the tracking controller leading to consensus.

The ideal trajectory is generated by sliding mode based consensus algorithm. The tracking controller for each agent is also designed based on sliding mode. In the following subsections, methods are described for the design of stability and tracking controller.

A. Stability Design

According to the Assumption 4, for each agent, there exists a local state feedback Hurwitz controller assuring stability of each system.

$$u_{s_i} = -K_i x_i \quad (4)$$

This ensures that the matrix A_i is Hurwitz which is represented as $A_i = \bar{A}_i - B_i K_i$. Therefore, the system dynamics

in (1) can be represented in closed loop form as:

$$\begin{aligned} \dot{x}_i &= Ax_i + B_i u_i \\ y_i &= x_i \quad \forall i \in \mathcal{N} = 1, \dots, N \end{aligned} \quad (5)$$

$$z_i = C_i x_i \quad (6)$$

The objective is to design a finite time consensus algorithm which guarantees that the measurement vectors z_i s reach an agreement. In the literature, classical distributed consensus algorithms have been intensively studied. Inherently, their stability and performance properties are well documented see, for instance, [9], [22], etc.

B. Distributed Consensus Algorithm

A closed loop Model-Reference-Tracking-Controller which tries to compare the measurement output z_i of an agent with an ideal reference trajectory for consensus is proposed. The reference trajectories are generated by introducing N -number of simple first order homogeneous agents. First a sliding mode based finite time consensus controller is designed for these N simple agents. Then these N ideal trajectories are followed by N -number of heterogeneous agents with sliding mode based finite time tracking controller. Therefore, in this paper SMC and graph theories are used for the development of consensus algorithms for a group of heterogeneous agents connected with fully connected graph.

1) *Reference Trajectory Generation:* To generate reference trajectories N -number of m th order (same as the measurement variable order of the heterogeneous agents) agents are considered as follows:

$$\dot{m}_i = v_i \quad i = 1, \dots, N \quad (7)$$

where $m_i \in \mathcal{R}^m$ represent the agent's state and $v_i \in \mathcal{R}^m$ is its input. The agents are said to reach consensus when

$$m_i = m_j, \quad i, j = 1, \dots, N \quad (8)$$

The agents are assumed to constitute directed and connected communication graph same as heterogeneous agents. The inputs v_i are designed based on SMC to satisfy the consensus condition. Therefore, switching surfaces are designed so that if the sliding mode occurs then the consensus condition (8) holds.

2) *Preliminaries:* In this section, a few basic results of SMC and algebraic graph theories pertinent to the consensus problem will be discussed.

Sliding Modes: Consider the design of an SM controller for the system of the form

$$\dot{x} = f(x) + b(x)u, \quad x \in \mathcal{R}^n, u \in \mathcal{R}^m \quad (9)$$

The state $x \rightarrow 0$ involves the selection of switching functions $s(x) \in \mathcal{R}^m$ and controls u acting discontinuously on $s(x)$

in the form

$$u_i = \begin{cases} u_i^+ & \text{if } s_i(x) > 0, \\ u_i^- & \text{if } s_i(x) < 0 \end{cases} \quad \forall i = 1, \dots, m \quad (10)$$

With the appropriate choice of control magnitudes, the states of the system reach $s(x)$ in finite time and then continue to remain on it. The system motion on the surface $s(x) = 0$ is known as sliding mode and is of reduced order (by m). Details can be found in [23]. For 1st order system $\dot{s} = u$,

Fig. 2: Fully Connected Directed Graph

the discontinuous controller $u = -M \text{sign}(s)$, $M > 0$ will enforce sliding mode on the surface $s = 0$ at the time instant

$$T_s \leq \frac{s_0}{M}, \quad s_0 = s(t = 0). \quad (11)$$

This is used to tune the consensus time. Sliding mode consensus algorithm assume occurrence of ideal sliding mode on the surface $s(t)$ after a finite-time interval T_s , so that $s(t \geq T_s) = 0$.

Algebraic Graph: It is natural to model information exchange between agents in a cooperative team by directed/undirected graphs (e.g. [24]). A digraph (directed graph) consists of a pair (\mathcal{N}, E) , where \mathcal{N} is a finite nonempty set of nodes and $E \in \mathcal{N}^2$ is a set of ordered pairs of nodes, called edges. A directed path is a sequence of ordered edges of the form $(v_{i1}, v_{i2}), (v_{i2}, v_{i3}), \dots$, where $v_{ij} \in \mathcal{N}$, in a digraph. An undirected path in an undirected graph is defined analogously, where (v_{ij}, v_{ik}) implies (v_{ik}, v_{ij}) . A digraph is called strongly connected if there is a directed path from every node to every other node. An undirected graph is called connected if there is a path between any distinct pair of nodes. For a directed algebraic graph \mathcal{G} with N vertices and an edge set given by $E = \{(i, j) : j \in \mathcal{N}_i\}$, the following matrices can be formulated: the $N \times N$ adjacency matrix $\mathcal{A}(\mathcal{G}) = [a_{ij}]$ with $a_{ij} = 1$, if $(i, j) \in E$ and $a_{ij} = 0$, otherwise. Therefore, if there is an edge connecting two vertices i, j , i.e. $(i, j) \in E$, then i, j are called *adjacent*. The *degree* d_i of vertex i is defined as the number of its neighboring vertices, i.e., $d_i = \#j : (i, j) \in E$. Define $d_{max} = \max\{d_i\}$. The $n \times n$ diagonal degree matrix $\Delta(\mathcal{G}) = \text{diag}\{d_i\}$ and the Laplacian matrix $L(\mathcal{G}) = \Delta(\mathcal{G}) - \mathcal{A}(\mathcal{G})$. As example, the Laplacian

matrix for the agents connected as in Fig. 2 is

$$L = \begin{bmatrix} 1 & -1 & 0 & 0 \\ 0 & 1 & -1 & 0 \\ 0 & 0 & 1 & -1 \\ -1 & 0 & 0 & 1 \end{bmatrix} \quad (12)$$

As the Laplacian matrix is at the core of the consensus algorithms, one of its important property is highlighted here. An $N \times N$ Laplacian matrix is positive semi-definite with rank $(N - 1)$. Its single zero eigenvalue corresponds to a right eigenvector made up of identical elements—it is this property that is used to provide consensus. For instance, if there exists a vector of non-zero elements $m = [m_1 \dots m_n]^T$ that satisfies the system of algebraic equations

$$L(G)\mathbf{m} = \mathbf{0} \quad (13)$$

then $m_i = m_j \forall i, j = 1 \dots N$. In fact, if the inputs v_i are selected to yield the closed-loop dynamics for the system in (7) as

$$\dot{\mathbf{m}} = -L\mathcal{G}\mathbf{m} \quad (14)$$

then the agents reach a consensus with value found in [8], [25]

$$m_c = \frac{1}{N} \sum_{i=1}^N m_{i0}, \quad m_{i0} = m_i(t=0). \quad (15)$$

This well-known algorithm, however, ensures consensus only asymptotically.

These relations gives clue at the role of sliding mode control: if the inputs v_i are chosen to enforce sliding mode on $s = L(G)\mathbf{m} = 0$, then the agents reach a consensus. Below we states a theorem [26]

Theorem 1 ([26]). *Considering N - fully connected agents with at least 2 agents and the following properties: 1) The dynamics of each agent is given by $\dot{m}_i = v_i$; and 2) Its graph, G , generates the $N \times N$ Laplacian matrix $L(G)$ If the inputs $\mathbf{v} = [v_1 \dots v_N]^T$ are selected to be discontinuous, component-wise, on the surfaces*

$$\mathbf{s} = [s_1 \dots s_N]^T = L(G)[m_1 \dots m_N]^T,$$

in the form $v_i = -M \text{sign}(s_i)$, $M \geq 0$, so that sliding mode occurs on each s_i , then the agents reach a consensus within a finite time interval. Moreover, the consensus value attained by the agents is a constant.

Theorem 2 ([26]). *Consider N agents having same properties as those mentioned in Theorem 1. In addition, if there are agents m_p and m_q whose initial states $m_{p,q0}$ satisfy*

$$m_{p0} \geq 0, m_{p0} \geq m_{k0} \geq m_{q0}, \quad k = 1 \dots N, \quad k \neq p, q,$$

than, once sliding mode occurs on $\mathbf{s} = 0$ owing to the discontinuous inputs, the agents reach a consensus value $m_c = (m_{p0} + m_{q0})/2$ at the time instant $T_c = (m_{p0} -$

$m_{q0})/2M$.

The rest of the contribution consists in using this well known sliding mode based consensus algorithm to reach an agreement on those reference dynamics, while applying a sliding mode based model tracking controller to the original heterogeneous system. Thus, reference trajectory is generated in order to achieve

$$(m_i - m_j) = 0 \quad \forall i, j \in \mathcal{N}^2 \quad \text{in finite time} \quad (16)$$

In other words, system (7) or (14) can then be seen as a reference model for the system in (1).

3) *Model Reference Tracking Controller:* The objective of the tracking controller is fulfilled by defining

$$(m_i - z_i) = 0 \quad \forall i, j \in \mathcal{N}^2 \quad \text{in finite time} \quad (17)$$

The above objective is achieved in finite time by sliding mode based tracking controller. This ensures that the real MASs will have identical performances as the reference model. To meet the objective in (17), we define the sliding surface by

$$s_i = z_i - m_i, \quad \forall i \quad (18)$$

To ensure that sliding mode occurs on each $s_i = 0$ in finite time, the dynamics of s_i has the following form

$$\dot{s}_i = -\beta \text{sign}(s_i), \quad \beta \geq 0 \quad (19)$$

Thus, it follows:

$$\dot{z}_i - \dot{m}_i = -\beta \text{sign}(z_i - m_i) \quad (20)$$

$$C_i(A_i x_i + B_i u_{ti}) + L(G)_i \mathbf{m} = -\beta \text{sign}(z_i - m_i) \quad (21)$$

Due to the Assumption 3, $(C_i B_i)$ is invertible for all agent i , and thus the reference tracking controller is defined by

$$u_{ti} = (C_i B_i)^{-1}(\dot{m}_i - \beta \text{sign}(z_i - m_i) - C_i A_i x_i) \quad (22)$$

Therefore, the design of tracking controller is independent of the consensus algorithm applied to ideal homogeneous agents generating reference trajectories. In other words, control strategy for heterogeneous agents is decoupled from consensus algorithm.

IV. CONVERGENCE ANALYSIS

The following theorem states our main result:

Theorem 3. *If Assumptions 1-5 are satisfied, then the control law (3) given by*

$$u_i = -K_i x_i + (C_i B_i)^{-1}(\dot{m}_i - \beta \text{sign}(z_i - m_i) - C_i A_i x_i) \quad (23)$$

where \dot{m}_i is given by (7), guarantees that the closed loop system of (1) is stable and reaches consensus on measurement variable in finite time.

Proof. According to Assumption 3, there exist a change in coordinates [27], in the form

$$P_i x_i = \begin{bmatrix} \chi_i \\ z_i \end{bmatrix}$$

such that system in (5) can be decomposed in the form as

$$\begin{bmatrix} \dot{\chi}_i \\ \dot{z}_i \end{bmatrix} = \begin{bmatrix} A_{11i} & A_{12i} \\ A_{21i} & A_{22i} \end{bmatrix} \begin{bmatrix} \chi_i \\ z_i \end{bmatrix} + \begin{bmatrix} 0 \\ B_{2i} \end{bmatrix} u_{ti} \quad (24)$$

where $\chi_i \in \mathcal{R}^{n_i-m}$ and

$$P_i A_i P_i^{-1} = \begin{bmatrix} A_{11i} & A_{12i} \\ A_{21i} & A_{22i} \end{bmatrix}$$

In the above representation, $A_{11i} \in \mathcal{R}^{(n_i-m) \times (n_i-m)}$ is Hurwitz, $B_{2i} \in \mathcal{R}^{m \times m}$ is full rank and invertible and satisfies $T_i B_i = [0 \ B_{2i}^T]^T$. [27] proposed a method to construct the matrix P_i for changing coordinates of a system. This type of representation is called canonical representation of a system. The system is now represented in an appropriate manner with respect to the problem of measurement variable consensus. Applying the canonical transformation to the system, the control law in (23) can be rewritten as:

$$u_i = -K_i x_i + B_{2i}^{-1} [\dot{m}_i - \beta \text{sign}(z_i - m_i) - [0 \ I_m] P_i A_i x_i] \quad (25)$$

With the above control law (25) each closed loop system in (1) becomes:

$$\dot{x}_i = (\bar{A}_i - B_i K_i) x_i + B_i (B_{2i})^{-1} [\dot{m}_i - \beta \text{sign}(z_i - m_i) - [0 \ I_m] P_i A_i x_i]$$

Recalling that $s_i = z_i - m_i$, one has

$$\begin{bmatrix} \dot{\chi}_i \\ \dot{s}_i \end{bmatrix} = \begin{bmatrix} A_{11i} & A_{12i} \\ 0 & -\beta \frac{I_m}{|s_i|} \end{bmatrix} \begin{bmatrix} \chi_i \\ s_i \end{bmatrix} + \begin{bmatrix} A_{12i} m_i \\ 0 \end{bmatrix} \quad (26)$$

The variable \mathbf{m} is obtained by solving a sliding mode based consensus problem $\dot{\mathbf{m}} = -\beta L(\mathcal{G}) \text{sign}(\mathbf{m})$ which guarantees consensus in finite time interval. Moreover the consensus value attained by the first order homogeneous agents is a constant [26]. Consequently, $(m_i - m_j) = 0 \ \forall i, j \in \mathcal{N}^2$ is achieved in finite time. Finally, according to the separation principle, conclusion on the stability of the multi-agent system in (26) for all $i \in \mathcal{N}$ can be made. Thus, for all $i \in \mathcal{N}$, $m_i - z_i = 0$ is achieved in finite time [23]. \square

Remark 1. Note that, control strategy for heterogeneous agents is decoupled from consensus algorithm. In other words, analysis of each agent is separated from the analysis of distributed consensus algorithm. It has been shown that (1) will achieve consensus on measurement variables z where the final value of z_i depends on the initial conditions of the consensus variables m_i . Thus, no matter what the initial state of the system is, (1) will always achieve consensus on the agreement value of m (see for instance Figure 5).

V. SIMULATION RESULTS

In this section, simulation results regarding the efficiency of the approach introduced in the previous sections is presented. Therefore, consider a set of $N = 4$ heterogeneous Unmanned aerial systems as considered in recent paper [28]. The matrices \bar{A}_i , B_i and C_i in equation (1) for the MAS are considered as

$$\begin{aligned} \bar{A}_1 &= \begin{bmatrix} -1 & 0.5 \\ 0.05 & -1 \end{bmatrix}; & B_1 &= \begin{bmatrix} 0 \\ 1 \end{bmatrix}; & C_1 &= \begin{bmatrix} 0 \\ 1 \end{bmatrix}^T \\ \bar{A}_2 &= \begin{bmatrix} -2 & 1 \\ 0 & -0.9 \end{bmatrix}; & B_2 &= \begin{bmatrix} -1 \\ -1 \end{bmatrix}; & C_2 &= \begin{bmatrix} 0 \\ 1 \end{bmatrix}^T \\ \bar{A}_3 &= \begin{bmatrix} 0 & 1 & 1 \\ -2 & 0.1 & 2 \\ 1 & 2 & 3 \end{bmatrix}; & B_3 &= \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix}; & C_3 &= \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}^T \\ \bar{A}_4 &= \begin{bmatrix} 0 & 1 & 1 & 0 \\ -2 & 0.1 & 2 & 2 \\ 0 & 1 & 2 & 3 \\ 0.2 & 0.4 & 0.1 & 0.3 \end{bmatrix}; & B_4 &= \begin{bmatrix} 1 \\ 0 \\ 1 \\ 1 \end{bmatrix}; & C_4 &= \begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \end{bmatrix}^T \end{aligned}$$

Clearly the considered agents are heterogeneous as they have different dimensions and stability properties. Also, the Assumptions considered in Section II are all fulfilled for all the systems. Therefore, a pole placement controller gain K_i 's can be found such that $A_i = \bar{A}_i - B_i K_i$ are Hurwitz for all agents.

The above considered four agents are connected through a graph expressed by the following Laplacian matrix satisfying

$$\text{Assumption 5, } L = \begin{bmatrix} 1 & -1 & 0 & 0 \\ 0 & 1 & -1 & 0 \\ 0 & 0 & 1 & -1 \\ -1 & 0 & 0 & 1 \end{bmatrix}.$$

The unmanned aerial agents achieve a consensus on the common height by applying a control strategy described in Section III. To generate ideal reference trajectory, four first order homogeneous agents are considered. They meet consensus in finite time by applying sliding mode control as detailed in Section III-B1. Heterogeneous agents track the reference trajectory in finite time by applying the control as derived in (22). Simulation results are shown on the effect of identical and non-identical initial conditions between the ideal and practical agents.

Figure 3 compares asymptotic approach and sliding mode based approach for achieving altitude consensus for the ideal agents. The initial conditions for the agents m_i s are considered same as $z_i(0)$ s. $m_1(0) = z_1(0) = 10$, $m_2(0) = z_2(0) = 20.6$, $m_3(0) = z_3(0) = -3$, $m_4(0) = z_4(0) = 14$. Thus, consensus is achieved on the average value of $m_i(0)$ s according to (15). These trajectories will be considered as the reference trajectories for the practical heterogeneous agents to follow. Clearly in Figure 4, SM based consensus approach reaches agreement value in finite time compared

Fig. 3: Evolution of the variable m_i 's without and with sliding mode approach

Fig. 4: Evolution of the variable m_i 's and measurement z_i 's when $m_i(0) = z_i(0)$

to the asymptotic approach adopted in [28]. In Figure 4, the measurement variables z_i s in MASs (1) accurately follow the final consensus value achieved by MASs in (7), where initial condition on both the variables z_i s and m_i s are considered same. Thus, system (1) achieves consensus converging to the agreement value of the ideal agents m_c . Figure 4 and 5 show a comparison results among SM based and Asymptotic based approach on how the practical agents track the reference trajectories in the case when the practical agents have identical and non-identical initial conditions. In 5, $m_i(0)$ s are considered as $m_1(0) = 30$, $m_2(0) = 25$, $m_3(0) = -2$, and $m_4(0) = -13$ which are different than $z_i(0)$ s.

Figure 6 shows how the asymptotic based approach adopted in [28] failed to meet consensus on the measurement variables z_i s in presence of matched disturbances. Whereas with the SM based approach, z_i s successfully track the final agreement value m_c in presence of disturbances. Disturbance applied through the input channel of heterogeneous agents is given in Figure 7.

VI. CONCLUSIONS

In this paper, an approach for heterogeneous multi-agent systems to reach measurement variable consensus in finite-time has been presented. The main advantage with this approach remains in the separation of the stability of each

Fig. 5: Evolution of the variable m_i 's and measurement z_i 's when $m_i(0) \neq z_i(0)$

Fig. 6: Evolution of the variable m_i 's and measurement z_i 's when $m_i(0) \neq z_i(0)$ in presence of disturbances

agent and the distributed consensus algorithm. Sliding mode based distributed consensus algorithm for simple integrator dynamics is used in order to derive an appropriate tracking control law for a MASs composed of non-identical heterogeneous agents. Both the distributed consensus control for first order agents and tracking control for heterogeneous MASs are designed based on sliding mode approach. It is shown that the performance of both the algorithms improves in terms of convergence time w.r.t the literature.

Abstract—The purpose of this work is to develop a method for classifying hand signals and using the prediction output in a drone control algorithm. To achieve this, methods based on Convolutional Neural Networks (CNNs) were applied. The hand signals chosen were the numerical hand signs for one through five for two-dimensional movement with a separate idle signal, and a fist for land. A script was created to automate one minute of training image capture for each class. Transfer learning with PyTorch (Python) was performed using a pre-trained 18-layer residual learning network (ResNet-18). The training process completed in three minutes and 43 seconds with five epochs and a final overall validation accuracy of over 99%. Implemented with the drone control, the classification performed as desired at approximately 60 predictions per second on desktop and 20 predictions per second on a Nvidia Jetson Nano.

Index Terms—Convolutional Neural Network, Drones, Human-Machine Interaction

I. INTRODUCTION

Deep learning is a subset of artificial intelligence (AI), and computer vision (CV) can be thought of as a subset of deep learning. CV utilizes deep learning while focusing on models that can interact with and interpret digital imaging. A fundamental component of CV is the convolutional neural network (CNN). CNNs receive inputs with grid-like topologies such as digital images and are trained to perform various classifications and other AI applications using the pixel data [1]. Traditional neural networks do have the capability of receiving pixel data in the form of an array, and can be trained to perform basic classifications based on this data. However, a traditional neural network does not infer image data with the same methods as human brain. For example, a human brain can see an image of the number three and determine it is in fact the number three based on its edges which combine to

form shapes and features. A traditional neural network does not find these edges and is only observing the encoded pixel color values themselves while trying to relate and detect patterns with each pixel. This method can be successful to a degree when trained adequately, but it fails in some circumstances. Hypothetically, if the neural network were to receive a random noise image that activated the correct nodes, the network would be tricked into a false positive with complete confidence. With CNNs, the convolutional layers can extract edges, features, etc. from the image before the data is put into the network. Fig. 1 shows this basic architecture, which allows CNNs to process and train on images in a way that more closely aligns with the human brain.

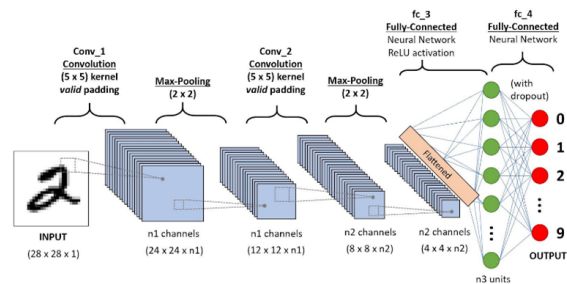

Fig. 1. Convolutional Neural Network layer diagram [2]

Consumer drones typically come with a dedicated remote controller or mobile software application that allows for multiple dimensions of movement. These controllers and the mobile devices running the control applications often require both hands to operate an assortment of joysticks and buttons. With the popularity of drones increasing within many age groups, these controls are sometimes considered too complex or even completely inaccessible to some persons with disabilities. In recent years, alternative control options that are more intuitive and accessible have been developed.

These include examples of hand gesture control utilizing CV concepts [3] [4]. Most current CV hand-based control models utilize the first-person view (FPV) camera of the drone. It is a simple and reliable method due to the camera being included on nearly every consumer drone. By using the FPV camera, the pilot is able to move with the drone and ensure its safe operation. However, this method has two primary disadvantages. The first is that with the constantly changing background of the FPV feed, more complex CV models must be utilized to isolate the pilot for effective and reliable flight control. Secondly, FPV camera CV applications require the pilot to always be in the camera view, often without a reference feed that shows the current drone FPV camera image. If the pilot mistakenly exited the frame, it would cause an unexpected idle, premature landing or potentially a collision depending on the control algorithm. More importantly, there are a significant number of people who would be unable to follow the drone due to physical limitations i.e., age and disabilities. Therefore, it becomes necessary to combine the accessibility of CV hand control with a stationary form of remote operation. With a stationary CV application, a more simplified model can be trained to the specific user given that setup time remains limited.

II. BASIC DRONE CONTROL

A. Drone Selection

This work is primarily focused on the high-level control aspect of the drone system i.e., movement commands. Therefore, emphasis was placed on having a complete pre-manufactured system with open compatibility for control methods via desktop applications. Fortunately, the Ryze Robotics Tello drone provides an inexpensive and fully developed platform with all required specifications for this and future research. Shown in Fig. 2, the Tello is a small quad-copter drone designed for indoor use. It satisfies both requirements of being a pre-built system while also having open connectivity for control through its 2.4 GHz WiFi connection. When connected, the drone is capable of sending and receiving data using set user datagram protocol (UDP) ports and sockets. The UDP ports are outlined in the Tello documentation [5].

B. Drone Control

After the drone was selected, a desktop software for controlling the drone had to be chosen. With the desktop software development kit (SDK) of the Tello, essentially all programming languages and software that can send encoded string messages using sockets and UDP ports are compatible. These include C++, MATLAB, and Python. C++ is a fast programming language capable of both controlling the drone and running AI models. However, this language contained the least amount of immediately available official documentation for the Tello,

Fig. 2. Ryze Robotics Tello drone

and is less intuitive for initial development. MATLAB offers an add-on package specifically for Tello drone control [6] and toolboxes that include many popular computer vision models. The Tello package simplifies WiFi connection and control messaging but omits useful commands such as the RC control command. This command allows a movement state to be sent to the drone that contains speed values for three dimensions of movement and a fourth value for yaw rotation speed [5]. This state command can be updated and sent with minimal delay and is therefore the best method for real-time control when compared with set time and distance movements.

This leaves Python, which was chosen for this work. It is the main language used in official documentation and example programs while providing full access to all SDK commands [5] [7]. Python also has optimized AI libraries which will allow the computer vision model and the control algorithm to run in the same script.

III. CNN DEVELOPMENT

A. Dataset Creation

The processes outlining the development of the CNN and its real-time application are shown in Fig. 3. The first step in performing transfer learning with a CNN model is collecting data for the training process. These photos must be taken in the same style as the resulting real-time classification, so the equipment setup for dataset creation must be identical to the final application. Fig. 4 shows the webcam, monitor and desktop used to create the stationary remote operation. The desktop system contains an Intel i7-6700k with a Nvidia 980Ti. The webcam (left) pointing downwards at the table allows for a constant background and a comfortable position for left-handed control. The sheet of paper taped below the camera eliminates glare from the camera light and provides a reference area to calibrate the camera position.

To create the image dataset, a Python script utilizing the OpenCV library was used to capture 1800 images at the webcam frame rate of 30 frames per second (FPS). This script was executed six times, once for

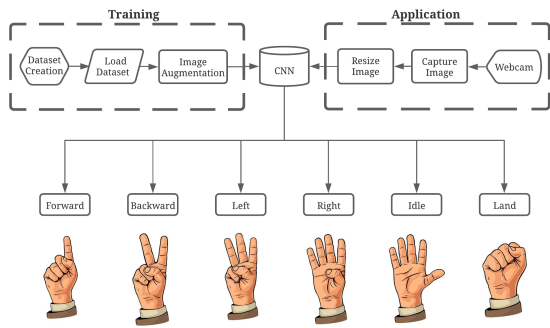

Fig. 3. CNN training and application process diagram

Fig. 4. Development workbench

each class. This dataset creation process generated a total of 10,800 images with a total run-time of approximately six minutes excluding breaks between program executions. A common flaw that can arise when training image classifiers is a concept referred to as overfitting. Overfitting occurs when the training data contains little variation and is not representative of the real-world data that will be given to the model. This results in a model that is “overfitted” to the training data, where the model appears to perform well until it is applied with this real-world data. This method of drone control does contain a level of overfitting by nature, it is certainly overfitted to the user’s hand and the table background. This is acceptable on the basis that this model is purposely trained to recognize only the user’s hand in this specific stationary position. However, further overfitting was reduced by moving the hand around the reference area during the image capturing process.

B. Transfer Learning with ResNet-18

Once the dataset has been captured, a pre-trained model must be chosen for transfer learning. Transfer learning is the process of slightly modifying an existing CV architecture and retraining it with a custom dataset to classify a new set of classes. The model chosen for this work was ResNet, specifically ResNet-18. ResNet is a residual learning network, which contains the core architecture of a series network with added skip con-

nections to reduce the effect of the vanishing gradient. Simply put, this negative effect on the gradient occurs when the depth of series architectures becomes so vast that accuracy lowers and training error increases. The skip connections in ResNet work to counter these effects and allow for more accurate and deeper CNNs [8].

ResNet networks perform accurately in a wide variety of configurations. These configurations include ResNet-18, ResNet-50, and ResNet-101. There are additional configurations, each with an appended numerical value. This value corresponds to the number of residual blocks in the network. Therefore, ResNet-150 is deeper than ResNet-101, ResNet-101 is deeper than ResNet-50, and so on. As the network increases in depth, the number of parameters increases. These parameters contribute to the complex calculations occurring during training and application, so increasing the number of parameters increases computing power required. Since the dataset being used contains only a few classes against a constant background, ResNet-18 was chosen for improved computational speed. With ResNet-18, a rapid training time and responsive real-time classification can be achieved.

Fortunately, the ResNet-18 model is included with the PyTorch torchvision library. This library is capable of importing a ResNet model that is pre-trained from popular large datasets with many classes [8]. Before the model can begin training, the dataset must be split between training and validation images. Of the complete dataset, 70% were set for training and 30% were separated for validation for each class. This selection was randomized and performed before any image augmentation took place. Image augmentation was used on the training images to further reduce overfitting while also adding robustness to the lightweight network.

These augmentations on the training images include:

- Resize to fit ResNet input layer
- Randomized horizontal flip to give appearance of right hand images
- Perspective shifting to account for inconsistent camera positioning
- Randomized “color jitter” (hue and brightness shifting) to account for inconsistent lighting and ignore skin tone

For the validation set, images were only augmented to what will be seen in application. Therefore, the only augmentation for the validation set was image resizing that was required for all images to convert the native webcam resolution to the 224x224 resolution of the standard ResNet input layer. A set of test images passed through this augmentation algorithm is shown in Fig. 5. Once the augmentations have been defined, the remaining training parameters can be set. In this training procedure, the cross entropy loss function was implemented. The optimizer was set with a learning rate of 0.001 and a momentum of 0.9. This learning rate

was decayed by a factor of 0.1 every two epochs. The training process was set to complete five epochs in total.

Fig. 5. Sample of augmented images
Note: This also contains images of a volunteer and is not a part of the official dataset

C. Real-time Inference and Control

After training was complete, the model outputs a set of class probabilities when given an input image. A function was used to extract the highest probability among all the classes which is ultimately the model’s main prediction for that image. The output classes were all labeled generically by their movement, which is not compatible with the Tello SDK. However, the extracted prediction label is a variable that can be implemented in a conditional statement algorithm for controlling the drone based on the prediction value. Within each conditional statement, the algorithm can send the corresponding Tello command in the correct syntax. OpenCV was used to show the drone camera feed which is required since the pilot will not be following the drone during flight. This was achieved in a similar manner as example programs utilizing the Tello SDK [7]. To enhance the user experience and interaction with the CV model, OpenCV was also used to display the webcam feed along with the current prediction. This allowed the user to adjust if necessary and ensure that the AI and the pilot are always in understanding with each other.

After a model trained, its new parameters were saved as a PyTorch accessible file. This saved file was then loaded into the control script previously mentioned. In the setup portion of the control script, the base ResNet-18 model from the PyTorch library is loaded into the algorithm. The parameter file is then loaded and used to overwrite the base ResNet parameters. This creates a replica of the model that was just trained for hand signal detection. This process is worth noting as it was repeated to load the same hand control ResNet-18 model on a Nvidia Jetson which represents edge devices such as modern laptops.

IV. RESULTS

As mentioned previously, the training process was set to complete a total of five epochs. For both the training and validation sets, the combined overall loss and accuracy of all classes were printed to the terminal after each epoch. After the five epochs were completed, the

```

Best val Acc: 0.999567
```

Fig. 6. Terminal output of training process

final training time and validation accuracy are displayed. Fig. 6 shows the terminal results for the final training procedure.

The final validation accuracy is nearly equal to one which is expected for a small dataset that is highly overfitted to a small list of classes. This accuracy value is artificial when compared to real-time classification. However, if it was exactly equal to one it would be indicative of saturation and the network learning could have ceased entirely. The training time completed in under four minutes, which is crucial to achieve a rapid setup time and allow for a unique model for the user.

While in use, the control algorithm displays the FPV camera feed from the drone along with the webcam feed and current prediction. The drone FPV camera feed is irrelevant in terms of displaying CNN performance, so shown in Fig. 7 is only a real-time classification instance of each class with the desktop that was used for training the network. The title of each window corresponds to the current prediction, and the current predictions per second (PPS) value is also included to show the speed at which the model is performing.

Fig. 7. Real-time output for each class with predictions per second

Each title shows an accurate prediction along with an approximate PPS of 60. This value doubles the frame rate of the webcam and provides a smooth and

responsive control algorithm. For the Nvidia Jetson, the webcam was moved from the previous workbench shown in Fig. 4 to a temporary station. The same real-time classification script and model was executed by the Jetson. Fig. 8 shows a classification instance in the same format as Fig. 7. The model and inference script performs accurately on the Nvidia Jetson and is shown detecting the "land" signal. However, the limited power of the Jetson results in 20 PPS. This is slower than the desktop by a factor of three, yet still provides a smooth and consistent experience.

Fig. 8. Jetson Nano real-time prediction

V. CONCLUSION

CNNs allow for digital image classification, which can detect objects in images based on edges and features without any additional sensing required. This form of classification can detect signals given by humans in an intuitive way that is completely non-invasive. When implemented in drone control, a stationary form of remote operation allows the pilot to operate the drone without having to remain in view of its FPV camera. This can provide more accessibility to those that want to pilot drones but are unable to use its included control device or physically follow the drone to utilize existing CV methods. This stationary model was capable of being mapped to the user with a ResNet-18 model by removing variables such as changing backgrounds and camera positions. By using this lightweight model, a total program execution time of under ten minutes was achieved during the user mapping process. This included six minutes for executing dataset collection, followed by less than four minutes of ResNet-18 transfer learning. With its low setup time and performance capabilities on edge devices, this hand signal model presents a viable option for intuitive drone control.

