

IEMTRONICS

International Conference

Toronto, Canada

2022 CONFERENCE PROCEEDINGS

Date: 1st - 4th June, 2022

Editors:

Satyajit Chakrabarti, Rajashree Paul, Bob Gill,
Malay Gangopadhyay, Sanghamitra Poddar

About the Conference

IEMTRONICS 2022

Continuing with the outstanding success of IEEE IEMCON, IEEE CCWC, IEEE UEMCON, IEMANTENNA we are proud to present IEMTRONICS 2022 (International IOT, Electronics and Mechatronics Conference) which will be held during **1st- 4th June, 2022 at Toronto, Canada, in online mode**. Keeping in mind the pandemic situation prevalent globally due to Covid 19 and following the legacy of organizing highly successful conferences, we have planned for the online conference. The conference aims to bring together scholars from different backgrounds to emphasize dissemination of ongoing research broadly in the fields of IOT, Electronics and Mechatronics. Research papers are invited describing original works in above mentioned fields and related technologies. The conference will include a peer-reviewed program of technical sessions, special sessions, tutorials and demonstration sessions.

All accepted papers which will be presented during the parallel sessions of the Conference will be submitted for publication in IEEE Xplore Digital Library (Scopus, DBLP, Ei Compendex, Web of Science and Google Scholar).

This conference will also promote an intense dialogue between academia and industry to bridge the gap between academic research, industry initiatives, and governmental policies. This is fostered through panel discussions, keynotes, invited talks and industry exhibits where academia is exposed to state-of-practice and results from trials and interoperability experiments. The industry in turn benefits by exposure to leading-edge research in networking as well as the opportunity to communicate with academic researchers regarding practical problems that require further research.

Our Reviewers

IEMTRONICS 2022 followed a rigorous triple-blind review process in order to identify suitable papers for both presentation and publication. This process helped the organizers to shortlist good quality papers from diverse regional areas and across various domains. A detailed review process was possible due to the excellent and enthusiastic support extended by the strong technical review team of IEMTRONICS 2022. For every stage of submission, IEMTRONICS had a specific template review procedure to analyze the submissions and provide suitable comments for the authors to incorporate. The review team which formed the technical backbone for the selection of submissions for the edited book and the conference presentation was supervised by:

NAME	AFFILIATIONS
Amany Abood	Al-Esraa University College
Qasem Abu Al-Haija	Princess Sumaya University for Technology (PSUT)
Naheem Adesina	Louisiana State University
Md Imtiaz Ahmed	Prime University
Baker Al Smadi	Grambling State University
Md Ali	Rider University
Ali Abdullah S. AlQahtani	North Carolina A&T State University
Nesreen Alsbou	University of Central Oklahoma
Ahmed Ammari	INSAT - Carthage University Tunisia
Mohammad Anees	Xilinx
Vaibhav Anu	Montclair State University
Asif Mohammed Arfi	University of Yamanashi
Haissam Badih	Lawrence Technological University
Anindya Bal	BRAC University
Kuhaneswaran Banujan	Sabaragamuwa University of Sri Lanka
Doina Bein	California State University, Fullerton
Aleksandr Below	National Research University Higher School of Economics
La Verne Certeza	University of Santo Tomas
Pratik Chattopadhyay	Indian Institute of Technology (BHU), Varanasi
Ritu Chaturvedi	University of Guelph
Sangay Chedup	Jigme Namgyel Engineering College
Yuanzhu Chen	Queen's University
Jingyuan Cheng	University of Science and Technology of China
Syantika Chowdhury	Jadavpur University

Ronnie Concepcion II	De La Salle University
José Cornejo	Universidad Tecnológica del Perú
Monica Costa	Polytechnic Institute of Castelo Branco
Omar Darwish	Eastern Michigan University
Arighna Deb	KIIT University
Mohan Dehury	Koneru Lakshmaiah Education Foundation
Sukomal Dey	Indian Institute of Technology, Delhi
S Dhivya	VIT University
Ke-Lin Du	Concordia University
Pallav Dutta	Aliah University
Mahmoud Elkhodr	Central Queensland University
Amin Fadlalla	Mashreq University
Zainab Faisal	Al-Esraa University College
Vilas Gaidhane	Birla Institute of Technology and Science Pilani, Dubai Campus, UAE
Sebastian Garcia	none
Soham Ghosh	University of Kansas
Rajib Kumar Halder	Jagannath University
Maryam Heidari	George Mason University
Deyby Huamanchahua	Universidad de Ingeniería y Tecnología - UTEC
Maysam Hussein	Al-Esraa University College
Qaiser Ijaz	The Islamia University of Bahawalpur
Mohammad Tariq Iqbal	Memorial University of Newfoundland
Ashwini Jadhav	University of the Witwatersrand
Asif Uddin Khan	Silicon Institute of Technology, Bhubaneswar
Shahriar Khan	Independent University
Haruo Kobayashi	Gunma University
Moises Levy	Florida Atlantic University
Pravir Malik	Deep Order Technologies
Olusiji Medaiyese	University of Louisville
Morteza Modarresi Asem	Tehran Medical Sciences University
Nabilt Moggiano	Universidad Continental
Bhabendu kumar Mohanta	GITAM Deemed to Be University
Erkin Navruzov	National University of Uzbekistan
Moses Onibonoje	Afe Babalola University, Ado Ekiti
Madhumita Pal	Institute of Engineering & Management, Kolkata
Rajvardhan Patil	Grand Valley State University
Loreen Powell	Bloomsburg University of Pennsylvania
Kumar Rahul	XILINX
Kuvonchbek Rakhimberdiev	National University of Uzbekistan Named After Mirzo Ulugbek
Biplob Ray	Central Queensland University
K Himaja Reddy	KLEF Deemed to be University
Ashiq Sakib	Florida Polytechnic University
Sowmya Sanagavarapu	Anna University
Daniel Semwayo	University of Witwatersrand
Abhijit Sen	KPU
Ahmed Shafkat	Fareast International University
Lugen Sheet	UNIVERSITY OF MOSUL
Sodessa Shonkora	Arba Minch University

Mayer Silva	none
Rohit Singh	University of Colorado Denver
Kanika Sood	California State University, Fullerton
M. Srilatha	Vardhaman College of Engineering
Elvis Supo	Universidad Nacional de San Agustín de Arequipa
Sourabh Swarnkar	Xilinx
Tri Tran	Gunma University
Yuan Xing	University of Wisconsin-Stout
Wael Yafooz	Taibah University
Lasith Yasakethu	Sri Lanka Technological Campus
Hasan Yasar	Carnegie Mellon University

ORGANIZING COMMITTEE

General Chair:

Rajashree Paul

University of Engineering & Management, Kolkata, India

Technical Co-Chair:

Bob Gill

British Columbia Institute of Technology, Burnaby, Canada

Malay Gangopadhyay

Institute of Engineering & Management, Kolkata, India

Finance Chair:

Sanghamitra Poddar

Institute of Engineering & Management, Kolkata, India

Publicity Chair:

Fatima Hussain

**Professor, Ryerson university, Canada, Editor IEEE
Newsletter, IEEE Toronto section**

ADVISORY COMMITTEE

Name	University
Dr. Chuck Easttom	University of Dallas, USA & Georgetown University, USA
Dr. Phillip Bradford	University of Connecticut-Stamford, USA
Dr. Ronald F. DeMara	University of Central Florida, USA
Dr. Fatima Hussain	Professor, Ryerson university, Canada, Editor IEEE Newsletter, IEEE Toronto section
Dr. Ashutosh Datta	Johns Hopkins University, USA
Dr. Yang Hao	Queen Mary University, London
Dr. Vien Van	University of Alberta, Canada
Dr. Omar Ramahi	University of Waterloo, Canada
Dr. Yahia Antar	Royal Military College, Canada
Dr. Zhizhang (David) Chen	Dalhousie University, Canada
Dr. Detlef Streitferdt	Technische Universitat Ilmenau, Germany
Prof. Shahab Tayeb	California State University, Fresno.

TECHNICAL COMMITTEE

Name	University
Dr. Nabeeh Kandalaft	Grand Valley State University, USA
Dr. Alex "Sandy" Antunes	Capitol Technology University, USA
Dr. Izzat Alsmadi	Texas A&M, San Antonio, USA
Dr. Lo'ai Tawalbeh	Texas A&M University-San Antonio, USA
Dr. Pratik Chattopadhyay	Indian Institute of Technology (BHU), Varanasi
Dr. Doina Bein	California State University, Fullerton, USA
Dr. Hasan Yasar	Carnegie Mellon University, USA
Dr. Moises Levy	West Texas A&M University, USA
Dr. Christian Trefftz	Grand Valley State University, USA
Dr. Mrinal Sen	Indian Institute of Technology(ISM), Dhanbad
Dr. Petros Spachos	University of Guelph, Canada
Dr. Kanika Sood	California State University, Fullerton
Dr. Ke-Lin Du	Concordia University, Canada
Dr. Wenlin Han	California State University, Fullerton
Dr. Ashiq Adnan Sakib	Florida polytechnic University, USA
Dr. Morteza Modarresi Asem	Islamic Azad University, Iran
Dr. Md. Liakat Ali	Rider University, USA
Dr. Tarek El Salti	Sheridan College, Canada
Dr. Sukomal Dey	Indian Institute of Technology, Palakkad
Dr. Maysam Chamanzar	Carnegie Mellon University, USA
Dr. Kean Boon Lee	Sheffield University, UK

Track Topics:

IoT & Data Science:

- IoT and blockchain
- IoT and big data
- Next-generation infrastructure for IoT
- Cloud computing and IoT
- Edge computing and IoT
- IoT platforms, tools, and applications
- IoT systems development methodologies
- IoT applications

Electronics:

- Antenna and wireless communication
- Microwave Engineering
- Photonics
- Nano science & Quantum Technology
- VLSI and Microelectronic Circuit Embedded Systems
- System on Chip (SoC) Design
- FPGA (Field Programmable Gate Array) Design and Applications
- Electronic Instrumentations
- Sensors & Systems
- NEMS & MEMS
- Integrated circuits & power electronics
- Electronic Power Converters and Inverters
- Electric Vehicle Technologies
- Control Theory, Optimization and Applications
- Robotics and Autonomous Systems
- Intelligent, Optimal, Robust, Adaptive Control
- Linear and Nonlinear Control Systems
- Complex Adaptive Systems
- Industrial Automation and Control Systems Technology
- Modern Electronic Devices
- Biomedical devices & Imaging
- Energy Harvesting & Conversions
- Energy Efficient Hardware systems

Mechatronics:

- Sensing and Control Systems
- Mechatronics Systems
- Mechanical Systems
- Artificial Intelligence
- Applications of Robotics

Information Technology:

- Business Intelligence and Applications
- Computer Network
- Evolutionary Computation and Algorithms
- Intelligent Information Processing
- Information System Integration and Decision Support

- Image Processing and Multimedia Technology
- Signal Detection and Processing
- Technique and Application of Database
- Software Engineering
- Mobile Computing
- Distributed Systems
- Artificial Intelligence
- Visualization and Computer Graphic
- Natural Language Processing
- Deep Learning
- Machine Learning
- Internet of Things, Data Mining
- Data Science
- Cloud Computing in E-Commerce Scenarios
- E-Business Systems Integration and Standardization, E-government
- Electronic Business Model and Method
- E-Commerce Risk Management
- Recommender system
- Semantic Web Service Architecture for E-Commerce
- Service Oriented E-Commerce and Business Processes
- Data Analytics and Big Data
- Software defined networking
- Secured distributed systems

Mobile Communication:

- Ad hoc networks
- Body and personal area networks
- Cloud and virtual networks
- Cognitive radio networks
- Cyber security
- Cooperative communications
- Delay tolerant networks
- Future wireless Internet
- Local dependent networks
- Location management
- Mobile and wireless IP, Mobile computing
- Multi-hop networks
- Network architectures
- Network Security, Information Security, Encoding Technology
- Routing, QoS and scheduling
- Satellite communications
- Self-organising networks
- Telecommunication Systems
- Vehicular networks
- Wireless multicasting, Wireless sensor networks

Chief Guest of IEMTRONICS 2022

Nobel Laureate

Prof. Takaaki Kajita

Honourable Nobel Laureate, Distinguished University Professor, Institute for Cosmic Ray Research, The University of Tokyo, Japan

Bio: Kajita Takaaki, (born 1959, Higashimatsuyama, Japan), Japanese physicist who was awarded the 2015 Nobel Prize in Physics for discovering the oscillations of neutrinos from one flavour to another, which proved that those subatomic particles have mass. He shared the prize with Canadian physicist Arthur B. McDonald.

Kajita received a bachelor's degree from Saitama University in 1981 and a doctorate from the University of Tokyo (UT) in 1986. That year he became a research associate at the International Center for Elementary Particle Physics at the UT, where he worked on the Kamiokande-II neutrino experiment, a tank containing 3,000 tons of water located deep underground in the Kamioka mine near Hida. Most neutrinos passed right through the tank, but on rare occasions a neutrino would collide with a water molecule, creating an electron. Those electrons travelled faster than the speed of light in water (which is 75 percent of that in a vacuum) and generated Cherenkov radiation that was observed by photomultiplier tubes on the walls of the tank. In 1987 Kajita was part of the team that used Kamiokande-II to detect neutrinos from Supernova 1987A, which was the first time neutrinos had been observed from a specific object other than the Sun.