Abstract—Objective of this paper is to design a suitable control algorithm for cooperative transportation of an object using multiple drones based on decentralized control technique. A terminal sliding mode control (TSMC) based algorithm for motion tracking of a system of multiple Quad-rotor type Unmanned Aerial Vehicle (UAV) is proposed. TSMC is a novel class of sliding mode control giving rise to a finite time convergence of reduced order dynamics, delivering fast response, high precision, and strong robustness. A TSMC based robust cooperative control strategy is proposed for the system with multiple drones and individual control vectors are defined for controlling the combined system in presence of wind disturbances. The finite time convergence of control laws are proved using homogeneous Lyapunov function. The simulation results demonstrate the effectiveness and superior performance over conventional sliding mode-based technique for the cooperative quad rotors to transport a common payload.

Keywords—cooperative control, drones, UAV, sliding mode control, terminal sliding mode control, load transportation using drones, finite time convergence.

I. INTRODUCTION

The word ‘drone’ is very popular now a days. They are being used in various technological sectors. Recently they are being considered as future load transporting vehicles. Various MNC’s are already testing delivery using drones. But for large scale load transportation multiple drones are required and there lies the importance of cooperative control of drones. Cooperative control between robots, robot and human are already very popular. Cooperative and decentralized controlling techniques for drones are discussed in the works [1],[7],[8],[9].

There are various methods or control techniques for controlling a drone. The dynamics of drone are highly affected due to aerial disturbances and cross coupling effects due to translational and rotational motion. For this reason a robust control system is required which can handle this non linearities and dynamic stability problem. Sliding Mode Control(SMC) is quite popular among them because it is quite robust towards uncertainties and disturbances. The importance and application of sliding mode control are well described in the works [10],[12]. But sliding mode control provides asymptotic convergence and thus has very slow response. So to overcome this sliding mode control has been modified with a terminal attractor and named as Terminal SMC(TSMC). TSMC provides finite time convergence, and thus also provides fast convergence compared to normal SMC. The nature of TSMC are documented in the works [5],[6],[11],[13].

In this work, we developed a fast and robust cooperative aerial load transport system. For this decentralized cooperative control laws for a group of drones in a formation are developed where each vehicle is controlled individually. The modelling and behavior of cooperative systems are documented in the works [1], [2], [7], [8], [9]. Moore Penrose optimization theory is applied for robust modelling of cooperative system.

In this paper we have developed a TSMC based decentralized cooperative system for a system of four quad rotor type drones and a common payload. The proposed controller can successfully handle external disturbances for the cooperative system and also provides very fast convergence in finite time. The organization of this paper I as follows. In Section II,

mathematical modelling of drone is established. In Section III, the cooperative control strategy is discussed. Section IV focusses on derivation of control vectors for individual drones. In Section V, simulation results are presented in the presence of disturbance and system uncertainties. Section VI discusses the conclusions and future scopes of this project.

II. MATHEMATICAL MODELLING OF DRONE

Figure 1. Configuration, Inertial and body reference frame

Quadrotor has 6 degree of freedom [x,y,z,θ,Φ,Ψ], 3 translation and 3 rotational respectively. x,y,z denote the body frame axes, Φ denotes roll angle, θ denotes pitch angle and Ψ denotes yaw angle in body frame(Drone body frame). Forces acting on body frame are to be mapped on inertial earth reference frame using Euler Rotation Matrices[3].

$$\begin{aligned}
 R_\Phi &= \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos(\Phi) & \sin(\Phi) \\ 0 & \sin(\Phi) & \cos(\Phi) \end{bmatrix} \\
 R_\theta &= \begin{bmatrix} \cos(\theta) & 0 & -\sin(\theta) \\ 0 & 1 & 0 \\ \sin(\theta) & 0 & \cos(\theta) \end{bmatrix} \\
 R_\Psi &= \begin{bmatrix} \cos(\Psi) & \sin(\Psi) & 0 \\ -\sin(\Psi) & \cos(\Psi) & 0 \\ 0 & 0 & 1 \end{bmatrix} \\
 R_B^E &= \begin{bmatrix} c\theta c\Psi & s\theta s\theta c\Psi - c\theta s\Psi & -c\theta s\theta c\Psi + s\theta s\Psi \\ -c\theta s\Psi & -s\theta s\theta s\Psi + c\theta c\Psi & c\theta s\theta s\Psi + s\theta c\Psi \\ s\theta & -s\theta c\theta & c\theta c\theta \end{bmatrix} \\
 \begin{bmatrix} i_E \\ j_E \\ k_E \end{bmatrix} &= R_B^E \begin{bmatrix} i_b \\ j_b \\ k_b \end{bmatrix} \quad (1)
 \end{aligned}$$

Total Lift force generated by rotors given by ,U1=F1+F2+F3+F4, where Fi are the thrust force generated by ith rotor. $F_T^b = [0 \ 0 \ U1]^T$, lift force given with respect to body frame.

Forces with respect to earth frame, $F=R_B^E * F_T^b$ (3)

Translational dynamics of quadrotor are given by following equations:

$$\begin{aligned}
 \ddot{x} &= \frac{U_1(\sin(\theta)\cos(\phi)\cos(\Psi) + \sin(\phi)\sin(\Psi))}{m} + w_x \\
 \ddot{y} &= \frac{U_1(\sin(\theta)\cos(\phi)\sin(\Psi) - \sin(\phi)\cos(\Psi))}{m} + w_y \\
 \ddot{z} &= \frac{U_1(\cos(\theta)\cos(\phi)) - mg}{m} + w_z \quad (2)
 \end{aligned}$$

$\ddot{x}, \ddot{y}, \ddot{z}$ are the acceleration of drone with respect to Earth frame due to thrust control U1. w_x, w_y, w_z are air gust disturbances, m is the mass of drone, and g is the gravitational constant (9.8 m/s²). Rotational dynamics of drone are given by following equations:

$$\begin{aligned}
 I_x \dot{p} &= (I_y - I_z)qr - J_r q\Omega + LU_2 \\
 I_y \dot{q} &= (I_z - I_x)pr - J_r p\Omega + LU_3 \\
 I_z \dot{r} &= (I_x - I_y)qp + LU_4
 \end{aligned}$$

L is the arm length of quad rotor. I_x, I_y, I_z are the moments of inertia about x, y, z axis respectively. p, q, r are the angular speeds on body frame. LU_2, LU_3, LU_4 are the moments about x, y and z axis respectively. J_r is the moment of inertia of each propeller. The inputs U_2, U_3, U_4 are related to the rotations of the quad rotor. So final rotational dynamics are given by following equations:

$$\begin{aligned}
 \dot{\Phi} &= \frac{(I_y - I_z)\theta\dot{\Psi} + LU_2 - J_r \theta\Omega}{I_x} + w_\Phi \\
 \dot{\theta} &= \frac{(I_z - I_x)\phi\dot{\Psi} + LU_3 - J_r \phi\Omega}{I_y} + w_\theta \\
 \dot{\Psi} &= \frac{(I_x - I_y)\dot{\theta}\phi + LU_4}{I_z} + w_\Psi
 \end{aligned}$$

w_Φ, w_θ, w_Ψ are the air gust disturbances. Ω is the overall residual angular speed. $\Omega = \Omega_2 + \Omega_3 - \Omega_1 - \Omega_4$, where Ω_i are the angular speed of ith rotor. Relation of Ω with control vectors are given by following,

$$\begin{bmatrix} \Omega_1^2 \\ \Omega_2^2 \\ \Omega_3^2 \\ \Omega_4^2 \end{bmatrix} = \begin{bmatrix} \frac{1}{4b} & -\frac{1}{2bl} & 0 & \frac{1}{4b} \\ \frac{1}{4b} & 0 & -\frac{1}{2bl} & -\frac{1}{4d} \\ \frac{1}{4b} & \frac{1}{2bl} & 0 & \frac{1}{4d} \\ \frac{1}{4b} & 0 & -\frac{1}{2bl} & -\frac{1}{4d} \end{bmatrix} \quad (4)$$

Here, d is thrust coefficient and b is drag coefficient. Therefore, the desired motor speed can be calculated and corresponding input can be sent to motor controllers. The drone model can be written in state space form $\dot{X} = f(X, U)$ by introducing $X = [x_1, x_2, \dots, x_{11}, x_{12}]$, where

$$[x_1 = \Phi, x_2 = \dot{\Phi}, x_3 = \theta, x_4 = \dot{\theta}, x_5 = \Psi, x_6 = \dot{\Psi}, x_7 = x, x_8 = \dot{x}, x_9 = y, x_{10} = \dot{y}, x_{11} = z, x_{12} = \dot{z}]$$

Assumption 1: It is assumed that roll, pitch and yaw angle satisfy the conditions, $\Phi \leq \pi/2, \theta \leq \pi/2, \Psi \leq \pi$ for $t > 0$.

III. MATHEMATICAL MODELLING OF COUPLED SYSTEM

Figure 2 shows a team of four quad rotor drones manipulate a cross configuration payload in three dimensions. The coordinate systems include the world frame W, and body frame B. The body frame axes are considered as the principle axes of the entire system and each quad rotor has an individual body frame Qi, where $i = \{1, 2, 3, \dots, n\}$ and n is the number of drones in the system. Here x-y-z Euler angles are used to define roll, pitch and yaw angles.

The rotation matrix B to W is given by R_B . Center of mass of ith drone is considered (x_{Qi}, y_{Qi}, z_{Qi}) .

Assumptions for quad rotor drones:

- 1)The payload is rigid and completely homogeneous, has a cross configuration structure and the center of mass of the object is intended as the center of mass of the coupled system.
- 2)The mass of payload is sufficiently small such that four drones are able to lift the object.
- 3)The payload does not flip during manipulation.

Figure 2. Scheme of payload transportation using 4 drones

The motion equation of each quad rotor is given by,

$$m_i z_{Qi}'' = -m_i g + F_{Bi} \quad (5)$$

Here m_i is the mass of i th quad rotor, g is gravity and F_{Bi} is the lift force generated by each quad rotor. Also by Newton's 2nd law

$$m_L z_{Qi}'' = -m_L g \quad (6)$$

Where m_L is the mass of the payload. Now as all the forces are used for lifting and moving toward positive Z direction, the equation of motion for the coupled system can be given as,

$$m \ddot{z} = -mg + F_B \quad (7)$$

F_B is the total lift force of all quad rotors and m is the sum of drones and object's mass, $m = m_1 + m_2 + m_3 + m_4$. The acceleration of center of mass is given by, $m \ddot{r} = -mg + R_B F_B$. r is the position vector to the center of mass of i th drone.

By considering forces and moments generated by each UAV, a relationship between the behaviour of system and the agents has to be developed. Finally the equation of motion of coupled system is obtained as,

$$\begin{bmatrix} F_B \\ M_{XB} \\ M_{YB} \\ M_{ZB} \end{bmatrix} = \sum_i \begin{bmatrix} 1 & 0 & 0 & 0 \\ y_i & \cos(\psi_i) & -\sin(\psi_i) & 0 \\ -x_i & \sin(\psi_i) & \cos(\psi_i) & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} F_{Qi} \\ M_{xQi} \\ M_{yQi} \\ M_{zQi} \end{bmatrix}$$

Where M_{XB} , M_{YB} , M_{ZB} are the body moments in Z_{Qi} direction and F_{Qi} is the total force of each quadrotor, and M_{xQi} , M_{yQi} , M_{zQi} are the moments around each quad rotor body frame axis.

IV. COOPERATIVE CONTROL STRATEGY

This control algorithm is a decentralized control algorithm and includes three parts. In the first part of this the control fundamental vectors for n quad rotors that define a pseudo inverse matrix of the mathematical theory of optimal control using Moore - Penrose are determined. The second part consists of determining individual control vectors by TSMC. Finally in the last part the cooperative control algorithm can be established by combining the individual control vectors and fundamental control vectors.

A. Control Vectors of Cooperative Control Law

The derivation of these control vectors are well described in the works [1],[2],[7]. From there the cooperative strategy is established. By using all force vectors of the coupled system in linear system (X), four equations for four quad rotor drones can be described as,

$$[F_B, M_{XB}, M_{YB}, M_{ZB}]^T = Xu \quad (8)$$

Where $X \in R^{4 \times 4n}$, is a constant vector containing the states of translational and rotational subsystems, and $u \in R^{4n}$ includes four control input vectors for n quad rotors,

$$u = [F_{Bq1}, M_{XBq1}, M_{YBq1}, M_{ZBq1}, \dots, F_{Bqn}, M_{XBqn}, M_{YBqn}, M_{ZBqn}]^T \quad (9)$$

The cost function to minimize control inputs is given by,

$$J = \sum_i (\Lambda_{Fi} F_{qi}^2 + \Lambda_{Mxi} F_{xqi}^2 + \Lambda_{Myi} F_{yqi}^2 + \Lambda_{Mzi} M_{zqi}^2) \quad (10)$$

in which, Λ_{Fi} , Λ_{Mxi} , Λ_{Myi} , Λ_{Mzi} are the weight of each of the control inputs. By considering the features of theory of Moore - Penrose inverse, pointwise minimization of J will be done and optimal control vector can be written as,

$$u^* = \Gamma^{-2} X^T (X \Gamma^{-2} X^T)^{-1} [F_B^{des}, M_{XB}^{des}, M_{YB}^{des}, M_{ZB}^{des}]^T \quad (11)$$

$$\Gamma = [\sqrt{\Lambda_{F1}}, \sqrt{\Lambda_{Mx1}}, \sqrt{\Lambda_{My1}}, \sqrt{\Lambda_{Mz1}}, \dots, \sqrt{\Lambda_{Fn}}, \sqrt{\Lambda_{Mxn}}, \sqrt{\Lambda_{Myn}}, \sqrt{\Lambda_{Mzn}}]$$

By assuming the weight of basic control vectors,

$$\Lambda_{Fi} = \Lambda_F, \Lambda_{Mxi} = \Lambda_{Myi} = \Lambda_{Mxy} \quad (12)$$

$$\Gamma^{-2} X^T (X \Gamma^{-2} X^T)^{-1} = [U_{Fqn}, U_{Mzqn}, U_{Mxqn}, U_{Myqn}]$$

Assumption 2: While forming the control law we have assumed the X and Y coordinates of the centroid of the object and centroid of quad rotors coincide according to Figure 2. The following assumptions were made, $\sum x_i = \sum y_i = 0$, $\sum x_i y_i = 0$.

Also, since all the quad rotor drones have a common role in lifting the object off the ground and equal partnership, the body force F and yaw produced by each of them is almost equal. Thus the total force and yaw moment, roll moment and pitch moment of the coupled system are obtained as follows,

$$U_{Fqn} = \frac{1}{n} [1, 0, 0, 0, \dots, 1, 0, 0, 0]^T$$

$$U_{Mzqn} = \frac{1}{n} [0, 0, 0, 1, \dots, 0, 0, 0, 1]^T \quad (13)$$

$$U_{Mxqn} = \frac{1}{\Lambda_F \sum y_i^2 + n} \left[\frac{\Lambda_{Mxy}}{\Lambda_F} y_{q1}, C\psi_{q1}, S\psi_{q1}, 0, \dots, \frac{\Lambda_{Mxy}}{\Lambda_F} y_{qn}, C\psi_{qn}, S\psi_{qn}, 0 \right]^T$$

$$U_{Myqn} = \frac{1}{\frac{\Lambda_{Mxy}}{\Lambda_F} \sum x_i^2 + n} \left[-\frac{\Lambda_{Mxy}}{\Lambda_F} x_{q1}, -S\Psi_{q1}, C\Psi_{q1}, 0, \dots, -\frac{\Lambda_{Mxy}}{\Lambda_F} x_{qn}, -S\Psi_{qn}, C\Psi_{qn}, 0 \right]^T$$

It is important to notice to the increment of the force produced by each n quad rotor drones will lead to decrement of the individual body moments generated by them, according to the factor $\frac{\Lambda_{Mxy}}{\Lambda_F}$. In next step individual control vectors $[F_B^{des}, M_{xB}^{des}, M_{yB}^{des}, M_{zB}^{des}]^T$ are to be found and the cooperative control vectors for n collaborative drones is obtained as follows,

$$U_{coop|Qn} = U_{Fqn} F_B^{des} + U_{Mxqn} M_{xB}^{des} + U_{Myqn} M_{yB}^{des} + U_{Mzqn} M_{zB}^{des} \quad (14)$$

B. Derivation of Individual Control Vectors Based on TSMC

The In this section we will derive individual control vectors based on terminal sliding mode control. The control law consists of two parts, one continuous part which is to be derived from sliding equation and second part is discontinuous switching function which reduces chattering phenomena.

$$U_{\tilde{x}} = U_{\tilde{x}con} + U_{\tilde{x}dis} \quad (15)$$

Where $\tilde{X}=[x, y, z, \Phi, \theta, \Psi]$. The discontinuous part is given by $U_{dis} = k_D \frac{s}{|s|+\delta}$, where k_D and δ are tuning parameters [14].

Now we first derive the continuous part of control law. The sliding surface equations are given by,

$$\begin{aligned} S_x &= \dot{e}_x + \lambda e_x + b * \text{sign}(e_x)^{\frac{p}{q}} \\ S_y &= \dot{e}_y + \lambda e_y + b * \text{sign}(e_y)^{\frac{p}{q}} \\ S_z &= \dot{e}_z + \lambda e_z + b * \text{sign}(e_z)^{\frac{p}{q}} \\ S_\Phi &= \dot{e}_\Phi + \lambda e_\Phi + b * \text{sign}(e_\Phi)^{\frac{p}{q}} \\ S_\theta &= \dot{e}_\theta + \lambda e_\theta + b * \text{sign}(e_\theta)^{\frac{p}{q}} \\ S_\Psi &= \dot{e}_\Psi + \lambda e_\Psi + b * \text{sign}(e_\Psi)^{\frac{p}{q}} \end{aligned} \quad (16)$$

$$e_{\tilde{x}} = \tilde{x}_D - \tilde{x}$$

$$\text{sign}(e_{\tilde{x}})^{\frac{p}{q}} = \text{abs}(e_{\tilde{x}})^{\frac{p}{q}} * \text{sign}(e_{\tilde{x}}) \quad (17)$$

Here λ, b are positive constants and p and q are positive integers, where $p < q$. The time derivative of sliding surface is given by,

$$\dot{S}_{\tilde{x}} = \ddot{e}_{\tilde{x}} + \lambda \dot{e}_{\tilde{x}} + b * \frac{p}{q} * \text{sign}(e_{\tilde{x}}) * \text{abs}(e_{\tilde{x}})^{\frac{p}{q}-1} * \dot{e}_{\tilde{x}} \quad (18)$$

By generating sliding mode reaching law [4],

$$\dot{S}_{\tilde{x}} = -\xi_{\tilde{x}} S_{\tilde{x}} - \eta_{\tilde{x}} \text{sign}(S_{\tilde{x}}) \quad (19)$$

And replacing the acceleration equations, the control inputs are obtained as follows,

$$U_{1con} = \left[g + \left(\lambda + b * \frac{p}{q} * \text{abs}(e_z)^{\frac{p}{q}-1} * \text{sign}(e_z) \right) \dot{e}_z + \ddot{z}_D + \xi_z S_z + \eta_z \text{sign}(S_z) - w_z \right] \frac{m}{\mu_3}$$

$$U_{2con} = \left[\left(\lambda + b * \frac{p}{q} * \text{abs}(e_\Phi)^{\frac{p}{q}-1} * \text{sign}(e_\Phi) \right) (\dot{\Phi}_D - \dot{\Phi}) + \ddot{\Phi}_D - \dot{\theta} \dot{\Psi} \left(\frac{I_y - I_z}{I_x} \right) + \xi_\Phi S_\Phi + \eta_\Phi \text{sign}(S_\Phi) - w_\Phi \right] \frac{I_x}{I}$$

$$U_{3con} = \left[\left(\lambda + b * \frac{p}{q} * \text{abs}(e_\theta)^{\frac{p}{q}-1} * \text{sign}(e_\theta) \right) (\dot{\theta}_D - \dot{\theta}) + \ddot{\theta}_D - \Phi \dot{\Psi} \left(\frac{I_z - I_x}{I_y} \right) + \xi_\theta S_\theta + \eta_\theta \text{sign}(S_\theta) - w_\theta \right] \frac{I_y}{I}$$

$$U_{4con} = \left[\left(\lambda + b * \frac{p}{q} * \text{abs}(e_\Psi)^{\frac{p}{q}-1} * \text{sign}(e_\Psi) \right) (\dot{\Psi}_D - \dot{\Psi}) + \ddot{\Psi}_D - \dot{\theta} \dot{\Phi} \left(\frac{I_x - I_y}{I_z} \right) + \xi_\Psi S_\Psi + \eta_\Psi \text{sign}(S_\Psi) - w_\Psi \right] \frac{I_z}{I}$$

$$U_{Xcon} = \left[\left(\lambda + b * \frac{p}{q} * \text{abs}(e_x)^{\frac{p}{q}-1} * \text{sign}(e_x) \right) \dot{e}_x + \ddot{x}_D + \xi_x S_x + \eta_x \text{sign}(S_x) - w_x \right] \frac{m}{\mu_1}$$

$$U_{Ycon} = \left[\left(\lambda + b * \frac{p}{q} * \text{abs}(e_y)^{\frac{p}{q}-1} * \text{sign}(e_y) \right) \dot{e}_y + \ddot{y}_D + \xi_y S_y + \eta_y \text{sign}(S_y) - w_y \right] \frac{m}{\mu_2} \quad (20)$$

Where μ_1, μ_2, μ_3 are function of Euler angles and are given by,

$$\mu_1 = \cos(\Phi) \sin(\theta) \cos(\Psi) + \sin(\Phi) \sin(\Psi)$$

$$\mu_2 = \cos(\Phi) \sin(\theta) \sin(\Psi) - \sin(\Phi) \sin(\Psi)$$

$$\mu_3 = \cos(\Phi) \cos(\theta) \quad (21)$$

Remarks 1: In the above equations term containing moment of inertia of rotor (J_r) has been removed. Compared to the moment of drone body, the moment of propeller is negligible.

Now for proving stability of the control law, a Lyapunov function is defined as, $V = \frac{1}{2} S^2$. For stable system the time derivative of the function must be negative definite. Now, for altitude control, $\dot{V} = S_z \dot{S}_z$ must be $\dot{V} < 0$.

$$\begin{aligned} \dot{V} &= S_z (-\xi_z S_z - \eta_z \text{sign}(S_z)) \\ \dot{V} &= -\xi_z S_z^2 - \eta_z |S_z| \end{aligned} \quad (22)$$

ξ_z and η_z are positive tuning constants, so for all non zero S_z , $\dot{V} < 0$. Now, equivalent control law consists of continuous and discontinuous part and is given by,

$$U_{1eq} = \left[g + \left(\lambda + b * \frac{p}{q} * \text{abs}(e_z)^{\frac{p}{q}-1} * \text{sign}(e_z) \right) \dot{e}_z + \ddot{z}_D + \xi_z S_z + \eta_z \text{sign}(S_z) - w_z \right] \frac{m}{\mu_3} + k_{Dz} \frac{S_z}{|S_z| + \delta}$$

$$U_{1eq} = U_{1con} + U_{1dis} \quad (23)$$

Now for designing discontinuous signal, we take a Lyapunov function $V1 = \frac{1}{2} S_z^2$. For stable control law,

$$\begin{aligned} \dot{V}1 &= S_z \dot{S}_z \\ \dot{V}1 &= S_z (\dot{e}_z + \lambda e_z + b * \frac{p}{q} * \text{sign}(e_z) * \text{abs}(e_z)^{\frac{p}{q}-1} * \dot{e}_z) \\ \dot{V}1 &= S_z \left(\ddot{z}_D - \frac{U_{1eq} * \mu_3 - mg}{m} - w_z + \lambda e_z + b * \frac{p}{q} * \text{sign}(e_z) * \text{abs}(e_z)^{\frac{p}{q}-1} * \dot{e}_z \right) \end{aligned}$$

$$\dot{V}_1 = S_z \left(-k_{Dz} * \frac{S_z}{|S_z| + \delta} * \frac{\mu_3}{m} \right) \quad (24)$$

So, for $k_D > 0$, for all non zero S_z , $\dot{V} < 0$. The same stability can be proved for altitude control also [14]. So finally the individual control vectors are given as follows,

$$\begin{aligned} F_{Bn}^{des} &= \left[g + \left(\lambda + b * \frac{p}{q} * \text{abs}(e_{zn})^{\frac{p-1}{q}} * \text{sign}(e_{zn}) \right) \dot{e}_z + \ddot{z}_D + \xi_z S_{zn} \right. \\ &\quad \left. + \eta_z \text{sign}(S_{zn}) - w_z \right] \frac{m}{\mu_{3n}} + k_{Dz} \frac{S_{zn}}{|S_{zn}| + \delta} \\ M_{XBn}^{des} &= \left[\left(\lambda + b * \frac{p}{q} * \text{abs}(e_{\phi n})^{\frac{p-1}{q}} * \text{sign}(e_{\phi n}) \right) (\dot{\Phi}_D - \dot{\Phi}_n) + \ddot{\Phi}_D \right. \\ &\quad \left. - \dot{\theta}_n \dot{\Psi}_n \left(\frac{I_y - I_z}{I_x} \right) + \xi_\phi S_{\phi n} + \eta_\phi \text{sign}(S_{\phi n}) - w_\phi \right] \frac{I_x}{I} \\ &\quad + k_{D\phi} \frac{S_{\phi n}}{|S_{\phi n}| + \delta} \\ M_{YBn}^{des} &= \left[\left(\lambda + b * \frac{p}{q} * \text{abs}(e_{\theta n})^{\frac{p-1}{q}} * \text{sign}(e_{\theta n}) \right) (\dot{\theta}_D - \dot{\theta}_n) + \ddot{\theta}_D \right. \\ &\quad \left. - \dot{\Phi}_n \dot{\Psi}_n \left(\frac{I_z - I_x}{I_y} \right) + \xi_\theta S_{\theta n} + \eta_\theta \text{sign}(S_{\theta n}) - w_\theta \right] \frac{I_y}{I} \\ &\quad + k_{D\theta} \frac{S_{\theta n}}{|S_{\theta n}| + \delta} \\ M_{ZBn}^{des} &= \left[\left(\lambda + b * \frac{p}{q} * \text{abs}(e_{\psi n})^{\frac{p-1}{q}} * \text{sign}(e_{\psi n}) \right) (\dot{\Psi}_D - \dot{\Psi}_n) + \ddot{\Psi}_D \right. \\ &\quad \left. - \dot{\theta}_n \dot{\Phi}_n \left(\frac{I_x - I_y}{I_z} \right) + \xi_\psi S_{\psi n} + \eta_\psi \text{sign}(S_{\psi n}) - w_\psi \right] \frac{I_z}{I} \\ &\quad + k_{D\psi} \frac{S_{\psi n}}{|S_{\psi n}| + \delta} \\ U_{Xe q} &= \left[\left(\lambda + b * \frac{p}{q} * \text{abs}(e_{xn})^{\frac{p-1}{q}} * \text{sign}(e_{xn}) \right) \dot{e}_{xn} + \ddot{X}_D + \xi_x S_{xn} \right. \\ &\quad \left. + \eta_x \text{sign}(S_{xn}) - w_x \right] \frac{m}{\mu_{1n}} + k_{Dx} \frac{S_{xn}}{|S_{xn}| + \delta} \\ U_{Ye q} &= \left[\left(\lambda + b * \frac{p}{q} * \text{abs}(e_{yn})^{\frac{p-1}{q}} * \text{sign}(e_{yn}) \right) \dot{e}_{yn} + \ddot{Y}_D + \xi_y S_{yn} \right. \\ &\quad \left. + \eta_y \text{sign}(S_{yn}) - w_y \right] \frac{m}{\mu_{2n}} + k_{Dy} \frac{S_{yn}}{|S_{yn}| + \delta} \quad (25) \end{aligned}$$

Where,

$$\begin{aligned} \mu_1 &= \cos(\Phi_n) \sin(\theta_n) \cos(\Psi_n) + \sin(\Phi_n) \sin(\Psi_n) \\ \mu_2 &= \cos(\Phi_n) \sin(\theta_n) \sin(\Psi_n) - \sin(\Phi_n) \sin(\Psi_n) \\ \mu_3 &= \cos(\Phi_n) \cos(\theta_n) \end{aligned} \quad (26)$$

C. Final Cooperative Control Vectors

Now combining the control fundamental vectors in eqns (13) with individual control vectors in eqns (25), the derived cooperative control vectors are given by following,

$$\begin{aligned} &\begin{pmatrix} U_{coop|q1} \\ U_{coop|q2} \\ U_{coop|q3} \\ U_{coop|q4} \end{pmatrix} \\ &= \begin{pmatrix} U_{Fq1} F_{Bq1}^{des} + U_{MXq1} M_{XBq1}^{des} + U_{MYq1} M_{YBq1}^{des} + U_{MZq1} M_{ZBq1}^{des} \\ U_{Fq1} F_{Bq2}^{des} + U_{MXq1} M_{XBq2}^{des} + U_{MYq1} M_{YBq2}^{des} + U_{MZq1} M_{ZBq2}^{des} \\ U_{Fq1} F_{Bq3}^{des} + U_{MXq1} M_{XBq3}^{des} + U_{MYq1} M_{YBq3}^{des} + U_{MZq1} M_{ZBq3}^{des} \\ U_{Fq1} F_{Bq4}^{des} + U_{MXq1} M_{XBq4}^{des} + U_{MYq1} M_{YBq4}^{des} + U_{MZq1} M_{ZBq4}^{des} \end{pmatrix} \quad (26) \end{aligned}$$

To test the robustness of controller against external disturbances, we simulate wind effects as sinusoidal velocity function against the motion of drones. The wind velocity $w(t)$ is given as follows,

$$\begin{bmatrix} w_x(t) \\ w_y(t) \\ w_z(t) \end{bmatrix} = \begin{bmatrix} 0.5 \sin\left(\frac{\pi(t-20)}{20}\right) + 0.2 \sin\left(\frac{\pi(t-20)}{10}\right) + 0.06 \sin\left(\frac{\pi(t-20)}{5}\right) \\ 0.5 \sin\left(\frac{\pi(t-30)}{20}\right) + 0.2 \sin\left(\frac{\pi(t-30)}{10}\right) + 0.06 \sin\left(\frac{\pi(t-30)}{5}\right) \\ 0.5 \sin\left(\frac{\pi(t-40)}{20}\right) + 0.2 \sin\left(\frac{\pi(t-40)}{10}\right) + 0.06 \sin\left(\frac{\pi(t-40)}{5}\right) \end{bmatrix} \quad (27)$$

D. Finite Time Convergence of TSMC

TSMC sliding surface equation is defined as ,

$$s = \dot{e} + \lambda e + b * \text{sig}(e)^{\frac{p}{q}} \quad (28)$$

Where λ, b are positive constants and p and q are positive integers such that $p < q$.

$$\dot{e} = -\lambda e - b * \text{abs}(e)^{\frac{p}{q}} * \text{sign}(e) \quad (29)$$

Considering t_2 the time from initial non zero state error $e(t_0)$ to $e(t_2)=0$,

$$\int_{e(t_0)}^{e(t_2)} \frac{de}{-\lambda e - b * \text{abs}(e)^{\frac{p}{q}} * \text{sign}(e)} = \int_{t_0}^{t_2} dt$$

$$t_2 = \frac{1}{\lambda \left(1 - \frac{p}{q}\right)} * \ln \left(\frac{\lambda * \text{abs}(e(t_0))^{(1-\frac{p}{q})} + b}{b} \right) \quad (30)$$

Here t_2 does not tend to infinite, so convergence is proved.

E. Derivation of Individual Control Vectors Based on SMC

For comparing the results of TSMC with conventional SMC, we also define SMC control vectors. The sliding surface of SMC is given by,

$$S_{\bar{x}} = \dot{e}_{\bar{x}} + \lambda e_{\bar{x}} \quad (31)$$

The control vectors will be given by,

$$\begin{aligned} F_{Bn}^{des} &= [g + \lambda \dot{e}_z + \ddot{z}_D + \xi_z S_{zn} + \eta_z \text{sign}(S_{zn}) - w_z] \frac{m}{\mu_{3n}} + k_{Dz} \frac{S_{zn}}{|S_{zn}| + \delta} \\ M_{XBn}^{des} &= \left[\lambda (\dot{\Phi}_D - \dot{\Phi}_n) + \ddot{\Phi}_D - \dot{\theta}_n \dot{\Psi}_n \left(\frac{I_y - I_z}{I_x} \right) + \xi_\phi S_{\phi n} + \eta_\phi \text{sign}(S_{\phi n}) \right. \\ &\quad \left. - w_\phi \right] \frac{I_x}{I} + k_{D\phi} \frac{S_{\phi n}}{|S_{\phi n}| + \delta} \\ M_{YBn}^{des} &= \left[\lambda (\dot{\theta}_D - \dot{\theta}_n) + \ddot{\theta}_D - \dot{\Phi}_n \dot{\Psi}_n \left(\frac{I_z - I_x}{I_y} \right) + \xi_\theta S_{\theta n} + \eta_\theta \text{sign}(S_{\theta n}) \right. \\ &\quad \left. - w_\theta \right] \frac{I_y}{I} + k_{D\theta} \frac{S_{\theta n}}{|S_{\theta n}| + \delta} \\ M_{ZBn}^{des} &= \left[\lambda (\dot{\Psi}_D - \dot{\Psi}_n) + \ddot{\Psi}_D - \dot{\theta}_n \dot{\Phi}_n \left(\frac{I_x - I_y}{I_z} \right) + \xi_\psi S_{\psi n} + \eta_\psi \text{sign}(S_{\psi n}) \right. \\ &\quad \left. - w_\psi \right] \frac{I_z}{I} + k_{D\psi} \frac{S_{\psi n}}{|S_{\psi n}| + \delta} \\ U_{Xe q} &= [\lambda \dot{e}_{xn} + \ddot{X}_D + \xi_x S_{xn} + \eta_x \text{sign}(S_{xn}) - w_x] \frac{m}{\mu_{1n}} + k_{Dx} \frac{S_{xn}}{|S_{xn}| + \delta} \\ U_{Ye q} &= [\lambda \dot{e}_{yn} + \ddot{Y}_D + \xi_y S_{yn} + \eta_y \text{sign}(S_{yn}) - w_y] \frac{m}{\mu_{2n}} \\ &\quad + k_{Dy} \frac{S_{yn}}{|S_{yn}| + \delta} \quad (32) \end{aligned}$$

V. SIMULATION RESULTS

In this section the simulation results and the data used for simulation are given. The simulations are carried out in MATLAB and from the output the effectiveness of controller

is verified. The system parameter values are listed in table 1 and simulation parameter values are listed on table 2.