Kamiokande-II could also observe neutrinos generated by cosmic rays, high-speed particles (mainly protons) that collide with nuclei in Earth's atmosphere and produce secondary particles. Those secondary particles decay and produce two of the three flavours of neutrinos: electron neutrinos and muon neutrinos. In 1988 Kajita and the other Kamiokande scientists published results showing that the number of muon neutrinos was only 59 percent of the expected value.

Kajita joined the UT's Institute for Cosmic Ray Research in 1988 as a research associate and continued his work at Kamiokande-II. He became an associate professor at the institute in 1992. That same year he and his team published results confirming the deficit of atmospheric muon neutrinos. They suggested that neutrino oscillations in which the "missing" muon neutrinos changed into the third neutrino flavour, tau (which could not be observed by Kamiokande-II), could be the culprit. Neutrinos were thought to be massless, but, in order to oscillate flavours, they must have a very small mass. In 1994 Kajita and his team found a slight dependence of the number of detected muon neutrinos on direction, with more neutrinos coming down than coming up.

In 1996 Kamiokande-II was replaced by Super-Kamiokande, which contained 50,000 tons of water, and Kajita led the studies of the atmospheric neutrinos. After two years of observations, his team definitively confirmed that the number of muon neutrinos coming down from the atmosphere is greater than the number of muon neutrinos coming up from Earth. Since neutrinos rarely interact with matter, the number of neutrinos observed should not depend on the arrival angle. However, that angle effect proved the existence of neutrino flavour oscillations and thus neutrino mass. The neutrinos coming up through Earth travel a longer distance, thousands of kilometres, than the neutrinos coming down, which only travel a few dozen kilometres. Therefore, the up-going neutrinos have more time to undergo an oscillation into tau neutrinos than those coming down.

Kajita became a professor at the Institute for Cosmic Ray Research and director of the Research Center for Cosmic Neutrinos there in 1999. He became director of the institute in 2008.

Guest of Honour of IEMTRONICS 2022

Nobel Laureate

Prof. Konstantin Novoselov

Honourable Nobel Laureate, Professor at the Centre for Advanced 2D Materials, National University of Singapore, Langworthy Professor in the School of Physics and Astronomy, University of Manchester, Manchester, United Kingdom

Bio: Kostya Novoselov made it into a shortlist of scientists with multiple hot papers for the years 2007–2008 (shared second place with 13 hot papers) and 2009 (5th place with 12 hot papers).

In 2014 Kostya Novoselov was included in the list of the most highly cited researchers. He was also named among the 17 hottest researchers worldwide—“individuals who have published the greatest number of hot papers during 2012–2013”.

Novoselov joined the National University of Singapore’s Centre for Advanced 2D Materials in 2019, making him the first Nobel laureate to join a Singaporean university.

Awards and honours

- 2007 Nicholas Kurti European Science Prize “to promote and recognise the novel work of young scientists working in the fields of Low Temperatures and/or High Magnetic Fields.”
- 2008 Technology Review-35 Young Innovator
- 2008 University of Manchester Researcher of the Year.
- 2008 Europhysics Prize, jointly with Geim, “for discovering and isolating a single free-standing atomic layer of carbon (graphene) and elucidating its remarkable electronic properties.”
- 2008 International Union of Pure and Applied Physics Young Scientist Prize, “for his contribution in the discovery of graphene and for pioneering studies of its extraordinary properties.”
- 2010 Nobel Prize in Physics, jointly with Andre Geim, “for groundbreaking experiments regarding the material graphene.” Novoselov was the youngest Nobel laureate in physics since Brian Josephson in 1973, and in any field since Rigoberta Menchú (Peace) in 1992.
- 2010 Knight Commander of the Order of the Netherlands Lion
- 2010 Honorary Fellow of the Royal Society of Chemistry (HonFRSC)
- 2010 Honorary Professor of Moscow Institute of Physics and Technology
- 2011 Honorary Doctorate from the University of Manchester
- 2011 Honorary Fellow of the Institute of Physics (HonFInstP)
- 2011 Elected Fellow of the Royal Society (FRS)
- 2011 W. L. Bragg Lecture Prize from the International Union of Crystallography “... for his work on two-dimensional atomic crystals”
- 2012 Knight Bachelor in the 2012 New Year Honours for services to science.
- 2012 Chosen among “Britain’s 50 New Radicals” by NESTA and The Observer

- 2012 The Kohn Prize Lecture “...for development of a new class of materials: two-dimensional atomic crystals”
- 2013 Appointed Langworthy Professor of Physics, University of Manchester
- 2013 Leverhulme Medal (Royal Society) “...for revolutionary work on graphene, other two-dimensional crystals and their heterostructures that has great potential for a number of applications, from electronics to energy”
- 2013 Awarded Honorary Freedom of the City of Manchester “for his groundbreaking work on graphene”, see List of Freedom of the City recipients
- 2013 Elected a foreign member of the Bulgarian Academy of Sciences
- 2014 2nd place in the Discovery Section of the National Science Photography Competition.
- 2014 included in a list of the most highly cited researchers. He was also named among the 17 hottest researchers worldwide – “individuals who have published the greatest number of hot papers during 2012–2013”.
- 2014 awarded the Onsager Medal.
- 2015 elected to be a member of the Academia Europaea.
- 2016 awarded the Carbon Medal.
- 2016 awarded the Dalton Medal.
- 2019 elected a foreign associate of the US National Academy of Sciences
- 2019 elected to be a member of the Asia Pacific Academy of Materials
- 2019 Otto Warburg Prize and Lecture by The Otto Warburg Chemistry Foundation “for the discovery of the unusual quantum properties of one atom thick two-dimensional materials”

His certificate of election to the Royal Society in 2011 reads

Kostya Novoselov’s research interests cover a wide range of topics from mesoscopic superconductivity and ferromagnetism to materials science and biophysics. He studied vortex structures in mesoscopic superconductors, observed atomic-scale movements of ferromagnetic walls, monitored heartbeats of individual bacteria and mimicked gecko’s adhesion mechanism. His breakthrough moment was the discovery of graphene. Novoselov is now widely recognised to be one of the pioneers in this field (as a number of international awards prove) and, together with Prof Geim FRS, leads research on various applications of this new material ranging from electronics, photonics, composite materials, chemistry, etc. Prof. Novoselov is strongly committed to disseminating science through public lectures and media interviews.

Keynote speakers

Dr. Xiaodong Wang

Professor, Columbia University, New York

Bio: Dr. Xiaodong Wang is a professor of electrical engineering in Columbia University in the city of New York. His research interest includes statistical signal processing, genomic signal processing, machine learning, wireless communications, and information theory.

Among his publications is a book entitled “Wireless Communication Systems: Advanced Techniques for Signal Reception”, published by Prentice Hall in 2003. He has served as an associate editor for the IEEE Transactions on Communications, the IEEE Transactions on Wireless Communications, the IEEE Transactions on Signal Processing, and the IEEE Transactions on Information Theory. He is a Fellow of the IEEE and listed as an ISI Highly-cited Author.

Wang received the 1999 NSF CAREER Award, the 2001 IEEE Communications Society and Information Theory Society Joint Paper Award, and the 2011 IEEE Communication Society Award for Outstanding Paper on New Communication Topics. Xiaodong Wang received the Ph.D degree in Electrical Engineering from Princeton University. He is a Professor of Electrical Engineering at Columbia University in New York.

Dr. Kenneth Paterson

Professor, ETH Zürich, Switzerland

Bio: Dr. Kenneth Paterson obtained a B.Sc. in 1990 from the University of Glasgow and a Ph.D. from the University of London in 1993, both in Mathematics. He was then a Royal Society Fellow at the Institute for Signal and Information Processing at the Swiss Federal Institute of Technology, Zurich, from 1993 to 1994. After that, he was a Lloyd's of London Tercentenary Foundation Research Fellow at Royal Holloway, University of London from 1994 to 1996.

In 1996, he joined Hewlett-Packard Laboratories Bristol, becoming a project manager in 1999.

He then joined the Information Security Group at Royal Holloway in 2001, becoming a Reader in 2002 and Professor in 2004. From March 2010 to May 2015, he was an EPSRC Leadership Fellow working on a project entitled Cryptography: Bridging Theory and Practice. In May 2015, he reverted to being a Professor of Information Security.

In April 2019, he joined the Department of Computer Science at ETH Zurich. Since 1 January 2021, he has held the role of Associate Department Head. In addition, he is director of the CAS/DAS in Cyber Security and the Masters programme in Cyber Security. His research over the last two decades has mostly been in the area of Cryptography, with a strong emphasis being on the analysis of deployed cryptographic systems and the development of provably secure solutions to real-world cryptographic problems. He co-founded the Real World Cryptography series of workshops to support the development of this broad area and to strengthen the links between academia and industry. From 2014 to 2019, he was co-chair of the IRTF's research group on Cryptography, CFRG. This group is working to provide expert advice to the IETF in an effort to strengthen the Internet's core security protocols.

His research on the security of TLS (the Lucky 13 attack on CBC-mode encryption in TLS and attacks on RC4) received significant media attention, helped to drive the widespread adoption of TLS 1.2 with its support for modern encryption schemes, and was an important factor in the TLS Working Group's decision to abandon legacy encryption mechanisms in TLS 1.3.

He is lucky to have been the recipient of several prizes and awards for my research. These include a Google Distinguished Paper Award for his joint work with Nadhem AlFardan presenting plaintext recovery attacks against DTLS published at NDSS 2012; an Applied Networking Research Prize from the IRTF for his work with Nadhem AlFardan on the Lucky 13 attack; and an Award for Outstanding Research in Privacy Enhancing Technologies for his work with Mihir Bellare and Phil Rogaway on the Security of symmetric encryption against mass surveillance published at CRYPTO 2014. My work with Martin Albrecht, Jean Paul Degabriele and Torben Hansen on symmetric encryption in SSH won a best paper award at ACM CCS 2016. In 2018, his work won best paper awards at CHES and IMC.

Other career highlights include being selected as Programme Chair for EUROCRYPT 2011, being an invited speaker at ASIACRYPT 2014, and being editor-in-chief of the Journal of Cryptology from 2017 to 2020. He was made a fellow of the IACR in 2017.

Dr. Gil Zussman

Professor, Columbia University, New York

Bio: **Gil Zussman** received the B.Sc. degree in Industrial Engineering and Management and the B.A. degree in Economics (both summa cum laude) from the Technion – Israel Institute of Technology in 1995. He received the M.Sc. degree (summa cum laude) in Operations Research from Tel-Aviv University in 1999 and the Ph.D. degree in Electrical Engineering from the Technion – Israel Institute of Technology in 2004. Between 1995 and 1998, he served as an engineer in the Israel Defense Forces. Between 2004 and 2007 he was a Postdoctoral Associate in LIDS and CNRG at MIT.

In 2008 he joined the faculty of the Department of Electrical Engineering at Columbia University where he is now a Professor. His research interests are in the area of networking, and in particular in the areas of wireless, mobile, and resilient networks. He has been an associate editor of IEEE Transactions on Control of Network Systems, IEEE Transactions on Wireless Communications and Ad Hoc Networks, the Technical Program Committee (TPC) co-chair of ACM MobiHoc'15, IFIP Performance 2011, and a member of a number of TPCs (including the INFOCOM, MobiCom, SIGMETRICS, and MobiHoc committees).

Gil received the Knesset (Israeli Parliament) award for distinguished students, the Marie Curie Outgoing International Fellowship, the Fulbright Fellowship, the DTRA Young Investigator Award, and the NSF CAREER Award. He was the PI of a team that won the 1st place in the 2009 Vodafone Foundation Wireless Innovation Project competition. He is a co-recipient of seven best paper awards, including the ACM SIGMETRICS / IFIP Performance'06 Best Paper Award, the 2011 IEEE Communications Society Award for Advances in Communication, and the ACM CoNext'16 Best Paper Award.

Dr. Kin K. Leung

Professor, Imperial College, London, United Kingdom

Bio: **Dr. Leung** had completed his Ph.D. in computer science, Univ. of California, Los Angeles in 1985; M.S. in computer science, Univ. of California, Los Angeles in 1982 and B.S. in electronics, The Chinese Univ. of Hong Kong, Hong Kong in 1980. His major

Honors and Awards are:

- IEEE Communications Society Leonard G. Abraham Prize, 2021
- S.-UK Science and Technology Stocktake Award for the DAIS ITA Team, 2021
- IET Fellow, 2021
- Member of Academia Europaea, 2012
- IEEE Fellow Evaluation Committee for Communications Society: Member 2009-2011, Chairman 2012-2015
- Royal Society Wolfson Research Merit Award, 2004-2009
- IEEE Fellow for contributions to “Performance analysis, protocol design and control algorithms for communications networks,” 2001
- Lanchester Prize Honorable Mention Award, 1997
- Bell Labs Distinguished Member of Technical Staff Award, 1994

He is Journal Editor of the following:

- ACM Computing Survey (2009-now)
- Journal of Sensor Networks (2005-now)
- IEEE Trans. on Mobile Computing, Steering Committee Chairman (2020-2022) and Member (2014-2016)
- IEEE Trans. on Communications (1997-2011)
- IEEE Trans. on Wireless Communications (2001-2009)
- IEEE Journal on Selected Areas in Communications: Wireless Series (1999-2001)
- Guest editor: IEEE Wireless Communications, 2007
- Guest editor: Journal of Wireless Communications and Mobile Computing, 2005
- Guest editor: Journal on Special Topics in Mobile Networking and Application (MONET), 2003
- Guest editor: IEEE Journal on Selected Areas in Communications, 1997

His current Research Interests includes:

- Machine learning, distributed optimization, stochastic modeling and queueing theory.
- Wireless communications: resource allocation, power control, spread spectrum, MIMO/beamforming antennas, cross-layer designs, link adaptation, MAC, wireless TCP/IP, QoS, network protocols, and sensor, vehicular, ad-hoc and mesh networks.
- Wireless technologies: GSM, EDGE, 3G, 4G and 5G cellular networks, and IEEE 802.11, 802.16 and 802.15 networks.
- Communication networks: TCP/IP, mobility management, real-time applications, network control protocols, traffic modeling.