TABLE I. VALUES OF SYSTEM PARAMETERS

System Parameters	Values
Mass of each Drone	1.8 kg
Mass of Payload	1.8 kg
Arm length of Drone(<i>l</i>)	0.42m
Inertia about X axis (<i>I_x</i>)	2.16x10 ⁻³ kg. m ²
Inertia about Y axis (<i>I_y</i>)	2.16x10 ⁻³ kg. m ²
Inertia about Z axis (<i>I_z</i>)	0.33x10 ⁻³ kg. m ²

TABLE II. VALUES OF SIMULATION PARAMETERS

Simulation Parameters	Value for x,y,z tracking	Value for Φ, θ, Ψ tracking
b	5	2
ξ	5	20
η	0.1	0.1
<i>k_D</i>	100	20
p/q	5/7	5/7
λ	2	10
$\frac{\Delta_{Mxy}}{\Delta_F}$	1/400	1/400
δ	0.8	0.8
η	0.1	0.1
<i>k_D</i>	100	20
p/q	5/7	5/7
λ	2	10
Λ_{Mxy}/Λ_F	1/400	1/400
δ	0.8	0.8

Remarks 1: Since while modelling of cooperative system, it was assumed that all the quad rotors have common role in lifting the payload thus mass of payload is divided in four and added to each drone weight while carrying out the simulation. We have carried out point to point tracking in our simulation. The desired values and the initial values are considered as follows, Initial Values

Quad rotor	x	y	z	Φ	θ	Ψ
Quad rotor 1	0.1	0.0	0.0	0.35	0.4	0.65
Quad rotor 2	2.5	0.1	0.0	0.25	0.45	0.6
Quad rotor 3	2.6	2.5	0.0	0.3	0.5	0.55
Quad rotor 4	0.0	2.6	0.0	0.37	0.55	0.5

TABLE III. DESIRED VALUES(FOR ALL DRONES)

x	y	z	Φ	θ	Ψ
2	2	2	0	0	0

Figure 3, Figure 5, Figure 7 shows x, y and z displacements respectively and Figure 4, Figure 6, Figure 8 shows the errors in x, y and z direction respectively. Figure 9, Figure 11, Figure 13 shows Φ, θ and Ψ rotations respectively and Figure 10, Figure 12, Figure 14 shows the errors in roll, pitch and yaw angles respectively. From the graphs it is clearly observable that all the drone converge faster to final value with TSMC than SMC. Thus TSMC has lower settling time compared to SMC, thus it is proved to be a fast responsive system.

VI. CONCLUSION AND FUTURE WORKS

We discussed the problem of cooperative load transportation using multiple drones in three dimensions. A decentralized control law based on TSMC has been proposed. From the simulation results it is observed that system of drones has converged to desired values in finite time and thus a fast responsive system. The responses are faster in TSMC compared to conventional SMC. Also the system successfully maintained stability in the presence of wind disturbances. So the robustness of controller is verified well. The cooperative system has successfully exhibited point to point tracking. The chattering of system has been reduced to almost zero by using proper tuning parameters and discrete switching law. In future works we will be proceeding with variable point tracking and more enhanced load sharing with heavy loads.

ACKNOWLEDGMENT

We thank our mentor Prof. Dr. Madhumita Pal (Associate Professor, Department of Electrical Engineering, Institute of Engineering & Management, Kolkata) for her continuous guidance and assistance through out our project work.

Abstract—In many countries, the rehabilitation of partial disability of the lower limbs performs the process traditionally due to the high cost of implementing physiotherapy and rehabilitation centers with robotic devices. Therefore, the primary motivation of this work is to propose the first design of an exoskeleton with adjustable links that can be adapted depending on the height of the user, muscle sensors (EMG) and position are used to achieve a better response of the patient's intention of movement and thus achieve rehabilitation of the legs. The exoskeleton in question was designed using the VDI 2206 methodology, and this work presents a proposal for mechanical and electronic design with the ability to withstand the user's weight. A study of stress analysis and simulation of the electronic circuit was carried out. The electronic circuit was simulated in the Proteus software, where the correct interaction of the sensors with the motors is achieved. The results obtained show that the design of the proposed exoskeleton manages to support the weight of a person of 75 Kg with a maximum height of 170 cm. These results were obtained after being subjected to the design of the exoskeleton to the stress analysis in the SolidWorks software. Another feature of the exoskeleton design is its low weight because the material chosen is aluminum alloy 6061 T-6, which can withstand all stress tests.

Keywords— *exoskeleton, muscle sensors, rehabilitation.*

I. INTRODUCTION

In recent decades, the area of robotics has been going through a process of considerable evolution in scope and dimension [1]. Initially, the creation of robots focused on applications in industrial processes to replace labor in cyclical tasks; however, current robotic devices have significant interaction with humans [2].

Today's robots are increasingly found in the environment of the activities carried out by human beings. Robotics is in development and growth and is being applied in various branches of study such as medicine, military forces, mining, household services, etc. [3]. In medicine, mechanical structures such as exoskeletons are being created to contribute to and help human limbs in different tasks [4]. Exoskeletons are mechanical structures attached to human limbs to amplify or increase the user's strength. The main applications are in industries, military technology, and medicine [5]. The exoskeleton can be applied to perform rehabilitation therapies

on the upper and lower limbs due to a disease or accident that produces a temporary loss of muscle activity [6].

The development of exoskeletons for the lower limb began in the 60s; the reasons for their development were muscle weakness. This robotic mechanism contributed to patients with spinal cord injury recovering their gait [7].

The main reasons for disabilities are muscle diseases and diseases that affect the nervous system; in both cases, you must opt for a treatment that favors the recovery of the affected parts [8]. It is essential to perform rehabilitation therapy when suffering from temporary upper and lower limbs [9]. Research trends show that failure to perform good rehabilitation therapy results in the ultimate loss of limbs [10]. Based on the literature, exoskeletons are developed primarily for military, industrial, and medical purposes [11].

For this reason, this research aims to design and control an exoskeleton that manages to perform the hip, knee, and ankle joints, achieving 3 DoF on each side. The exoskeleton for rehabilitation of lower limbs may be used by patients whose height varies from 150 centimeters to 172 centimeters having the ability to regulate the lengths of the links.

II. METHODOLOGY

The exoskeleton design for the partial rehabilitation of lower limbs comprises the mechanical part and the electronic part. It is crucial to achieving a good selection of components and materials suitable to be subjected to simulations.

The VDI 2206 design methodology is taken as a reference, as shown in Fig. 1. Stage 1 is the technical information, which helps obtain the process of operation of the robotic system, where each stage is shown in detail in a flowchart to obtain a didactic and easy-to-understand process. Stage 2 details the design of the robotic system where the structure of the exoskeleton is shown with the respective components that make it up. Stage 3 details the electronic design showing the sensors' interaction with the motors controlled by an Arduino Uno® board, detailing all the components that make it up in Table 3.

Finally, in Stage 4, the final design is shown where the mechanical and electronic parts of the entire exoskeleton system are joined.

Wiper Actuator Model GP-WD3	
Mark	GP
Model	GP-WD63
Voltage	12V
Type of motor	DC
Power	20-200W
Engine noise	Low noise (50dB)
Relation of reduction	1:20; 1:24; 1:60; 1:68; 1:75
No-load rpm	90 rpm
Loaded rpm	60 rpm

TABLE II. TECHNICAL CHARACTERISTICS OF THE ACTUATOR

Note: the features were extracted from the actuator datasheet.

The motors that make up the exoskeleton will be controlled by the Arduino Uno® controller, which will be programmed to process the signals recorded by the sensors. In Fig. 5, the flowchart is shown with all the process blocks that will make up the operation of the exoskeleton, where the procedures that will be performed are detailed. The robotic system will be operated by an on and off button, and the power of the system will be from a 12 V source when the user performs the movements of the legs in the EMG sensor and positions the potentiometer. Subsequently, the sensors will send data to the controller to process and operate the corresponding motor; when the user does not generate any intention of moving, the device will not move; the design proposal is for patients who count partial movements of the legs.

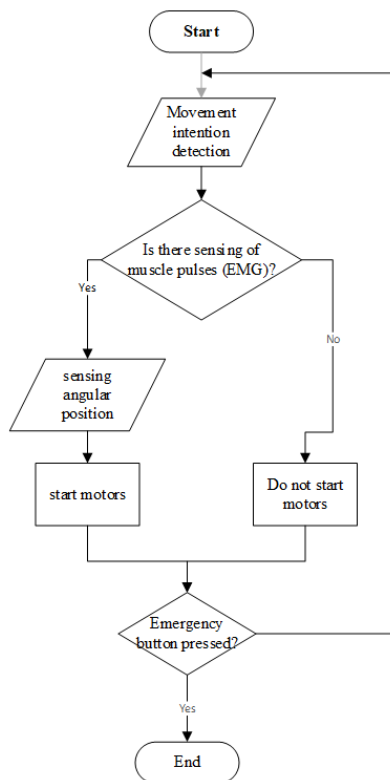

Fig. 5. Flowchart of the exoskeleton system

B. Physical design

To design the exoskeleton, the human body's standardized proportions were considered a function of the height, whereas the measurements in Fig. 6 were considered a reference.

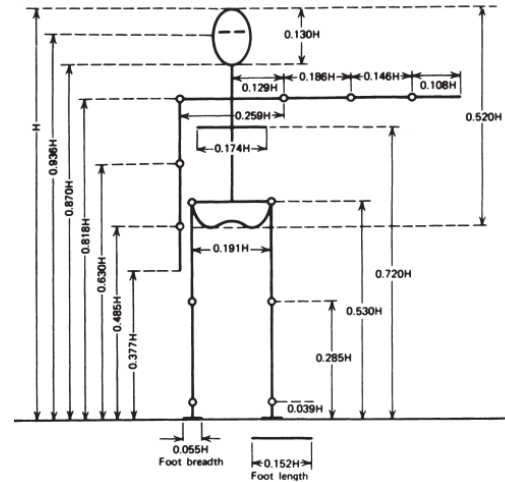

Fig.6. Standardized proportions of the female and male body as a function of height. Source: D. A. Winter, "Biomechanics and motor control of human movement", Canada: Waterloo, [2009].

Based on these standardized proportions, the prototype of the lower limb exoskeleton was designed as shown in Fig. 7, the comparison with the close links for people of a height of 150 cm and the stretched links for people with a height of 172 cm.

Fig. 7. 3D model of a lower limb exoskeleton (a) Exoskeleton with stretched links (for patients 172cm), (b) Exoskeleton with close links (for patients 150cm).

Fig. 8 shows the location of the motors, EMG sensors, and position potentiometers that make up the prototype of the exoskeleton structure.

Fig. 8. Structure of the prototype design of the exoskeleton.

- (1-3-5) The position potentiometers will be in each joint (hip, knee, ankle) in total, and there are six potentiometers. These sensors will help to have better control of each motor; in this way, the independent drives are achieved depending on the force that the patient needs in each joint.
- (2-4) The EMG sensors will be located on the thigh and leg to capture the muscle pulses of the lower limbs, detecting the intention of movement; the controller will process these signals to generate the activation of the appropriate actuator.
- (6) The bases of the fasteners are variable so that they have better adaptability in the user's legs.
- (7) The links are adjustable, having the ability to cover patients between the sizes of 150 cm to 172 cm.
- (8) The exoskeleton design has six motors with their respective gearboxes, which generate a force.

C. Electronic design

The electronic design is considered a circuit connected to a 16x2 LCD screen, which allows programming a series of routines to perform the simulation in the Proteus® software Arduino libraries were linked. For the control of this screen, an Arduino Nano board and a 5V power supply were used, as can be seen in Fig. 9.

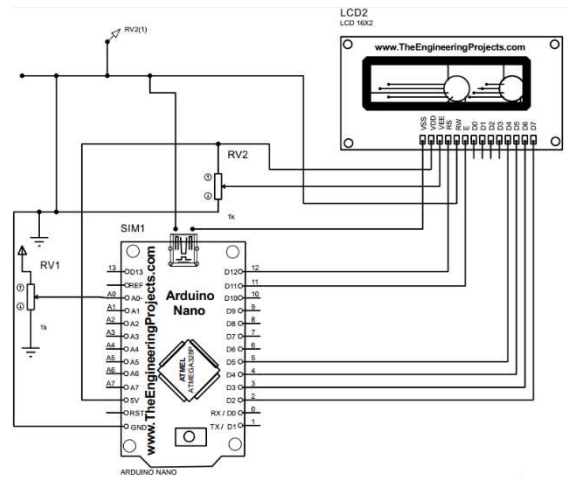

Fig. 9. LCD screen circuit.

For an electronic system of the exoskeleton prototype, it is proposed to use Arduino Uno® plates, taking into account that the movements of both legs of the design are of equal operation; that is, the circuit that is presented in Fig. 10 will be implemented in each leg of the exoskeleton, in the figure two EMG sensors are shown that will be located in the thigh and calf of each leg the signals of analog inputs of the thigh is in the A3 and calf port on the A5 port, these input signals will allow the intention of the patient's movement to be processed.

The position potentiometers enter the analog input signals through ports A0 (ankle), A1 (knee), and A2 (hip). These signals allow the exoskeleton to have better control of the motors. Each motor has the L293D driver, which inside is built the circuit of the bridge H, this allows to drive the engine in both directions anti-clockwise rotation and hourly rotation, for an exemplary operation of the motors is powered by a 12 V source. Table III shows all the electronic components that make up the system.

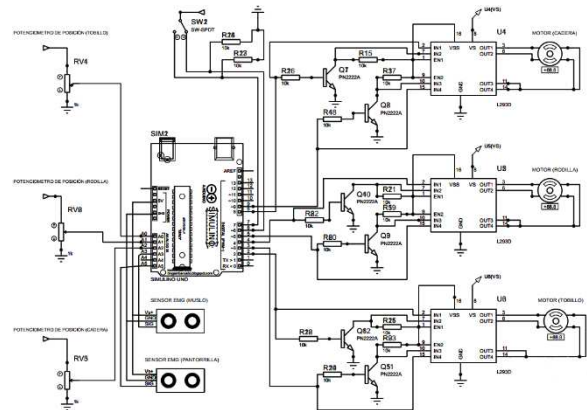

Fig. 10. Actuator control circuit.

TABLE III LIST OF ELECTRONIC COMPONENTS

Components	Description	Amount
Arduino Uno®	Motor control card	1
Arduino Nano	LCD Display Control Card	1

Sensor EMG	The capture of the muscular pulses of the leg	4
Position potentiometer	Motor motion control	6
Driver L293D	Control of the clockwise and anti-clockwise rotation of the motors	6
Screen LCD	Control and scheduling of routines	1

III. RESULTS

A. Analysis of the pieces

To verify that the design of the parts and the material are suitable, the simulation of finite element analysis is carried out with the SolidWorks program, where the essential parts of the exoskeleton structure will be subjected to critical loads. For the choice of material, it must be considered that it is lightweight, resistant, and commercially accessible; under these criteria, the aluminum alloy 6061-T6 is selected. Table IV shows all the technical specifications acquired from the SolidWorks simulator.

TABLE IV. CHARACTERISTICS OF ALUMINUM ALLOY 6061-T6

Aluminum alloy 6061-T6	
Elastic module	69 GPa
Poisson's ratio	0.33
Traction limit	310 MPa
Elastic limit	275 MPa
Bulk density	2700 kg/m ³

Note. The data acquired was from the SolidWorks simulator.

To perform the analysis of the exoskeleton system, the fastenings and connections of the hip, knee, and ankle are identified to determine the natural behavior that the structure will suffer, the maximum force and torque that will be subjected are also determined depending on the maximum weight the exoskeleton can support which is 70 kilograms. Table V shows the exoskeleton parts' weights, strength, and torque data.

TABLE V. DATA ON WEIGHT, STRENGTH, AND TORQUE

	Material Analysis			
	Hip	Thigh	Leg	Ankle
<i>P</i> _{thigh} (Kg)	7			
<i>P</i> _{leg} (Kg)	3.3	3.3		
<i>P</i> _{foot} (Kg)	1.1	1.1	1.1	1.95
<i>P</i> _{lower limb} (Kg)	11.4	4.4	1.1	1.95
<i>F</i> _{lower limb} (N)	111.83	43.16	10.79	19.13
<i>T</i> _{lower limb} (N-m)	41.5	30.5	28.5	18.5

D. System integration

The interaction of the mechanical and electronic system of the exoskeleton design would be located as shown in Fig. 11, were to observe the distribution of the electronic circuits, considering that each lower extremity of the design will have its controller that will be controlling three motors, the circuit of the LCD screen will be in the back of the hip where the specialist can program the routines according to the need of the patient. In Fig. 12, the exoskeleton can be seen in a frontal view implemented in a human body model and a side view of the exoskeleton.

Fig. 11. Interaction of the mechanical and electronic system.

Fig. 12. View of the exoskeleton design. (a) Front view of the exoskeleton. (b) Side view of the exoskeleton.

Fig. 13 shows the finite element analysis simulation with Von Mises' theory of hip assembly.

Fig. 13. Static analysis and von Mises stress of the hip assembly.

Fig. 14 shows the finite element analysis simulation with Von Mises' theory of thigh assembly.

Fig.14. Static analysis and von Mises stress of thigh assembly.

Fig. 15 shows the finite element analysis simulation with Von Mises' theory of leg assembly.

Fig. 15. Static analysis and von Mises stress of leg assembly.

Fig. 16 shows the finite element analysis simulation with Von Mises' theory of ankle assembly.

Fig.16. Static analysis and von Mises stress of the ankle assembly.

With these results of static analysis and tensions of Von Mises, the proposed prototype with the material of Aluminum Alloy 6061-T6 typically supported 70 kilograms.

IV. CONCLUSIONS

The design of the exoskeleton structure could graduate the links, being able to cover patients who have a size from 150 to 172 centimeters.

The analyses of the parts that make up the structure of the exoskeleton were subjected to an analysis of Von Mises stress, resulting in displacements and unit deformations, in the SolidWorks software, where results provided show that the alloyed material of aluminum 6061-T6 is strong enough to withstand the weight of a person and by the characteristics of the material makes the mechanical structure a lightweight design.

With the interaction of the electronic and mechanical systems, the design of the exoskeleton has different methods of control through the sensors that are part of the design, the EMG sensors control the intention of movement of the patient, and the potentiometers show the position of the motors to generate an adequate rotational rotation.

Abstract—In today’s world of information technology, information security is an important issue. In addressing information security issues, identification of attacks on the system, search for countermeasures to eliminate them, analysis of the causes of attacks, algorithmic review and algorithmization are carried out. Attacks were taken as an example in the analysis of attacks. Issues such as traffic changes and packet overload are investigated in the origin of attacks. Processes can be fully described through algorithmization in research. Identifying a specific set of information security threats by analyzing Functioning tables for algorithmic models and synthesizing and verifying incoming and outgoing data in their different versions allows any complex protection to be achieved through algorithmic descriptions. This is especially noteworthy. The diversity of system blocks means their ability to grow automatically to increase data size and provide redundant data protection. Therefore, additional safety precautions should be taken, as this article discusses the use of certain types of Functioning tables.

Index Terms—formalization, functioning table, information security, algorithmization, analyzing.

I. INTRODUCTION

The 21st century has entered human life with the rapid development of information technology and its deep application in all spheres of human activity. Thanks to the rapid development of computer technology [1]–[9], people can access a variety of information, exchange information and communicate in real time anywhere in the world. For free navigation in information flows, a modern specialist of any profile must receive, process, and use data using computers, telecommunications, and other means of communication. But to do that, you need to know the rules of navigation through the vast amount of information available and have a certain cultural background [10]–[14].

The emergence of new information technologies and their penetration into various spheres of society has led to the emergence of a new field of informatics, the science of social informatics. Social informatics studies the following issues: spacing

- Laws and problems of information society development;
- Information resources as socio-economic and cultural factors of society development;
- A person in an informed society;
- Information culture;

- Information security.

Information has always played an important role in the life of society as well as in the life of the individual. In the history of mankind, the development of the means of collecting, storing and transmitting information has not been smooth, and there have been several events of global significance in the field of information called the "Information Revolution". While information technology [15]–[20] is one of the most important pillars of society, information itself has become one of the most valuable assets of today. Man has always taken care of his valuables, not allowing them to be stolen or damaged. The above points show that information technology and information are the most important assets to protect. This is because information technology refers not only to systems for automated processing [21]–[25] of information, but also to any system (even if it is based on manual labor) that is weighed on the basis of information in the implementation [26]–[28] of an arbitrary process, related to planned activities. provided. Therefore, the security of information and information systems is a topical issue of our time.

No one in this century can question which smart robots, advances and other technical gadgets will be made that people cannot indeed envision. The advancement of information technology will lead to an increment in efficiency, quality and, over all, high efficiency in each organization. Present day information and communication technologies and the creation of conveniences moreover posture modern challenges. In later a long time, the fast improvement of information and telecommunications technologies within the world has altogether impacted the worthy place of states within the worldwide information society.

Nowadays, the risk to the security [29]–[33] of data put away in databases and circulating in telecommunications frameworks is developing quickly. As a result, the issue of information security has gotten to be a topical issue for the world. To date, one of the foremost solid devices in guaranteeing information security [34]–[36] is cryptographic protection of data. Within the world, this heading is creating quickly. New cryptographic systems, algorithms, measures are being created and connected in different areas. It is known that the data assets of any organization are one of the components

determining its financial and military potential. The successful utilize of this asset will guarantee the security of the country and the effective arrangement of a equitably educated society. In such a society, the speed of information exchange [10] will increment, the application of progressed information and communication technologies for the collection, capacity, preparing and utilize of information [18] will be widespread.

II. MATERIALS AND METHODS

A systematic study of the organizational and functional structure for algorithmic analysis of information protection [37], [38] has made it possible to highlight a number of general rules arising from the specific characteristics of the activity that must be followed at all stages of information protection development and implementation. Electronic key management system.

The main task of creating an information protection system is to choose the principles of management (objectives, criteria and restrictions on the operation of various parts of the system); distribution of functions between system levels and selection of appropriate decision schemes; establishing the right relationship between levels; coordinating the goals of subsystems at different levels and optimally stimulating their work; distribution of rights and obligations; in the distribution of functions performed between executors and technical means; selection of a set of technical means for data transmission and processing.

The most important principles to be applied in the operation of the management system are taken into account when creating an information protection system. The most important principles:

The principle of legality. Decisions made using automated information systems must be clear and unambiguous in accordance with applicable law, which is ensured by all entities (task manager, programmer, etc.) that interact in the process of creating them.

The importance of this principle can hardly be overestimated, although it is very difficult to ensure its scrupulous observance in our time due to the imperfection of legislation, which does not have time to properly regulate the mechanism of legal regulation of perestroika processes. place in the World. The principle of system security(Fig 1). A logically understandable principle that assumes the universality of protective measures against all forms of threats to objects of protection, which is a consequence of the uncertainty of the protection process. This principle is usually associated with the presence of a "human factor", since it is not clear: who, when, where and how can violate the security of the protected object.

This principle is also necessary to protect the system (Fig 2) from unauthorized access to it by unauthorized persons. An illustration of following this principle is the availability of means of protection against attempts to unauthorized changes to the software, which, in turn, implements some kind of protective function in information systems, for example, access control. Another example is an intruder alarm device that functionally supports a security line and is in turn protected by

some special means (eg masking). Closing channels for unauthorized information retrieval should begin with controlling user access to information system resources. This challenge is being tackled on the basis of a number of fundamental principles(Fig 3). Access validity principle. This principle

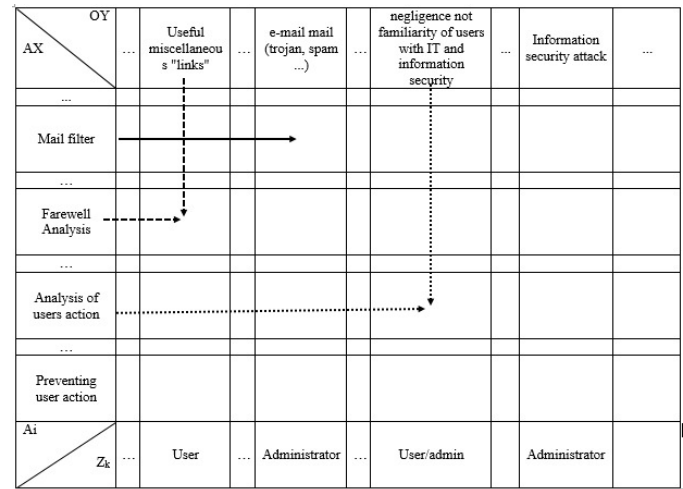

Fig. 1. Formalization scheme of system components by means of control algorithm

consists in the mandatory fulfillment of two basic conditions: the user must have a sufficient "form of clearance" to obtain information of the required level of confidentiality, and this information is necessary to perform his production functions. Note that in the field of automated information processing, active programs and processes, as well as information carriers of varying degrees of aggregation, can act as users. Then the access system involves the definition for all users of the appropriate software and hardware environment or information and software resources that will be available to them for certain operations.

III. RESULT AND DISCUSSION

The evolution of information technology (IT) is associated with intelligent systems in which there are processes of origin, adaptation and development. The systems approach defines the methodology and principles of building IT systems. The principle of the possibility of modeling helps prevent design errors in cybernetic systems. The principle of connectivity in the development of an effective system considers the object of protection comprehensively, combining the object of protection, the external environment, means of protection and threats of the attacker and taking into account the relationship: source of threat - factor (vulnerability) - threat (action) - consequences (attack).

Building a security system is a prerequisite for ensuring the security of confidential information stored and processed in the information system. Requirements for the information security system are formed based on the results of the survey of the information system and are focused on neutralizing system vulnerabilities.

Fig. 2. A model showing the dynamics and algorithmic description of the system in terms of functionality

$AB-\theta_{ij} = \{Y, P_{ij}, U_{ij}, T_{ij}, O_j, A_i, Z_k\}$ coordinates of the initial threat to IS and steps to prevent:

- 1) To proceed to the next stage, you must always have at least 3 inputs: 1) the source of the threat; 2) counteraction; 3) user privilege level.
- 2) In each cell, the function $\theta_{ij} = \{Y, P_{ij}, U_{ij}, T_{ij}, O_j, A_i, Z_k\}$ will be considered from the beginning.

$\{X, Y, A, O, \Theta, T, U, S, F, P\}$ ACS for ensuring IS security, as well as preventing any kind of threats to IS and IR.

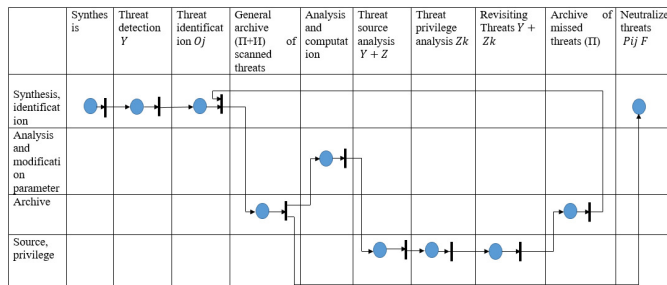

Fig. 3. Schematic of an algorithmic model of threat synthesis and dynamic modification

Y a set of possible threats $Y\{O_j\}$;

- X a set of threat prevention solutions $X\{A_i\}$;
- A Defined threat prevention solution;
- O Defined action of threats;
- Θ Coordinates between A_i and O_j ;
- T Time (to prevent the threat and successfully implement the threat);
- U External impact (on $\Theta_{ij}\{A_i, O_j\}$);
- S Transitions graph (transition from one Θ_{ij} to another $\Theta_{i+n, j+m}$);
- F Transition process;
- P Computational and logical operations of input, output and control;
- Z Privilege.

This algorithmic model includes the following processes and components: source blocking; some action of the program (set by the IS policy by the administrator) has been stopped; ineffective work of the program and inhibition of the action; ACS (computer and other equipment); revision of the program's action by the OS; no convenience and uninstallation of the program; analysis of the life of the program, adding to the archive as a threat; open access to IR; changing OS parameters; changing the parameters of installed programs; downloading other programs; modifying and deleting files; transfer information; prevention of automatic control; prevent automatic change; analysis of incoming traffic; analysis of outgoing traffic.

IV. CONCLUSION

Thus, the algorithmic models allow to perform arbitrary complex protection by analyzing the Functioning tables designed to synthesize and verify the incoming and outgoing information in their analog version, as well as to describe a certain part of the threats to information security through algorithmic formalization. It can be emphasized. The variability of elemental piece structures means their ability to grow automatically to increase data volume and introduce redundant data protection. It is therefore necessary to take additional protective measures, as this article discusses the use of specific types of Functioning Tables. In addition to the above material scope, it can be applied to other areas: the socio-economic system and various scientific fields, the possibility of their use will undoubtedly help to develop algorithmic descriptions to solve effective protection problems.

Abstract— The wind power industry has made the most recent age of wind turbines (WTs) on all platforms, from small windmills to ocean wind turbines. An emerging approach to reducing overall costs is to make wind turbines smarter. At the time of diagnosing fault concern personnel have to reach the particular location. As human beings are more prone to committing errors, electronic gadgets such as microcontrollers and sensors could be entrusted. To ensure the structural integrity of the tower and its components to assure the low cost of energy and safety of the surroundings, the Control Centre is responsible for Monitoring and Controlling WTs in those locations. Various parameters like oil level, speed of the generator, level of vibration, environmental conditions like rain, humidity, and temperature are to be monitored and controlled for the proper working of WTs. This paper describes monitoring and controlling of speed and vibration of a WT with the assistance of IoT. By the use of this described system, the speed of the turbine, temperature, voltage, and vibration can be monitored and controlled from anywhere, or just through a PC or smartphone. To show the described model in the hardware prototype, simply a DC motor is used as a WT and IoT is implemented through Arduino Uno microcontroller and Bolt IoT Wi-Fi Module. The proposed framework is based on the Bolt-Arduino (Boltuino) IoT platform that provides Wireless Fidelity (Wi-Fi) and a cloud facility. One of the major objectives behind the integration of web and cloud networks is that the user controls all devices and data from far away over a web, local area network (LAN), or cloud. Also, by using the Bolt IoT module in this proposed system, code size can be decreased by around 80%.

Keywords — *Wind turbine, vibrations, temperature measurements, internet of things, remote condition monitoring & control.*

I. INTRODUCTION

Nowadays, the world is developing towards renewable energy at a great rate because of the quantitative and qualitative impact of fuels on nature. Instead of fuel, wind can be replaced with renewable energy, which is still pure. Wind energy is a source of renewable energy from blowing air on the surface of the earth. Since the wind energy system has some valuable and

useful advantages over solar energy, so the tracking of the wind and wind turbine system is very essential [1]. Currently, wind power plants are unique and the uppermost sources of power generation across the globe. The Government of India is focusing on accomplishing 227 GW of sustainable energy capacity (including 114 GW of solar capacity addition and 67 GW of wind power capacity) by 2022 [2].

The reason behind wind turbine failures due to faults in generator and gearbox in practical turbines and the downtime due to such failures is more significant. So, the appropriate operation and conservation techniques are required to provide reliable and worthwhile green energy [3]. In general, wind turbine systems are more liable to fault, and maintenance of wind turbines in remote locations is really a difficult task. Hence, it is required a proper operating approach to measure and acknowledge crucial parameters for industrial purposes. Condition monitoring and investigation strategies for wind turbines are a universally utilized tool for early detection of failure, which reduces time and increases system efficiency and pro-activeness [4]. The prime area of wind turbine downtime is due to bearing screw-ups, especially inside the generator and gearbox [5]. It is necessary to assemble an authentic condition monitoring and controlling system to enhance maintenance efficiency. These limitations can be controlled by installing vibration sensors in the gear box of the WT [6] and the speed of the WT generator can be maintained by installing an infrared sensor (IR) in front of the generator. Also, temperature and voltage sensors are used to get updated information about atmospheric temperature and generated voltage accordingly. Monitoring, controlling, and updating Arduino programs can be done from the central station. Also, with the help of simple Bolt IoT program, the activity can be monitored via any web-connected internet browser of Computer or Smartphone or Tablets. Through the ideas of IoT, the link between bridging the gap and wind turbines that are situated at a distance from the controlling center can be controlled through software or a new tool. In the following section configuration of the proposed system is discussed briefly.

II. LITERATURE SURVEY

In some recent work, several attempts have been made to improve the existing wind turbine (WT) system so that a cost-effective controlling and monitoring system can be made for all. So, executing a more reliable system can reduce the manpower

requirements, and time as well. However, many methods are still operating; some of these are discussed below:

H. F. Liew et al.[4] 2020 introduced a system where they described an IoT application and ESP 8266 to track, take data, and determine issues in wind turbines. This permits the user to manage the whole framework remotely through a protected web-connected internet. This framework assists end-users to control energy sources, physically and remotely just by simply using smartphones or PCs. The parameters that have been taken utilizing ESP 8266 are current, voltage, wind speed, and power. When the wind turbine generates electricity, it will show the results in think-speak. The major drawback of this framework is that it requires writing more code to take data in think-speak. As well as it provides service up to a limited time period.