Dr. Dayan Ban

Professor, University of Waterloo, Canada

Bio: Dayan Ban is a full Professor in Electrical and Computer Engineering and is a researcher at the Waterloo Institute for Nanotechnology.

His expertise lies in the conversion of near infra-red light directly to visible light, design and fabrication of high-performance quantum devices and the development of ultra-sensitive surface plasmon sensors.

Professor Ban successfully improved the efficiency of hybrid organic/inorganic devices by more than one order of magnitude and applied time-domain terahertz spectroscopy to study the device physics of terahertz quantum cascade lasers. Professor Ban's research has also accomplished the fabrication of prototype hybrid organic/inorganic devices by direct tandem integration and the study of the effects of interfacial states on device performance. These devices are responsible for the conversion of near-infrared light directly to visible light (green) at room temperature.

Professor Ban pioneered the development of new methods in scanning probe microscopy to observe, with nanometric spatial resolution, two-dimensional profiles of conductivity and potential inside actively-driven lasers. He also resolved the nanoscopic reason for anomalously high series resistance encountered in ridge waveguide lasers. In addition, Professor Ban reported the first direct experimental observation of electron overbarrier leakage in operating buried heterostructure multi-quantum-well –lasers. His work has provided the first experimental visualization of the inner workings of operating semiconductor lasers, and has also provided a platform for enabling tools for quantum semiconductor device and nanotechnology research.

Research Interests

- Semiconductor quantum devices
- Photonics
- THz technology
- Nanotechnology
- Atomic force microscope
- Fiber-optical communication system
- Silicon Devices
- Terahertz Quantum Cascade Lasers
- Biophotonics
- Scanning Probe Microscopy
- Connectivity and Internet of Things
- Nanofabrication
- IoT Devices
- Application domains

Education

- 2003, Doctorate, Ph.D., University of Toronto
- 1995, Master's, MS, University of Science and Technology of China
- 1993, Bachelor's, BA, University of Science and Technology of China

Dr. Torsten Hoefler

Professor, ETH Zürich, Switzerland

Bio: **Torsten Hoefler** directs the Scalable Parallel Computing Laboratory (SPCL) at D-INFK ETH Zurich. He received his PhD degree in 2007 at Indiana University and started his first professor appointment in 2011 at the University of Illinois at Urbana-Champaign.

Torsten has served as the lead for performance modeling and analysis in the US NSF Blue Waters project at NCSA/UIUC. Since 2013, he is professor of computer science at ETH Zurich and has held visiting positions at Argonne National Laboratories, Sandia National Laboratories, and Microsoft Research Redmond (Station Q).

Dr. Hoefler's research aims at understanding the performance of parallel computing systems ranging from parallel computer architecture through parallel programming to parallel algorithms. He is also active in the application areas of Weather and Climate simulations as well as Machine Learning with a focus on Distributed Deep Learning. In those areas, he has coordinated tens of funded projects and an ERC Starting Grant on Data-Centric Parallel Programming.

He has been chair of the Hot Interconnects conference and technical program chair of the Supercomputing and ACM PASC conferences. He is associate editor of the IEEE Transactions of Parallel and Distributed Computing (TPDS) and the Parallel Computing Journal (PARCO) and a key member of the Message Passing Interface (MPI) Forum.

He has published more than 200 papers in peer-reviewed international conferences and journals and co-authored the latest versions of the MPI specification. He has received best paper awards at the ACM/IEEE Supercomputing Conference in 2010, 2013, and 2014 (SC10, SC13, SC14), EuroMPI 2013, IPDPS'15, ACM HPDC'15 and HPDC'16, ACM OOPSLA'16, and other conferences. Torsten received ETH Zurich's Latsis Prize in 2015, the SIAM SIAG/Supercomputing Junior Scientist Prize in 2012, the IEEE TCSC Young Achievers in Scalable Computing Award in 2013, the Young Alumni Award 2014 from Indiana University, and the best student award 2005 of the Chemnitz University of Technology. Torsten was elected into the first steering committee of ACM's SIGHPC in 2013 and he was re-elected in 2016. His Erdős number is two (via Amnon Barak) and he is an academic descendant of Hermann von Helmholtz.

Dr. M. Jamal Deen

Distinguished University Professor , McMaster University, Canada

Bio: **M. Jamal** is a Distinguished University Professor and Senior Canada Research Chair in Information Technology at McMaster University in Hamilton, Ontario, Canada. He is also the Director of the Micro- and Nano-Systems Laboratory. His research specialty are in the broad areas of electrical engineering and applied physics. He has done his Ph.D. (Electrical Engineering and Applied Physics) from Case Western Reserve University, Cleveland, OH, U.S.A in 1985; M.S. (Electrical Engineering and Applied Physics), from Case Western Reserve University, Cleveland, OH, U.S.A in 1982 and B.Sc. (Physics/Mathematics), from University of Guyana, Turkeyen, Guyana in 1978. His expertise includes Micro-/Nano-/Opto-Electronics, Nanotechnology and Data Analytics for Health and Environmental Applications, Bioimagers, Biosensor; his areas of specializations are Imaging, Sensing and Detection, Integrated Systems, Biomedical, Microelectronics, Communications, Biomedical. His achievements includes:

- F.R.S.C., F.C.A.E., M.E.A.S.A., F.N.A.S.I., F.I.N.A.E., F.I.E.E.E., F.A.P.S., F.E.I.C., F.E.C.S., F.A.A.A.S.;
- Distinguished University Professor; Professor and Senior Canada Research Chair in Information Technology ;
- 2017 Distinguished Visiting Fellowship Award from Royal Academy of Engineering, UK;
- 2017 PIFI Distinguished Scientist Award from Chinses Academy of Sciences;
- 2017 Overseas Academic Masters Scholar Award;
- 2014 IEEE Canada Ham Outstanding Engineering Educator Award;
- 2013 IEEE Canada AGL McNaughton Gold Medal;
- 2013 UWI Vice-Chancellor's Award;
- 2013 Faculty of Engineering Research Achievement Award from McMaster University;
- 2011 IEEE Canada R.A. Fessenden Silver Medal Award;
- 2011 Electronics and Photonics Divison (EPD) Award from the Electrochemical Society ;
- 2009 Technology Achievement Award from the Indo-Canada Chamber of Commerce;
- 2008 Eadie Medal from The Royal Society of Canada;
- 2008 Guyana Award from the Academic Excellence Guyana Awards Council – Canada;
- 2006 Humboldt Research Award from the Alexander von Humboldt Foundation;
- 2006 IBM Faculty Award from IBM Corporation, USA;
- 2002 Distinguished Lecturer from IEEE Electron Device Society;
- 2002 Thomas D. Callinan Award from the Electrochemical Society.
- Doctor – Honoris Causa El Instituto Nacional de Astrofísica, Óptica y Electrónica, Puebla, Mexico, 11 Nov 16.
- Doctor – Honoris Causa Universitat Rovira I Virgili, Tarragona, Spain, 7 March 2014.
- Doctor – Honoris Causa Universidad de Granada, Granada, Spain, 25 May 2012.
- Doctor of Engineering – Honoris Causa University of Waterloo, Waterloo, Ontario, Canada, 18 June 2011.

Content:

SL NO.	PAPER NAME	AUTHORS WITH AFFILIATION	PAGE NO.
1	Integrating Mechanistic Information to Predict Drug-Drug Interactions and Associated Relevance for Decision Support	Adeeb Noor (King Abdulaziz University, Saudi Arabia)	1
2	Design and Implementation of a Very-Low-Power Wireless Network of Sensors in an Underground Utility Tunnel for Medium and High Voltage Transmission Lines	Adil Rachid (Polytechnic University of Catalonia, Spain); Antonio Miguel Lopez Martinez (Polytechnic University of Catalonia (UPC), Spain); Sebastian Moreno Garcia (& Infisat, Spain)	5
3	Design of 24 GHz ISM Band Microstrip Patch Antenna for 5G Communication	Debalina Mollik, Rima Islam, Afrin Binte Anwar and Prodig Kumar Saha Purnendu (American International University Bangladesh Address Including Country Name, Bangladesh)	12
4	Detection of Corona Virus Infection Using Convolutional Neural Network	Al Sameera (Birla Institute of Technology and Science Pilani, Dubai Campus, UAE, United Arab Emirates); Vilas H Gaidhane (Birla Institute of Technology and Science Pilani, Dubai Campus, UAE, India)	18
5	A Review of Cognitive Dynamic Systems and Cognitive IoT	Alessandro Giuliano, Waleed Hilal, Naseem Alsadi and Stephen Andrew Gadsden (McMaster University, Canada); John Yawney (Adastra Corporation, Canada)	24

6	IoT Devices Proximity Authentication in Ad Hoc Network Environment	Ali Abdullah S. AlQahtani (North Carolina A&T State University, USA); Hosam Alamleh (University of North Carolina Wilmington & Louisiana Tech University, USA); Baker Al Smadi (Grambling State University, USA)	31
7	Dynamic Modeling of a Micro Solar Electric Vehicle for Pakistan Using Simulink	Ali Husnain and Mohammad Tariq Iqbal (Memorial University of Newfoundland, Canada)	36
8	An Optimum Sizing for a Hybrid Storage System in Solar Water Pumping Using ICA	Amirhossein Jahanfar and Mohammad Tariq Iqbal (Memorial University of Newfoundland, Canada)	45
9	A Real-Time Parking Space Occupancy Detection Using Deep Learning Model	Raktim Raihan Prova, Title Shinha, Anamika Basak Pew and Rashedur M Rahman (North South University, Bangladesh)	51
10	Solar PV System for Self-Consumption	Ananna Khan, Abdul Kahar Siddiki and Rashedur M Rahman (North South University, Bangladesh)	58
11	Provision of Information and Detection Systems on Two-Wheeled Motorcycle Accidents	Andi Nur Faisal and Amil Ahmad Ilham (Hasanuddin University, Indonesia); Syafaruddin Syafaruddin (Universitas Hasanuddin Makassar, Indonesia)	66
12	A Data-Centric Machine Learning Approach for Controlling Exploration in	Antonio Jose Bolufe-Rohler and Jordan Luke (University of Prince Edward Island, Canada)	72

	Estimation of Distribution Algorithms		
13	Aggregated Modeling of Synchronous Generators Using Transfer Matrices	Arash Safavizadeh and Erfan Mostajeran (The University of British Columbia, Canada); Seyyedmilad Ebrahimi (University of British Columbia, Canada); Taleb Vahabzadeh (The University of British Columbia, Canada); Juri Jatskevich (University of British Columbia, Canada)	81
14	Systematic Analysis and Proposed AI-Based Technique for Attenuating Inductive and Capacitive Parasitics in Low and Very Low Frequency Antennas	Kate G Francisco, R-jay Relano, Mike Louie Enriquez, Ronnie Concepcion II, Jonah Jahara Baun, Adrian Genevie G. Janairo, Ryan Rhay P. Vicerra and Argel Bandala (De La Salle University, Philippines); Elmer P. Dadios (Philippines, Philippines); Jonathan Dungca (De La Salle University, Philippines)	88
15	IoT Enabled Smart Solar Panel Monitoring System Based on Boltuino Platform	Pallav Dutta, Ashim Mondal and Md Jishan Ali (Aliah University, India)	95
16	A Practical Approach to the Development of a Decision-Supporting System Based on Fuzzy Neural Network in Information and Telecommunication Systems	Avaz Ergashevich Kuvnakov (TUIT, Uzbekistan)	102
17	A Universal Method for Solving the Problem of Bending of Plates of Any	Azamatjon Yusupov (Andijan Machine Building Institute, Uzbekistan)	106