In 2016, D. Kalyanraj et al. [6] proposed a wind turbine (WT) monitoring and control system using the Internet of Things (IoT) where they describe a minimal expanse framework having data logger facilities. Parameters of the particular wind plant like the magnitude of voltages, currents, amount of power generation, turbine speed, temperature, humidity, and level of vibration can be observed by utilizing this system. In this very paper, control of the turbine is embraced based on the turbine vibration and IoT is executed by Arduino Uno and Raspberry Pi. However, this framework suffers from overheating and many users complain that it is not able to run in the most user-friendly Windows OS. This system is costly as Raspberry Pi is used as a cloud server storage device.

In Celal Bayar University Journal of Science 2019, Ersin Akyuz et al. [7] raised that crucial parameter are measured for the performance analysis of a small wind turbine model. Estimating the performance of the framework and avoiding faults in the framework measures can be done. Basic parameters like air temperature, wind speed, battery voltage, and current were recorded and calculated through a data logger. These calculation results were sent back to the Microsoft Azure cloud computing framework and taken down in it. Simultaneously, representation with the guide of the cloud system was taken place and visualized on the web browser through the Power BI (Microsoft) platform. But according to users, the main disadvantage of this Power BI platform is that it takes a little more than normal time or even hangs while processing millions of lines and segments of information. Also, this framework does not provide information about the vibration level of WT.

Peter J. Tavner et al. [8] in the year 2010 described a paper where a wind turbine (WT) condition monitoring strategy utilizes the generator output power and speed of rotation to determine a fault identification signal. The fault calculation utilizes a continuous wavelet-change-based adaptive filter to follow the energy in the time-fluctuating fault-related frequency bands in the power signal. The frequency of the filter is constrained by the speed of the generator, and the filter bandwidth is adapted to the fluctuation of speed. Utilizing this method, fault characteristics can be removed, with the low calculation of times. But in this model, MQTT utilizes the

transmission control protocol (TCP) protocol, which requires more memory and more processing power.

In the year 2017, Fran Lizza. M et al. [9] published a paper in the International Journal of Advanced Research in Management, Architecture, Technology, and Engineering where they proposed a monitoring framework with IoT and UART (Universal Asynchronous Receiver/Transmitter) to check and determine the issue in the WT application. In this system, the major drawback can be noticed that the speed for data transfer is less compared to parallel communication.

III. CONFIGURATION OF THE PROPOSED SYSTEM

Figure 1 describes the overall block diagram of the proposed framework. To save costs, give more usability to consumers, and avoid economic problems. The microcontroller has been considered a major and significant system. This system consists of three parts i.e., sensing unit, control unit and monitoring unit. The entire process of monitoring and control will be controlled by the connected microcontroller. The sensor will detect various information and send it to the microcontroller and then the microcontroller will send the data to the Bolt IoT cloud. According to the data, the fault can be diagnosed or the program can be changed. If the vibration data of WT is more than the threshold value then the relays will trip and also give alarms to alert the operator; then WT will turn OFF and ON accordingly.

Figure 1: Overall Block Diagram of the Proposed System

Here in figure 2 shows the Schematic Diagram of the Proposed System. The infrared, temperature, voltage and vibration sensors are interfaced with the Arduino that will be responsible for taking the data from the sensors and for communicating with Wi-Fi module. Bolt IoT Wi-Fi module is mainly used to implement the IoT technology that will take data to the Bolt cloud to control the process from anywhere to reduce the man power requirements and save time. Also, a manual process will be available to display the data through LCD/LED display from a particular central station.

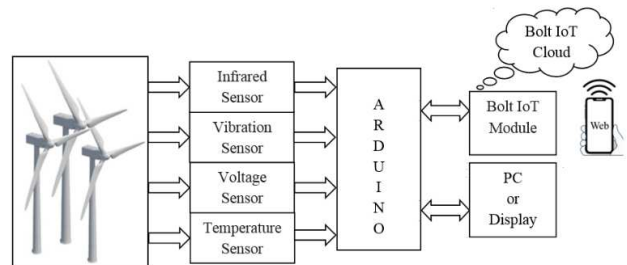

Figure 2:- Schematic Diagram of the Proposed System

The functional block diagram of the system is shown in figure 3. In the sensing unit, parameters like generator speed, vibration level of turbine, voltage, and atmospheric humidity and temperature are calculated using the respective sensors. Detected signals collaborate with the Arduino for safe activity. Bolt Wi-Fi module and Arduino are connected through USB ports accordingly. The control unit is associated with a PC or a cloud server. The values of the control unit are compared with the reference values occasionally. Whether the actual given value crosses the maximum secure limit, the control unit will give necessary signals to the corresponding relays in order to keep the ideal system performance. In the proposed framework, turbine control is acquired based on the level of vibration in the wind turbine (WT). Since turbine vibration is an extremely critical factor, therefore, the monitoring system should give essential protection to the turbine [10]. The turbine could get higher vibrations when the speed of air is beyond the cut-off values. During this circumstance, reliable and fast protection is mandatory, or else the entire system might get harmed. Under this condition protection of wind turbines is provided by relays by turning OFF, the generation of power.

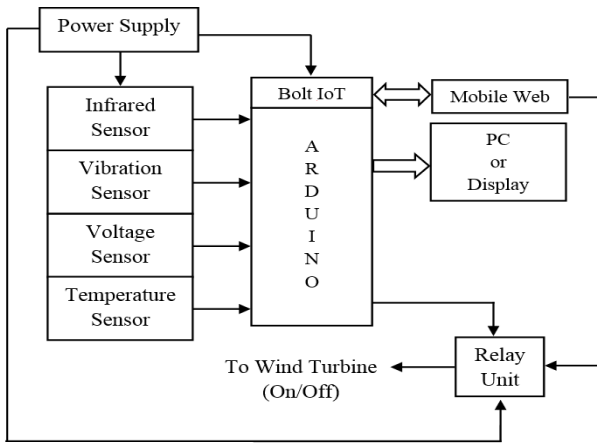

Figure 3: Functional Block Diagram

IV. SYSTEM DETAILS & HARDWARE ARCHITECTURE

The system comprises of Arduino Uno microcontroller, Bolt IoT Wi-Fi module, Bolt cloud, and few essential electronic components i.e. breadboard, relay, buzzer, vibration sensor, voltage sensor, temperature sensor infrared sensor, Connecting wires etc. A DC motor is used as a prototype for a wind turbine (WT).

A single system is capable of controlling the speed of the wind turbine and vibration which generally occurs in the gear box of a WT. At the same time, generated voltage and atmospheric temperature can be monitored from the web browser. Connection required for the proposed system that is shown in figure 4 where a prototype wind turbine (WT) is connected to the Arduino Uno microcontroller pin number 10 through a single channel relay to control the WT. The Arduino Uno microcontroller board is powered up by a battery or PC through a USB cable. The RX and TX of Bolt IoT Wi-Fi module are interfaced with Arduino Uno microcontroller digital

pin numbers 9 and 8 respectively for the purpose of serial communication. Here the four sensors, vibration sensor, IR sensor, temperature sensor, and voltage sensor are interfaced to the board. The particular VCC and ground pins of all the sensors are connected to the 5V and pins of the Arduino Uno microcontroller, respectively. A buzzer is connected for alerting purpose when there are some problems in WT, then the buzzer turns ON at the same time relay gets interrupt and wind turbine turns OFF. At the same time, information about temperature and generated voltage can also be taken from the respective sensors [11]. The purpose of connecting Bolt IoT Wi-Fi module is to take the data to the Bolt cloud, which can be accessed and controlled over laptop /mobile/tablet through HTTP & HTTPS protocols [7]. A message alerting system will be there to inform the surveyor if some crucial fault occurs in the system. Moreover, the data or the information of the system can also be monitored, as well as updating new programs to the system can be done manually from the central stations by PCs or LCDs. The entire circuit and hardware connection diagram is shown in figure 4. Flowcharts for the infrared (IR) and the vibration sensors as well as relays that are programed on the microcontroller are presented in figure 5.

A. Bolt IoT Wi-Fi Module

The entire framework depends on the Bolt IoT. The user-friendly Bolt IoT module is an IoT platform that provides Wi-Fi (Wireless Fidelity) and in-built cloud connectivity to the connected sensors. This platform is based on the ESP-8266 Wi-Fi module [12].

Figure 4:- Connection Diagram

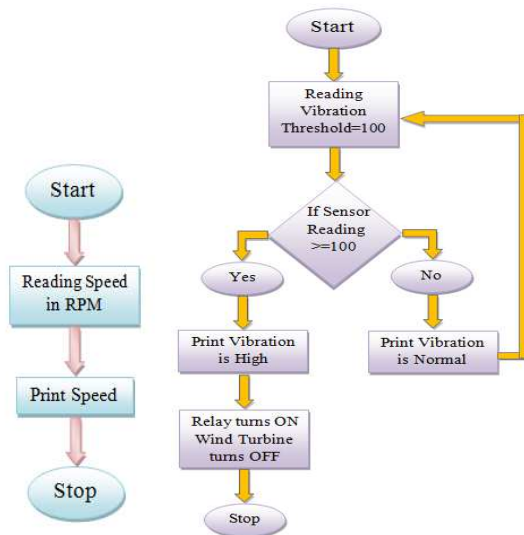

Figure 5: Flowchart for Infrared and Vibration Sensors

The entire framework depends on the Bolt IoT. The user-friendly Bolt IoT module is an IoT platform that provides Wi-Fi (Wireless Fidelity) and in-built cloud connectivity to the connected sensors. This platform is based on the ESP-8266 Wi-Fi module [12]. It has fundamental Machine Learning (ML) algorithms that can be simply incorporated with Bolt IoT projects for detecting sensor values. The reason behind choosing the Bolt IoT module is that it has the capacity to reduce the entire code size by about 80% [13]. Table I below portrays the specifications of the Bolt IoT Wi-Fi module [14] and Figure. 6 shows the pin details of the module.

Table I: Some Details of Bolt IoT Wi-Fi Module

Parameters	Features
Processing and Connectivity Module:	ESP8266 with custom firmware
MCU:	32-bit RISC : Tensilica Xtensa LX106
Power:	5V & GND pins or 5V/1A DC- Micro-USB port
Operating Voltage:	3.3V
GPIO pins:	5 Digital pins (0,1,2,3,4)
Clock Frequency (CPU):	80 MHz
PWM:	All 5 Digital pins capable of PWM
Boot Time:	Less than 1 (< 1) second

Figure 6: Pin Details of Bolt IoT Wi-Fi Module

B. Arduino Uno

Arduino Uno [15-17] is a single-board microcontroller based on the ATmega328 microcontroller. In this work, Arduino Uno plays a crucial role. It has 14 digital input and output pins, 6 analog inputs, a USB connection, a 16 MHz quartz crystal, a power jack, an ICSP header, a reset button, a USB connection, and a reset switch. It contains everything needed to help a microcontroller, simply interface it to a computer through a USB cable or battery or power it with an AC-to-DC adapter to get started.

C. Vibration Sensor

The vibration sensor module based on the vibration sensor SW-18010P is used to detect vibrations. When it is in static mode the switch is open circuit OFF-state, when external force to touch and corresponding vibration, or movement speed achieved at that instant, the circuit gets ON-state; when external force disappears, switch back to open circuit OFF-state. Here vibration sensors are used to take the vibration in the gear box of a wind turbine due to some internal faults or excessive wind [16]. This sensor helps to protect the costly wind turbine systems from unbearable internal conditions or odd atmospheric situations.

D. Infrared (IR) Sensor

An IR sensor is an electronic component that can transmit light to detect some object in its surroundings [13]. An infrared sensor (IR) can evaluate the heat of an object as well as detect motion. It includes an emitter (IR-Led) and receiver (Photo-diode). In this work, an IR sensor is used to detect the motion of the wind turbine (WT) prototype.

E. Voltage Sensor

Voltage sensors are utilized to monitor or measure and compute the amount of voltage [6]. This module is a basic and exceptionally valuable module that utilizes a potential divider to lessen the value of the input voltage by a factor of 5. For instance, with a 0V - 5V Analog info range, one can measure a voltage up to 25V.

F. Temperature Sensor

The Temperature & Humidity Sensor based on the DHT11 sensor module [12] with a digital signal output. Here this sensor gives updates on atmospheric conditions. It includes a resistive-type humidity measurement component and a Negative Temperature Coefficient (NTC) measurement component, and connects to the high-performance microcontroller, providing quick response, and cost-effectiveness.

G. Buzzer

A buzzer is an audio signaling electronic component; it might be piezoelectric or mechanical or electromechanical type. The main principle of the device is to convert the signal from audio to sound. In this very project buzzer is used as an alerting device when there is any fault in the gear box of WT it produces some vibration if that vibration is more than the threshold value then it gets interrupt and gives an alert signal.

H. Relay

A relay is an automatic switch that operates between the inputs operating voltage 0-5V [9]. In this proposed work relay plays a crucial role. When faults occur in the wind turbine relay automatically switches ON and the turbine gets disconnected from the main circuit to reduce the damages and after diagnosing the fault the WT turns ON and relay turns OFF in this very manner controlling of the system can be done.

V. RESULTS & DISCUSSIONS

In this IoT-based monitoring and controlling work, a DC motor is used as a prototype of a practical Wind Turbine. The complete hardware configuration is shown in figure 7. A 9V D.C voltage is taken from a variable voltage source. Here speeds will take from the infrared sensor, generated voltage will be taken from the respective voltage sensor, in the same way, information about the atmospheric weather and humidity will collect from temperature and humidity sensor and a vibration sensor is installed to take the vibration of gear box at every instant. The purpose of this initiative is to provide reliable condition monitoring and control of a costly wind energy generation system from a remote location.

Figure 7: Prototype of the Proposed System

Wind turbine failures due to the cause of excessive vibration over the gear box and bearings, generally above 80km/hr. The wind speed causes massive vibration in the WT system. This problem can be overcome by counting vibrations. The vibration

sensor is programmed up to a threshold value of 100th count; after this very threshold value, the relay gets opened and the turbine gets stopped automatically to diagnose the fault in the turbine. At the same time, a notification is shown on the OLED as Vibration High and a preset message alert [18] will be sent to the operator's mobile/tablet/PC. After diagnosing the fault, the turbine turns ON automatically.

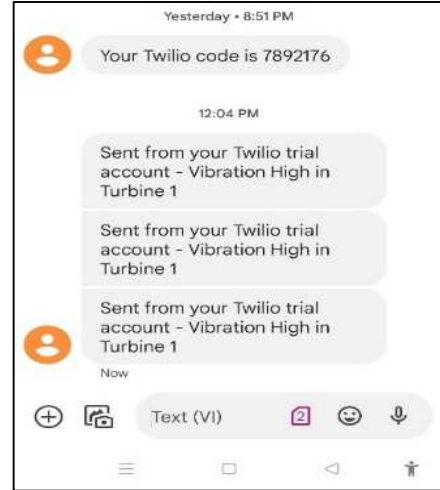

Figure 8: Fault SMS alert with Turbine Number [18]

Wind Turbine Monitoring & Control using IoT

Figure 9: Data & graph obtain from Bolt IoT Cloud

To compute the turbine speed, an IR sensor is used; an IR sensor is attached to the rotor side of the WT (wind turbine) to calculate the wind turbine speed instantaneously. Vibration sensor will attach to the gearbox of the WT. At the moment, voltage and atmospheric temperature and humidity will also record in Bolt Cloud.

VI. CONCLUSION

Most of the existing systems utilize old memory cards or PCs for data logging. Only a specific PC alone can access the stored data. Today, with the assistance of IoT Technology, the restriction can be overcome. By the utilization of this proposed system, various parameters such as speed of wind turbine (WT), vibration level, power generation, voltage, currents, temperature, and humidity can be controlled, monitored effectively from anywhere, just by a web browser. The proposed system effectively reduces time, manpower requirements, and costs as well. Therefore, various industries can acquire this system, as this could be an attractive arrangement for wind turbine control & monitoring. In this system, turbine control is adopted based on the level of vibration, speed of the generator, generated voltage, atmospheric temperature and humidity. The IoT structure is implemented through Arduino uno microcontroller and Bolt IoT module. The proposed system secures system reliability and provides safe operation.

Sentiment Analysis and NLP models for Identifying Biases of Online News Stations

Anuska Acharya
aachary4@gmu.edu

Grace Cox
gcox4@gmu.edu

Abstract—This work attempts to identify potential reporting bias surrounding recent controversial decisions for articles published from August 2019 to October 2021 within four major news organizations: FOX, CNN, NBC, and NPR. This potential bias is determined by conducting a Sentiment Analysis using NLTK’s (Natural Language Tool Kit) VADER (Valence Aware Dictionary and sEntiment Reasoner) Sentiment Intensity Analyzer. Copious amounts of literature have been published regarding sentiment analysis and bias identification of news articles, though none employ VADER. The team determines the overall sentiment for an article using the Polarity Compound calculated by the Sentiment Intensity Analyzer, which then corresponds to a political tone indicated within the verbiage and context of the article. Upon completion of the analysis, it was found that CNN, NBC, and NPR tend to have the most negative sentiment surrounding this topic, while FOX tends to be more neutral though still on the positive side. This translates to the surprising identification of a slightly democrat tone for articles published by FOX, and a more republican tone for those articles published by NPR, CNN, and NBC.

Index Terms—Machine learning, Sentiment analysis, NLP, News

I. PROBLEM DESCRIPTION

The U.S. War in Afghanistan informally began in 1999 when the United Nations declared al-Qaeda and the Taliban to be terrorist entities and, “impose[d] sanctions on their funding, travel, and arms shipments” [1]. With that being said, the United States became formally involved in the War in Afghanistan following the Terrorist Attacks on the World Trade Center and Pentagon on September 11, 2001, that were sparked by the assassination of Ahmad Shah Massoud, the commander of an anti-Taliban coalition called the Northern Alliance. The September 11 terrorist attacks on the United States resulted in a rapid increase in the number

Fig. 1: Levels of US Troops in Afghanistan from 2002-2020

of troops on the ground in Afghanistan, up until 2012 when U.S. involvement in the middle east began to see a rapid decline (Figure 1). Although the U.S. has been decreasing the troop levels in Afghanistan since 2012, the complete removal of all American troops from Afghanistan on August 30, 2021, sparked major political upset, both in the Middle East and here in the United States.

The following diagram (Figure 2) displays the timeline of events surrounding the United States’ complete withdrawal from Afghanistan, beginning with the signing of the Doha Agreement by President Donald Trump and the Taliban in February 2020, and ending with Joe Biden’s decision to pull all remaining troops from Afghanistan on August 30, 2021 [2].

Being that the United States’ complete withdrawal from Afghanistan is major international news, there is value in understanding the potential biases that lie within the many news organizations reporting on this topic throughout the United States.

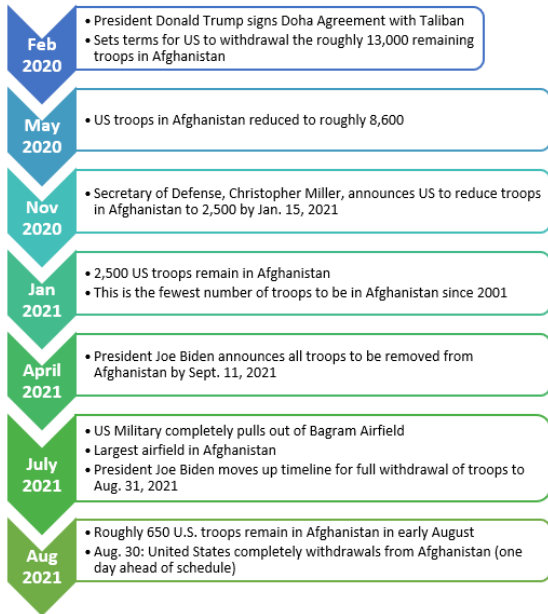

Fig. 2: Timeline of the United States' Withdrawal from Afghanistan

This project will focus conducting a sentiment analysis of 30 news articles written and released by each of four major news stations, to include: FOX, NBC, CNN, and ABC, regarding the United States' withdrawal from Afghanistan earlier this year. This sentiment analysis will aid in identifying potential biases that lie within these different organizations when reporting on a major political event.

II. IMPORTANCE OF PROBLEM

The decision by the U.S. to withdrawal from Afghanistan is a history-making decision that has ended the United States' nearly 20-year involvement in the war against terrorism, al-Qaeda, and the Taliban in Afghanistan and was met with mixed reactions of support and opposition from the general American public (Figure 3) [3]. We note that roughly 70% of individuals identifying as Democrat and Independent support this decision, mirroring the 70% overall support this decision received. This is contrasted by the near split in support/opposition responses seen within individuals who identify as Republican.

The Republican and Democrat parties appear to be on opposing sides of this issue, with the majority

Fig. 3: Political Support regarding the US Withdrawal from Afghanistan

Fig. 4: PEW Research Center Poll regarding US Troop Pullout

of individuals with Republican leanings believing that the United States made the wrong decision in completely pulling out of Afghanistan and the majority of Democrats believing that the U.S. decision to withdraw troops from Afghanistan was the right decision (Figure 4) [4]. Despite the public's varying levels of support surrounding the United States' decision to withdrawal from Afghanistan, there has been an abundance of news coverage regarding this hot topic. Machine learning models for fake news detection and text analysis could help to better understand the online posts [?], [?], [?], [5]–[17].

III. PRELIMINARY LITERATURE REVIEW

Many researchers have worked in sentiment analysis on different news stations. Research conducted by Reis, Benevenuto, Melp, Prates, Kwak collected a total of 69,907 headlines from four different news sources: BBC News Online, Daily Mail Online, The

New York Times, and Reuters Online [18]. The primary purpose of the analysis was to identify the sentiment of the headlines of various news articles produced by these big and popular news sources. The research focused on identifying if such positive or negative sentiment of the headlines was able to generate more clicks. This research found that the polarity of the headlines of the article impacted the popularity of the news article leading to more clicks. The study also revealed the headline with a positive or negative tone attracted more readers compared to the headlines with a neutral sentiment.

Similarly, in another research article by Islam, Ashraf, Abir and Mottailb [19] conducted sentiment analysis to detect the polarity based on sentence structure and dynamic dictionary. The research used detection of sentences and the use of a library for the classification of the news article. The library was defined using a list of reserved words. The proposed algorithm selected online news articles and extracted paragraphs, sentences, phrases, and words. The end of the sentence was detected if the sentence included the “.” full stop sign. Once the end of the sentence was detected, the algorithm then searched for positive or negative words, sentences and phrases and determined the polarity of the news articles. The researchers utilized java programming languages and NetBeans IDE to develop the interface for the algorithm. The experiment included the extraction of 56 random news articles from The Independent, The Telegraph, and The Daily Star which resulted in only an 8.93% margin of error which is only 5 out of 56 articles. Further analysis of the error showed these articles had a smaller number of sentences which resulted in difficulty in determining the polarity.

A research article by Jagdale, Deshmukh, and Shirsath [20] explained the three levels of sentiment analysis and advanced online text analysis [21]–[33]. These levels are document level, sentence level, and entity and aspect level. In document-level sentiment analysis, the whole document is analyzed, and the polarity of the entire document is identified. Similarly, in sentence-level sentiment analysis, each and all sentences are analyzed to determine the polarity; positive, negative, or neutral. Entity and aspect level sentiment analysis is based on opinion. The research involved 2225 documents

TABLE I

News Organizations Covered in Analysis and Number of Articles Used	
News Organization	Number of Articles Scraped
FOX	20
NBC	20
CNN	20
NPR	20

TABLE II

Sentiment Analyses to be Conducted on News Articles Covering U.S. Withdrawal from Afghanistan	
1	2
Positive	Democrat
Negative	Republican
Neutral	Independent

from the BBC. The methodology used in this research was tokenization, stop words, stemming, and then assigning scores based on sentiments.

IV. PROPOSED APPROACH

To complete our Sentiment Analysis successfully and adequately, the team will focus on four major news organizations, previously listed, and will scrape a sufficient number of articles from the websites of each organization. The following table (Table I) provides an overview of the four major news organizations analyzed throughout this project as well as the number of articles regarding the United States’ withdrawal from Afghanistan that were scraped for use throughout our Sentiment Analysis.

Two types of Sentiment Analysis (Table 2) will be conducted throughout this project. The first is a general Sentiment Analysis that describes the overall tone of the article as either Positive, Negative, or Neutral, which will aid the team in determining the overall attitude within each news organization regarding the United States’ complete withdrawal from Afghanistan. The second Sentiment Analysis will describe the political tone of the article as being Democrat, Republican, or Independent, which will aid in highlighting the overall political biases present within each news organization surrounding the United States’ withdrawal from Afghanistan.

V. PROPOSED METHOD FOR EVALUATION

The team intends to take advantage of various Natural Language Processing (NLP) techniques using programs such as Python and R to conduct a

sentiment analysis on each of the 120 articles covering the United States' withdrawal from Afghanistan published by one of four news stations (FOX, CNN, NBC, NPR). The team will then use the results of this sentiment analysis to identify any potential biases surrounding major political events that are apparent within each of these major news organizations. Several text preprocessing steps must be completed on all text to successfully complete a sentiment analysis on these articles published by each of the four major news organizations. These text preprocessing steps can include tokenization, stop word and punctuation removal, lemmatization, stemming and more, and are described in detail below.

A. Text Preprocessing Definition

Preprocessing text data refers to the process of transforming the text input into a, "predictable and analyzable" [34] form for the task at hand and the ultimate goal of cleaning and preprocessing text data is to, "... reduce the text to only the words that you need for your NLP goals" [35]. It should be noted that different tasks require an emphasis on different steps within the preprocessing procedure. Some common types of text preprocessing techniques include tokenization, punctuation/noise removal, and text normalization (lowercase tokens, stop word removal, and lemmatization/stemming).

B. Tokenization

Tokenization refers to the preprocessing task of, "breaking up text into smaller components of text (known as tokens)" [36]. A token may be an entire word, a part of a word, or characters like punctuation. Tokenization is one of the most important parts of NLP preprocessing, as it defined what our models can express. In this project, tokenization was done using SpaCy [37], a Python package often used in NLP settings. SpaCy not only provides generic tokenization functions, but also allows the user to, "customize the tokenization process to detect tokens on custom characters" [38]. This custom tokenization in SpaCy could be used for words including hyphens or apostrophes that should be processed as a single token.

TABLE III

Raw Text Data	Lowercase Text Data
CaMeL	camel
UPPER	upper
lower	lower

C. Punctuation & Noise Removal

Punctuation in text data does not add much, if any, value to the data and the meaning behind it and thus is typically removed from the raw textual data during the preprocessing steps. Punctuation includes characters including, but not limited to commas, periods, exclamation/question marks, hyphens, and apostrophes.

D. Lowercase Tokens

Text data usually contains characters that have different cases, some of which may not be conducive to the Natural Language Processing procedure. In order to further normalize textual data for ease of analysis, all tokens are typically converted into a lowercase capitalization scheme. The following table (Table III) displays a few examples for creating lowercase tokens from raw textual data.

E. Stop Word Removal

Stop words are commonly used words in a language that provide little to no information to the text. Some examples of stop words in the English language can include, but are not limited to: "the", "is", "a", "are" [34]. There are many packages available within Python that are capable of detecting and removing stop words from the provided text, with the most popular being the NLTK package. Stop word removal is one of few text preprocessing tasks that are used for text normalization.

F. Lemmatization & Stemming

Stemming refers to the NLP preprocessing task that is concerned with, "bluntly removing word affixes (prefixes and suffixes)" [2]. There are two major errors that can arise from Stemming Algorithms: Over Stemming and Under Stemming. Over stemming occurs when two words that have different stems are stemmed to the same root word; for example, the words "universal", "university", and "universe" are stemmed to "univers" which

```
[am, is, are] → be
[walk, walked, walking] → walk
[watches, watching, watched] → watch
```

Fig. 5: Lemmatization Examples

would not be correct since their modern meanings are in different domains and are generally not synonymous [39]. Under stemming occurs when, “two words that should be stemmed to the same root are not” [39]. For example, the words “alumnus”, “alumni”, and “alumnae” should all be stemmed to the same word, but typically are not. Textual data can contain tokens that are different forms of a certain word (i.e. walk, walked, walking) and condensing all of the tokens in a text to their root word increases the ease of analysis while at the same time reducing inflectional forms. Lemmatization refers to this process of taking each token and bringing it down into its root form. The goal of lemmatization is to “... remove inflectional endings only and to return the base or dictionary form of a word” [40]. The dictionary form of a particular word is referred to as the lemma for that word. The example below (Figure 5) displays lists of possible words contained in text data as well as the respective lemma for each list of words.

VI. RESULTS

Prior to conducting this sentiment analysis, date metadata was scraped from each of the 80 articles to determine the month and year that each article was published in (Figure 6). This date metadata was provided in a schema.org annotation format within @type: NewsArticle and will provide the team with further context for the sentiment analysis to be conducted. We note all articles, except for one, were published in 2021, with the majority of articles being published in August and September 2021. This coincides with the previously mentioned timeline regarding the United States’ complete withdrawal from Afghanistan.

This sentiment analysis of four major news organizations is based on 20 articles published by each of FOX, NBC, CNN, and NPR regarding the United States’ withdrawal from Afghanistan; the links for each of the articles used within this analysis can be found in Table 1 within Appendix A. It should

be noted that though the team initially explored this text data upon completion of textual pre-processing, due to time constraints, the team decided to approach the problem from a different angle. Each webpage is scraped using the BeautifulSoup and urlopen libraries within Python, then using NLTK’s VADER (Valence Aware Dictionary and sEntiment Reasoner) Sentiment Intensity Analyzer, a Polarity Compound score indicating the articles overall sentiment is calculated. This Polarity Compound score is a normalized sum of the Positive, Negative, and Neutral scores that ranges in value from -1 to 1, with positive values indicating a positive sentiment, negative values indicating a negative sentiment, and values close to 0 indicating a more neutral sentiment. It should be noted that VADER’s Sentiment Intensity Analyzer is pretrained and thus does not require any training effort, making it ideal considering the time constraints placed on this project.

The following Figure 7 displays the Polarity Compound scores for each of the 20 articles regarding the United States’ withdrawal from Afghanistan that were published online by FOX News. This figure displays that FOX is relatively split between articles classified as having a positive sentiment and those having a negative sentiment. With that being said, the articles with positive sentiment tend to have a stronger positive sentiment than those articles with negative sentiments, in which case we see weaker negative sentiments (indicated by polarity compound scores that are closer to 0 e.g., -0.158, -0.271).

Fig. 6: Publication Dates for Scraped Articles, by News Organization

Fig. 7: Sentiment Analysis for FOX News Articles

Fig. 9: Sentiment Analysis for CNN News Articles

Fig. 8: Sentiment Analysis for NBC News Articles

Fig. 10: Sentiment Analysis for NPR News Articles

The following Figure 8 displays the Polarity Compound scores for each of the 20 articles regarding the United States’ withdrawal from Afghanistan that were published online by NBC News. This figure displays that NBC tends to have a largely negative sentiment within articles regarding this controversial political decision. There were only two articles out of the 20 that were used within this analysis that were classified as having a positive sentiment. We note that of the selected articles published, the majority have a very strong negative sentiment, indicated by Polarity Compound Scores that are either -1 or very close to -1.

The following Figure 9 displays the Polarity Compound scores for each of the 20 articles regarding the United States’ withdrawal from Afghanistan that were published online by CNN News. We note that, like NBC, CNN tends to have a largely negative sentiment within the published articles regarding this monumental decision. Only four of the 20 articles were classified as having a positive sentiment. Also, we noted that the articles with a negative sentiment are typically stronger than those

with a positive sentiment for the articles published by CNN.

The following Figure 10 displays the Polarity Compound scores for each of the 20 articles regarding the United States’ withdrawal from Afghanistan that were published online by NPR. We note that, like NBC and CNN, NPR tends to have a largely negative sentiment within the published articles regarding this monumental decision. Only six of the 20 articles were classified as having a positive sentiment. Also, we noted that the articles with a negative sentiment are typically stronger than those with a positive sentiment, and most of the Polarity Compound scores for these articles are both very strong (i.e. close to 1) and negative.

The following Figure 11 displays the Average Sentiment for the four major news organizations FOX, NBC, CNN, and NPR. The Average Sentiment of all 20 articles is determined by calculating the average polarity compound score across all articles published by each of the major news organizations previously mentioned. This figure aids in highlighting the overall bias that is present within

Fig. 11: Average Sentiment Analysis by News Organization

the articles published by FOX, NBC, CNN, and NPR regarding the United States’ withdrawal from Afghanistan. We see that while FOX tends to be relatively neutral when reporting on this topic, there is still a slightly positive overall bias present. In contrast, NBC, CNN, and NPR all have a negative bias, with NBC having a strong negative bias when reporting on the United States’ decision to withdrawal completely from Afghanistan, indicating their strong disapproval of this decision, and CNN & NPR having a relatively moderate negative bias’.

In addition to determining the overall general sentiment, we want to determine whether the articles published by each of these four major news organizations tend to have a Democrat, Republican, or Neutral leaning. Figure 12 depicts the Polarity Compound scores for each of the 20 articles for ABC, CNN, NPR, and FOX, with blue shades indicating a more Democrat leaning, red shades indicating a more Republican leaning, and white shades indicating a Neutral leaning. It should be noted that the political leaning of an article is determined by the value of its polarity compound calculated by VADER. Polarity Compound values closer to 1 indicate a democrat tone and those values closer to -1 indicate a republican tone. CNN appears to have the most neutral articles (though still Republican in leaning), with only two articles having strong Democrat leanings, while NBC and NPR are clearly the most Republican leaning in nature as there are more deep red shades present in Figure 10. One surprising result from both Figure 11 and Figure 12 is that FOX typically tends to be more Republican in nature, while NBC and CNN tend to lean more Democrat. This result could be

Fig. 12: Political Tone Analysis for Individual Articles by News Organization

explained by the fact that there was a change of presidency during the process of the United States’ withdrawal from Afghanistan. Another explanation for this surprising result for FOX News stems from the information displayed above in Figure 3, which shows that Republicans are fairly split regarding the United States’ decision to completed withdrawal from Afghanistan, with only 56% of surveyed republicans supporting this decision.