	Shape		
18	Development of Stochastic Distribution Model of Contaminated Water Treatment Complex	Bakhadir Begilov (Nukus Branch of Tashkent University of Information Technologies Named After Muhammad-Al Khorezmi, Uzbekistan)	111
19	Predictive Maintenance and Condition Monitoring in Machine Tools: An IoT Approach	Brett Sicard and Naseem Alsadi (McMaster University, Canada); Petros Spachos (University of Guelph, Canada); Youssef Ziada (Ford Motor Company, Canada); Stephen Andrew Gadsden (McMaster University, Canada)	117
20	Research on Ambient Backscatter Communication Signal Detection Algorithm Based on Digital Terrestrial Multimedia Broadcast	Chen Ruan and Hongyi Wang (National University of Defense Technology, China); Zheng Liming (National University of Defence Technology, China); Jianfei Wu (National University of Defense Technology, China); Fengxian Ma (Tianjin Institute of Advanced Technology, China)	126
21	Dynamic Analysis of Demographic Sentiment	Joshua Weston, Brenden Bickert and Caleb Stasiuk (Thompson Rivers University, Canada); Fadi Alzhouri (Trent University, Canada); Dariush Ebrahimi (Thompson Rivers University, Canada)	131
22	Use of Drones (UAVs) for Pollutant Identification in	Deyby Huamanchahua (Universidad de Ingeniería y	139

	the Industrial Sector: A Technological Review	Tecnología - UTEC, Peru); Julio Huamanchahua and Fabiola Flores (Universidad San Ignacio de Loyola, Peru)	
23	Nursery With Automation and Control Systems for the Production of White Chuño (Tunta)	Deyby Huamanchahua (Universidad de Ingeniería y Tecnología - UTEC, Peru); Alem Huayta Uribe, Jalber Macuri Vasquez and Hitan Cordova Sanchez (Universidad Continental, Peru)	145
24	Biological Signals for the Control of Robotic Devices in Rehabilitation: An Innovative Review	Deyby Huamanchahua (Universidad de Ingeniería y Tecnología - UTEC, Peru); Luis Alberto Huamán Lévano (Universidad Continental, Peru); Jose Asencios Chávez (Universidad Tecnológica del Perú, Peru); Nicole Caballero Canchanya (Universidad Nacional Mayor de San Marcos, Peru)	150
25	Human Cinematic Capture and Movement System Through Kinect: A Detailed and Innovative Review	Deyby Huamanchahua (Universidad de Ingeniería y Tecnología - UTEC, Peru); Jhon Rodrigo Ortiz Zacarias, Yerson Taza Aquino and Jhon Quispe Quispe (Universidad Continental, Peru)	157
26	Transtibial Electromechanical Prosthesis Based on a Parallel Robot: A Innovate Review	Deyby Huamanchahua (Universidad de Ingeniería y Tecnología - UTEC, Peru); Diego Osores Aguilar and Victor André León Sales (Universidad Nacional Mayor de San Marcos, Peru); Yadhira	164

		Samhira Valenzuela Lino (Universidad Continental, Peru); Harold Huallanca Escalera (Universidad Peruana de Ciencias Aplicadas, Peru)	
27	Knee and Ankle Exoskeletons for Motor Rehabilitation: A Technology Review	Deyby Huamanchahua (Universidad de Ingeniería y Tecnología - UTEC, Peru); Elvis J. de la Torre Velarde (Universidad Peruana de Ciencias Aplicadas, Peru); Ana Quispe Piña (Universidad Tecnológica del Perú, Peru); Cesar Luciano Otarola Ruiz (Universidad de Ingeniería y Tecnología UTEC, Peru)	171
28	Hand Exoskeletons for Rehabilitation: A Systematic Review	Deyby Huamanchahua (Universidad de Ingeniería y Tecnología - UTEC, Peru); Sayda Huacre (Universidad Nacional Mayor de San Marcos, Peru); Pedro Toledo Garcia (Universidad de Ingeniería y Tecnología - UTEC, Peru); Jack Aguirre (Universidad Nacional de Trujillo - UNT, Peru)	178
29	Artificial Intelligence Applied in Human Medicine With the Implementation of Prostheses	Deyby Huamanchahua (Universidad de Ingeniería y Tecnología - UTEC, Peru); Ismael Alvarado Landeo, Erick Surichaqui Montalvo and Kener Velasquez Colorado (Universidad Continental, Peru)	184
30	Land-Mobile Robots for	Deyby Huamanchahua	191

	Rescue and Search: A Technological and Systematic Review	(Universidad de Ingeniería y Tecnología - UTEC, Peru); Kevin Aubert, Mirella Rivas, Eduardo Guerreo, Laura Kodaka and Diego Guevara (Universidad de Ingeniería y Tecnología UTEC, Peru)	
31	Efficient Simulation of Variable-Speed Diesel-Engine Generators Using Constant-Parameter Voltage-Behind-Reactance Formulation	Erfan Mostajeran and Arash Safavizadeh (The University of British Columbia, Canada); Seyyedmilad Ebrahimi and Juri Jatskevich (University of British Columbia, Canada)	197
32	Detection and Analysis Types of DDoS Attack	Erkin Navruzov (National University of Uzbekistan, Uzbekistan)	203
33	Suicide Rate and Factors Analysis: Pre and Post COVID Pandemic	Maryam Heidari and EswaraChandraSai Pamidimukkala (George Mason University, USA)	210
34	Employee Turnover Prediction Model for Garments Organizations of Bangladesh Using Machine Learning Technique	Lutfun Nahar, Farzana Tasnim, Zinnia Sultana and Farjana Akter Tuli (International Islamic University Chittagong, Bangladesh)	218
35	Machine Learning Models to Predict COVID-19 Cases in the DC Metro Area	Maryam Heidari, Michael Thompson, Thao Tran, Ghadah Alshabana and Ashritha Chitimalla (George Mason University, USA)	223
36	Server-Side Distinction of User Mobility Using Machine Learning on Incoming Data Traffic	Hosam Alamleh (University of North Carolina Wilmington & Louisiana Tech University, USA); Ali Abdullah S.	230

		AlQahtani (North Carolina A&T State University, USA); Baker Al Smadi (Grambling State University, USA)	
37	Data Centric DAO: When Blockchain Reigns Over the Cloud	Kamal Azghiou (Mohammed First University & El team, Morocco); Ibrahim Mehdi (University Mohammed 1, Morocco); Moussaab Sbai (Mohammed First University (UMP), Morocco); Mohamed Mazlin (Université Mohammed Premier & ENSAO, Morocco)	234
38	Algorithmic Analysis of the System Based on the Functioning Table and Information Security	Inomjon Yarashov (National University of Uzbekistan, Uzbekistan)	241
39	Using Algorithmic Modeling to Control User Access Based on Functioning Table	Islambek Saymanov and Inomjon Yarashov (National University of Uzbekistan, Uzbekistan)	246
40	Sensory Data Fusion Using Machine Learning Methods for In-Situ Defect Registration in Additive Manufacturing: A Review	J Akhavan (Stevens Institute of Technology, USA); Souran Manoochehri (Chair of Dept ME, Stevens Institute of Technology)	251
41	Unmanned Aerial Vehicle Control Using Hand Gestures and Neural Networks	Rocio Alba-Flores and Jack Nemecek (Georgia Southern University, USA)	261
42	Feature Selection Algorithm Characterization for NIDS Using Machine	Jyoti Verma (Punjabi University Patiala & Punjab Institute of Technology, India);	265

	and Deep Learning	Abhinav Bhandari (Punjabi University, India); Gurpreet Singh (Maharaja Ranjit Singh Punjab Technical University, India)	
43	An Approach to Design Keyboard and Mouse Assisting Device for Handicap Users	Kamran Hameed (Imam AbdulRahman Bin Faisal UNiversity, Saudi Arabia); Syed Mehmood Ali and Uzma Ali (Imam Abdulrahman Bin Faisal University, Saudi Arabia)	272
44	Design of Monitoring System for Respiratory Diagnosis	Kamran Hameed (Imam AbdulRahman Bin Faisal UNiversity, Saudi Arabia); Sana Ijlal Shahrukh and Ijlal Shahrukh Ateeq (Imam Abdulrahman Bin Faisal University, Saudi Arabia)	278
45	Enhanced DV-Hop Node Localization Algorithm Based on Nearest Neighbour Distance and Hop-Count Evaluation in WSNs	Kanika Sood (NITTTR, Chandigarh, India); Kanika Sharma (Punjab University, India); Amod Kumar (CSIR-Central Scientific Instruments Organisation, India)	286
46	An Exploration of Mis/Disinformation in Audio Format Disseminated in Podcasts: A Case Study of Spotify	Kevin Matthe Caramancion (University at Albany, SUNY, USA)	293
47	Same Form, Different Payloads: A Comparative Vector Assessment of DDoS and Disinformation Attacks	Kevin Matthe Caramancion (University at Albany, SUNY, USA)	299
48	Mathematical Modeling of	Kuvonchbek Rakhimberdiev	305

	Credit Scoring System Based on the Monge-Kantorovich Problem	(National University of Uzbekistan Named After Mirzo Ulugbek & Nuuz, Uzbekistan)	
49	Forecasting Model Comparison for Soil Moisture to Obtain Optimal Plant Growth	Sachintha Balasooriya (Kyoto University of Advance Sciences, Japan); Lasith Yasakethu (Sri Lanka Technological Campus, Sri Lanka)	312
50	Detection and Quantitative Prediction of Diplocarpon Earlianum Infection Rate in Strawberry Leaves Using Population-Based Recurrent Neural Network	Oliver John Alajas, Ronnie Concepcion II, Argel Bandala, Edwin Sybingco and Ryan Rhay P. Vicerra (De La Salle University, Philippines); Elmer P. Dadios (Philippines, Philippines); Christan Mendigoria, Heinrick Aquino and Leonard Ambata (De La Salle University, Philippines); Bernardo Duarte (University of Lisbon, Portugal)	319
51	Lower-Limb Exoskeleton Systems for Rehabilitation And/Or Assistance: A Review	Dana Terrazas-Rodas, Lisbeth Rocca-Huaman, César Ramírez-Amaya and Angel E. Alvarez-Rodriguez (Universidad Tecnológica del Perú, Peru)	327
52	Deep Learning: An Empirical Study on Kimia Path24	Shaikh Rahman and Hayden Wimmer (Georgia Southern University, USA); Loreen Powell (Bloomsburg University of Pennsylvania, USA)	334
53	Biomechanical Prosthesis With EMG Signal	Deyby Huamanchahua (Universidad de Ingeniería y	343

	Acquisition for Patients With Transradial Amputation	Tecnología - UTEC, Peru); Luis Alberto Huamán Lévano (Universidad Continental, Peru)	
54	Bangla Handwritten Character Recognition Method	Lutfun Nahar (International Islamic University Chittagong, Bangladesh)	350
55	The Iso-RSA Cryptographic Scheme	Mamadou I Wade (Howard University, USA)	355
56	The Iso-ElGamal Cryptographic Scheme	Mamadou I Wade (Howard University, USA)	365
57	Connected and Autonomous Vehicles Against a Malware Spread: A Stochastic Modeling Approach	Manal El Mouhib (El Research Team, Morocco); Kamal Azghiou (Mohammed First University & El team, Morocco); Abdelhamid Benali (El Research Team, Morocco)	373
58	Cassava Leaf Disease Detection Using Deep Learning	Manick Manick and Jyoti Srivastava (NIT Hamirpur, India)	379
59	IoT-Based DDoS on Cyber Physical Systems: Research Challenges, Datasets and Future Prospects	Manish Snehi and Abhinav Bhandari (Punjabi University, India)	387
60	Resilience Evaluation of Cyber Risks in Industrial Internet of Things	Mayer Fernandes Silva (Brazil); Herman Lepikson (CIMATEC, Brazil)	395
61	Detecting Various Chemical Samples and Cancer Cells With a Bio-Chemical Sensor by Using LNOI Based Optical Micro Ring	Md Ashif Uddin (Khulna University, Bangladesh); Uzzwal Kumar Dey (Khulna University of Engineering & Technology, Bangladesh);	401

	Resonator (OMRR)	Moriom Akter (Khulna University, Bangladesh)	
62	Proposing A Cloud and Edge Computing Based Decision Supportive Consolidated Farming System by Sensing Various Effective Parameters Using IoT	Md Ashif Uddin (Khulna University, Bangladesh); Uzzwal Kumar Dey (Khulna University of Engineering & Technology, Bangladesh); Moriom Akter (Khulna University, Bangladesh)	407
63	Artificial Magnetic Conductor Unit Cell Design Using Machine Learning Algorithms	Tasfia Nuzhat (Chittagong Independent University, Bangladesh); Md Nazmul Hasan (The University of British Columbia, Canada)	413
64	Development of an IoT-Based Low-Cost Multi-Sensor Buoy for Real-Time Monitoring of Dhaka Canal Water Condition	Ikbal Hasan, Malobika Mukherjee, Rumi Halder and Farzana Yeasmin Rubina (Independent University, Bangladesh, Bangladesh); Md. Abdur Razzak (Independent University, Bangladesh)	420
65	A High Gain Cascaded DC-DC Boost Converter for Electric Vehicle Motor Controller and Other Renewable Energy Applications	Md. Rezanul Haque (Independent University, Bangladesh); K. M. A. Salam (North South University, Bangladesh); Md. Abdur Razzak (Independent University, Bangladesh)	426
66	Performance Evaluation of Secured Blockchain-Based Patient Health Records Sharing Framework	Meryem Abouali (City College of New York, USA); Kartikeya Sharma (City University of New York, USA); Oluwaseyi Ajayi (Vaughns College of Aeronautics and Technology, USA & City College of New	431

		York, USA); Tarek Saadawi (The City University of New York/The City College, USA)	
67	Input Fuzzing for Network-Based Attack Vector on Smartphones	Hosam Alamleh (University of North Carolina Wilmington & Louisiana Tech University, USA); Micah Noyes (University of North Carolina Wilmington, USA)	438
68	Developments Pertaining to the Characteristics of the Sites of HIV Integration Highlighting Its Role in Clinical Research and Its Future With AI: A Review	Minakshi Boruah and Ranjita Das (NIT Mizoram, India)	442
69	Design and Development of a Smart Garage Door System	Mohamed Imran Mohamed Ariff and Farah Diyana Mohamad Fadzir (UiTM Cawangan Perak, Kampus Tapah, Malaysia); Noreen Izza Arshad (Universiti Teknologi Petronas, Malaysia)	449
70	IronMan: An Android-Web Based Application for Laundry Services	Mohammad Moshfique Uddin, Rohit Roy, Saima Alam Miduri and Rashedur M Rahman (North South University, Bangladesh)	455
71	A Brief Overview on Security Challenges and Protocols in Internet of Things Application	Gajjala Savithri (YSR Architecture and Fine Arts University, India); Bhabendu kumar Mohanta (GITAM Deemed to Be University, India); Mohan Kumar Dehury (Koneru Lakshmaiah Education Foundation, India)	463