VII. FUTURE WORK

One potential area of future work regarding discovering biases within articles published by major news organization regarding the United States’ complete withdrawal from Afghanistan includes creating a model that is unique to the verbiage and context of these articles. Due to the time constraints of the course, the team was unable to both train and employ a Natural Language Processing model with adequate accuracy. Since the team decided to use the Polarity Compound scores for each article to represent the articles political tone, another area for future work would entail creating dictionaries and lists of keywords that are representative of each political leaning (Democrat, Republican, or Independent).

Machine Learning models for Customer Relationship Analysis to Improve Satisfaction Rate in Banking

Patricia Fabijanczyk

Lahari Bagam

Nan Jia

Ebrima Ceesay

Abstract—The purpose of this research project was to analyze customer complaint data from financial institutions and identify areas of opportunity for these institutions to improve their customer satisfaction rate. In addition to pointing out areas for improvement, this paper also looks into similar research and tries to understand if themes found in this analysis are consistent with those done by other researchers. Banking is an essential piece to everyday life for all people across the world. Banks need to ensure that their products and processes are simple and accessible to all. Although banks have a monopoly on our financial needs their desire to retain existing customers and gain new ones drives the necessity of providing excellent and timely customer service.

The study was conducted using a dataset of over two million customer complaint records and examining what were the top three financial institutions receiving complaints and which products received them. In addition, other aspects of complaints such as state of origination was also looked at. Analysis was done using machine learning, python, tableau and other tools to show the data points and their correlation. Understanding the top financial institutions methods of handling customer complaints, we are able to make recommendations for further product improvements to increase customer satisfaction. Concluding the research project is a list of challenges and opportunities for further research projects. In addition, there are recommendations for the financial institutions investigated in this project on how to move forward from analyzing customer complaint data.

Index Terms—Machine learning, Finance, NLP, online information

I. INTRODUCTION

With the development and increased use of technology providing feedback has become instant and easy. Feedback can be negative or positive but to companies it should be what they constantly ask

for and want to receive. Customer feedback can also make or break a company [1]. With either positive or negative customer feedback a company can capitalize on what customers offer to them via multiple channels and incorporate it back into their innovation chain. Time and time again we have seen companies that do not listen to their customers fail – whether it be they continue to exist but struggle to gain momentum or they fail completely and are forced to shut their doors. One prime example of this is the sad fate of Blockbuster; although they had plenty of opportunities to reimagine the way they brought movies to families across the United States they took the stance that they knew their customers and they would stick to what they knew – brick and mortar stores with VHS tapes [1]. Netflix entered the scene and completely changed the landscape of at-home entertainment and eliminated their first competition, Blockbuster [1]. Although it is difficult to compare services between Netflix and Blockbuster to financial institutions, fundamentally they serve to provide a service to us the customers, whether it be entertainment or keeping our money secure in a checking account or helping us finance a home [1]. The Blockbuster example is a prime example of why companies should ask for and utilize customer feedback. Financial institutions are a staple to our lives but with banks competing to differentiate themselves there are institutions that can fold to others by not evolving to meet customer needs.

A. Research Paper's Structure

This research paper is structured to explain the importance of customer satisfaction to a financial

institution. Section two focuses on explaining the problem in detail and its significance to the market. Section three highlights the dataset used to conduct the analysis and how it was prepared for processing. Section four discusses the approach and methods used to analyze the large dataset. Section five, and six dive deeper into published research found over the course of the project that guided and informed this research. Section seven investigates the data analysis and tools used to conduct the research, such as using machine learning to develop a series of graphs from the data set. Section ten rounds off the research project by highlighting some challenges in the project and opportunities to expand the research while provide recommendations to the top three banks on where focus should be for improvements within their product lines to ensure customer satisfaction remains high and drives higher customer retention in return.

Banking is a necessity everyone must interact with on a regular basis. The days of cash only transactions are over and financial institutions Capital One, Bank of America, Wells Fargo, BB&T just to name a few, now take on the role of intermediary when it comes to us and our assets. Each of the financial institutions given as an example and many more provide us with a number of services when it comes to finances – checking and savings accounts, loans, mortgages, credit cards. If we do not like something in the services, we receive we naturally turn to the company we are experiencing problems with and voice our dislikes in hopes that it will alter the way we do business with them moving forward and avoid similar issues in the future. Complaining to a financial institution can be done through multiple channels – via the web, over the phone, even sometimes over their app or on social media.

The market today offers numerous companies to pick from when it comes to banking – there are small town banks, credit unions, and large financial institutions that offer a variety of products to customers. When customers have a number of options companies strive to differentiate themselves in the market and win customers – either by providing competitive rates for loans, checking rates with a higher than average interest rate, rates on mortgages, incentives for opening up credit cards, and

quality customer service [2]. Customer satisfaction counts for a lot today than all of the products a company can provide [2]. “If your customer is not satisfied, he or she will stop doing business with you [2].” Customer satisfaction is defined as the customer’s “perception that his or her expectations have been met or surpassed [2].” For banking, customers expect their funds to be available to them when needed, that includes making sure the technology that supports customers is working properly. When customers have a good experience with a company with a product it is more likely that they will return the next time they have a need for that product or a new one [2]. Financial institutions want customers to build portfolios with them, it results in greater profits for them, so customer satisfaction is what every bank strives for.

Since interacting with financial institutions is such a fundamental part of everyone’s lives it is important to do further research and analysis into what customers struggle with to identify areas of opportunity for banks – not only for their product development but also for overall customer service and interaction. There is plentiful literature available on the importance of customer satisfaction and the impact on business if it is low. Each financial institution might define success has something different, but it is at the heart of a bank to serve a customer for all their financial needs so in our analysis and research we will look to provide insight into areas that they can focus on improving to hopefully reach new customers or encourage existing customers with other products to expand their services.

II. DATASET

The first dataset was sourced from DataWorld [3]. The dataset consists of fifteen thousand records. Information that is provided includes: date complaint was received, product and sub-product, issue with product and complaint narrative, company response, company name, state and zip code of complaint origination, complaint submission method, time response, and whether the consumer disputed or not. The data fields that will be used for analysis will be product and sub-product, issue with the product, company response, company name, state of complaint origination, complaint submis-

sion method, and consumer disputed field. All records that are not complete with these fields will be excluded from evaluation. Complaint narratives will be used for a more detailed description of the issue submitted. The dataset spans the years 2011 to 2019 allowing us to do a year-over-year comparison of complaint volumes in certain products and states.

The second dataset was sourced from the Consumer Financial Protection Bureau and has over two million records to analyze for this project [4]. Fields from the first dataset can be mapped to the fields in the second dataset thus creating a larger sample to run analysis on. Things to note about the CFPB dataset are that complaints in this set are only published after the company responds and the relationship with the consumer is confirmed [4]. Data points collected and that appear in both data sets are: company name, company’s response to the consumer, whether the response was timely (a yes or no response), date and state received, the product the complaint is against, and the issue, some complaints have additional details provided in the form of sub-issue [4]. A full list of data provided can be seen in Table 1.

Not all datapoints in the dataset were used during this research project. The most important datapoints and those that were used in the analysis were: company, product, sub-product, issue, sub-issue, complaint ID, and state. Timely response was considered as an additional aspect for correlation but responses were only limited to ‘yes’ and ‘no’ which do not provide enough to draw out any conclusions. Additional details for timely response would have required criteria that would define what timely is for each bank.

A. Data Cleaning, Processing and Input Tools

We have processed our data in order to find if there are any duplicate or null values present in our dataset. While processing the data, we found that there were no duplicate values but there were two null values that were removed in order to visualize the data in Tableau.

For initial data analysis we used Tableau (Table 2 for initial code) to create some visualizations for a subset of the data set. Moving forward we plan to make use of Python Jupyter Notebook and some of their libraries like Seaborn and Pandas for achiev-

TABLE I: Complete List of Complaint Data Consumer Financial Protection Bureau publishes. [1: direct pull of descriptions from CFPB]

Field Name	Description
Date received	The date the CFPB received the complaint. For example, “05/25/2013.”
Product	The type of product the consumer identified in the complaint. For example, “Checking or savings account” or “Student loan.”
Sub-product	The type of sub-product the consumer identified in the complaint. For example, “Checking account” or “Private student loan.”
Issue	The issue the consumer identified in the complaint. For example, “Managing an account” or “Struggling to repay your loan.”
Sub-issue	The sub-issue the consumer identified in the complaint. For example, “Deposits and withdrawals” or “Problem lowering your monthly payments.”
Consumer complaint narrative	Consumer complaint narrative is the consumer-submitted description of “what happened” from the complaint. Consumers must opt-in to share their narratives. We will not publish the narrative unless the consumer consents, and consumers can opt out at any time. The CFPB takes reasonable steps to scrub personal information from each complaint that could be used to identify the consumer.
Company public response	The company’s optional, public-facing response to a consumer’s complaint. Companies can choose to select a response from a pre-set list of options that will be posted on the public database. For example, “Company believes complaint is the result of an isolated error.”
Company	The complaint is about this company. For example, “ABC Bank.”
State	The state of the mailing address provided by the consumer.
ZIP code	The mailing ZIP code provided by the consumer. This field may: i) include the first five digits of a ZIP code; ii) include the first three digits of a ZIP code (if the consumer consented to publication of their complaint narrative); or iii) be blank (if ZIP codes have been submitted with non-numeric values, if there are less than 20,000 people in a given ZIP code, or if the complaint has an address outside of the United States).
Tags	Data that supports easier searching and sorting of complaints submitted by or on behalf of consumers. For example, complaints where the submitter reports the age of the consumer as 62 years or older are tagged “Older American.” Complaints submitted by or on behalf of a service member or the spouse or dependent of a servicemember is tagged “Servicemember.” Servicemember includes anyone who is active duty, National Guard, or Reservist, as well as anyone who previously served and is a veteran or retiree.
Consumer consent provided?	Identifies whether the consumer opted in to publish their complaint narrative. We do not publish the narrative unless the consumer consents, and consumers can opt-out at any time.
Submitted via	How the complaint was submitted to the CFPB. For example, “Web” or “Phone.”
Date sent to company	The date the CFPB sent the complaint to the company.
Company response to consumer	This is how the company responded. For example, “Closed with explanation.”
Timely response?	Whether the company gave a timely response. For example, “Yes” or “No.”
Consumer disputed?	Whether the consumer disputed the company’s response.
Complaint ID	The unique identification number for a complaint.

identifying the areas of issues and will help with predicting product and issues using the historical complaint data. From this, we will be able to provide plotting graphs, scatter plots, histograms, and correlation matrix.

IV. REASON FOR BIG DATA SOLUTION

A big data solution will allow for greater detection about customer sentiment regarding a company's products or services. Using Machine Learning will allow for a more robust way to process information [27]. The machine power can process the dataset in order to calculate various types of variables from the population [27] at a faster and more efficient way. In addition to overall sentiment, we will be able to look at multiple facets of the complaints received, such as, channel complaint was received through, the company that received the complaint, the state from which the complaint originated from, and whether or not it was resolved in a timely manner. Similarly, the Consumer Financial Protection Bureau uses the large dataset of complaints to analyze it and help govern and guide companies with more informed financial laws, rules and regulations [4].

V. PUBLISHED RESEARCH

To understand how a company can be successful one needs to begin by understanding what complaints most are received. Merriam-Webster defines complaint as “[an] expression of grief, pain, or dissatisfaction”. “Customer experience is the emotion felt by customers¹ when they come into any contact with a company – no matter how or by what means. It is what customers remember from their interaction with a business. [28]” There are a number of studies that have been done that show that customers that have a positive experience with a company are 86% more likely to return and do business with that company again and goes up to 92% when that customer is already an existing customer [28]. In addition to those higher percentages, losing customers can be very costly for a business. In another study done, 50% of customers said they left because they did not feel valued and had a poor experience with customer service [28]. Another staggering number is that 80% of customers would willingly pay more for a product or service if the

customer experience is better [28]. If those numbers are not enough to convince a company the value that customer satisfaction provides then it has been analyzed that acquire new customers can cost five to twenty-five times more than retaining an existing customer [28].

A. Customer Satisfaction & Measurement

To effectively measure and predict customer satisfaction one must define how to measure it. An important piece to measuring satisfaction is also understanding quality as it plays a key role in how the customer determines their expectations of the product they are interacting with [2]. Quality is difficult to define in the realm of customer satisfaction for the simple fact that it can vary person-to-person – thus making it more difficult to quantify [2]. One way to gather measurement for customer satisfaction is through the use of surveys [29]. Surveys give companies the insights directly from their customers. “Strong relationships lead to higher levels of loyalty with customers [thus] resulting in profitability [29]”. Service quality, when looking at the “Relationship Survey Framework” (Figure ??), depends on the following customers experiences: installation, complaint, billing, purchase, pre-sales, and any other ones they interacted with [29]. When all those experiences are positive then it builds or improves upon the relationship resulting in an overall better product experience, price, and increase in corporate reputation [29].

B. Customer Complaint Handling on Customer Satisfaction

Another study was done on banks in Asia on the “effect of bank commitment, bank communication, and handling customer complaint on customer loyalty through customer satisfaction” was completed by obtaining a sample from customers [30]. “The commitment of a service provider greatly impacts on customer loyalty. In this case, when the service provider is highly committed to providing services to its customers, it will make customers satisfied and then will not switch to other competitors and continue to use the service or product” [30]. Similarly, as seen by the top three banks identified in this research project, the banks are heavily focused on providing exceptional service to their customers.

Fig. 3: Frequency of Key Words

The study found that commitment, communication and the way incidents are handled all have a great impact on one another [30].

A third aspect of the study done focused on the bank’s communication and its impact on customer satisfaction. The research data showed that bank communication also had a positive and significant effect on customer satisfaction [30]. “Communication is very important in a business.

From the two million data records natural language processions identified the top complaints that companies received: top three being around loans, mortgages and payments(Figure 3). To identify areas of opportunities analysis of the top three financial institutions will be compared to the three financial institutions that have the least number of complaints against them. In addition to the bar chart in Figure 3 that shows the frequency of key words, the word cloud in Figure ?? clearly illustrates which words are most likely used in the complaints data.

The three companies that received the most complaints in our dataset against them were Equifax, Experian, and TransUnion regarding credit reporting. Since these three companies are not financial institutions and only serve as credit reporting bureaus they will be excluded as part of this analysis.

C. Bank of America

Bank of America first came into the market in 1923 but was established as the leading bank with the merger between BankAmerica and NationsBank

in 1998 [31]. Bank of America offers a large variety of products to their consumers, to include personal banking such as checking and savings accounts, home and personal loans, credit cards, small business accounts, wealth management activities, and products and support to larger businesses and institutions [32]. In 2019 Bank of America received the J.D. Power U.S. Retail Banking Advice Study highest ranking for customer satisfaction [33]. “The study measures satisfaction across twenty-three of the largest banks across the U.S.” [33].

D. Wells Fargo

Wells Fargo was first founded in 1852 but similar to Bank of America current day Wells Fargo was established in 1998 with the merger of Wells Fargo & Company and Norwest Corporation [34]. Wells Fargo customers have many products to choose from including banking and credit cards, loans, investing and retirement support, wealth management, services to small businesses, and commercial products as well [35]. Wells Fargo is committed to transforming their business and practices, with a focus on customer experience and customer-focused innovation [36]. One of Wells Fargo’s goals is customer service and advice and like Bank of America, Wells Fargo ranked third in customer satisfaction in the J.D. Power 2019 U.S. Retail Banking Advice Study [36].

E. Comparison of Top Three Companies with Highest Complaints

Initial word processing on the dataset, we were able to compare Bank of America, Wells Fargo, and JPMorgan Chase & Co. on the volume of complaints they received. As seen in Figure 4 the most seen words in customer’s complaints for the three companies include loan, mortgage, and payments. Figure 5 further breaks the words most used in the complaints across the companies and looks to show how frequently it was used.

VI. HOW ANALYSIS WILL HELP CUSTOMER SATISFACTION

Understanding where customers complain the most will helps guide financial institutions towards improvements that will hopefully alleviate the pain points. A Bain & Company brief discusses the

Fig. 4: Comparison of Word Frequency between Bank of America, Wells Fargo, and JPMorgan Chase & Co.

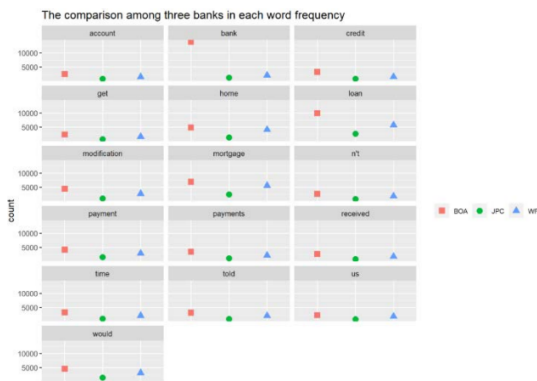

Fig. 5: Comparison of Word Frequency between Bank of America, Wells Fargo, and JPMorgan Chase & Co.

importance of analytics in deepening customer relationships in banking [37]. They outline that analytics “enable banks to activate, not just retain, their high-value customers” and harnessing the full power of analytics works best with five principles: “segmenting customers by value, automating forecasts, predicting loyalty, understanding what causes churn, and taking a test-and-learn approach” [37]. Our focus on complaints will help to inform why a customer might leave thus understanding customers’ struggles. Our analysis of complaint data will lead to predicting behavior of customers on certain products and issues. Bain & Company discusses how a predictive model using a data set with known drivers of Net Promoter Score (NPS) [37]. “A predictive model starts with basic features

present in ordinary segmentation, such as channel usage, the frequency and nature of sales and service interactions, product usage, and revenue. It then taps more advanced sources of data, such as natural language processing of contact center conversations, including volume and tone [37].”

As seen in Figure ??, Bain & Company did a study on the impact of predictive NPS model and “using a predictive model achieves 70% predictive accuracy and a 30% success rate on commercial campaigns, compared with a roughly 5% success rate for the average campaign” [37]. Using the support of these successful number we will look to predict possible outcomes for Bank of America, Wells Fargo, and JPMorgan Chase & Co.

A. Complaints Handling on Bank Brand

In a study on “the impact of the magnitude of service failure and complaint handling on satisfaction and brand credibility in the banking industry” there is a correlation between customer satisfaction and how complaints are handled [38]. The study also points out the variability in what is considered “effective” handling; the fact that humans are involved introduces the variable that cannot be controlled [38]. An individual, despite what the bank may consider timely, can have differing opinions on how a complaint should be handled and what timeframe it should be handled in [38]. “Davidow (2003) concluded that there are six aspects of responsiveness: timeliness, redress, apology, credibility, attentiveness, and facilitation. Among these factors, timeliness is a controllable element that customers consider and judge firms regarding it since failure occurs” [38].

VII. THE RESEARCH

The research was conducted using machine learning and there were several graphs and matrixes produced. In the following sub-sections graphs generated will be discussed and a code snippet used to generate the graphs is shown as well.

The histogram (code in Figure ??) is an acquainted graphical presentation for addressing the frequency of a batch of data. The scope of the information is divided into intervals and the number of qualities falling into each interval is counted. The histogram then, at that point, comprises of

Fig. 6: Distribution graphs

a progression of square shapes whose widths are characterized by as far as possible inferred by the bin widths, and whose statures rely upon the number of qualities in each bin.

In the above graphs (Figure 6), we are identifying the distribution graph for columns from the dataset which has no NAN values. The histograms are displayed with the frequency of counts in y-axis while x-axis contains the values of the column picked.

A. Correlation Graph & Matrix

The correlation graph (code in Figure ??) is a $(K \times K)$ square and even framework whose ij passage is the connection between the sections I and j of X . Huge data in this graph show genuine collinearity between the factors involved (Figure 7). In any case, the nonexistence of outrageous relationships doesn't suggest the absence of collinearity. The regressor factors for numerous relapses can be profoundly multicollinear even though no pairwise connections are huge. In the above dataset (Figure 7), we only have complaint-id as numerical with int64 data type. All other columns are objects. So, the graph is linear showing for only complaint-id.

B. Scatter Plot/Density Plot

A scatterplot (code in Figure 8) is quite possibly the most impressive yet basic visual plot accessible (Figure 9). In a scatterplot, the data points focused are set apart in Cartesian space with qualities of the dataset lined up with the directions. The credits are as a rule of nonstop information type. One of the critical perceptions that can be closed from a scatterplot is a connection between two ascribes under

Fig. 7: Correlation Matrix on Consumer Complaints dataset on Complaint ID

```
# Scatter and density plots
def plotScatterMatrix(df, plotSize, textSize):
    df = df.select_dtypes(include=[np.number]) # keep only numerical columns
    # Remove rows and columns that would lead to df being singular
    df = df.dropna('columns')
    df = df[[col for col in df if df[col].nunique() > 1]] # keep columns where there are more than 1 unique values
    columnNames = list(df)
    if len(columnNames) > 10: # reduce the number of columns for matrix inversion of kernel density plots
        columnNames = columnNames[:10]
    df = df[columnNames]
    ax = pdy.plotting.scatter_matrix(df, alpha=0.75, figsize=(plotSize, plotSize), diagonal='kde')
    corrs = df.corr().values
    for i, j in zip(*plt.subplots_indices_from(ax, k = 1)):
        ax[i, j].annotate('Corr. coef = %.3f' % corrs[i, j], (0.8, 0.2), xycoords='axes fraction', ha='center', va='center', size=textSize)
    plt.tight_layout('Scatter and Density Plot')
    plt.show()
```

Fig. 8: Snippet of Code for creating Scatter and Density Plot

request. Assuming the qualities are directly connected, then, at that point, the information focuses adjust more like a fanciful straight line; in case they are not associated, the information focuses are dispersed. Aside from essential relationships, scatterplots can likewise demonstrate examples or gatherings of groups in the information and distinguish exceptions in the data.

VIII. CHALLENGES & OPPORTUNITIES

Getting access to data was straightforward and it was plentiful in quantity once downloaded. Access to customer complaints is made easy through the collection process of the Consumer Financial Protection Bureau. To really calculate customer satisfaction a deeper understanding of the resolution would have been needed, such as the definition of what timely response means and whether the customer actually received a resolution to their

Fig. 9: Scatter and Density Plot for Complaint ID

complaint that did not require any further follow-up. This data would be gathered easily via a survey to customers. Companies use a CSAT, a customer satisfaction score, as a performance indicator for how their service is doing for certain products [39]. CSAT is measured through customer feedback and is done so by allowing customers a scale of one to five, ranging from Very Unsatisfied to Very Satisfied [39]. Once responses are collected, they are averaged out to provide a composite customer satisfaction score [39].

Another challenge to the research was having no demographic attributes to run analysis one in correlation with complaints. As seen in previous studies done on Indonesian banks, they were able to further extract insights based on age, gender, and education level. Such information could prove to be valuable to companies in identifying the root cause of the issue and adjusting their marketing towards those demographics that need it based on the data showed.

To further develop this research topic, it would recommend collecting more data on the customers having the problems. In addition to more data on the customers themselves, expanding the banks in this research project would be helpful in under-

standing if these issues are only limited to one company or whether there is an overarching problem with the industry.

Machine learning Models for Mental Health Analysis based on Religious Impact

Waseem Ashraf

kdontha@gmu.edu

Tarun Kumar Kancheti
tkanchet@gmu.edu

Abstract—Once a taboo topic, recently we have seen a greater awareness of suicide and the factors that influence the suicide rate. There are many factors that influence the suicide rate, among these factors are religious affiliation and religious diversity. Most of the research on religion's influence on the suicide rate has relied on the study of published articles retrieved from a plurality of databases and surveys performed on the selected population. In addition, hardly any research addresses the impact of religious diversity on the suicide rate. The present paper proposes studying the impact of religion on suicide using a quantitative approach. A data set containing the suicide rate, and religious affiliation rate of over 150 countries is constructed from 1990 to 2010. The countries that constituted a population with a single religion over a threshold percentage are identified as countries lacking religious diversity. The analysis indicates that different religions impact suicide differently. A baseline of suicide rate was generated using countries that are mostly affiliated with no religions. The preliminary research was limited to the top four religions of the world. Our research revealed that countries that are mostly affiliated with Christianity, Hinduism, and Buddhism had lower suicide rate compared to countries with no religious affiliation at all. Even the countries that are religiously diverse shield against suicide compared to countries that are not affiliated with any religion.

Index Terms—Machine learning, Mental Health, NLP, Online Information

I. INTRODUCTION

Every death caused by any fact or is distress for the family. The experience is even more painful when the cause of death is self-inflicted. The World Health Organization (WHO) estimates that each year approximately one million people die from suicide, which represents a global mortality rate of 16 people per 100,000 or one death every 40 seconds. It is predicted that by 2020 the rate of death will increase to one every 20 seconds [?]. Based

on different studies and statistics the suicide has been a major issue in the past, and the situation is only getting worse over the years. A lot of research has been performed on different factors that impact the suicide rate such as age, socio economics, sex, culture, region, race, mental health etc... The study off actors that impacts the suicide are complex as suicide rate could be impacted by factors ranging from parenthood to the environment; however, understanding each of the factors that could influence suicide is essential for suicide preventions. One of the factors that could potentially impact the suicide rate is religion. A handful of studies over the past ten years have examined the relationship between religion and suicide risk. Most of these have not found an association, while two found more suicide ideation among persons who gave low importance to religion [2]. Majority of these studies are based on literature reviews, and surveys performed with selected questionnaires. There is hardly any research available that takes a quantitative approach to study the impact of religious affiliation on the suicide rate. In addition, world is becoming religiously diverse, and there have not been any study performed that determines the influence of religious diversity on the suicide rate. Thus, there is a need to investigate impact of religious affiliation, and religious diversity on the suicide rate. The analysis from these study aids us to make data-driven decisions to reduce suicide rates. These decisions include (i) restrictive access to common means of suicide such as (pesticides, firearms) (ii) public awareness of common suicide signs and available help (iii) social support within communities (iv) improving living conditions (v) providing essentials like food (vi) public transportation, education, and jobs (vii) regularly implementing Mental Health

Screenings by health organizations.

II. LITERATURE

Ying and Tyler studied first on religion, suicide ideation, and suicide attempts and second investigated on religion and completed suicide. From their first analysis, they found that spirituality may reduce the risk of suicide ideation through some evidence. They also found that communal forms of religious participation such as service attendance may reduce the risk of suicidal behaviors. In their second part of the analysis, they found religious affiliations may be associated with a lower risk of suicide, but the associations vary across religious denominations and social contexts. They found stronger evidence that proves that frequent religious service attendance may reduce the risk of death by suicide. They suggest there is a need to understand the association between religion and suicide in the broader context of secularization and shift in the age of distribution of suicide from older to younger groups in many modern societies [3].

Danah and Andrew found predominant religion is significantly associated with the sex suicide ratio. They performed analysis on cultural factors such as geography, religion and life expectancy, PPP, education total fertility rate, and gender development index on male and female ratio. They also found Christianity is one of the major religions for suicide rates due to colonial history in countries that may lead to a variety of societal influences in addition to religion. Another religion was Hinduism which ranked third highest suicide mortality ratio. Additionally, they found that as societies become richer and more educated, males have a higher risk of dying as a consequence of suicide relative to females [4] and it shows in the analysis of online comments. [?], [1]–[4]

Philippe's analysis revealed religion was important for many of the patient suffering from psychotic or other psychiatric disorders [7]. emotion and sentiment analysis [5]–[10] of the online comments could help us to detect mental health patients. For this work, we used machine learning and NLP models for analytic of online texts based on the NLP models developed by our research mentors at George Mason University and other

researchers to detect mental health based on text analysis on online information. [11]–[23]

Agnus reveals income level of the region showed the strongest negative association with the suicide rate, followed by heavy drinking, the population aged 65 and had positive associations with the suicide rate [8].

Lawrence et al. examined the relationship between suicide attempts and ideation. Three hundred and twenty-one adult inpatients and outpatients with current diagnoses of Major Depressive Disorder or Bipolar Disorder were recruited for the study. Based on the diagnostic interview results, the study found past suicide attempts were more common among depressed patients with a religious affiliation. Additionally, suicide ideation was more severe among depressed patients who said religion is more important, and among those who Brito et al. examined the association between religious beliefs and observance and the prevalence of psychiatric disorders, psychotic symptoms and history of suicide attempts in the French general population. The study involved interviewing 38,694 subjects at 47 study sites. A positive association was found with psychotic disorders. Conversely, a negative association was found between religiosity and history of suicide attempts [9].

Religiosity has been shown to be associated with lower levels of aggression and hostility, drug use, and risky sexual activity, which are related to suicidal behavior. In a prospective study with depressed youth, for a more complex understanding of the relationship between depression and religiosity, finding not all religious beliefs and experiences corresponding with better mental health. Research suggests that only certain aspects of religiosity/spirituality (e.g., importance of religion, sense of connectedness) might be associated with suicidal behavior. Research regarding religion/spirituality in youth, requires more exploratory studies to further this understanding [6].

Gearing et al. discusses the impact of religion on the suicide rate [5]. The study states “an accurate understanding of a client's religious faith and participation may indicate potential suicide risk. In addition, assessing religiosity may also identify potential areas that treatment could target and enhance life affirming beliefs and expectations.” The

methodology used in this study involved searching the databases for peer reviewed articles on religion and suicide between 2008 and 2017. The study concluded that the influence of religiosity on suicide appears to vary by gender. Similarly, the research also identified that individuals with lower religious orientation are at increased risk of suicide compared to individuals with higher religious orientation. This study was restricted to males. In addition, the study identifies that research is needed to better understand the unique protective role that religions exert against suicide, specifically as it may be moderated by demographic characteristics (e.g., gender, age, and belonging to specific subgroups) and degree of religiosity (e.g., participation in religious activities).

The above papers researched on suicide rate influenced by spiritual beliefs, religious rituals, psychotic disorders, heavy drinking, tobacco, alcohol, geographical area, life expectancy, PPP, education, fertility rate, and gender development. However we use applications of machine learning in natural language processing [17], [24]–[40] in other domains such as health, security and business, and apply transfer learning models to analyse the online comments [41]–[55]. There are only a few papers that have concentrated on religion and suicide rate relation. Additionally, they conducted research based on other paper analyses. This paper aims to analyze the suicide rate based on sex, religion and few other attributes using publicly available data. There are six major religions in the world. These religions are Buddhists, Muslims, Christians, Hinduism, Jews, and folk religions. We would be identifying which religions contributes lowest and highest suicide rate among them. Additionally, we will explore which sex has contributed high suicide rate in top-ranked religion. The above analysis can help to visualize a broader context in society.

A. Problem Description

Between 2008 and 2017, publications on religion and suicide were published in the PsycINFO, MEDLINE, SocINDEX, and CINAHL databases. The influence of religious variety, as well other factors, on the suicide rate was not understood in the studies undertaken during these years. To prevent suicide and reduce the ever-increasing suicide rate,

we must first determine the relationship between the elements that influence suicide. The literature evaluation suggests that religion may have a significant role in suicide prevention; however, this is not the focus of their study. Determining and forecasting the cause of suicide will help us make data-driven decisions in the health curriculum and take proactive preventative efforts through suicide prevention organizations like NSPL, NOFA, AFSP, NIMH, SPTS, and CDC...etc Furthermore, the study will educate the public about the impact of religion on the suicide rate.

B. Problem Investigation

Investigation into the problem set included data collection for the following primaries:

- The factors caused to suicide by the religious believes and its impact when there are diversified religions.
- Is there a link between religion and suicide, the results of this study will be determined by comparing the suicide rates of various faiths to the suicide rates of non-religious persons. The greatest influences of religions on suicide.

III. METHODOLOGY

The methodology was divided into two steps:

- Dataset Preparation
- Analytical Approach

A. Dataset Preparation

We searched trusted sources for data related to suicide rate of different countries over the years, and religious affiliation of different countries over the years. We retrieved the suicide rate data from world health organization, and religious affiliation data from data world. Once datasets were received and their validity verified, the next step was to combine the datasets to build a dataset that could correlate religious affiliation with suicide rate. The dataset was merged using the countries and years as common attribute.

B. Analytical Approach

In order to analyze the impact of religions on the suicide rate, first we needed to determine the countries that are not affiliated with any country as baseline. The non-religious countries were

Fig. 1: Most Popular Religions in the World -[Tableau]

determined, and their suicide rate was analyzed. Next, we determined the most popular religions in the world. Once the most popular religions were determined, analysis were performed to determine the countries that belong to each of the popular religions. In order to ensure that influence of single religion is determined, we selected the countries where the predominant population belongs to a single religion, thus lacking religious diversity. For majority of popular religions, threshold of 95% and above was used to ensure that these areas are only influenced by a single religion. In addition, countries with religious diversity were also determined to analyze the influence of religious diversity on suicide. The results of individual religions were compared with each other, and the baseline of non-religious affiliation to determine the religious influence on the suicide rate.

1) *Top Five Religions in the World:* For this study we focused on top five religions in the world. Figure 1 shows the religious population over the years in the world. As can be seen from the above figure, Christianity, Islam, non-religion, Hinduism, and Buddhism makeup top five religions in the world. In addition, top five religion's population have kept increasing over the time. Christianity is still the leading religion, whereas Islam is growing on faster rate than any other religions.

2) *Countries that Lack Religious Diversity:* Next, for each of the top five popular religions in the world, we identified the countries that belong to a single religion (thus lacking religious diversity).

Countries with Dominant Christian Affiliation

Fig. 2: : Predominant Christian Countries -[Tableau]

The countries that have a single dominant religion were selected based on religious affiliation threshold. For majority of popular religions, we were able to select countries that have at least 90% religious' affiliation.

3) *Predominant Christian Countries:* Figure 2 bar graph shows ranked snippet of the Christian affiliation for each country in the dataset for year 2010. The analysis was performed from 1995-2010 by each five years. The following table shows countries with at least 95% of the population that belongs to Christianity in 2010.

A Survey on the Jamming and Spoofing UAV Network Attacks and How Machine learning is an Effective Against them

Faisal Alrefaei

*Electrical Engineering and Computer Science
Embry Riddle Aeronautical University
Daytona Beach, USA
Alrefaei@my.erau.edu*

Abstract—Recently, the unmanned aerial vehicle (UAV) has attracted companies, governments, and organizations to execute valuable missions. The security of UAV networks has become an urgent need to avoid disaster consequences. Jamming and spoofing attacks are the most dangerous attacks used against UAV networks. The jamming attack is a stealthy attack that is hard to detect and leads to unavailability of the service over the wireless network. In some cases, unintentional interference caused by the traffic network is similar to a jamming attack. Therefore, the efficient anomaly detection technique must be capable to distinguish them either as normal or abnormal behavior. The Global Position System (GPS) is an important critical system on which the United States relies in some missions. However, hackers target the Global Position System (GPS) signal to manipulate it to deviate the UAV to their extreme zones. Some detection methods used for GPS spoofing attack that are classified into three categories, such as digital signatures, encryption, and some characteristics of Automatic Dependable Surveillance Broadcast (ADS-B). This article reviews the impact of the jamming and spoofing attack and previous traditional security detection and defense techniques. In addition, it addresses the benefit of deep learning technology to show that deep learning technology is an effective technique when it comes to protecting UAV communication networks.

Index Terms—UAV, cyber attack, jamming attack, deep learning, orthogonal frequency

I. INTRODUCTION

In the past decades, revolution technology in computing and sensor capabilities has emerged as promising solutions to play a key role in the modern era. It is used as small devices that rely on an open network to execute a specific mission in a limited time and at low cost, such as unmanned aerial vehicles (UAVs) or drones. UAVs have been used broadly in rescue tasks, packet delivery, remote sensing, rely communication, etc. The components of the UAV network include the UAV, GPS, the ADS-B receiver, and the Ground Control Station (GCS) as shown in Figure 1 [1]. The UAV is considered an autopilot based on self-flying and control without human intervention or the presence of a pilot on the board. All of these components are completely dependent on ADS-B and GPS for navigation. Therefore, the UAV application has been increasingly used due to its unique characteristics. UAVs are present in some critical

fields to perform special tasks in extreme environments. In addition, it is easy to learn how to fly UAVs and they are easily programmed for specific missions in a short time. Therefore, the UAV has been attracting the military and civilian sectors to perform various missions.

Although the growth use of UAVs and the facilities that can be made, the network UAV system is prone and subject to malicious threats to degrade the performance of the UAV system for example, Jamming and Spoofing attacks. A UAV uses an air-ground (line of sight) signal to transmit the data. This link is exposed to be blocked by (jamming attack) or being compromised by malicious hackers who deliberately violate the integrity of the data transmission (spoofing attack). Therefore, the security of the UAV network is an urgent issue.

Jamming attack is one of the dangerous threat attack techniques used against the UAV's node network to disrupt the communication between UAVs and other legitimate entities. It is an action that violates the policies of the media access control protocol or PHY in wireless communication to disrupt transmissions [2]. It is a form of denial-of-service (DOS) attack that leads to interrupting the ongoing communication and making it unavailable. Hackers execute the jamming attack technique by sending radio signals to flood the channel node. Jamming attacks can be classified into four categories: constant, reactive, random, and deceptive [3]. Each of these attacks is executed on the basis of their knowledge and technique to execute their malicious action correctly.

GPS and ADS-B play a critical role in the UAV's navigation and position. The spoof attack is an attack that aims to deviate the UAV from its planned path to the unsafe zone. Hackers deliberately alter the GPS signal to manipulate the navigation system [4]. In ADS-B the spoofing attack subjects ADS-B of the ground or aircraft-based attacks by manipulating the international Civil Aviation Organization (ICAO) addresses that are positioned in each aircraft as a unique identifier [5]. Hackers spoof the ICAO to show a fake non-existent aircraft to mislead the Air traffic Control ATC.

Scientists and researchers have innovated and published many suggestions and strategies to detect and defend against

jamming and spoofing attacks. These traditional techniques are impractical and ineffective when applied in UAV networks. UAVs are classified as small devices that have limited resources, such as size, power consumption, and high mobility. Therefore, the researchers try to define a suitable technique that is effective taking into account the limited resources.

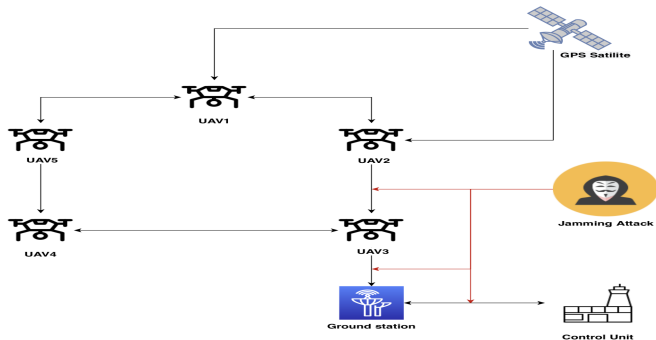

Fig. 1. Jamming Attack on the UAVs

II. JAMMING ATTACK

Jamming attack is a version of the Internet Denial of Services (DOS) attack. Data communication in the UAV network is classified into four types [6]. The first is the data link between the UAV and the GCS. The second is a UAV and another nearby UAV. The third is a UAV and the GPS. The last is the UAV and ADS-B at the ground station. Automatic Dependent Signal Broadcast (ADS-B) is a system that is being deployed on aircrafts to control air traffic. The UAV depends significantly on the ADS-B to easily drive it to its safe home land. The compromising or blocking these system’s signals Attackers use this jamming attack to disrupt UAV communication by sending unwanted radio signals. Hackers aim to distribute ongoing communication to degrade UAV communication performance by broadcasting noise radio signals to flood the channel nodes.

1) *Constant Jamming Attack*: A constant jamming attack is a malicious action that continuously sends a high power noise signal without following any protocol to prevent communication and consume the power of the receiver as shown in Figure 2. This malicious action aims directly at arbitrary achieve tow goals, which create congestion over communication links or lead the receiver to consume its resources by receiving a large number of data packets [8]. An extra number of data packets is a reason to consume power or memory size. This action prevents the legitimate entity from sending signals over the network and causes delays in the time required for the new signal to reach the receiver side channel. Therefore, hackers intentionally continue to target quality signals by sending arbitrary signals [8], disrupting quality signals to make the signal disappear and making it impossible to decode it.

2) *Deceptive Jamming Attack*: A deceptive jamming attack is the most stealthy attack among the four types of jamming attack. its intention constantly sends authentic packets to

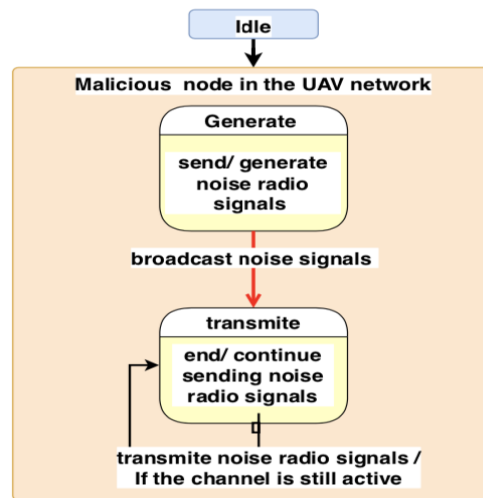

Fig. 2. Constant Jamming attack on the UAVs

mislead the other aircraft [7]. The deceptive jamming attack occurs in the ADS-B as an injection of a message attack, as shown in Figure 3. The adversaries inject empty data packets into the transmission link during the data transmission being active. They exploit the transmission gap that occurs when the sender sends the data packet [8]. The deceptive jamming attack, intending to inject its injection packet as empty useless payload in the receiver channel.

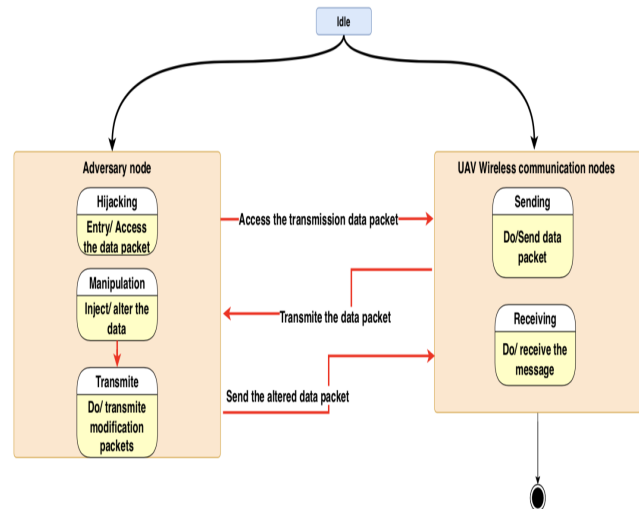

Fig. 3. Deceptive Jamming Attack on UAVs

3) *Random Jamming Attack*: The preservation of resources is the main goal of performing efficient malicious action against targets. The intermittent jamming attack preserves its resources by changing between idle and active modes [9]. It sends noise signals intermittently. This kind of jamming attack leads to not consuming its power resources by continuing to send signals as constant jamming signals, as shown in Figure 4. This attack is called random jammer, where it

is a combination of message injection attack and constant jamming attack [9]. Its technique aims to preserve its power resources.

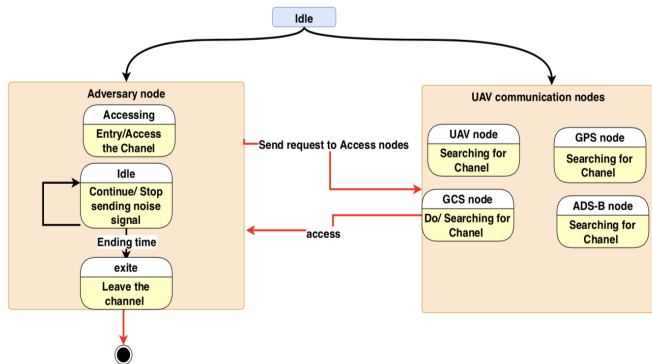

Fig. 4. Random Jamming Attack on the UAVs

4) *Reactive Jamming Attack*: The reactive jamming attack aims to sense the status of the reception channel. This technique needs to sense the activation status of the channel in the nodes of the UAV network to start its action, as shown in Figure 5. Once hackers discover that the channel is activated, they start sending the noise signal to the reception nodes [9]. Another technique used by hackers in this type of attack is that hackers can distinguish sender quality signals. once the hackers distinguish that weakness in the sender signals is achieved, they stop sending the noise signals; otherwise, it continues sending the signal unless those two conditions are not achieved [9].

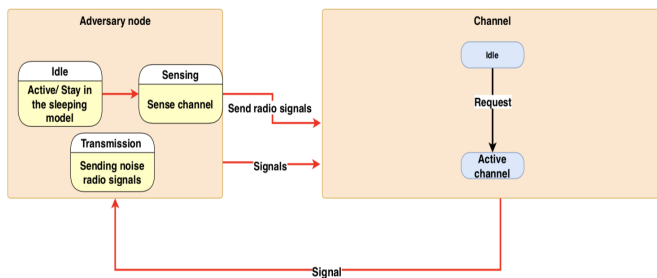

Fig. 5. Reactive Jamming Attack on the UAVs

III. SPOOFING ATTACK

Hacker lanch spoof attack on the two data links and GSC based on the GPS and ADS-B data packet, as shown in Figure 6. The components of the UAV network include the UAV, the navigation satellite system, the ADS-B receiver, and the ground station. All of these components are completely dependent on ADS-B and GPS for navigation. However, natural communication is vulnerable to being compromised by

malicious actions to violate ongoing data packet transmission integrity. The malicious action then is to collect the ADS-B and GPS data to execute their malicious action.

ADS-B is one of the main components of next-generation air transportation systems. This system plays a crucial role in the management of spaces to avoid congestion and collisions. The aircraft is equipped with ADS-B out and ADS-B in [13]. The two channels transmit and receive control to keep the airspace safer than ever before. The content of the information in the transmission packets includes the position, speed, altitude, and other information for another flight in the sky.

GPS plays a key role in the self-flying of the UAV in space. The GPS widely used by UAV recovers from the navigation and positioning system. The United States developed the GPS system to be used for navigation and flying [12]. The GPS signal is divided between two fields of military or civilian missions. Most of the signal is sent as plain text, so anyone can see it or alter it to achieve specific objectives.

GPS spoofing attack is a common technique used by hackers to inject false GPS signals into the UAV. The adversary uses the GPS signal to send it as a fake signal with higher signal power [14]. Hackers use this attack to drive the UAV to an unsafe zone or deviate the UAV from its planned flying path to cause a collision in the space. They can be gradually simulated at different locations by presenting fake positions.

Relying on non-encrypted packets of ADS-B broadcasting and GPS signals attracts attention to the vulnerability that can be exploited for malicious actions. ADS-B spoofing is divided into two categories, aircraft and ground-based [15]. The hacker found that targeting the ADS-B signal leads to misleading the GSC and other nearby UAVs. They always initiate their malicious plan by modifying or altering the data to drive the UAV to dangerous zones.

IV. SPOOFING ATTACK ON THE GPS AND ADS-B

UAV system was fully dependent on and guided by GPS and ADS-B to control its direction or perform its tasks. The UAV uses GPS to perform specific tasks such as landing in the planned zone. Additionally, the aircraft uses the ADS-B to exchange data with the nearby ground station [16]. The execution of malicious actions by the adversary can lead to catastrophic consequences. Hackers can inject malicious packets to drive the UAV to unsafe zones or a fake aircraft presence to mislead the air traffic control or the nearby UAV to cause a collision or disrupt airspace traffic [8].

A. Spoofing Attack on GPS

GPS is the main component in driving the UAV in the planned direction. UAVs rely on the data sent by GPS to fly, but the link between GPS and UAVs is prone to adversaries. The spoofing of this link is the main threat to civilians or military. GPS spoofing can be a form of eavesdropper that listens to the transmission of data between UAVs and GPS signals in space [17]. It can cause the UAV to have the wrong position or cause manipulation of the predefined position to

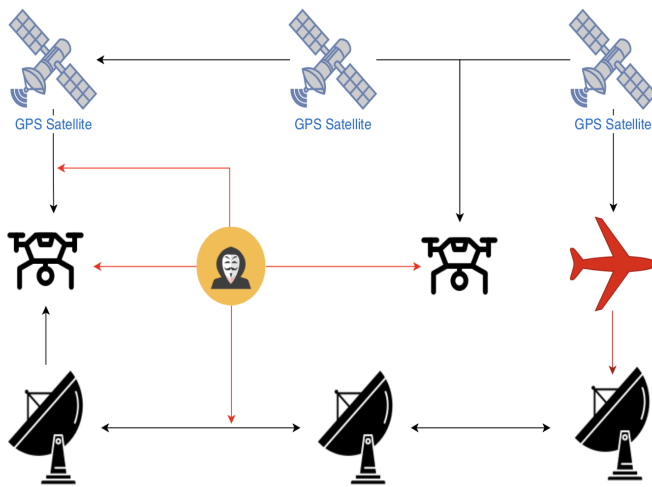

Fig. 6. Spoofing and Jamming Attack Framework on the UAVs

mislead UAV tasks. Therefore, the GPS spoofing signal can be effective in disrupting a military or civilian mission.

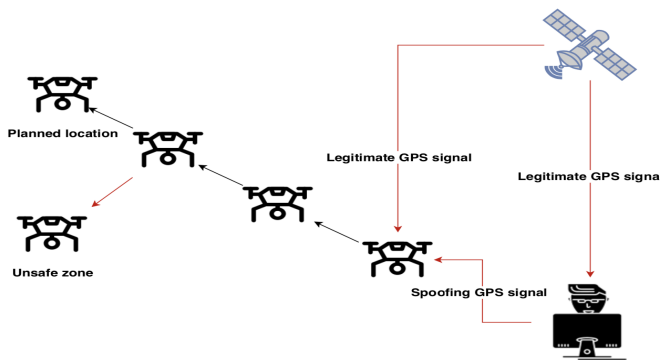

Fig. 7. Spoofing attack framework for UAVs

B. Spoofing attack on the ADS-B

ADS-B spoofing attack is executed in two forms: aircraft-based attackers and ground-based attackers [5]. Each of these attackers has a specific technique. In aircraft-based attackers, the adversary modifies the ICAO addresses to mislead the nearby aircraft or the aircraft control to present itself as a legitimate aircraft, as shown in Figure 7. In ground-based attackers, the adversary does not face any challenges, such as using high power to launch their attacks [18]. Malicious action is initiated using the low-cost SDR device.

C. Aircraft Spoofing Attack

aircraft spoofing attack hides its entity and is executed by spoofing ICAO addresses [5]. They spoof the ICAO addressee to perceive the aircraft as a legitimate entity to mislead either the air traffic control or nearby aircraft. Using this technique is an effective way where secondary radar surveillance can not detect the attack because the aircraft is physically present.

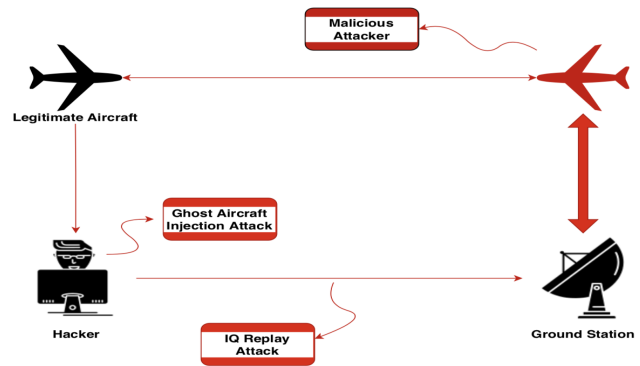

Fig. 8. ADS-B Spoofing Attack on UAVs

D. Message or IQ data replay attack

Message or IQ data replication attack is similar to the replay attack, but the way IQ data replication works is clever and stealthy. The attacker in this attack preserves the message that is re-generated and re-transmits it by SDR devices without any change or modification previously recorded in the messages [5].

E. Ghost aircraft injection attack

in the ghost aircraft injection attack, hackers send a fake ADS-B signal [5]. The adversary in this attack uses the SDR to execute this malicious action.

V. ADS-B SYSTEM BACKGROUND

Automatic dependent surveillance broadcast (ADS-B) is a technology system that was used to adopt new technology and ride of the traditional radar system [?]. It is a satellite-based system that is used to be deployed and equipped in aircraft to broadcast data. The two data links used by the ADS-B are 1090 and 987 MHz [?]. In addition, this system consists of two main components: ADS-B out and ADS-B in. The ADS-B out subsystem periodically broadcasts to the nearby entities (aircraft and ground station) the data related to the airplane identification such as ICAO addresses and the airplane statuses data such as velocity, altitude, and speed. The ADS-B on the device is used to receive a broadcast generated by a near-aircraft or ground station. The data received are spanning such as weather, ATC guidelines, and other data statuses. All these parameters lead to improve the performance of the aircraft in the sky, aircraft control, and avoid collisions in the space.

VI. PREVIEW WORKS AND DRAWBACKS

Recently, some techniques have been developed to resist jamming attacks. These jamming attack techniques vary depending on the type of jamming attack. Each of the four jamming attacks has characteristics that distinguish them from each other. For example, reactive jamming sensing the channel statuses if this channel started receiving the packets, reactive attack jamming attack emits a noise signal otherwise, still ideal [19]. Therefore, the reactive jamming attack is headed to be detected [20].

The traditional approach to jamming attacks is to redirect network traffic, change channel, frequency, or move to a safe zone to stop receiving the jamming signal again [21]. The famous technique to prevent jamming is frequency hopping and channel hopping [?]. In frequency hopping, once the disruption signal is presented over the network, the new frequency is chosen to be used over the network, so all receivers are asked to move on these new transmission frequency bands. Channel hopping is used frequently to countermeasure the integrity or blocking effect of the network [6].

Game theory has been widely used to resist against the jamming attack. Game theory models the jamming attack and the scenario to understand it and then builds resister techniques against the jamming attack [7]. In this theory, the jamming and the nodes are formulated as a follower and leader. The follower monitors the behavior of the leader and some signal features, such as signal power. Therefore, the follower launches its jamming signal based on the leader feature signals.

Innovation and the development of new techniques to protect UAV communication from being compromised are a continuous motivation of researchers to suggest methods to secure UAV communication. They innovated authentication, cryptography, and verification techniques that use the non-cryptography schema for the UAV security field [11]. The non-cryptography technique aims to verify the location of the UAV using the Kalman filter, distance bounding, etc.

Multichannel receiver techniques proposed against the jamming attack against the ADS-B jamming attack. Singular value decomposition used to use algebraic manipulation. These techniques provide different signals from different resources [9].

The increasing number of spoofing attacks and their catastrophic results encouraged researchers to continue to develop new techniques to withstand this attack. There are three methods that have been created for these goals, which are cryptography, authentication-based signals and external UAV communications [8]. Cryptography techniques are used to encrypt transmission packets and decrypt at the receiver through a shared key. In the authentication-based signal, the author [12] used two algorithms: ECC and RSA. In the third detection technique, anomaly detection uses characteristics to recognize attacks such as UAV speed and acceleration.

GPS spoofing attack to mislead the UAV or the automatic control to hijack the UAV to an unsafe zone. Adversity targets the GPS signal and counters the GPS signal to achieve its objectives. Researchers emphasize this vulnerability and innovate defense techniques to resist the GPS spoofing attack again. The GPS spoofing attack can be divided into three categories: signal processing techniques, hardware techniques, and combination of hardware and signal processing techniques [5]. In signal processing techniques, the adversary uses it to collect data from the transmitted and processed signals to use it to launch the attack. In the sequence, an attack is required to the presnet sensor and control system to lanch the attack. In the third spoofing techniques

VII. MACHINE LEARNING

Machine learning technology has been increasingly used in different aspects due to its characteristics in dealing with different missions. Machine learning is known as deep learning, which has several hidden layers that use different abstractions to learn new features [23].

Fig. 9. Deep Learning Layer Structure

Deep learning aims to identify the attacker from unknown distributed inputs in layers [4]. This technique in deep learning is used to store new data and process them to learn new features as output. Therefore, the prevalence of deep learning is determined by the number of training examples. Deep learning performs better when it has enough hidden layers to be high. In the form section, show the classification of the DL into three sections supervised, unsupervised, and reinforcement learning.

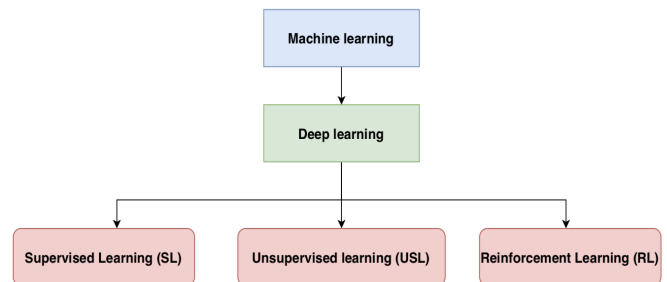

Fig. 10. Machine learning Algorithms

VIII. REINFORCEMENT LEARNING

Reinforcement learning algorithm is considered a reward algorithm. It is used to achieve optimal results. RL first uses the regimented learning process with a specific, specific parameter to achieve optimal results [?]. Security engineers use Q-learning, which is an extension of RL. They use it widely in defenses against jamming attacks.

IX. UNSUPERVISED LEARNING USL

Unsupervised learning algorithms have been widely used to identify patterns and define correlation without training in the predefined data set. It includes clustering in the USL to identify similarity between data groups [23].

X. SUPERVISED LEARNING

the supervised learning algorithm is trained on the pre-defined data set to reach specific output and precision. The predefined data set consists of two tubules label and attribute [23]. The label represents the output, while the attribute represents the input.

In classification tasks, algorithms are used to classify the input data into different classes. The security engineer uses these algorithms to classify different classes on the network under spoofing and other attackers. Also, it is useful to categorize other destructive executions such as malware and spyware.

In regression, this algorithm is used to predict specific output. In security fields, the regression algorithm is an efficient approach to predict the parameters of the data packet transferred over the network. Predicting these parameters helps security engineers distinguish the original and manipulated packets. It is useful to deny anomaly detection to recognize abnormal behavior such as a malicious log in or location. In addition, it can be used to build anomaly detection to recognize HTTP requests [23].

XI. FEATURE SELECTION

feature selection technique is an effective way to help security engineers build a robust ML model [1]. It leads to extracting details and shows how the correlation between features in the dataset. During the construction and training of the ML model, some ineffective features are presented. These features have to be removed [1]. However, these features are the reason for increasing the tiem'building model, complexity, and being the main reason for reducing accuracy. Therefore, the security engineer needs to use efficient feature selection techniques to extract usable features to overcome the ML model. Here are some feature selection:

A. Bit Error Rate (BER)

BER is used effectively to select features during non-coherent receivers. The presentation of the jamming attack implies an increase in the rate of the erroneous. for example, it is used in the ADS-B receiver and was calculated as [24]

$$BER = \frac{1}{2} \exp\left(-\frac{E_b}{2N_0}\right) \quad (1)$$

B. Spearman Correlation

The Spearman correlation is used to identify the feature after that ride of the correlated features [1]. The security engineer likes to use this technique to measure the monotonic relation that is presented between two variables. However, this technique is used to show all the details better than other feature selections. By using this technique, the security engineer has

the ability to demonstrate the strongest relationship between variables through:

$$r = \frac{Cov(X_r, Y_r)}{Std(X_r)Std(Y_r)} \quad (2)$$

C. Bad packet ratio (BPR)

The cyclic redundancy check (CRC) is the standard to recognize whether jamming attacks occur on continuous transmission or not. Given the ADS-B protocol, the CRC is used to check the received packets at the receiver if they fail, which is a sign of a jamming attack [1]. Therefore, increasing the error on the receiver side leads to increased drooping of the packet.

D. Extra Tree Classifier

Extra tree classifier is used to reduce complexity in computation and processing time. This technique selects the feature efficiently. In this technique, the pre-description is calculated by averaging the results using the decision tree. Therefore, this technique leads to the delivery of an accurate prediction, reduces variance, and overfits the control.

XII. DEEP LEARNING AND INTRUSION DETECTION

The traditional attack detection and defense methods are not suitable when it comes to resisting attacks or spoofing UAV network links. Limited resources and high mobility are the main reason. In addition, some detection techniques addressed in this article lead to updating the architecture of the ADS-B protocol. Therefore, these techniques are not effective in applying them to the communication of the UAV network.

Deep learning has been widely used in different fields with different tasks. Building intrusion detection systems using deep learning techniques has attracted researchers' attention. The deep learning algorithms are used to implement IDS accuracy to recognize the unknown attacker. They are also used to learn new features of the unknowable label data set. so, deep learning technology can build its data set by collecting unlabeled data sets.

XIII. CONCLUSIONS

The UAV shows its ability to be used and applied for different missions. Natural UAV communication links are subject to some threats that cause degradation in the performance of the UAV system. The adversary found that it is an easy task to listen to the transmission data traffic and execute their malicious actions. The jamming and spoofing attack was used with malicious intent to put the UAV under threat and cause catastrophic consequences. In this article, some attack defense and detection techniques that are used to detect these threats are addressed. However, these techniques are not suitable for application in UAV technology. Machine learning has emerged as a promising technology. Deep learning has the ability to learn and know new features from an unknown label data set, so it is an effective way to be used against jamming and spoofing attack even if they launched simultaneously.

Abstract—This work aimed to manufacture a highly sensitive hydrogen gas sensor based on Fe₂O₃:ZnO thin film. The Fe₂O₃:ZnO based sputtering target was synthesized by a solid-state synthesis method. Gas-sensitive thin films were deposited onto alumina substrate by the high-frequency (RF) magnetron sputtering method. The thickness of the sensing film was measured and the morphology of the sensing layers was studied. The Fe₂O₃:ZnO sensor showed the highest hydrogen gas response at 100 °C and the operating temperature of 150 °C was selected as the optimum working temperature. The sensor showed sensitivity even to extremely low concentrations of hydrogen (100 ppm), where the response was 4.6. The sensing parameters of the fabricated sensor confirm that the Fe₂O₃:ZnO nanostructure is challenging for the detection of low concentrations of hydrogen.

Keywords—gas sensor, hydrogen, zinc oxide, thin film, sensitivity

I. INTRODUCTION

As know, the hydrocarbon-based energy sources on the Earth will be consumed in the next few decades, which is why intensive research is being done today to find alternative energy sources and to develop new technologies for this purpose. Among alternative energy sources, hydrogen is considered to be the most preferred due to its high calorific value, green emissions during combustion, and the presence of an unlimited amount on the Earth and in Space. Hydrogen has already been used as a source of energy in cars, airplanes, spacecraft, and in industry and technology, it is used as an essential gas for the synthesis of various materials and for carrying out various technological processes. Such widespread uses of hydrogen and their expansion in the future require the development of storage and transportation technologies for this gas. From this point of

view, hydrogen is not a preferred gas, as it is extremely flammable and explosive. The best way to avoid a hydrogen gas explosion is to use sensor systems. All this proves that the development of hydrogen sensors with high sensitivity, speed, low energy consumption, and advanced performance parameters are very urgent issues [1-7].

There are now hydrogen sensors on the market based on different physical principles, which do not meet modern requirements. The main problem is with the sensor performance parameters. The fact is that the existing sensors are not very fast, they work at high temperatures and they have a rather high detection limit and low sensitivity [8-13].

Nowadays, various nanostructured materials based on metal oxide semiconductors (MOS), such as SnO₂, In₂O₃, WO₃, ZnO, TiO₂, Fe₂O₃, CuO, and Ga₂O₃ are widely used in the manufacturing of resistive gas sensors sensitive to low concentration of hydrogen gas. As one of the most widely used oxides, hematite (Fe₂O₃) has n-type semiconducting properties with a bandgap of 2.1 eV under ambient conditions. It has the most thermodynamically stable phase among all iron oxides, low cost, nontoxicity, high chemical and temporal stability, and superior sensing performance towards reducing gases. Despite the above-mentioned advantages, pure iron oxide has fairly poor sensitivity to reducing gases and the introduction of dopants in pure Fe₂O₃ leads to the improvement of almost all performance parameters [14-20].

This work presents the design and development of a resistive sensor based on semiconductor Fe₂O₃:ZnO nanostructures with high sensitivity to low concentrations of hydrogen. The manufactured sensor can be successfully applied in a variety of

fields, as it has a low operating temperature, fast response/recovery behavior, high sensitivity and selectivity, and low gas detection limit.

II. EXPERIMENTAL

To synthesize the Fe₂O₃:ZnO sputtering target, Fe₂O₃ (99.9%) and ZnO (99.9%) nanopowders were purchased from Alfa Aesar. Fe₂O₃:ZnO ceramic target was synthesized by solid-phase reaction methods [21].

Using the Fe₂O₃:ZnO sputtering target thin sensing layer was deposited on Multi-Sensor-Platforms by VTC-600-2HD DC/RF Dual-Head High Vacuum Magnetron Plasma System. The Multi-Sensor-Platforms were purchased from TESLA BLATNA (Czech Republic). The factory-designed substrate consists of a temperature sensor (Pt 1000), a platinum heater, and interdigitated electrodes on the alumina substrate. The temperature sensor and heater were isolated with a glass layer. Fe₂O₃:ZnO layer was deposited onto the non-passivated platinum electrodes to convert the Multi-Sensor-Platform into a gas sensor (Fig. 1). The deposition time, input power, and substrate temperature during deposition were 20 min, 70 W, and 200 °C, respectively. In the final stage of the fabrication, palladium catalytic particles were deposited onto the sensing layer for sensitization of the active surface.

Fig. 1. The schematic diagram of the Multi-Sensor-Platform and the Multi-Sensor-Platform based sensor.

In the case of magnetron sputtering, the film thickness is controlled by the changing of sputtering time at a constant input power. One of the most important factors in terms of gas sensitivity is the thickness of the film, which was measured for 20 minutes of sputtering duration. The thickness of the film corresponding to this value was measured by the Alpha-Step D-300 (KLA Tencor) profiler. As shown in Fig. 2, the thickness of the Fe₂O₃:ZnO film was equal to 144 nm.

Morphological characteristics of the gas sensor have a great influence on sensor performance, the study of which is successfully carried out with the help of scanning electron microscopy (SEM). The SEM study of the Fe₂O₃:ZnO film was carried out by Vega 5130 MM (Tescan) (Fig. 3). The film has a granule structure with an average grain size of 150 nm.

Fig. 2. The thickness measurement result of Fe₂O₃:ZnO film.

Fig. 3. SEM image of Fe₂O₃:ZnO film

The hydrogen sensing performance of the Fe₂O₃:ZnO sensor was tested by the laboratory-made computer-controlled gas testing system, which contains a test chamber, pressure sensor (Motorola-MPX5010DP), and a data acquisition system (PCLD-8115) [22]. For gas sensing measurements, the Fe₂O₃:ZnO sensor was installed in the gas chamber connecting

the six pins (two pins of a temperature sensor, two pins of the heater, and two pins of resistance measurement electrodes (Fig. 1) with the corresponding inputs on the sensor holder.

III. GAS SENSOR STUDY

The manufactured sensors are resistive type and the operation of this type of sensor is based on a change in the electrical resistance of a gas-sensitive layer under the influence of target gases. This is due to the exchange of charges between the molecules of the adsorbed target gases and the semiconductor film. So, the sensor response is defined as $S=R_a/R_g$, where R_a and R_g are the electrical resistances of the active layer in air and the presence of a target gas, respectively. Response and recovery time is defined as the time required to achieve 80-90% of the change in resistance from the corresponding steady-state value of each signal. The gas sensing characteristics of the $Fe_2O_3:ZnO$ sensors in the presence of hydrogen gas are shown below.