72	Brain Waves Pattern Recognition Using LSTM-RNN for Internet of Brain-Controlled Things (IoBCT) Applications	Mokhles Mawlood Abdulghani (University of North Dakota, Canada); Farah Fargo (Intel, USA); Haider Khaleel Raad (Xavier University, USA); Olivier Franza (Intel, USA)	470
73	Low-Power and High Speed SRAM for Ultra Low Power Applications	Neha Meshram and Govind Prasad (IIIT Naya Raipur, India); Divaker Sharma (Jamia Millia Islamia- A Central University, India); Bipin Chandra Mandi (DSPM IIIT Naya Raipur, India)	475
74	Smart Home Automation IoT System for Disabled and Elderly	Nesreen Alsbou (University of Central Oklahoma, USA); Naveen Thirunilath (UCO, USA); Imad Ali (University of Oklahoma Health Sciences Center, USA)	481
75	IoT-Based Smart Hospital Using Cisco Packet Tracer Analysis	Nesreen Alsbou (University of Central Oklahoma, USA); Dakota Price (UCO, USA); Imad Ali (University of Oklahoma Health Sciences Center, USA)	486
76	Simulators and Testbeds for IIoT Development and Validation	Nicholas J Jeffrey (University of Oviedo, Canada); Qing Tan (Athabasca University, Canada); Jose R. Villar (University of Oviedo, Spain)	491
77	Image Captioning- Bangladesh's Heritage Perspective Using Deep Learning	Sarowar Alam, Khalidul Islam, Nishat Sharmila, Ziaur Rahman Sovon and Rashedur M Rahman (North South	496

		University, Bangladesh)	
78	Audio Band Analog Signal Measurement Instrument for Vocational School Practicum Aids	Nyoman Karna, Ridha Negara, Bagus Aditya and Adinda Fatkhah Gifary (Telkom University, Indonesia); Dewa Rahyuni (Universitas Padjajaran, Indonesia)	504
79	Enhancing SARS-CoV-2 Variants Research With Blockchain Architecture	Oluwaseyi Ajayi (Vaughns College of Aeronautics and Technology); Tarek Saadawi (The City University of New York/The City College, USA)	510
80	Convolutional Neural Network Structure to Detect and Localize CTC Using Image Processing	Shorouq Al-Eidi (Memorial University of Newfoundland, Canada); Omar Darwish (Eastern Michigan University, USA); Ghaith Husari (East Tennessee State University, USA); Yuanzhu Chen (Queen's University, Canada); Mahmoud Elkhodr (Central Queensland University, Australia)	517
81	FPGA Implementation of Phase Recovery Technique for Complex Transforms	Poorvi Bhaskar (SRM Institute of Science and Technology, Kattankulathur, Tamil Nadu, INDIA, India); Yuvaraj S (SRMIST, India); Palanisamy P (National Institute of Technology, Tiruchirappalli & NIT, Trichy, India); Thilagavathy R (NIT Trichy, India)	524
82	VLSI Implementation of a Real-Time Modified	Pradyut Kumar Sanki (SRM University-AP, India); Bevara	530

	Decision-Based Algorithm for Impulse Noise Removal	Vasudeva (SRMAP, AMARAVATI, India); Medarametla Depthi Supriya, Devireddy Vignesh, Peram Bhanu Sai Harshath and Sravya Kuchina (SRM University AP, India)	
83	Envisioning A Light-Based Quantum-Computational Nano-Cyborg	Pravir Malik (Deep Order Technologies, USA)	540
84	Smart Irrigation Systems: Soil Monitoring and Disease Detection for Precision Agriculture	Premsai Peddi and Anuragh Dasgupta (Birla Institute of Technology and Science Pilani, Dubai Campus, UAE, United Arab Emirates); Vilas H Gaidhane (Birla Institute of Technology and Science Pilani, Dubai Campus, UAE, India)	548
85	Bimetals (Au-Pd, Au-Pt) Loaded WO ₃ Hybridized Graphene Oxide FET Sensors for Selective Detection of Acetone	Radha Bhardwaj (BITS, Pilani, India)	555
86	Intelligent Reflecting Surfaces in UAV-Assisted 6G Networks: An Approach for Enhanced Propagation and Spectral Characteristics	Mobasshir Mahbub (Ahsanullah University of Science and Technology, Bangladesh); Raed Shubair (New York University (NYU) Abu Dhabi, United Arab Emirates)	560
87	Intelligent Reflecting Surfaces for Multi-Access Edge Computing in 6G Wireless Networks	Mobasshir Mahbub (Ahsanullah University of Science and Technology, Bangladesh); Raed Shubair (New York University (NYU)	566

		Abu Dhabi, United Arab Emirates)	
88	Probing the States Around the Charge Neutrality Point of Reduced Graphene Oxide With Time-Resolved Gated Kelvin Probe Force Microscopy	Ragul S (Sardar Patel Road & IIT Madras, India); Soumya Dutta and Debdutta Ray (Indian Institute of Technology Madras, India)	572
89	Broadband Printed Dipole Antennas	Rajendra Ghosh (Vidyasagar University, India)	579
90	SQL ChatBot - Using Context Free Grammar	Rajvardhan Patil, Sorio Boit and Nathaniel Bowman (Grand Valley State University, USA)	587
91	Multiobjective Optimal Control of Power Electronic Loads in Small Scale Power Systems	Ramitha Kalhara Dissanayake (University of Peradeniya, Sri Lanka); Amal Wimalarathna (RMIT University, Australia); Anushka Dissanayake (Schweitzer Engineering Laboratories, USA)	594
92	Explicite Model of a Wheel-Soil Interaction Over a Rough Terrain Using Terramechanics Low	Rania Majdoubi (Mohammed V University in Rabat & LCS Laboratory, Faculty of Sciences, Mohammed V University in Rabat, Morocco)	600
93	Optimal Inventory Policy in Oil Transportation: A Case Study	Rasha Kashef (Ryerson University, Canada); Shuo Xu (Adastra North America, Canada)	607
94	Simulating Software Support Delays in a 24/7 Environment Using	Rasha Kashef (Ryerson University, Canada); Shabbir Mirza (TD Canada Trust,	613

	Discrete Event Simulation	Canada)	
95	Intelligent Feature Selection on Multivariate Dataset Using Advanced Data Profiling	Ritu Chaturvedi (University of Guelph, Canada); Vandana Patnaik (Mass General Brigham, Boston, MA, Canada)	619
96	Optimization of Subsurface Imaging Antenna Capacitance Through Geometry Modeling Using Archimedes, Lichtenberg and Henry Gas Solubility Metaheuristics	Adrian Genevie G. Janairo, Jonah Jahara Baun, Ronnie Concepcion II, R-jay Relano, Kate G Francisco, Mike Louie Enriquez, Argel Bandala, Ryan Rhay P. Vicerra and Melchizedek Alipio (De La Salle University, Philippines); Elmer P. Dadios (Philippines, Philippines)	625
97	Employing Nonlinear Model Based PI Like Controller for the Time Varying System	Atanu Panda (IEM, India); Samrat Banerjee and Indrajit Pandey (Techno International New Town, India); Parijat Bhowmick (IIT Guwahati, India)	633
98	A Novel Multifaceted Deep Learning-Based Mobile Application for Accurate and Efficient Waste Classification and Increased Composting Engagement in Communities	Samyak Shrimali (Jesuit High School, USA)	637
99	Remote Elemental Analysis System for Liquid Using Sonoluminescence	Sardini Sayidatun Nisa Saillellah, Hideharu Takahashi and Hiroshige Kikura (Tokyo Institute of Technology, Japan)	642
100	Detailed Bond Graph	Sayed Arash Omid, Rideout	648

	Modeling of PV-Battery System	Geoff and Mohammad Tariq Iqbal (Memorial University of Newfoundland, Canada)	
101	Design and Simulate a 500 MW Grid-Connected PV Farm for Labrador	Sayed Arfat Alam Quadri, Mohamad Mahdi Baalbaki, Andrew Chacko and Mohammad Tariq Iqbal (Memorial University of Newfoundland, Canada)	655
102	Coordinated Motion and Force Control of Multi-Rover Robotics System With Mecanum Wheels	Serdar S Kalaycioglu (Toronto Metropolitan University & Canadian Space Research Inc., Canada)	663
103	Analysis of the Influence of Factors on Flight Delays in the United States Using the Construction of a Mathematical Model and Regression Analysis	Sergei Kurashkin, Timofey Kireev, Vladislav Kukartsev, Alesya Pilipenko, Anastasiya Rukosueva and Viktor Suetin (Reshetnev Siberian State University of Science and Technology, Russia)	672
104	Construction of a Factor Model Focused on the Reduction of Difficulties in Road Traffic	Sergei Kurashkin, Natalia Fedorova, Aleksander Myrugin, Elena Filushina, Yuriy Seregin, Elena Vaitekunene and Yuriy Danilchenko (Reshetnev Siberian State University of Science and Technology, Russia)	677
105	Theoretical Foundations of the Development Strategy of the Organization for the Production of the Refrigeration Equipment	Sergei Kurashkin, Aleksander Myrugin, Elena Filushina, Yuriy Seregin, Natalia Fedorova, Elena Vaitekunene and Dmitriy Eremeev (Reshetnev Siberian State University of Science and Technology, Russia)	683

106	Methods and Tools for Developing an Organization Development Strategy	Sergei Kurashkin, Vladislav Kukartsev, Elizaveta Shutkina, Kristina Moiseeva, Ekaterina Volneikina and Timofey Kireev (Reshetnev Siberian State University of Science and Technology, Russia)	690
107	Practical-Oriented Method of Development of Strategy of Development of a Production Enterprise	Sergei Kurashkin, Vladislav Dmitriev, Kristina Moiseeva, Alexander Korostelev and Alexander Stashkevich (Reshetnev Siberian State University of Science and Technology, Russia)	698
108	Road Map "TechNet" National Technological Platform	Sergei Kurashkin (Reshetnev Siberian State University of Science and Technology, Russia); Alena Stupina (Siberian Federal University, Russia); Natalia Fedorova, Yuriy Danilchenko, Dmitriy Eremeev, Elena Vaitekunene and Yuriy Seregin (Reshetnev Siberian State University of Science and Technology, Russia)	705
109	Analysis of Data in Solving the Problem of Reducing the Accident Rate Through the Use of Special Means on Public Roads	Sergei Kurashkin and Vladislav Kukartsev (Reshetnev Siberian State University of Science and Technology, Russia); Anton Mikhalev (Siberian Federal University, Russia); Alexander Stashkevich, Kristina Moiseeva and Igor Kauts (Reshetnev Siberian State University of Science	712

		and Technology, Russia)	
110	Establishment of a Model for Managing Organizational Attendance Based on Data Analysis	Sergei Kurashkin and Viktor Suetin (Reshetnev Siberian State University of Science and Technology, Russia); Anton Mikhalev (Siberian Federal University, Russia); Alexander Korostelev (Reshetnev Siberian State University of Science and Technology, Russia); Vladimir Grishko (Siberian Federal University, Russia)	716
111	Using UML to Describe the Development of Software Products Using an Object Approach	Sergei Kurashkin and Evgeniya Semenova (Reshetnev Siberian State University of Science and Technology, Russia); Vadim Sergeevich Tynchenko (Reshetnev Siberian State University of Science and Technology & Siberian Federal University, Russia); Sofya Chashchina, Viktor Suetin and Alexander Stashkevich (Reshetnev Siberian State University of Science and Technology, Russia)	722
112	IoT-Based Cyber-Physical Distribution System Planning	Shaben Kayamboo and Biplob Ray (Central Queensland University, Australia); Narottam K. Das (CQUniversity Australia, Australia); Mary Tom (Central Queensland University, Australia)	726
113	The Million Improvised	Shahriar Khan (Independent	732

	Electric Rickshaws in Bangladesh; Preliminary Survey and Analysis	University, Bangladesh)

Jeddah 80221, Saudi Arabia

arnoor@kau.edu.sa

Abstract—While computational methods offer great potential in predicting drug-drug interactions (DDIs), such predictions as of yet have limited utility in supporting clinical decision-making; in particular, there exists especial difficulty in deriving interaction mechanisms from the vast abundance of available information on potential DDIs. Here, we present a backward-chaining inference algorithm that operates on a knowledge graph integrating multiple types of mechanistic information, from metabolizing enzymes to genetic variants. Given two drugs of interest, this algorithm applies complex rules to identify evidence supporting their potential interaction, which in turn suggests their mechanism of interaction. An evaluation of the ruleset using two widely-used drugs with a suspected interaction, the antibiotic levofloxacin and the chemotherapeutic irinotecan, successfully identified pharmacological and biomedical features that support and may explain their interaction. This algorithm represents a first step toward effectively assessing the clinical relevance of identified DDIs, and of identifying pairs of interacting drugs that may be validated in the experimental setting to support clinical decision-making and ultimately improve medication safety.

Keywords—artificial intelligence, decision support, rule-based inference, knowledge graph, drug-drug interactions

I. INTRODUCTION

Adverse drug events contribute to patient morbidity, mortality, and healthcare costs, and are becoming of greater concern as the role of drug therapy expands and polypharmacy becomes more frequent. These include drug-drug interactions (DDIs), for example, toxicity or reduced efficacy, which may result when a patient is co-administered two or more drugs. In the US alone, DDIs were implicated in 231,000 emergency room visits in a 26-month period [1] and nearly a quarter of hospital admissions [2]. Accordingly, there is great interest in using available computational resources and published material to 1) efficiently identify combinations of drugs that can produce clinically meaningful effects and 2) effectively share that information with clinicians so as to make decisions that minimize patient risk. Realizing both of these objectives at once is challenging for extant methods of identifying DDIs.

Classically, DDI discovery has been carried out by means of single-pathway studies using either *in vivo* or *in vitro* approaches. These have often focused on cytochrome enzymes

(CYPs) and disregarded other possible interaction mechanisms; in addition, most are undertaken during clinical trials, hence typically consider few confounding factors and involve small sample sizes [3]. Thus, while traditional methods provide clinically meaningful information, they are low-throughput and limited in scope, making for a considerable bottleneck in DDI discovery. *In silico* methods of DDI prediction have become of great interest as a solution to this bottleneck. Such methods often begin with knowledge of pharmacologic properties and statistical associations of drugs with health outcomes; extant approaches have considered numerous features [4], [5] and utilized a wide variety of techniques [5]–[10]. However, they also have a common flaw in producing vast lists of prospective DDIs with uncertain clinical relevance. New tools are needed to resolve the critical challenge of accurately identifying clinically meaningful DDIs.

Here, we constructed a rule-based inference algorithm with the goal of simultaneously predicting DDIs and explaining their mechanisms, the better to elucidate the clinical significance of any prospective interaction. Rule-based DDI prediction systems have demonstrated considerable promise in this regard [11]; the present algorithm improves on prior efforts by simultaneously accounting for two different mechanistic layers and sourcing supporting evidence from a wide selection of available resources, thereby drawing upon an expansive knowledge base and distilling it into meaningful explanations of a prospective interaction. Thus, this algorithm represents a key step forward in leveraging the abundance of available information to efficiently identify DDI pairs with prospective clinical relevance and appropriately prioritize them for experimental validation.

II. METHODS

A. Creation of the knowledge graph

The inference algorithm applies rules on a knowledge graph encompassing four core categories of information relating to drug interaction mechanisms: biomolecular, physiological, pharmacological, and genetic. Included biomolecular and physiological information originated with Gene Ontology terms, the National Drug File Reference Terminology, and the National Cancer Institute Thesaurus [12]–[14]. Genetic and pharmacological information were

sourced in November 2021 from the Pharmacogenomics Knowledge Base and DrugBank respectively [15], [16]. All items in the graph were either included in the Unified Medical Language System (UMLS) or were mapped to UMLS concept unique identifiers [17]. All told, this graph represented six kinds of mechanistic information: physiology, biological processes, molecular functions, proteins, genes, and SNPs. To validate the graph, we employed the Protégé tool to construct an ontology and checked its consistency with the Pellet reasoner [18], which determined it to be appropriately consistent.

B. Development of the backward-chaining inference algorithm

We developed a rule-based model of the mechanisms by which drugs interact and used a backward-chaining inference algorithm to identify potential interactions through mechanisms. Emulating human decision-making, the algorithm starts from a hypothesis (that a given drug pair interacts), searches the knowledge graph for supporting evidence defined according to a set of if-then rules, and finally either accepts or rejects the hypothesis [19]. Our algorithm considered two potential levels of interaction: convergent pharmacological effects (inhibition or induction of a necessary transporter or enzyme) and sharing of some features in the four biomedical categories.

The ruleset employed by the algorithm was thus designed to elucidate potential DDIs and the mechanism by which they occur, illustrated in Fig. 1. These six rules were validated by a clinician and specifically identified the following situations:

Layer 1: Pharmacological

- Inhibition of one drug by the other at metabolism or transporter levels
- Induction of one drug by the other at metabolism or transporter levels

Layer 2: Biomedical features

- The drug pair has a pharmacological target in common
- The drug pair have common biomolecular features
- The drug pair have common physiological pathways
- The drug pair have common influencing genetic variations

A given pair of drugs were considered prospective interactors if found to have any positive hit in the pharmacological layer AND if they also fully shared features within at least two of the four categories of the biomedical layer.

C. Validation of predictions

To evaluate and validate the performance of the inference algorithm in predicting drug interactions, we tested it on a pair of drugs that are administered to cancer patients and that evidence suggests have potential to interact. The first, irinotecan, is an antineoplastic chemotherapy agent. The second, levofloxacin, is a broad-spectrum quinolone antibiotic frequently used to treat infections in cancer patients and, in those at high risk of febrile neutropenia, as a post-chemotherapy prophylactic [20]. The respective indications of these drugs mean they are likely to be concurrently administered. In addition, both drugs have well-documented pharmacokinetics profiles, which provide a wealth of data for the algorithm to consider. While no study has yet reported a conflicting interaction of irinotecan and levofloxacin in practice, there is some indication that concurrent administration of antineoplastic agents and oral quinolone antibiotics may lead to reduced plasma concentrations of the latter, and hence reduced therapeutic effect [21], [22]. Thus, this drug pair constitutes a likely candidate for interaction.

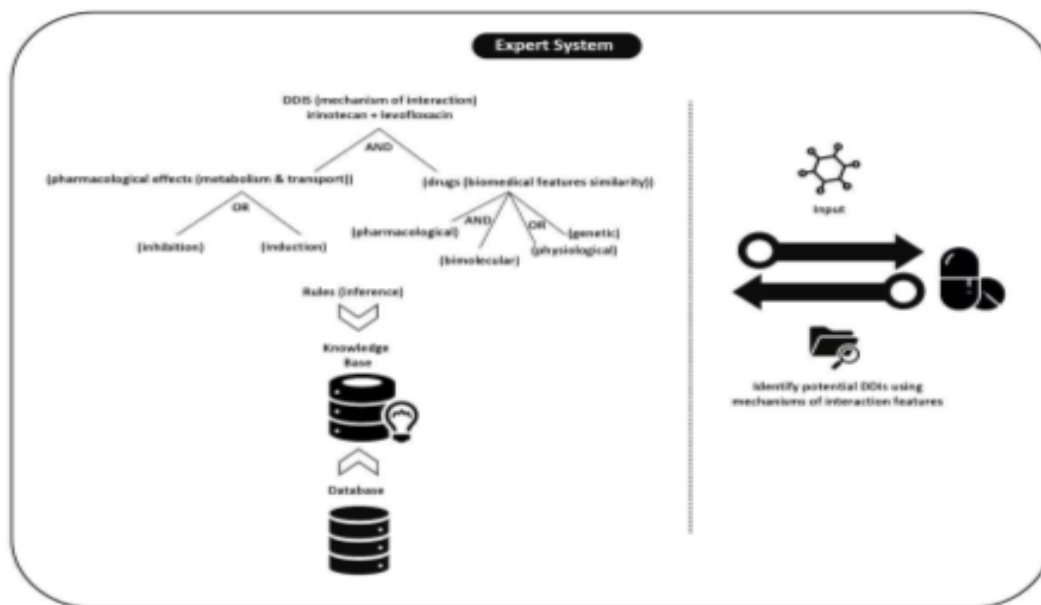

Figure 1: Summary diagram of the rule-based framework for predicting potential drug-drug interactions and their mechanisms.

III. RESULTS

Running the inference algorithm on the candidate interactors levofloxacin and irinotecan successfully identified potential mechanisms of interaction for these drugs on both pharmacological and biomedical feature levels. On the pharmacological level, the algorithm identified two proteins that mutually interact with the two drugs. First, the monooxygenase Cytochrome P450 Family 3 Subfamily A Member 4 (CYP3A4) utilizes irinotecan as a substrate and is inhibited by levofloxacin; and second, the transporter ATP binding cassette subfamily B member 1 (ABCB1, also known as P-glycoprotein) transports irinotecan and is inhibited by levofloxacin. Thus, these proteins represent two points of potential pharmacological conflict for this drug pair when concurrently administered to a patient.

On the biomolecular feature level, our algorithm also identified irinotecan and levofloxacin as sharing three features. First, if a patient is allergic to either of the drugs, administration of the other is also contraindicated; this represents a shared reaction of the body to the two drugs. Second, both drugs adversely affect DNA integrity, which constitutes a shared biomedical impact. Third, the two drugs have in common several classes of molecular groups and structures such as benzene rings, hydroxyl compounds, carboxylic acids and derivatives, hydroxyquinolines, and others; hence, they share chemical characteristics, which may relate to common interactions (as with CYP3A4) or effects of the two drugs.

IV. DISCUSSION

Current state-of-the-art methods for DDI prediction typically yield associations on either pharmacodynamic or pharmacokinetic bases alone; in addition, they consider few features and reference only a fraction of the biomedical resources available [23]–[25]. However, it is also true that existing DDI resources frequently have little overlap in their reported DDIs and may specialize in particular interaction types or mechanisms [26]. Our algorithm thus stands apart from extant methods in that it focuses on the process of evaluation and leverages four different categories of potential interactions to explore and explain DDI mechanisms on multiple levels simultaneously. Applied to irinotecan and levofloxacin as a case study, our algorithm identified two axes through which those drugs may interact: on the pharmacological level, mutual interactions with endogenous proteins, namely the enzyme CYP3A4 and transporter ABCB1, and on the biomedical feature level, commonalities in three feature patterns.

As the incidence of polypharmacy increases, there is potential for exponential growth in associated health risks [27]. It is straightforward to contraindicate concurrent use for drug pairs that have an overt adverse interaction documented in a clinical setting; however, not all DDIs are necessarily overt in their effects, and with the ever-increasing array of drugs on the market and in development, it is not practical to empirically test even a fraction of possible combinations. In addition, as DDIs are an important consideration during drug development and approval, it is imperative to be able to predict interactions before a drug sees wide clinical use. Thus,

it is urgently necessary to understand not only reported but also unobserved and potential DDIs and the mechanisms by which they occur, which in turn necessitates the development of new methods [6]. On top of this, it is essential to identify the clinical relevance of a hypothesized interaction so as to effectively inform regulatory and clinical decision-making. The algorithm presented here represents a first step towards development of a prediction tool that highlights prospective explanatory mechanisms and can be used by clinicians as well as researchers, and so may potentially bring substantial decision support value to present practice.

While this algorithm utilizes a relatively simplistic combined similarity determination in assessing sharing of biomedical feature patterns, that very simplicity represents a springboard on which future work can elaborate and expand. For example, each biomedical feature is currently given the same importance, with the implication that if drugs share a greater number of shared features, there is greater concern of their interaction [28]. As a basic premise this appears sound, and the false alarms reasonably low despite only relatively low similarity being required; however, there may be benefit in employing more comprehensive *in silico* methods to enhance or even replace the current similarity determination. Thus, our work not only constitutes a solid proof of concept but offers potential for further development that can help realize an effective DDI prediction system with utility in accelerating new drug approvals and facilitating clinical decision-making.

Abstract— The reliability of the electrical network and the need to minimize economic losses due to unexpected power outages have led electricity distribution companies to introduce diagnostic and preventive maintenance programs to assess the condition of facilities under normal working and power conditions in order to be able to react quickly in unexpected conditions (fire and floods). The developed system is composed of different types of sensors characterized by their very low power consumption, which detect anomalies in the operation of medium voltage (30Kv) and high voltage (220Kv) line installations located in underground utility tunnels for electricity distribution.

This article describes and develops a very low power communication system in the IoT field which improves the energy efficiency of radio communications between sensor nodes (WSN) by integrating systems that facilitate the operation of multiple hops of the wake-up signal. This provides a longer overall lifespan in comparison to other monitoring systems.

The developed WSN sensor network is installed and tested in an underground service utility tunnel including medium and high voltage transmission lines that belongs to the Endesa group (ENEL) and is located in the city of Barcelona. A web-type user environment has been designed to view the data sent by the sensor network.

Keywords: *Wake-up, Mesh network, IoT, Low-voltage charge pump, WuRx and WuTx radio.*

I. INTRODUCTION

Energy efficiency is one of the most important criteria in the design of a wireless sensor network (WSN). Nowadays,

WSNs are applied in a wide range of fields, such as environmental monitoring, machine surveillance, health monitoring, and traffic control. However, sensor nodes are generally battery-powered and therefore have a very limited lifespan if power management is not performed. Some problems found in most of the currently available applications are the limited time of operation and the need for short-term maintenance (change of batteries). Radio transmission and reception are the two main sources of power consumption. So when a node is up and waiting to receive data, it wastes energy due to listening idle. Therefore, it is essential to investigate new methodologies to avoid wasting the energy of the entire node.

WSNs are typically operated across multiple hops to provide an extended range of coverage. Multi-hop operation must coordinate multiple nodes to allow data to pass through each hop to the destination node, which requires sensor nodes to switch from receive to transmit modes based on the received trigger signal.

Through the efficient communication mechanisms in the sensor nodes, you can turn off your radio and set your microcontroller (MCU) to sleep power mode when it is idle and wake it up when there are possible transmissions. To wake up a sensor node, two methods can be used: a periodic sleep method programmed by the microcontroller with the help of a timer or the integration of an ultra-low power or passive auxiliary radio called wake-up radio (WuRx) to the sensor node waiting for the trigger signal sent by the trigger radio transmitter (WuTx).

Basically, our aim is to design a multi-hop ultra-low power sensor network in line topology, based on starting from the WuRx passive auxiliary radio integration method. In order to

carry out this method, the characteristics of currently existing WuRx will be improved, so they can be integrated in entation with a coverage range similar to the main radio.

The fact that these underground utility tunnels are not straight along their entire route, having curves to the left and to the right and unevenness, as well as the fact that they are underground difficult the communication between nodes and the output of information to the outside. In addition, inside the underground tunnel, a local network of sensors that communicates with an end point (gateway with internet connection) should be created to process the data flow and send it to the web server.