The sensing characteristics of the manufactured sensor were studied in the temperature range of 50–250 °C. The heater of the sensor platform allowed the temperature of the sensor to raise the temperature to 250 °C. All real-time measurements of the electrical resistance were carried out at 3 V DC voltage applied on the electrodes of the sensor.

The $Fe_2O_3:ZnO$ sensor demonstrated the maximal response value to 2000 ppm of hydrogen at 100 °C temperature where the resistance of the sensor changed more than 5000 times (Fig. 4).

Fig. 4. Dependence of the response of the $Fe_2O_3:ZnO$ sensor on the operating temperature at 2000 ppm of hydrogen.

At 50 °C, 150 °C, and 200 °C, the sensor response was higher than 1000, while the response value was significantly lower (287) at 250 °C. The real-time resistance change of the $Fe_2O_3:ZnO$ sensor at different operating temperatures toward 2000 ppm hydrogen is revealed in Fig. 5. Despite high responses in the temperature range of 50-100 °C, the significantly lower response and recovery times, as well as the higher recovery levels of the base resistance were demonstrated at 150 °C. At higher temperatures (>200 °C) the sensor response decreased and the energy consumption increased. Consequently, the temperature of 150 °C was determined as the operating temperature for hydrogen detection. The response and

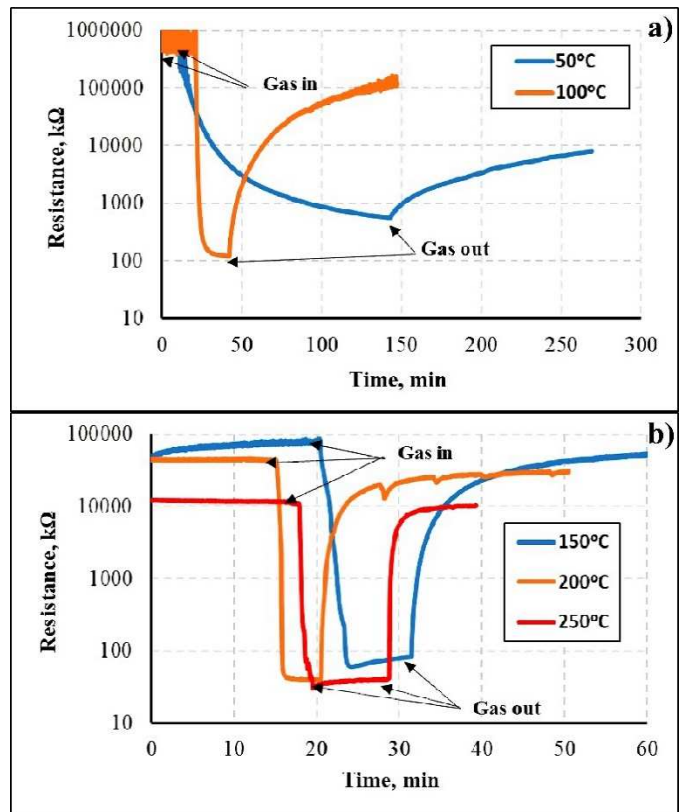

Fig. 5. The real-time resistance change of the $Fe_2O_3:ZnO$ sensor at different operating temperatures toward 2000 ppm hydrogen.

recovery times of the sensor toward 100 ppm hydrogen at operating temperature were found to be 9 min and 21 min, respectively.

The time-dependent response curves of the sensor in the presence of different concentrations of hydrogen and the dependence of the response of the sensor on hydrogen gas concentration at the operating temperature are presented in Fig. 6 and Fig. 7, respectively.

Fig. 6. The real-time response of the $Fe_2O_3:ZnO$ sensor at different concentrations of hydrogen gas at 150 °C operating temperature.

The sensor showed a clear and recoverable response in the hydrogen concentration range of 100-800 ppm. The sensor showed sensitivity even to extremely low concentrations of

hydrogen (100 ppm), where the response was 4.6. Toward the higher concentration (800 ppm), the response value exceeded 1042, which is a very promising result. The dependence of the response on hydrogen concentration has a linear characteristic which will allow not only to detect of H₂ traces but also to accurately measure the low concentrations of this gas. In order to check the selectivity, the gas sensing characteristics of the sensor were studied in the presence of acetone, ethanol, toluene, methane, and LPG. The sensor did not show any significant response to 400 ppm, 675 ppm, 700 ppm, 2000 ppm, 1000 ppm of acetone, ethanol, toluene, methane, and LPG, respectively, compared with the response to 300 ppm of hydrogen (Fig. 8), which confirmed the high selectivity of the sensor.

Fig. 7. Dependence of the response of the Fe₂O₃:ZnO sensor on hydrogen gas concentration at the 150 °C operating temperature.

Fig. 8. Comparison of responses of the sensor to 300 ppm of hydrogen, 400 ppm of acetone, 675 ppm of ethanol, 700 ppm, 2000 ppm of methane, and 1000 ppm of LPG.

IV. CONCLUSIONS

A nanostructured film based on the Fe₂O₃:ZnO material was deposited on an alumina substrate by high-frequency magnetron sputtering and the active surface was sensitized by Pd catalytic particles. The sensor showed a clear and recoverable response in the hydrogen concentration range of 100-2000 ppm and the dependence of the response on hydrogen concentration has a linear characteristic. The high selectivity of the sensor toward other environmental gases was also confirmed.

Abstract—This study aims to identify trends in the real estate market, as a lens to understand which home characteristics most are considered by home buyers in purchasing a home. This paper will uncover which important features (factors) need to be considered, how those factors affect the price of the home and gain an understanding for the geographic distribution of home types. The Northern Virginia (NOVA) housing market has witnessed various changes during the global pandemic, namely: increased migration of professionals in the region seeking employment opportunities with new companies such as Amazon, Facebook (Meta), and government-interfacing startups. The increased employment opportunities, along with additional construction activities has contributed directly to changes in mortgage and interest rates in the region. Accordingly, our predicted home prices in NOVA in 2023 are \$702K, \$700K, \$699K based on interest rates of 2%, 2.5%, and 3% respectively. According to our Zillow data analysis, the median home listing price as of March 2023 for the NOVA area was \$1,052,690. Comparatively, homes in Fairfax County are larger in square footage, and number of bedrooms and bathrooms, while Alexandria County has on average smaller sized homes.

Index Terms—Housing, Investment, Machine Learning, features

I. INTRODUCTION

Home prices have soared in the last decade, especially during the global pandemic. Within the

last year, we have observed home prices drastically shoot up while the national household income fell [1]. The current economic movements have made it difficult for first time homebuyers to secure their first home. Northern Virginia, due to its close proximity to Washington, D.C., a major metropolitan hub, has been affected more dramatically, which led to a price increase of 7% from October 2020 through 2021 (Kashino, 2020) [2]. In our analysis below, we will identify which factors contribute to an uneven real estate market, as well as look into the home characteristics that make certain listings more popular among buyers.

II. BACKGROUND

Purchasing a home is the biggest purchase in most Americans' lifetime. It allows them to not only have a home to live in, but also provides them with an opportunity to get a mortgage which will be a fixed cost over its lifespan, opposed to renting which continues to rise every year (Picchi, 2022) [3]. A paid off home is considered one of the foundations of the American dream, allowing homeowners to eventually retire without a monthly payment. Additionally, when the mortgage is finished, the homeowners are left with an asset that has greatly appreciated over the life of the loan.

With the rise of housing prices, most first home buyers are facing a massive barrier of entry as even the traditional 20% down payment can be in the hundreds of thousands of dollars. By being unable to secure a mortgage, first time homebuyers are stuck renting (Stahl, 2020) [4]. As rents increase in parallel to home prices, it becomes increasingly challenging to buy a home. Given this situation, it would take a long time to save enough for a down payment. Even when the mortgage is secured, the monthly mortgage would be much higher than if they had been able to purchase the property years ago. This causes Americans to have increasingly slower starts in building personal equity, making it harder to plan and save for retirement. By analyzing historical home prices data in Northern Virginia, we may be able to identify significant trends in the housing market and potentially increase future housing accessibility for first time homeowners.

New home buyers can also be assisted by gaining a better understanding of which important features to consider when buying a home. With such a big investment, it is important to think beyond immediate needs and to consider long-term goals and plans. It is important for new home buyers to understand which home attributes provide the most fiscal and livable value to the home. Location, lot size, number of bedrooms, and number of bathrooms are some of the most important attributes to consider (HOMEia) [5]. Homes tend to differ depending on their region and a new homebuyer can benefit by better understanding the geographic difference in homes in their area of interest.

III. ECONOMIC FACTORS TO BE CONSIDERED

In our analysis we described trends in the Northern Virginia (NOVA) housing market over the past two decades. According to the Survey of Consumer Finances by the Federal Reserve, 64.9% of American families owned their own primary residence in 2019 (“Changes in U.S. Family Finances from 2016 to 2019”). Hence for most people, real estate represents a significant portion of their wealth. As a family considers investing in real estate, a number of factors need to be considered: real estate prices, availability, and investment potential (Nguyen) [6].

Economists predict that real estate prices often follow the cycle of the economy. A major indicator

of economic activity is interest rates, as such we will be looking at the effect interest rates have historically on home price and identify a model for predicting future home valuations based on future interest rates. According to the economists Pažický and Falath, the US faces long-term elevated inflation rates over the coming decade as a result of the COVID pandemic (Pažický and Falath) [7]. This is in accordance with most sources we surveyed. The most frequented real estate mobile applications and websites predict increases in real estate prices in 2022 as rates were estimated to remain largely close to 11% to 2%. The following companies predicted an increase in real estate prices for 2023:

A. Projected Increases:

- Zillow predicted an increase of 11% in overall home prices across the U.S. [8]
- Fannie Mae predicts a 7.9% increase Freddie Mac predicts a 7% increase [9]
- Redfin Predicts A 3% Increase [10]
- Realtor.com Predicts A 2.9% Increase [11]
- Goldman Sachs predicts prices to increase by 16% (Walker) [12]

B. Projected Decreases:

- The Mortgage Bankers Association forecast model projects a 2.5% decrease in the median price of existing homes by the end of 2022 (“Northern Virginia Housing Market Forecast 2022 — Mashvisor”)

The housing market recorded a 40-year low in inventory this year—and this has put homebuyers at a greater risk of not securing their home. The ‘Bidding War’ has commenced, with a staggering 74% of homes receiving multiple competitive offers (“Housing Market Bidding War News - Redfin”) [10]. A topic of further study is understanding the unknown factors that contributed to such a range of predictions from the earlier section (Economic Factors). A topic of further study is to understand: why is there great level of uncertainty when it comes to the 2022 housing market?

Although in depth economic analysis is beyond the scope of the paper—we need to stress the importance of incorporating economics into gaining a holistic view of the real estate market for further study. From understanding inflation prices,

where the Federal Reserve predicted that inflation would remain relatively tame (at about 1.8%)—to now gaining perspective in knowing that the latest confirmed reading denoted a significant increase of inflation—6.2%, which is the highest rate of inflation since 1990 (Federal Reserve Data) [13]. Higher than expected inflation means that the federal reserve would raise the federal funds rate—a rate that has intentionally been kept zero during the pandemic to encourage more spending.

If the federal reserve raises rates, then it is only natural that the average 30-year fixed mortgage rate (which is currently at 2.98%) also rises (Federal Reserve Data) [13]. The increase in mortgage rates would directly influence higher monthly payments—which would disqualify buyers out of the market (Lambert) [14]. In addition to this context, the millennial workforce in most metropolitan cities are working from home—which has pushed the demand for suburban homes in greater numbers than previously recorded (Lambert) [11]. This would be a topic for further study, to analyze the impact of ‘Work from Home’ culture on the real estate market.

IV. LITERATURE REVIEW

James Conner published a U.S. Department of Housing and Urban Development (HUD) Housing Market Profile on Northern Virginia in June of 2021 which discusses economic activity, population changes, building activity, and sales and rental market conditions focusing on the most recent 24 months. The report covers 11 counties and 6 independent cities in the Northern Virginia Statistical Area. Northern Virginia sales market condition is characterized as “tight” with strong housing demands and high housing cost due to Northern Virginia’s relatively high incomes [15].

The Coronavirus pandemic has caused a strong increase in demand for home ownership in the region and the housing market had already been tightening prior to the onset of the pandemic. During the pandemic, prices for both existing homes and new homes increased while the number of existing homes sold rose 12 percent and the number of new homes sold decreased 12 percent. The pandemic slowed down construction efforts for new homes but construction has strengthened recently.

Professional and business services is the largest sector in Northern Virginia but experienced the smallest percentage decrease in jobs among all sectors throughout the pandemic. Overall, unemployment in the area has somewhat recovered from the pandemic. From May 2020 to May 2021, the economy in Northern Virginia outperformed the larger metropolitan area and the nation. The rate of seriously delinquent mortgages increased during the pandemic but were less than the Virginia and National rates. Recent building activities such as Amazon HQ2 in Arlington, Capital One in Falls Church, and Google expansion in Loudoun increase regional employment and may increase the housing market demand [15].

We identified that it’s imperative to look at the impact of monetary policy on housing prices in our evaluation. We will be looking at three data sets originated from the Federal Reserve, who set the interest rates for banks and lenders nationwide, as well as from the Federal Housing Finance Agency who are responsible for the supervision and regulation of the mortgage market, as well as secondary lenders such as Fannie Mae and Freddie Mac.

In addition to the recent economic changes and challenges the Northern Virginia housing market has experienced, the available inventory of homes in the region has dropped considerably. As of March 2022, there were 2,470 active listings in Northern Virginia in comparison to 3,029 active listings in March 2021. In combination to this 18% decrease, the average days on market has also decreased by 13% in comparison to March 2021 (Northern Virginia Housing Market Data). These changes emphasize the need for new home buyers to accurately assess the value of homes independent of economic conditions. This kind of assessment would allow new home buyers to better understand how much more or less they would potentially be spending on a home if listed at a different price.

A variety of research has been conducted on analyzing descriptive characteristics of homes to accurately assess the value of homes. Lian Pardoe proposes a multiple linear regression model analysis of home price data in his article “Modeling Home Prices Using Realtor Data”. Pardoe models’ sale price using a variety of property features as

predicting variables. He explains effective ways to modify and prepare the data for model creation such as converting certain numeric variables to ordinal variables, so the variables have a more realistic impact on the linear regression model. Pardoe discusses the use of statistical testing to determine which attributes are most correlated to the response variable before constructing the model. Pardoe also discusses the use of predictor effect plots which can be used to graphically show how a regression response variable changes with changes to the predictor variables. (Pardoe, 2017) [16].

V. DATASET

A. Northern Virginia Housing Data

We first explored a variety of online databases to find recent, relevant and reliable housing market data for the Northern Virginia area. The Northern Virginia Realtors (NVAR) [17] website provides historical month data broken down by monthly market stats spanning from 2000 - 2021 [18]. Northern Virginia counties include Arlington, Alexandria, Fairfax County, Fairfax City, Loudoun County, Falls Church, and Prince William. The attributes include those listed in yellow in Table ???. The original data downloaded was not formatted in a usable format for analysis. We transposed the data using excel to a more usable data format and the data was cleaned using R Studio (Historical Monthly Data) [19].

Originally, we decided to narrow our project scope to study the market from 2011-2021 and have a county level of granularity. We later decided to expand our dataset to include 2000-2021 to include more context to the history of the market. We also decided to aggregate counties together to have a holistic northern Virginia region dataset to allow the data to be merged with economic data. It is important to note that there is missing data for Prince William county for the months of 2000 through 2012 (Historical Monthly Data) [19].

Data for the Federal interest rates (blue) for each month from 2000-2021 was downloaded from the Federal Reserve database and merged with the NVAR housing data (Monthly Interest Rate Data). Data for the national average mortgage contract rate (green) and national average mortgage loan amount in thousands (green) was downloaded

from the Federal Housing Finance Agency through their National Mortgage database and merged with NVAR housing data (Table ??) (National Mortgage Database (NMDB) Aggregate Data) [20]. Data for Northern Virginia metropolitan area non-farm employees in thousands (red) was downloaded from the U.S. Bureau of Labor Statistics' BLS Data Finder and was merged with NVAR housing data (Table ??) (U.S. Bureau of Labor Statistics) [21].

B. Northern Virginia Zillow Home Listings

We also collected a dataset of active home listings for sale posted on Zillow in Arlington, Alexandria, Fairfax County, Fairfax City, Loudoun County, Falls Church, and Prince William County as of March, 23rd 2022 to explore differences in characteristics of homes in the different counties and see what factors are most predictive for a home's price (Table I). The dataset was collected using Zillow.com API in Python Jupyter Notebook. The code was executed using a Rapid API host and our Rapid API key. There was a total of 829 listings x 205 columns of features in the uncleaned original version.

Data cleaning was performed using Python. Each county's listings were collected independently then concatenated together. Eleven useful variables were extracted, missing data was either removed or managed effectively, and outliers were removed. Outlier listings were also removed based on outlier price of greater than \$4,334,000 and outlier lot size greater than 101,496 square feet. Duplicate listings were also removed by identifying duplicate street addresses. Data types were transformed for useful analysis. For example, timeOnZillow(days) values were originally formatted as "6 days". Lot Size values were either in square feet or acres units so acre values were converted to square feet by multiplying by a 43560 conversion factor. The final dataset is 396 rows x 11 columns.

VI. METHODOLOGY

The main purpose of the project is to explore the Northern Virginia (NOVA) real estate market from a time series perspective and a home characteristics perspective. The research questions of the project first section are the following:

TABLE I: Cleaned Northern Virginia Zillow Home Listings Data Variables Used

Variable Name	Description	Example
county	county	Alexandria
livingArea	living area square feet	1540
bedrooms	total number of bedrooms	2
bathrooms	total number of bathrooms	2
resoFacts.bathroomsFull	number of full bathrooms	2
resoFacts.bathroomsHalf	number of half bathrooms	0
resoFacts.hasGarage	whether the property has a garage or not (0 or 1)	0
resoFacts.garageSpaces	number of garage spaces	0
resoFacts.Stories	number of stories of the home	3
lotSize(sqft)	total size of lot in square feet	3920
resoFacts.isNewConstruction	whether or not the property is new construction or not (0 or 1)	0

TABLE II: Outlined Steps for Project Replicability

Step	Action	Resource
Step One	Collect relevant datasets	- Various offline online databases - Zillow Rapid API
Step Two	Data pre-processing and cleaning	- Excel - R - Python
Step Three	Compile necessary datasets	- House Pricing Data - Mortgage Data - Interest Rate Data
Step Four	Visualizations and Analysis	- Tableau - PowerBi - R
Step Five	Create a model incorporating a combination of the factors collected	- R or Weka

- What impact will increasing interest rates have on the values of NOVA home prices as a whole?
 - How does interest rates compare to other mortgage data such as the National Average Contract Mortgage Rate (NACMR) in regards to housing prices?
- What impact do other non-structure related attributes have on home prices?

Secondly, we will explore differences in home characteristics across the same counties by examining current Zillow home listings. The research questions of this project section are the following:

- Which counties have the most listings per capita and which counties have higher average prices?
- What is the distribution of characteristics on average across counties?
 - Example: Do listings in Fairfax County have larger living areas on average than all other counties?
- What home attributes have the most predicting power and influence on the price of home listing?

We will be exploring trends across different counties within NOVA, specifically historic real estate trends and active listings. Our paper will cover the following counties and cities:

- Arlington County
- Fairfax County
- Loudoun County
- Prince William County
- Alexandria City
- Fairfax City
- Falls Church City

We began with a collection of datasets relevant to our project including real estate data, economic data, and home listings data. Next, we conducted data preprocessing and cleaning methods such as normalization, data transformation, missing data management, and attribute selection. Necessary datasets were then merged or concatenated together. We then performed exploratory analysis of the data and created data visualizations which provide valuable insight into the trends and current state of the market. Finally, we created a model to predict future home prices based on projected interest rates. We also plan to develop a model to predict the price of homes based on descriptive characteristics of the property (Table #). Further research will be conducted to determine the best model type to employ for our specific application.

VII. PROPOSED METHOD FOR EVALUATION

It is interesting to note the major differences in listing prices from our historical analysis and our current market analysis. Our historical analysis of home prices showed an average home price in the region of \$707,990 in 2021 while our active listing analysis showed an average home price in the region of \$1,345,351 as of March 2023. This almost doubled figure difference presents challenges in evaluating our result. Although these averages were calculated for periods 2 years apart, It is unlikely the difference is realistically as dramatic. The large difference is likely due to the Zillow data having a right skewed distribution with a mean of \$1,345,351 and a median of \$1,052,690. We plan to further investigate this difference in the future.

We explored the statistical correlation between home listing attributes and home listing price to augment the regression model. As such we calculated the Pearson product-moment correlation

coefficient (PPMCC), to understand the correlation between interest rates and home prices. The standard error calculated from the data sample we took from the regression data.

VIII. RESULTS

A. Historical Analysis Northern Virginia Average Home Sold Price In Relation To Interest Rates

In our analysis we aimed to use interest rates as a predictor for home prices for 2023. We had already seen 2022 prices continue to rise with interest rates remaining low as predicted by major lenders such as Sallie Mae and Freddie Mac. Historically, interest rates have been associated as an indicator of housing prices (Sutton, 2017) [22]. As interest rates go down, house prices are expected to increase as homeowners will benefit from the lower interest on mortgages and will pay a higher premium on the purchase price for this trade off. Our datasets for mortgage rates only went up to 2018 for NOVA, thus we narrowed down the scope to just interest rates as they are very closely correlated regardless.

However, we found that over the last two decades home prices tended to steadily rise, regardless of interest rate (figure 1). During the Covid-19 pandemic, home prices skyrocketed. Although the latter could be attributed to interest rates, there were many factors which led to the increasing prices of homes such as the trillion dollar stimulus to facilitate economic growth during lockdowns, as well as the increase in work from home jobs. As these last two decades were atypical with the great recession of 2008 and the Covid-19 crisis, we assume that there may be a reversion to the mean with interest rates having a more direct impact on housing prices in NOVA again moving forward.

Our simple linear regression model showed that over the last 20 years, housing prices dropped \$24,850 per a 1% increase in federal interest rates (figure 2). With this calculation we aim to predict the trend in housing prices based on the federal reserve rate hike plan for 2023.

In March of 2022, the Federal Reserve announced their intention to hike interest rates by an average of .25% over the remaining 6 sessions of 2022, as well as three hikes in 2023 for an expected interest rate of 2%-3% in 2023 (Cox, 2023) [23]. Using a base of the average home price

Fig. 1: Nova Home Prices and Federal Interest Rate By Year

Fig. 2: Federal Interest Rates and Nova Home Prices

of \$707,990 in 2021 at an average interest rate of .08%, we can estimate three potential average home price values for NOVA in 2023 with our simple regression model based on a low, medium, and high interest estimate. (Table III.) Note this estimate does not account for error rates and it is assuming no other factors aside from interest rates affecting home prices from 2000-2021 in NOVA.

In our findings, we estimate home prices should drop significantly as interest rates increase in 2023.

This prediction is contingent on the behavior of interest rates impact on home prices reverting to historical norms aside from the abnormalities of the

TABLE III: Interest Rate predicted effect on NOVA Home prices in 2023

Interest Rate Effect on NOVA Home Prices in 2023				
Scenario	2021 Average	2023 Low	2023 Medium	2023 High
Interest Rate Estimate	0.08%	2%	2.5%	3%
Home Price Estimate	\$706,990	\$657,290	\$644,865	\$632,440

Fig. 3: NOVA Home Prices and National Average Mortgage Rate by Year

previous two decades. However, we do note that the relationship between interest rates and home prices is not the only factor to account for when predicting the price of home, hence we are implementing descriptive analysis in our findings.

B. Home Price Correlation With National Average Contract Mortgage Rate

House price has also held a strong correlation with National Average Contract Mortgage Rate (NACMR) over our collected data timeframe. The NACMR is an index derived from the Monthly Interest Rate Survey (MIRS) [24] which is conducted by the Federal Housing Finance Agency (FHFA) to describe mortgage loans through average interest rates, average loan maturity, average loan amount, and monthly average loan-to-value ratio (Monthly Interest Rate Survey, n.d.). However, MIRS is a lagging indicator, as the data is based on loan data from the two to three prior months, along with a month of processing for publishing by the FHFA (Monthly Interest Rate Survey, n.d.). As such, this metric may be less viable for future home predictions, whereas Federal Interest Rate changes may be announced in advance.

C. Exploring Active Northern Virginia Home Listings

We began by exploring the distribution of home listings across the NOVA region by county. The count was normalized by the 2022 population numbers (Population of Counties in Virginia (2022)). 43% of the listings in the dataset are from Fairfax County but also 46% of the population in the region

Fig. 4: Count of 2023 Home Listings Per County Normalized By 2022 Population

is in Fairfax county. Therefore, after normalizing the count of listings by population, Fall Church stands out as a county which is experiencing the most listings per capita (Figure #). Falls Church accounts for 6.8% of the listings but only contains 0.6% of the region’s population. This analysis indicates that Falls Church is experiencing the most real estate market activity per capita in the region.

The distribution of average listing home prices in NOVA counties varies and has a right skewed distribution. Due to the non-normal distribution, median was chosen over mean. The median home listing price in NOVA is \$1,052,690. Fairfax County, Arlington, and Falls Church median home listing prices are more than the overall median for the region while Alexandria, Fairfax City, Falls Church, Loudoun County, and Prince William median home listing prices are less than the overall median for the region (Figure #). Arlington and Fairfax county have large distribution of prices with standard deviations of \$824,270 and \$895,291 respectively. Prince William County and Fairfax City have small distribution of prices with standard deviations of \$215,037 and \$141,163 respectively. Loudoun County contains four outliers and Fairfax County has one (Figure 4).

46% of the listings in Falls Church are new constructions while only 1% of listings in Alexandria are new constructions. Homes in Fairfax County homes are on average the largest with an average of 4.97 bathrooms, 5.01 bedrooms, and 4,806 sq ft living area. Alexandria homes are on average the smallest with an average of 2.9 bathrooms, 3.6 bedrooms, and 2,146 sq ft living area. Loudoun County has the largest lot sizes on average at 26,694 square feet while Arlington has the smallest average lot sizes of 7,983 square feet (Figure 6).

Some characteristics of a home have more in-

Fig. 5: Median Northern Virginia Zillow Home Prices By County

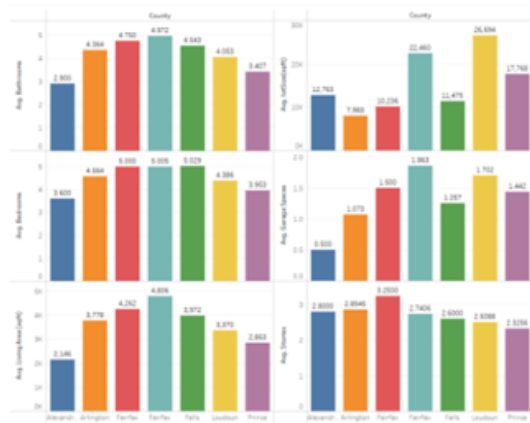

Fig. 6: Average Attribute Values For Home Listing In Each County

fluence on the price of the home than others. In this section we will explore this idea by performing correlation testing between home attributes and their listing prices on Zillow. The attribute with the strongest correlation to the price of a home is the number of bathrooms followed by the living area space, number of bedrooms, etc.. The correlation coefficient between the attributes and the price of the home were calculated using R studio code. Appropriate statistical testing methods were applied depending on the attribute data type. Ordinal data types were tested using the Spearman’s method while numeric and boolean data types were tested using the Pearson’s method [25]–[36].

TABLE IV: Attributes Correlation Coefficients to Price of Home

[HTML]EFEFEF Attribute	Statistical Method	Correlation Coefficient
Bathrooms	Spearman	0.805
Living Area	Pearson	0.718
Bedrooms	Spearman	0.646
Garage Spaces	Spearman	0.617

Preliminary Results on Analyzing Credit Card Fraud Detection

Abhishek Godavarthi
agodavar@gmu.edu

Raghad Almutairi
ralmuta@gmu.edu

Arthi Reddy Kotha
akotha2@gmu.edu

Abstract—Credit card use is not always the best way to use for payments, but the most demonstrable payment mode is through the credit card for both offline as well as for online payments, which can result in deficit of funds. As the online shopping is booming it helps in rendering the cashless payment modes. It can be used at shopping's, paying rent, paying utilities bill, internet bill, travel and transportation, entertainment, food. Using for all these things there is a chance of fraud transactions for a credit card, hence there is more risk. There are many types of fraudulent detections most of the banks and institutions are preferring fraud detection applications. It has become very hard to find out the fraud detections, After the transaction is done there is a chance of detecting fraudulent transactions in the manual business processing system. In real time the bunco transactions are done with real transactions, but it seems not to be sufficient for detecting [1]. Machine learning and data science both are playing a very important role in identifying the fraud detections. This study uses data science and machine learning for detecting the fraud detection to demonstrate various modellings. The problem enables the transactions of the previously done transaction data.

Index Terms—Credit card, Banking Services, Fraud detection, Cashless Payments

The dataset has been collected from a research collaboration of Worldline and the Machine Learning Group of ULB (Université Libre de Bruxelles) on big data mining and fraud detection. For statistical and visual analytics - Python has been used. The results would be visualized using various methodologies through these tools. The original dataset will be cleaned if necessary for accurate analysis of the data.

I. INTRODUCTION

Since 1950, when credit cards were first found and until this day, fraudsters have been competing to devise new ways to steal personal informa-

tion and reach people's credit cards and obtain money. With the popularity of e-commerce, most companies and institutions offer their products and services through websites that require consumers to create accounts and add personal information, including credit card information. Furthermore, unsecured websites may expose consumers to credit card fraud or identity fraud. Initially there was a two step verification method. Due to this users were effected of transaction fraud while shopping online. Consequently, companies and organizations with unsecured or less secured websites eventually lose their customers as customers will not trust sharing sensitive information with an unsecured site. Moreover, banks also play an essential role in keeping customers' personal information and transactions secured which is why banks can also lose customers if the level of security is not good enough. It shows the common terms and highlights the key statistics of credit card fraud detection. The proposals made in this paper in terms of savings and the time efficiency are the beneficial attributes. The techniques which are used in this paper reduces the credit card fraud but there is also a chance that it misguides the people to be misclassified as fraudulent. Sometimes there was some ethics in the banking and the complexity and efficiency obtaining the money. It deals with cases which involves the criminal cases which could be difficult in identifying sometimes.

Types of credit card fraud detections techniques, which helps to detect the transactions, the first one is fraud analysis which is used to analyze the fraud transactions of credit card and the second one is anomaly detection which is used to detect the anomalies based upon the previous data of transactions [2].

To detect credit card fraud using machine learning is to use and analyze data to investigate the habits and methods of fraudsters and build a model that helps detect and reduce fraudulent transactions [2]. To create a model to detect fraud, the data science team will need to collect the credit card users' data, such as the habit patterns, area, product types, amount, and spending, and then use the data and information to discover the fraudsters behavioral patterns [2]. The different techniques used by various companies for detecting the fraud transactions are Artificial Neural Networks, Hidden Markov Model, Naïve bayes, KNN classifier, Genetic Algorithm [2].

II. PROBLEM STATEMENT/OBJECTIVES

The increase in credit card fraud leads card users to lose money and companies to lose consumers. Credit card fraud directly affects consumer spending, which can also damage the economy. Every time consumer spending drops off, the prices drop, and the economic growth slows down [1].

In the United States, credit card fraud has significantly increased in the past few years as the number of reports went up from around 130K in 2017, to almost 400K report in 2020 [3]. Credit card fraud can happen in two different ways. The first way is stealing information or identity and opening a new bank account with someone's else's identity to be able to get their money while avoiding all responsibility. The second way is accessing an existing account. To succussed in credit card fraud, the fraudsters will have to access personal information such as full name, email address, ID number, credit card number and other sensitive information which can also leads to Identity theft.

Identity theft is another related issue as fraudsters steal people's personal information and use it to create a credit card with the stolen identity [4].

The goal of Identity thieves here is to steal money, and this can be a big issue as the number of people in debt will sharply increase causing more people to lose jobs, lose homes, and go to the prison which will also affect the economy as a result. The Covid-19's impact is one of the main reasons why Identity theft has become more common in the last two years. According to Daly (2021), about 1.4 million reports of identity theft were received in the

Fig. 1

United States in 2020, and a report from Aite Group stated that identity theft caused losses estimated at \$712.4 billion in 2020 [4]. In this research, we want to prevent this problem and reduce the losses as much as possible [3].

Another problem is credit card scams. These days scammers are creative and use many ways to scam people to steal their credit card information. Some scammers use phone calls to pretend to be bank employees, and others may send links to their victims, leading to a fake login page with the same original page design to steal people's login information [5]. Scammers use many ways that most people are not aware of, especially elderly and young people. Moreover, many hackers also use users' lack of awareness to steal and use their personal information.

Recognizing identity and credit card fraud transactions and identifying fraudsters' behavior is essential for every institution, including banks, to preserve the users' information and secure the institution's database and system. With the increase in the number of customers and technology development, creating a model that will help detect fraud transactions automatically and as accurately as possible is substantial.

- 1) How to process enormous data and how to build model that must be fast enough to respond to the scam in time.
- 2) Protecting the privacy of the user
- 3) How to deal with imbalanced data?
- 4) How to deal with misclassified Data?

- 5) Propose a conceptual framework from an almost anonymized real-world credit card dataset.

III. RATIONALE AND SIGNIFICANCE OF THE STUDY

Given the rapid digital transformation that businesses are witnessing, the need to improve credit card services and products' security is even more important and urgent. Such a need requires increasingly secure information systems in organizations [2]. Businesses need to ensure that their information technology infrastructure is upgraded with the latest that emerging and advanced technologies have to offer. To achieve this goal, a holistic understanding of the business is needed, as well as ongoing efforts to recognize any gaps and areas for improvement to safeguard the company's financial health. Because a substantial amount of financial dealings such as credit card processing are performed online, the transactional credit card data can help constantly learn from to detect anomalous activities.