II. LOCATION OF WSN NODES

A mesh network, capable of routing data based on DigiMesh [1], has been used as topology. Digimesh is an alternative proprietary protocol to Zigbee [2], which uses 2.4GHz XBee S1 pro modules [3] that allow that Packet routers can also sleep and can be synchronized with the rest times of the Network. This technique consists in synchronizing time periodically to save energy in the nodes of the WSN network.

The underground utility tunnel has a route of 2.4 km. The profile is shown in the following figure.

Fig. 1. Undergroun utility tunnel profile.

Fig. 2. Some photos of the underground utility tunnel route.

Currently, the network is made up of 27 nodes distributed along 2.4 km, which is the total length of the tunnel. Each node

commercial IoT radios. In addition, this process is required to achieve a multi-hop implem

works in the following way: firstly, the node takes measurements and send them, then enroutes the packets sent by other nodes to the network hub, and finally synchronizes with the sleep times established by the network. The system is divided into three sections, each section is made up of 9 DigiMesh sensor nodes and a gateway. Figure 3 illustrates the block diagram of a section of the implemented sensor network.

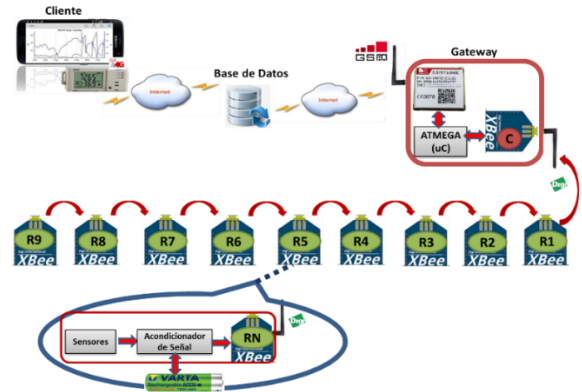

Fig. 3. General diagram of installed WSN

Most of the DigiMesh sensor nodes have been located taking into account the need of measuring environmental conditions in conflicting areas such as junction chambers or water pumps; the rest are located in less conflictive areas and all of them form the DigiMesh network. The gateways have been located at the tunnel entrances to take advantage of the coverage of the mobile network operator. Figure 4 shows the location in meters of each node following the route from the beginning of the tunnel.

Fig. 4. Location of the sensor nodes installed in the underground utility tunnel

The distribution of the sensor nodes has been based on the simulation of the Wireless InSite® program [4], where it is possible to configure the environment taking into consideration relevant parameters of mobile communications such as reflection and propagation coefficients of the materials, antennas, losses, transmitter and receiver, etc. We have applied the parameters so the transmission conditions that may be found in an underground utility tunnel are reproduced, meaning this that the parameters have been

configured in order to reflect the worst possible transmission conditions. chosen the worst transmission case that can be found inside a tunnel as a 90 degree curve. (figure 5)

Fig. 5. 90° curve Simulation Scenario. a) 3D design. b) 2D design.

Some simulation results, such as received power and gain versus distance, are illustrated in figure 6 below.

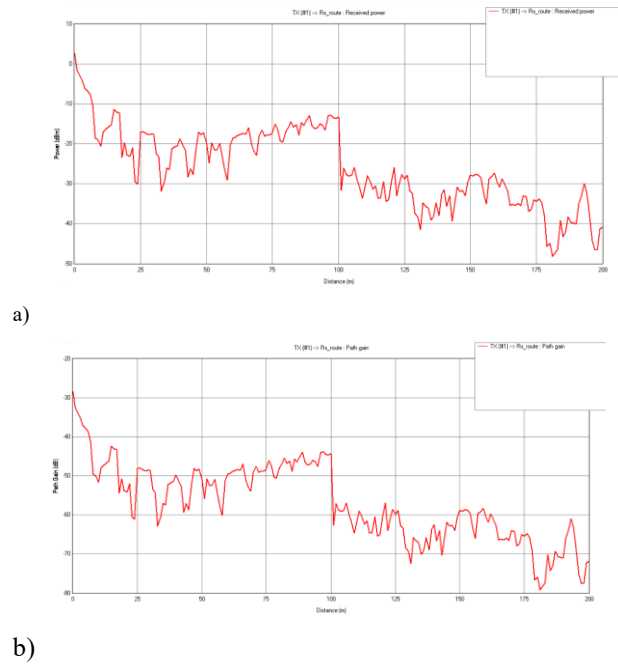

Fig. 6. 90° curve Simulation Scenario. a) Received signal power. b) gain

In the graph of Fig. 6, an attenuation of 19 dBm is observed in the tunnel curve.

III. SENSOR NODE OPTIMIZATION USING ULTRA LOW POWER

The proposal described below aims to reduce energy consumption in the sensor nodes of the system developed in the underground tunnel. The network configuration designed and installed in the tunnel has a line topology, where the nodes have serial communication. Our proposal, unlike other solutions, provides an improvement in range, sensitivity and energy performance, as well as hardware reduction. This can be achieved by eliminating WuTx in WSN sensor nodes in a difficult RF propagation environment, such as an underground electrical utility tun

nel. The designed system could be adaptable to any low consumption WSN network.

In figure 7, the essential block diagram of the proposed sensor node is shown.

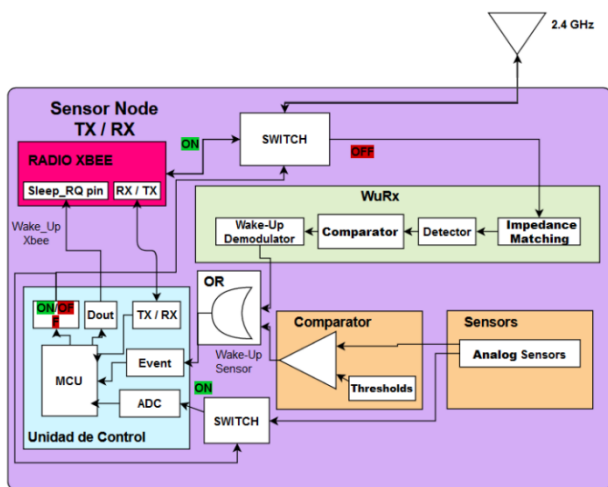

Fig. 7. General block diagram of the proposed sensor node.

Each sensor node proposed in the WSN works as a multi-hop node, both for wake-up signals and data signals. However, first all sensor nodes send a wake-up signal to wake up other nodes in case of detecting anomalies, comparing the sensor measurements of the node with the thresholds set by the client or the reception of a transmitted wake-up signal by another sensor node. In other words, the sensor node wakes up from sleep mode through a wake-up signal received in its WuRx or an anomaly detected by the average measurements of the sensor node. Therefore, two scenarios are contemplated in this design due to the need to incorporate the detection of anomalies for the activation of a sensor node. These are the following:

Activation due to an anomaly: It is a signal to activate the MCU, generated from a continuous comparison of the analog measurements of the sensors integrated in the proposed sensor node with a fixed threshold. Once the MCU is activated, the analog measurements are processed passing through the ADC converter and the antenna is selected to work with the main radio through the switches, then the MCU activates the main radio, Xbee, to send a wake-up signal to activate the next one within range. Then, the Xbee radio waits for an ACK signal and once the signal is received, it sends the data. Finally, it returns to the initial state until listening to a new wake-up signal by WuRx, so that energy is saved.

Activation with a wake up signal: Wake-up signal activates the MCU generated by the WuRx radio alarm clock. When activating the MCU, the sensor and comparator blocks are deactivated and the main Xbee radio is activated and sends the ACK signal, waiting at the same time to receive the measurement data. Then a wake-up signal is sent to the next node to wake it up, and so on until the hub is reached. It should be noted that in this case the sensor node behaves like a data router equipped with the WuRx radio alarm clock.

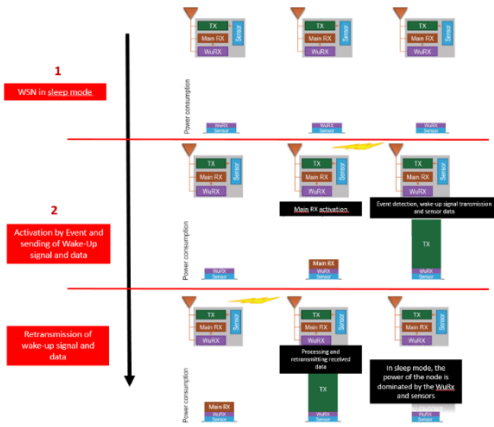

Fig. 8. Different way to activate the transmission node.

The main difficulty of the multi-hop enablement techniques is the complexity of the WuRx and WuTx hardware previously described. However, this level of complexity is necessary in order to guarantee a proper consumption [5]. In this system, the modulation technique used in the transmission of the wake-up signal is the same as the one used in the WuTx and WuRx modes. In this way, the main radio of an Xbee module can be used.

IV. WAKE-UP SIGNAL MODULATION

The proposed radio frequency module, Xbee, is a Digi implementation based on the Zigbee protocol under the IEEE 802.15.4 standard. The IEEE 802.15.4 standard specifies the type of modulation in its physical layer (PHY). In the case of the proposed Xbee of the 2.4Ghz band, the modulation used is the quadrature phase shift O-QPSK (Offset Quadrature Phase Shift Keying) with a bit rate of 250 kb/s, a symbol rate of 62.5 Ksymbol/s and the total number of symbols, 16-array orthogonal.

The wake-up signal transmitted by Xbee is modulated in OQPSK; in theory it would have to be demodulated at the receiver in OQPSK. In this development, OOK (On-Off Keying) digital amplitude demodulation is used for the correct detection of wake-up signals. So, you have to look for an OQPSK modulated signal capable of demodulating it with OOK technology.

OOK modulation is the simplest and most common form of ASK modulation. Its operation can be understood as that of a switch that turns the carrier signal on or off, in such a way that the presence of a carrier indicates a binary 1 and its absence a binary 0. The modulated signal follows the following equation:

$$S(t) \begin{cases} A \sin(2\pi ft) & \text{"1" binary} \\ 0 & \text{"0" binary} \end{cases} \quad (1)$$

An example of OOK modulation is illustrated in Figure 9.

Fig. 9. Amplitude Shift Modulation.

The OQPSK modulated wake-up signal is demodulated with an OOK receiver. The idea is based on taking advantage of the operating characteristics of OOK and OQPSK modulations to build a wake-up signal with the collaboration of a micro and hardware, capable of modulating it again using OOK technology. With OQPSK modulation, a sinusoidal signal can be sent in phase with a fixed amplitude over time, simulating a sequence of high bits "1" following equation 2.

$$S(t) = A \sin(2\pi ft + \frac{\theta}{4}) \quad (2)$$

In this case, the phase shift ($\theta/4=0$) can be neglected because it is not significant when constructing the signal that could be demodulated with the OOK technology. With which, it has been possible to build a carrier signal (equation 3), sending a sequence of binary "1" during a known time (tx).

$$S(t) = \int_0^{tx} A \sin(2\pi ft) dt \quad (3)$$

The next task is based on the OOK modulation of a bit frame to get the wake-up signal using a microprocessor and a time-controlled switch. The construction of a modulated signal in OOK of a frame of bits, is carried out by cutting the transmission of the carrier signal $S(t)$ during the time it takes to send the binary "0"; for this, a switch controlled by the microprocessor is used. An example of a binary frame is shown in Figure 10.

Fig. 10. OOK modulation example with two bits

In figure 11 you can see the block diagram of the WuTx including the controlled switch.

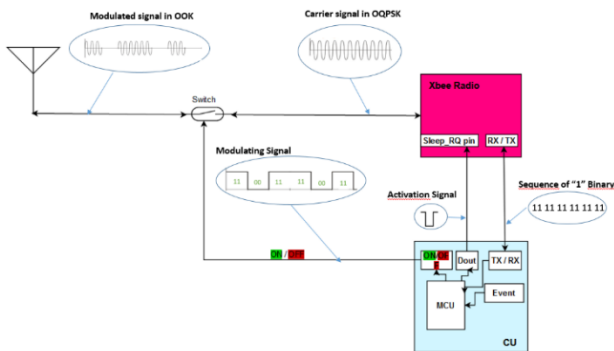

Fig. 11. WuTx block diagram

V. WAKE-UP SIGNAL DEMODULATION

The WuRx receiver design is based on the decoding of the wake-up signal. A wake-up signal is generated by detecting a data signal (wake-up) on a carrier frequency. The communication node has two receive paths, one to process a wake-up signal and one to communicate with the main radio of the node. The receive path is activated depending on the antenna switch. This switch is controlled through an output port of the microcontroller used in the design. Before entering low power mode, the controller configures the switch so that all incoming signals are routed to the WuRx circuit. After impedance matching, rectification, and low-pass filtering, only the envelope signal remains, which is connected to the input of the demodulation block. In the event of a valid wakeup signal and a positive correlation of the sent address with an internally saved bit stream, the WuRx receiver interrupts the microcontroller from its sleep mode. The Figure 12 shows the WuRx receiver block diagram.

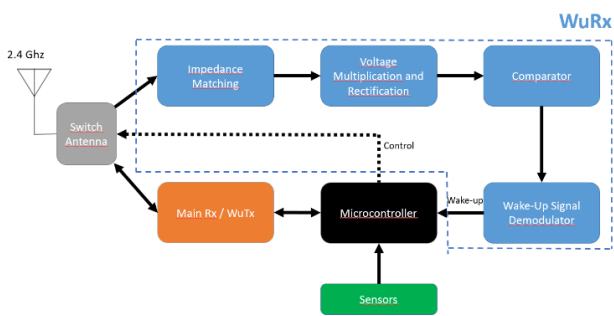

Fig. 12. WuRx receiver block diagram.