IV. LITERATURE SURVEY

Numerous research projects have been published about credit card fraud detection since the 90s and until now. Basically, the fraud transactions are one of the illegal activities that are going on in today's world, which is also considered a crime nationally as well as internationally. As we discussed above it will check all the possible ways on who the fraud transaction is done and accordingly the steps are taken forward. Since 19th century we are facing problem in solving the probabilities or to handle it, but in 20th century they introduced a new algorithm and that is Bayesian algorithm which was used in the different ways to solve the issues which also called as frequentist statistics. There was also some deep learning proposal and topologies which was derived from the detections. The two types of random forests that are used for fraud transaction detection are normal and abnormal transactions. In the investigation there were several techniques used for fraud transactions and are also used for comparing the credit data. When presenting the crime data of the credit card there are certain issues faced by the data mining as well as non-data mining thefts [6].

The invoice bills and the payments are also issued to the investigator to investigate about the credit card detections, which is known as no cash mobile applications. There is a alarm raised when your transaction is confirmed as a fraudulent transaction or malicious [6].

Machine learning Based Approach to financial fraud detection is also done using the mobile application. Mobile payment fraud is identified in the growing issues of the credit card. Decision tree is also used for the fraudulent detection in the credit card system. It proposed the sampling process and the selection process for the feature use with the large amount of the transaction data which has high accuracy in the mobile payment. There are four modules that are been used and they are data collection, data preprocessing, feature extraction, evaluation model. Random forest selects the best feature for the data resulting that in the better model for the users [7]. With the advancements of the techniques with the machine learning it gives us the complete information and new techniques to learn. Credit card fraud detection using the machine learning is done by developing the new classifications and the regressions [6].

This is an exceptionally applicable issue that requests the consideration of networks, for example, AI and information science where the answer for this issue can be mechanized. This issue is especially difficult according to the point of view of learning, as it is portrayed by different factors like class unevenness. The quantity of legitimate exchanges far dwarf false ones. Additionally, the exchange designs frequently change their factual properties throughout the natural process of everything working out. Extortion goes about as the unlawful or criminal trickiness expected to bring about monetary or individual advantage. A purposeful demonstration is illegal, rule, or strategy with a mean to achieve unapproved monetary advantage. Various written works relating to irregularity or extortion recognition in this space have been distributed as of now and are accessible for public use [8].

Many models have been recommended for precise fraud detection. For instance, we can consider the brain network proposed by Ghosh and Reilly which is prepared on a large sample of named

Visa exchanges. These transactions contain an assortment of misrepresentation cases, for example, lost cards, stolen cards, application extortion, email misrepresentation and so on. Training on an assortment of information absolutely makes the model resistant to almost any sort of misrepresentation. Subsequently, the quality or assortment of data matters more than the amount or bulk. There were numerous different methodologies before and there are going to be numerous later and there is still a ton of scope for this field as the cheats keep on being unavoidable [8].

V. RELATED WORKS

Some research papers covered different methods for detecting financial fraud, and others included different learning techniques. These research papers were used to develop and improve fraud detection systems and algorithms. The previous work discussed two methods for machine learning: deep learning and traditional machine learning.

Deep learning is machine learning, but the main difference is the performance. Deep learning “uses a programmable neural network that enables machines to make accurate decisions without help from humans” (Grieve, 2020, para. 5) [9].

The deep learning method was studied in research by Thang, Tahir, Abdelrazek, and Babar in 2020 about credit card fraud detection [2]. In the study, deep learning has been used to solve complex problems. The research paper includes studying deep learning methods for credit card fraud detection issues and comparing this method’s performance with other machine learning algorithms on three different financial datasets. This research shows that deep learning methods had better performance than traditional machine learning models and that the results can be effectively used in the real world.

Another study by Zanin, Romance, Moral, and Criado in 2017 discussed how to detect credit card fraud through parenclitic network analysis. This study presented the first complex network classification algorithm to detect illegal cases in an actual card transaction dataset. This research shows how including features from the network data representation can improve the obtained result

by a standard neural network-based classification algorithm [10].

Modes of Fraud Detection usually used

The algorithms that are used for the model detections of credit card are as follows, they are Random Forest Classifier, Decision tree, Support Vector machine.

Random Forest Classifier: It is an inconsequential classifier among all the classifiers. It is an essential module of the classification. For the better evaluation and performance depends on several factors that includes depth, maximum bins, impurity [2].

Decision Tree: There is a test node which is represented with the root not and each node. Occurrences, Target Attribute, Attributes List are their elements used for planning tree which is called as leaf node [2].

Support Vector Machine: Based on the other algorithms this is best used for fraud detection. In this all the information or data is combined into one category and SVM is one of the form used to separate the data which was converted or separated by the different classes [2].

VI. DATASET REVIEW

The dataset has been collected from a research collaboration of Université Libre de Bruxelles on big data mining and fraud detection. This study uses a sample of data to detect fraudulent credit card transactions and prevent any credit card charges that take place without the card owner’s permission. Moreover, utilizing the data to build a model that is simple but fast enough to stop the fraud in time as well as report it to the relevant authorities. The dataset contains transactions made using credit cards by European cardholders in September 2013 and it shows that out of 284,807 transactions that were made in two days, there were 492 frauds and only 0.17% of the transactions were fraudulent. Unfortunately, the dataset does not provide more background about the data, but we will try to search about more data in other datasets the future. The credit card detection model we will be building will include Anomaly Detection which is the process of finding rare events, items, or actions that is considered suspicious to detect fraudsters. The anomaly detection will be applied by using machine learning

Fig. 2

where both normal and anomalous samples will be included to make the model predict future actions. We want the model to be trained by using reports and feedbacks to find the probability of fraud to give an alert [11].

It contains only numerical input variables which are the result of a PCA transformation. Unfortunately, due to confidentiality issues, they cannot provide the original features and more background information about the data. Features V1, V2, ... V28 are the principal components obtained with PCA, the only features which have not been transformed with PCA are 'Time' and 'Amount'. Feature 'Time' contains the seconds elapsed between each transaction and the first transaction in the dataset. The feature 'Amount' is the transaction Amount, this feature can be used for example dependant cost-sensitive learning. Feature 'Class' is the response variable and it takes value 1 in case of fraud and 0 otherwise [11].

VII. PROPOSED APPROACH

The data obtained from the dataset will be processed and analyzed properly, cleaned, and visual-

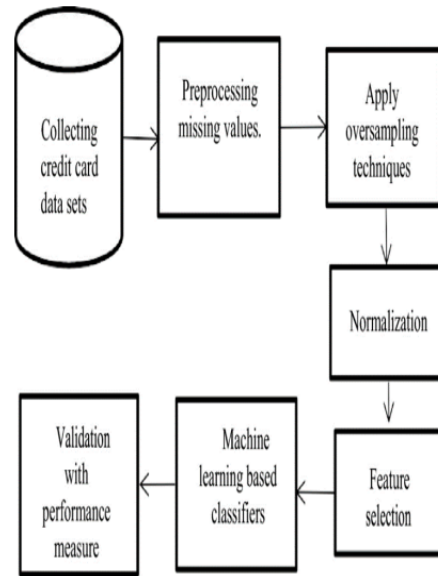

Fig. 3

ized. We will use the data later to try and build several machine learning models in order to find the best solution.

As shown in Figure 3, these are the steps to follow to accomplish the model.

After collecting, cleaning, and visualizing our data, the next step is to start building the model. Because the process of developing a data model may require several stages of editing, changing, or updating data over time during the development, we will be building several data model versions and comparing different versions using data modeling tools until we find the model that works best for us. The process will start by building a prototype and using PyCaret, which is an open-source machine learning library to facilitate the comparison process. First, after installing the PyCaret library, all the necessary files will be imported, the dataset will be loaded, and the PyCaret classifications will be set up [12]. Next, the comparison process begins as we start creating the best possible model, saving, loading, finalizing, and deploying the model.

A. Data Preprocessing

Data preprocessing involves transforming the raw data into the well-formed data sets so that the analysis can be performed in a better way. It

Fig. 4: Correlation Matrix

is used for both databases driven and rules-based applications normally it is a critical in some cases in the data processing when the dataset is large. Basically, the raw data which we have is normally incomplete and will be in an incontinent way.

Data preprocessing is done in steps that follows as formatting, cleaning, sampling. Formatting is used for putting the data in a way that it will be suitable for the work. The data and the formatting changes according to the needs of the people.

The most recommended or most used format is the CSV format. Data cleaning is the main and important procedure in the field of data science. It does a major part of the work. That is 80% of the work is done. Sampling is the technique for analyzing all the subsets with the whole large datasets, which gives us a better result for understanding and the pattern of the data in the integrated way.

Data is represented differently and are kept together with the help of data integration. When the data is large, or the dataset is huge then the databases can become very slow to work. To replace the data with the raw values within given intervals reduces the number of values by diving that in the given rage.

B. Correlation

There is no notable correlation between features V1- V28. There are certain correlations between

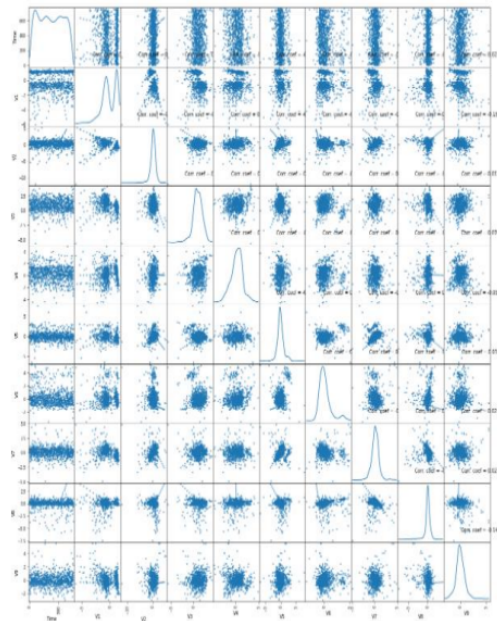

Fig. 5: Correlation - scatter and density plot

some of these features and Time (inverse correlation with V3). Features and Amount (direct correlation with V7 and V20, inverse correlation with V1 and V5).

There are no null values in the data.

C. Preliminary Results

Using the Random Forest method, a prototype that analyzes fraud identification was built. The Random Forest method is a good learning method that helps create an uncorrelated forest of trees with better prediction and more accurate results. The model's performance was evaluated on the test set. The results showed that the model scored a 0.88 f1-score, which is considered a good score for a good model that can detect fraud transactions. A PyCaret library was also used to compare the model with other versions to assure it is the best. Eventually, the results revealed that the first model we built will be able to detect fraud with a percentage of 90% accuracy.

vadabala@gmu.edu

Abstract—Since 2012, guests and hosts have used Airbnb to extend their travel options and provide more distinctive, personalized experiences. Airbnb is a one-of-a-kind service that is now known and used all over the world. The analysis of Airbnb’s millions of listings is critical to the company’s success. The millions of listings generate a lot of data, which can be analyzed and used for a variety of purposes, including security, business decisions, understanding customer and provider behavior and performance on the platform, guiding marketing initiatives, implementing innovative additional services, and so on.

The success of a firm is mainly determined by the loyalty of its clients. Data analysis aids in the understanding of the relationship between client loyalty, satisfaction, and image. This will be of great importance to both practitioners and scholars in the field of hotel management. The goal of this study is to discover the elements that lead to customer loyalty in the hotel business in Broward County, Florida.

The focus of this research paper is on the factors that influence the pricing of Airbnb rooms. By gathering data from several Airbnb resources, it is possible to determine how the Airbnb pricing is split throughout different neighborhood groups in Broward County, Florida, as well as the elements influencing the price, such as room type, rating, location, and service. To get structured data, associated data such as room service, covid policies, parking facilities, and complimentary breakfast is collected, cleaned, filtered, and modified.

Index Terms—Airbnb, prices, reviews, NLP, Data Analysis, Python, R

I. INTRODUCTION

Travel costs range from person to person, and everyone has distinct financial constraints. When planning a trip, one of the most important constraints to consider is lodging. We may look at the aspects that are crucial in increasing Airbnb’s income by performing big data analysis on its data. At first, revenue was

determined primarily by factors such as occupancy rate and average daily rates. Later, it was

discovered that these measures are insufficient for determining revenue production, and that more advanced measurements are required. As a result, to discover these measures, a thorough examination is required. Booking lead times only tell part of the picture when it comes to seasonality. You’ll need to look at the bigger picture of seasonality to properly master your vacation rental market using sophisticated Airbnb data research. Hosts can use the Demand Score to determine which days, weeks, and months should be priced higher and which should be priced lower by focusing on the Demand Score. Future Rates is the ideal place to go for hosts seeking for an all-in-one rental pricing solution to help them spot chances. Cancellation rules and minimum night stays are two aspects of property management that are sometimes disregarded. While some hosts choose to ignore these considerations, others strive to make the most of them. While aligning your listing’s settings with market norms is a wonderful method to improve your listing’s performance, you should also consider diverging from the conventions to make your listing stand out. Is a three-night minimum stay required by most hosts? Set yours for one or two nights to make yourself more accessible to more travelers.[12].

II. RELATED WORK

Airbnb is a website that connects people who wish to rent out their homes with people who are looking for lodging in specific areas. It presently includes over 5.6 million listings, encompassing over 100,000 cities and towns in over 200 countries throughout the world. Airbnb has revolutionized the travel industry by allowing homeowners and business owners to post their spare bedrooms, unoccupied hotel rooms, or entire houses for short-term rentals on the platform. In many urban areas, this disruption has resulted in housing shortages [1].

This analysis aimed to uncover intriguing insights that could be useful to a traveler, a host, an Airbnb decision maker, or even a D.C. housing regulator. Some of major insights include the cost of listings in relation to their proximity to the National Mall [1]. For those unfamiliar with Washington, DC, the National Mall is a grassy stretch of land bordered by many Smithsonian museums, the Capitol building, and the White House. Essentially, anyone staying in an Airbnb in DC has a good probability of seeing the National Mall at some time during their stay [1]. The data on Airbnb is updated on a regular basis. Some of the information was gathered from 2015 until the present day.

This project's datasets were collected in September 2019. Listings, Neighborhoods, Reviews, and Calendar data for the city are used. Each dataset comprised distinct data. statistics on all of D.C.'s Airbnb listings - listing ID, latitude, longitude, host, room type, price, number of reviews per listing, reviews per month, listings per host, neighborhood, availability for booking, and number of listings per host are all present in these listings.

III. BACKGROUND

The neighbourhood data comprises the names of 39 neighborhoods in Washington, D.C., as well as a JSON file containing the geographic coordinates of the neighborhood's outline. Over 358,000 reviews were written between January 2009 and September 2019 according to the Reviews statistics. We can cross-reference which listing they apply to because they all relate to a listing ID from the Listings dataset.

Finally, the Calendar dataset contains a yearly 'calendar' of pricing and listings for each day. Since DC is a popular tourist destination for visitors from all over the world as well as within the United States, they checked if the volume of visitors was related to some of the city's major events. Every year, 30,000 runners and their family and friends participate in the Marine Corps Marathon, which starts in Arlington, VA and passes through several of DC's landmarks. There are many other events, and organizations that attract visitors on a regular basis. They visualized the flow of tourists in relation to specific events in the Airbnb data. The inauguration of a new president always attracts

a large crowd. Supporters frequently organize a March on Washington for causes and movements that they want Congress to pay attention to and pass new laws for. Two of DC's professional sports teams have won national championships in the last two years [1]. Some of the findings include: What are the broad trends in the data? What is the relationship between Airbnb data and key events in the nation's capital during the previous 10 years? What can the data tell us about the impact of Airbnb on the housing market in Washington, D.C.?

IV. PROBLEM DESCRIPTION

Choosing a right location and making sure it is worth of, is very important while choosing our vacation spot (Airbnb). Any review a guest reads will reflect the actual experience another member of the Airbnb community had. Reviews include a rating system to quantify your performance as a host across both general and specific criteria. So, we are curious to find out this relationship between the reviews and prices of the bookings. What factors are making the people to choose Airbnb? Factors influencing the Airbnb prices and what are the quantifying parameters we should consider seriously while fixing the prices, can be detected by analyzing the data. Is it possible that these price values are depending only on the known factors like location, room type etc., or are there any hidden factors that are influencing these price values and therefore changing our decisions like cancellation policies that we could be missing? And how much weightage do these factors carry? Can they be ignored? Can they be taken seriously for the future success? How does the concept of Airbnb initially received and used by the people over the years (2022-2012) and what factors were improved to make it successfully?

Is it possible to predict the Airbnb price by using its features and how accurately can we build this model? Is it possible to do sentiment analysis of the reviews and find what keywords define low rated Airbnb's?

With these findings and insights, we can find where the potential value of Airbnb lies and what would be the possible changes in the Airbnb structure that can improve its value. Predicting Airbnb prices and identifying the most impactful features

of the price value can be helpful for the highlights of marketing and also provides a scope of improvement.

V. PROPOSED APPROACH

By gathering data from several Airbnb resources, it is possible to determine how the Airbnb pricing is split throughout different neighborhood groups in Broward County, Florida, as well as the elements influencing the price, such as room type, rating, location, and service. To get structured data, associated data such as room service, covid policies, parking facilities, and complimentary breakfast is collected, cleaned, filtered, and modified. This unstructured data must be transformed into structured data before it can be adequately analyzed, and insights extracted. The four iterative phases of deleting undesirable observations, addressing structural flaws, controlling undesired outliers, and handling missing data are used to collect and clean factors affecting the room pricing in Florida.

Fig. 1: Various Stages involved in the project

After cleaning the data, we can go on to exploratory data analysis with Python and RStudio. The data's linkages, patterns, and insights will be investigated and used to make decisions. To be useful, these relationships must be valid, not obvious, and human understood. Visualization technologies such as Power BI and Tableau are also used in exploratory data analysis to visually comprehend the correlations. Additionally, data modeling techniques such as regressions and classifications will be used to forecast the pricing of Airbnb in Broward County, Florida.

VI. DATA PREPROCESSING

Collected datasets needs to be prepared before we can apply any modeling techniques. Usually, raw data has inconsistent formatting, human errors,

and can also be incomplete. By preprocessing data, these issues can be resolved, and datasets can be analyzed more effectively and efficiently. Structured data is needed to apply any modeling technique. Data collected from different resources are merged and explored. Missing values and the data outliers were removed to avoid inaccurate and compromised results. The rows of the dataset were decreased by 1000 when the data cleaning techniques are applied to it. Used NumPy and pandas' libraries to clean the data. NumPy library is mainly used to explore the data and understand the domains of each attribute. Attributes such as cancellation policies and parking facilities of the Airbnb's were collected through various API's and open resources. The missing values have been filled with '*' values have been removed from the dataset. Attribute values greater than a threshold value have been considered as an outlier and have been removed from the dataset using panda's library in python. After making sure that the data quality attributes such as Accuracy, Consistency, Completeness, Validity, Timeliness are present, next step of analysis is proceeded.

Fig. 2: Python libraries used for data preprocessing

Fig. 3: Data cleaning steps for achieving structured data

Fig. 4: Visualization 1: Number of Reviews per Year

VII. PRELIMINARY ANALYSIS RESULTS

Despite the fact that Airbnb was launched in 2008, it was only in 2012 that online vacation rental properties became popular. As a result, we've counted the number of reviews from 2012 to 2021. As can be seen from the graph, Airbnb's first two years were not particularly successful, with nearly no reviews in each of those years. People began to recognize and explore Airbnb in 2015, and the number of reviews gradually climbed throughout the years, reaching a peak of over 9000 reviews in the most recent year of 2021. Airbnb did not become popular overnight; in fact, it took nearly ten years from the time it was formed to gain popularity.

Fig. 5: Visualization 2: Room type Vs Price

Airbnb primarily offers four different types of lodging: entire home/apartment, private room, shared room, and hotel room. Shared and private room kinds are those in which the entire home, including bedrooms, or just the kitchen and patio are shared. The visualization shows that shared rooms are less popular among all four since they lack privacy. People prefer private rooms to hotel rooms, which may be due to the fact that hotel rooms are more expensive. Finally, in terms of

Fig. 6: Visualization 3: Neighborhood Vs Price range

Fig. 7: Visualization 4: Price share of each Neighborhood

Airbnb rental homes, the entire room/apartment accommodation type is the most popular.

The Airbnb housings in the Florida region are the focus of this paper. The price ranges for each neighborhood in Florida where Airbnb homes are situated are shown in Visualization 3. The most expensive Airbnb properties are in the Hallandale Beach, Hollywood, and Lauderdale by the Sea neighborhoods. The most affordable areas are Pembroke Pines and Miramar.

The pricing share of each neighborhood in the Florida region is depicted in the doughnut chart above. The city of Hollywood accounted for over 38% of the total, with nearly 960K dollars, followed by Fort Lauderdale, which accounted for nearly 30% of the total, with 814K dollars. The areas of Dania Beach and Weston account for around 3% of

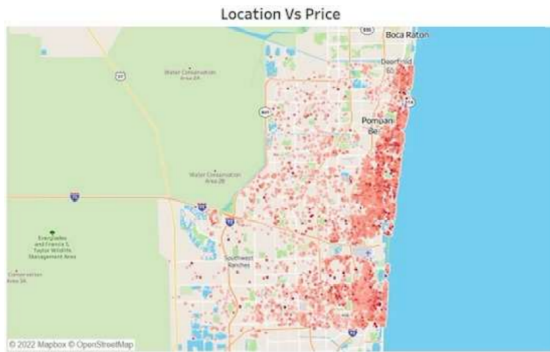

Fig. 8: Visualization 5: Location Vs Price

Fig. 9: Visualization6: Parking Facility Vs Cancellation Policy

the total proportion. Among Florida neighborhoods, West Park Zone has the lowest price share.

The above map chart depicts the pricing distribution of Airbnb rentals in various locations. The darker the hue, the higher the price, whereas the lighter the shade, the lower the price. From the map, we may deduce that coastal locations have denser hues and thus higher pricing, whilst off-the-coast places have lower prices. The increased prices in coastal counties may be owing to the tourist attractions, beaches, and varied activities accessible in these areas.

The price ranges for Airbnb listings with and without parking and cancellation policies are shown in the bar chart above. Rental properties with parking facilities are more expensive than those without. Customers are unconcerned about the cancellation policy while the parking facility is available. The cancellation policy has an impact on costs, but it isn't significant. Customers, on general, prefer

parking to cancellation policies.

VIII. FREQUENCY DISTRIBUTION ON REVIEWS USING NTLK

In this dataset we have reviews provided by the visitors regarding their stay in the Airbnb. All these reviews are used to use what are most of the user are talking about regarding their stay. The Natural Language Toolkit (NLTK) is a Python programming environment for working with human language data in statistical natural language processing (NLP). It includes tokenization, parsing, categorization, stemming, tagging, and semantic reasoning text processing packages. After filtering the reviews data and removing unnecessary words, NLTK used to first convert the sentences available in reviews to words as tokens. Then after removing the stop words, the frequency distribution is checked for the remaining words. From the below figure, we can see that most of the people who visited Airbnb in Florida are talking beach, pool, type of room they stayed in.

Abstract— In this article, we generated some data as a result of new technologies, the internet, and linked items. Putting these facts into context and structuring them so that they may be perceived, understood, and reflected is critical. Humans had traditionally studied data. As the availability of data grows larger, humans are progressively turning to computerized technologies that can replicate them. Machine learning refers to technologies that can resolve issues by learning from both data and data modifications. Artificial intelligence (AI) has a significant influence on e-learning studies, and machine learning-based methodologies may be used to improve Technology Enhanced Learning Environments (TELEs). This publication provides an outline of relevant study outcomes in this domain. Initially, we'll go over some basic machine learning ideas. Then, we'll go through the significant latest research in the domain of e-learning that uses machine learning.

Keywords— *E-Learning, Technology Enhanced Learning Environments, Machine Learning, Artificial Intelligence*

I. INTRODUCTION

Nowadays we lead our lives on a digital track that expresses our performance, identifies our situation, and comes up with many other facts about what we imagine, what we get, etc. Most of the gadgets, machines, and whatever we use that create data because of both data capacity and societal digitization as an example- bring out details from anywhere like smartphones, videos, audios, etc It is vital to profit and makes sense of all obtained data [1].

Understanding events, modeling behaviors and making predictions are all feasible with data analysis. Humans used to evaluate data, write algorithms and then have the computer use those methods to solve issues. Humans now provide data that allows the computer to learn on its own without having to be expressly programmed. Representation, evaluation, and optimization- these three make a machine learning model. So, machine learning works in this concept [2].

In reality, individuals see the worth of information and its true capacity for wealth. AI approaches for dissecting convoluted information have arisen as a critical region in an assortment of logical review disciplines including clinical, interest business, industry, instruction, interpersonal, organization, financial aspects, money, etc.

Machine learning has a close relationship to many related fields including AI, data mining, statistics, and other listed shortly. Machine learning is a many-sided area that is connected to all these fields in various ways. Data mining uses statistics to bring out unseen facts from raw data. Deep learning is the key technology of both AI and machine learning.

Figure 1: Machine Learning related fields

II. MACHINE LEARNING

The machine learning process is the first part of the ML process which involves gathering data from many roots and fine-tuning it, this data will be utilized for ML algorithms depending on issues such as prediction, classification, and other models that are accessible in the ML world. The machine learning process consists of seven stages which are described to come.

Data collection is the first step. It's a process where collecting and computing information from countless different sources. It's a vital task since it will define how effective the predictive model will be. But gathering information that is acquired is much of the time unstructured, has noise, or should be changed into various organizations to be useful for machine learning. So, the information needs to be cleaned and pre-handled [3].

Machine learning model building is next. It's working by gathering and summing up from preparing data, then applying that obtained data to new information it has never seen before to make forecasts and satisfy its motivation. To do so, we first do feature engineering in which we identify the most important data features and then strive to find the optimal machine learning algorithm for the situation at hand. It is critical to achieving the greatest potential outcomes [4].

The next door is training. In this stage, we progressively use a portion of our information to increase machine language prediction skills. After training, it's time to test and evaluate how it performs against the data that has yet to be seen. For evaluating performance used accuracy, precision, recall, etc various metrics. Sometimes it is feasible to go back and enhance training before retesting. The output of machine learning is the final phase. It might be a guess or an interface.

A. Machine Learning Paradigm

Machine learning helps to improve the e-learning framework by including the ability to place learners into those learning frameworks, as well as misleading and smart learning initiatives have been implemented [5].

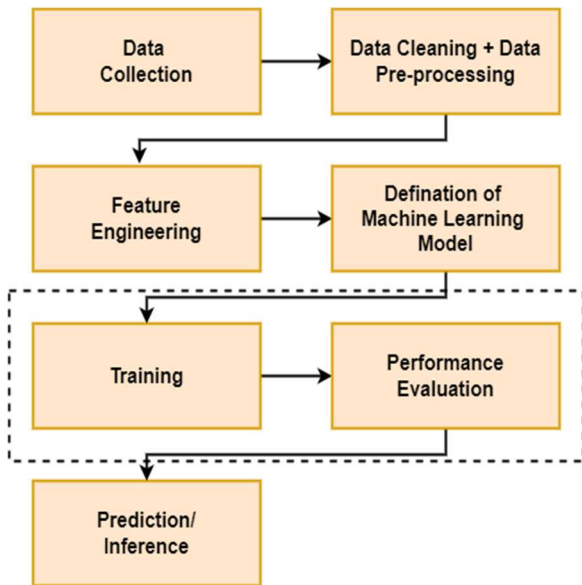

Figure 2: Machine Learning Process

Machine learning can be classified according to the approach used for the learning process. Four main categories identified-supervised, unsupervised, semi-supervised, and reinforcement learning.

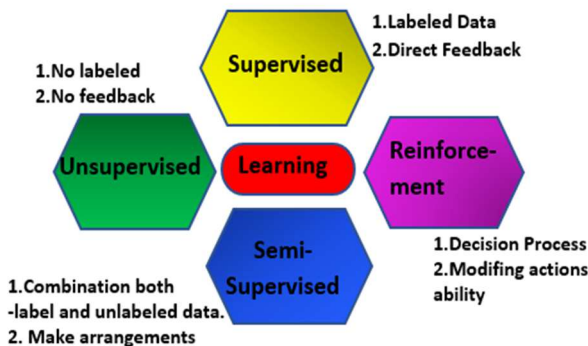

Figure 3: Machine learning Paradigms Categories [6]

In supervised learning, input information is called information prepared and has the specified spam/non-spam or storage costs at once. Place the model through the preparatory process it is obliged to produce predict and adjust if these are not met. The preparation methods are followed until the model achieves the desired precision on the preparing data. The concern, in this case, is grouping and relapse. Logistic Regression and the Back Propagation Neural network are used to calculate case values [7].

Conversely, Unsupervised learning is a machine learning technique that doesn't require the user to monitor the model. The model can work on itself to discover the patterns and data that were not before discovered. This case mainly handled unlabeled data.

However, semi-supervised learning which input data is a combination of labeled and unlabeled samples. There is a desired prediction issue, but the model takes into account the structure to compile the facts and produce expediencies. The challenges, in this case, are arrangement and regression [8].

At the end of the machine learning viewpoint when you know what you want but don't have the idea to gain it. The principle is to test solutions and then see which can achieve the desired result. Reinforcement learning issues can be formalized as agents which make good decisions and have good behavior [9 - 14]. This means modifying or acquiring new actions and abilities. So, this case doesn't require knowledge and control, it only needs able to be interact with the environment and collect information.

III. APPLICATIONS OF ML IN E-LEARNING

Now, in this 21st century people are learning and trying to utilize their skills at different levels, by researching and experimenting, Personalized and adaptive machine learning can change learning content or the mode of delivery on the fly and provide real-time feedback to learners. In machine learning, the computer learns from statistics to do with the given task this data will be utilized for ML algorithm depending on issues such as prediction, and classification. The next step is to create a machine learning model. It works by gathering and combining information gathered from data preparation, then applying that information to fresh information it has never seen before to produce projections and satisfy its goal [9]. We apply a portion of our data to gradually improve the prediction skill of machine language. After it has been trained, it is time to put it to the test and see how it performs against previously unseen data. Various criteria including accuracy, precision, and recall were utilized to evaluate performance these parts are the main vital parts of the application Before retesting, sometimes it is possible to go back and improve training. The final phase is the machine learning output. And we have to focus on the output and have a look carefully at what we have given the machine to do besides what he gives us as an output, it will help us to summarise the application and its success rate.

A. Sentiment Analysis

Sentiment analysis can be used to predict learner satisfaction by identifying multiple complex emotions researchers intend to determine the polarity of learners' attitudes by positive and negative sentiments using forum messages in MOCs. It supervised machine learning algorithms. logistic regression, support vector machine, decision tree, random forest, and nave Bayes have been employed more frequently in contributions linked to prediction in MOOCs. The random forest approach was shown to be the most reliable. It is critical to comprehend the function of emotion in MOOC students learning experiences, on the other hand, regulation of achievement emotions according to [10 - 14] may help to promote learner engagement with a supervised machine learning model based on SVM to categorize achievement emotions automatically. SVM was chosen because it outperforms nave Bayes, logistic regression, and the decision tree in terms of performance.

B. Student Behavior

The application of machine learning in forecasting student conduct was the subject of an interesting literature study. Two research objectives have been identified: dropout prediction and student classification.

1) Student Classification

Personalities, histories, knowledge, abilities, and preferences undoubtedly play an important role in the machine learning process. The recommender system helps each learner find the most appropriate content. Learner profiling and classification are essential not only for personalizing learning but also for identifying abandonment causes and verify of other purposes. In table 1 we just came out with some recent machine learning-based student classification studies.

Table 1. Student Classification [10]

ML Algorithms	Classification Goal	Results
k-means, SVM, Naive Bayes	Classification of engaged and disengaged faces of students with dyslexia	Accuracy: 97–97.8%
Backpropagation, Support Vector Machine (SVM), Gradient-Boosting Classifier (GBC)	classification of student performance	Accuracy: BP = 87.78%, GBC= 82.44%
Decision tree, Logistic Regression, k-nn, SVM, Random Forest	Classification of successful and unsuccessful students	KNN gives the higher accuracy = 85%
K-modes, Clustering, Naive Bayes	Classification of learner’s learning style	Accuracy: 89%

2) Dropout Prediction

To access interacting behavior traces leftover TELE a variety of machine learning approaches were used. Logistic regression(LR) has been the most commonly utilized technique to predict student dropout in the MOOC setting according to [1] who focuses on learners and clickstream data percentage.SVM and decision tree ranked 2nd and 3rd respectively. The neural language processing technique is ranked 3rd.

C. Self-regulated Learning

The majority of TELE has little external instructor monitoring, learners are expected to decide on their activities Individuals with good self-regulated learning (SRL) skills are

defined as the ability to plan, manage, and control one's learning process, it helps them to learn faster and better in the instance MOOC aims learners to self-evaluate the quality of the process of their work, it also helps them to make objectives, plans and prove them the option to read notes, logs, test or learning material to prepare for testing among other things [7]. As it is one of the e-learning platforms enabling SRL techniques despite all these advantages several researchers believe that it is still viral to improve student SRL using a machine learning technique.

IV. CONCLUSION

To improve the experience of learning, e-learning experts have invested a lot of time evaluating learners' data using machine learning approaches. This appears to be prudent, given that the student is the most integral part of the e-learning world. However, to the best of our knowledge, no research has been performed on using learning data to measure the quality of the content to enhance it.

Therefore, we will concentrate our future efforts on evaluating e-learning content using machine learning. The fundamental purpose is to encourage course creators in the educational conceptual framework based on using machine learning and a variety of parameters, including previous learner encounters.