The objective of the receiver design is to minimize the energy consumed that is related to the frequency spectrum to be used in the transmission. If low frequencies are used, lower consumption is achieved in the receiver circuit, but larger antennas are required at low frequencies. Therefore, to compensate for this practical situation, a carrier signal of 2.4 GHz with an OOK modulation of 125 KHz is chosen. The 2.4 GHz carrier is then turned on and off so that the resulting envelope represents a 125 kHz square signal. In addition, said signal contains additional modulated address information. Figure 13 shows OOK carrier modulation as described.

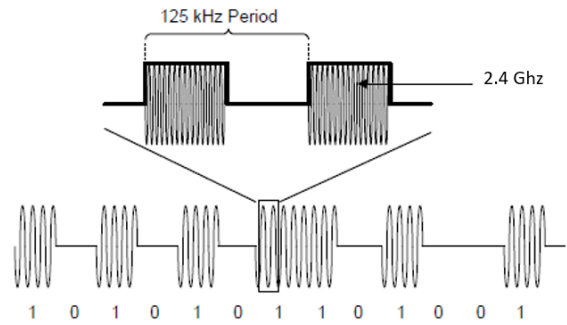

Fig. 13. 2.4GHz carrier and 125 KHz OOK modulation

The WuRx circuit includes the blocks shown in Figure 14.

Fig. 14. WuRx circuit blocks. Details.

The Voltage Multiplication and Rectification Block [6] is simply an envelope detector that demodulates the 2.4 GHz wake-up signal sent by WuTx to extract the 125 KHz signal. Since the RF energy at the rectifier input is very weak, a multi-stage rectifier is designed as shown in Figure 15.

Fig. 15. RF signal collection circuit, 5 stages

If an ideal collection system is considered and it work in open circuit, that is, with an infinite load, the output voltage V_{out} can be expressed as equation 3 where V_p is the peak voltage at the input. With this equation, for a 5-stage multiplier, V_{out} is ideally 10 times the peak voltage.

$$V_{out} = V_0 \times n = 2V_p \times n \quad (4)$$

The Impedance Matching Network Block is formed by an inductive-capacitive filter whose objective is to transfer the maximum power between the antenna and the rest of the circuit.

Fig. 16. 5-stage multiplier adaptation simulation.

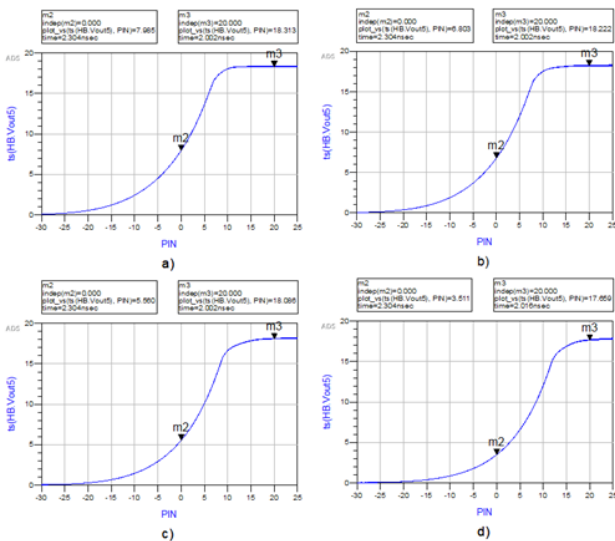

Fig. 17. Plot $V_{out}(V)$ vs $P_{in}(dbm)$, 5 stages with coupling circuit. a) $R_L=300K$, b) $R_L=100K$, c) $R_L=50K$, d) $R_L=20K$

The Voltage Compare Block which uses a comparator device to compare the 2.4 Ghz envelope output signal to a configurable reference level. In addition, it serves to protect the next circuit block against a voltage surge generated by the voltage multiplication and rectification block.

V. MONITORING SOFTWARE

For the treatment of the information, a web application has been designed and developed to monitor the measurements in real time, which is accessible through a browser in the form of a histogram and a table. Figure 18 illustrates the measurements of all the points of the underground utility tunnel in the form of a histogram.

Fig. 18. Histogram of the temperature and humidity measurements of the service tunnel

In addition, scripts have been developed within the web page for the generation of alarms (email and SMS) in case of exceeding the thresholds and the configuration of sensor thresholds (temperature, humidity and temperature increase) and registration of new accounts. of user or administrator type through authentication for, for example, the reception of alarm notifications.

VI. FEATURED RESULTS

The maximum energy consumption in the transmitting node is generated in the RF emission period. This consumption is much higher than that produced in the sensor block and the microcontroller. The estimation of the autonomy of the device in different scenarios and a comparison with other devices is illustrated below (Table 1). The best performance is due to the use of the developed Wake-up techniques.

Table 1. ESTIMATION OF THE AUTONOMY OF THE DEVICE IN DIFFERENT SCENARIOS

	Battery (mAh)	Scope (m)	Sleep time (h)	Enable time (s)	Autonomy(dies)
MH-REACH-Mote [7]	3600	9,1	4	3	413
prototype (a)	3600	100	4	3	631,34 (+53%)
prototype (b)	19000	100	24	2	3492 (+750%)
Other Prototypes (State of art)	3600	100	4	3	265,07 (-36%)

VII. CONCLUSIONS

A monitoring system has been developed using very low consumption communication nodes. Its operation has been installed and verified in an underground utility tunnel including medium and high voltage lines. This scenario requires a line network topology that makes the design difficult. Performance has been increased by lowering the power consumption required by each transmission node; Wake-up techniques are used to achieve this. There is a passive auxiliary radio in all nodes, WuRx, capable of receiving the wake-up signals, and also another radio, WuTx, to transmit another wake-up signal in order to wake up the other nodes. To take advantage of a previous system, the main radio of the sensor node has been redesigned so that it transmits the Wake-up signals. A passive energy capture system has been incorporated, taking advantage of radio frequency to activate the sensor node. Although the transmission range between nodes can be improved, the tests are positive. As a line of future research, it is desired to deepen the study of the RF Wake-up system, which is essential to reduce energy consumption. It will also be studied how to improve the renewable energy system constituted by the capture of tuned radiofrequency to enable the transmission node that is part of the IoT structure.

Abstract— With the growth of world communication, wireless communication has become one of the most prominent sectors. The design and simulation result of the 24 GHz (ISM band) antenna has been developed in this article. Many publications have addressed this research and developed antennas utilizing arrays. However, the proposed design provides a novel model of a small size patch antenna that is easier to build and has improved return loss, efficiency, and gain than previous research studies. The recommended patch antenna design is $18\text{mm} \times 2.451\text{mm} \times 0.257\text{mm}$. The substrate material for this antenna is Roger RT5880 (lossy), which has a permittivity of 2.2. According to the simulation results, this design has a return loss of -28.96 dB , a VSWR (Voltage Standing Wave Ratio) of 1.08497, a gain of 5.152 dB, and an antenna efficiency of 67.026%. The patch antenna is expected to function effectively and may be used for wireless communication based on simulation results.

Keywords—CST, 5G, Gain, ISM band, Radiation efficiency, Surface current, VSWR.

I. INTRODUCTION

Wireless communication technology is getting developed with the enhancement of 5th generation communication as it has the benefit of having large bandwidth, and a high-speed data rate. To support this, it is required to develop and design more improved characteristics of antenna such as high gain, beam width, VSWR, radiation efficiency, and return loss and needed to balance them with antenna size, cost, and design [1-3]. In addition, the Microstrip antenna contains low characteristics, light weight, moderate cost, light volume, low fabrication expense, smaller size, and flexible design. [4]. The proposed antenna is designed at 24 GHz which is within the range of industrial as well as scientific (ISM) bands. The ISM band 24-24.25 GHz is available for worldwide application, and licensed users of this frequency include earth exploration satellite services and armature satellite radiolocation. This frequency band is quite useful in high-performance and lower-cost health care sensors, radar applications, and communications [5-7]. The

recommended Microstrip patch antenna in this article has a high gain of 5.152 dB and a significant return loss of -28.91 dB , which are required for future 5G Wireless Communication Systems. The recommended model has an efficiency of 67.026% along with a bandwidth of 0.769 GHz. Among several previously completed works, the antenna model has a strong gain and a larger return loss, implying that the suggested design work is more efficient.

This paper is organized as follows: Section II describes the theory and methodology, section III illustrates the proposed antenna design, Section IV describes the simulation and analysis, and a comparative study is given. Finally, section V concludes the paper.

II. THEORY AND METHODOLOGY

The frequency range taken for the proposed Microstrip patch antenna is from 23 GHz to 25 GHz where the operating frequency is 24.068 GHz to have better performance and this is under the ISM band. Here, Fig. 1 delineates the geometric configuration of the designed antenna in free space.

Fig. 1. Structure of the recommended microstrip patch model for free space.

Fig. 2. (a) and (b) are the configurations of the designed antenna including slot size, depth, and feedline width in free space.

Roger RT5880 (lossy) is chosen as substrate with permittivity 2.2. Necessary formulas for the calculation of parameters are given below [8]. Patch antenna's width and length are being measured by using Eq. (1).

$$W = \frac{c_0}{2f_r \sqrt{\frac{\epsilon_r + 1}{2}}} \quad (1)$$

Here,

W= Patch's width

C = Light Velocity = 3×10^8 m/s

f = Resonant frequency

ϵ_r = Substrate's dielectric constant

The effect permittivity ϵ_{reff} and the effective length, L_{eff} are calculated by equations (2) and (3) respectively.

$$\epsilon_{reff} = \frac{\epsilon_r + 1}{2} + \frac{\epsilon_r - 1}{2} \left(1 + 12 \frac{h}{W}\right)^{-0.5} \quad (2)$$

$$L_{eff} = \frac{c_0}{2f_r \sqrt{\epsilon_{reff}}} \quad (3)$$

Where L_{eff} = Effective length. The extension of length is given by Eq. (4).

$$\Delta L = 0.412 \frac{\left(\frac{W}{h} + 0.264\right) (\epsilon_{reff} + 0.3)}{(\epsilon_{reff} - 0.258) \left(\frac{W}{h} + 0.813\right)} \quad (4)$$

ΔL = extension length.

The length of the patch is calculated by Eq. (5) below.

$$L = L_{eff} - 2\Delta L \quad (5)$$

III. ANTENNA DESIGN

CST software is used to design the antenna. Designed antenna views from different angles such as perspective, front, and rear, left and right, and top and bottom views are shown in Figures 3 to Figure 8.

Fig. 3. Standpoint vision of the antenna.

Fig. 4. Antenna's front view.

Fig. 5. Rear view of the antenna.

Fig. 6. Left & Right vision of designed antenna sequentially.

Fig. 7. Antenna's top view design.

Fig. 8. Recommended antenna's bottom view design.

Related specifications of the proposed antenna are shown in the following Table I.

TABLE I. THE PROPOSED MODEL'S PARAMETERS

Parameter descriptions and symbols	Measurements (mm)
Antenna Patch's width, W_p	18
Width of Single Patch, W_1	3.6
Length of Patch, L_p	2.451
Ground plane's width, W_g	20
Ground plane's length, L_g	20
Slot size, a	2.2
Slot size, b	0.15
Slot size, c	3
Slot size, d	1.8
Height of Substrate, h_s	0.257
Feedline width	0.695
Ground Thickness, h_t	0.045

IV. SIMULATION AND ANALYSIS

After designing the antenna, to run the simulation, two options can be selected. From the home section, an author can select setup solver or start simulation. For setup solver, the accuracy level has been kept at -40 dB. After that start option has been pressed. Besides, the start simulation option also can be pressed which will lead directly to the simulation process.

A. S-Parameter

S-parameter or return loss gives information about the amount of reflected power caused by impedance discontinuity and the acceptance range for return loss of an antenna is greater than -10 dB [9]. The value of return loss of this antenna is -28.96 dB which is quite good for a Microstrip antenna at the operating frequency of 24.07 GHz shown in Fig. 9. The bandwidth is frequency ranges within it, and the antenna radiates. Return loss is -10 dB at 23.4 GHz and -10dB at 24.169 GHz, as indicated

in Fig. 10. To determine the antenna's bandwidth, an axis marker is placed on both frequencies. The maximum frequency is 24.169 GHz, while the lowest frequency is 23.4 GHz. The bandwidth has been determined as the difference between the highest and lowest frequencies, which is 0.769 GHz.

Fig. 9. $S_{1,1}$ parameter in free space.

Fig. 10. Bandwidth in free space.

B. VSWR

The definition of voltage standing wave ratio-VSWR is the determination of the amount of matched impedance between antenna and transmission line. The least acceptable value is 1 for the VSWR [10]. For the proposed antenna the VSWR value is 1.08497, supporting the value shown in Fig. 11.

Fig. 11. VSWR vs. the Frequency in port 1.

C. Gain & Directivity

Gain and directivity are one of the most important parameters for antenna performance. The antenna's gain determines the quantity of power transmitted at the peak radiation direction [11]. Directivity is the term that explains about directivity of antenna radiation patterns [12]. Gain for the designed antenna is 5.152 dB and directivity 7.699 dBi shown in Figures 12-16.

Fig. 12. Farfield gain plot of the designed antenna at 24.068 GHz (3D).

Fig. 13. Farfield gain plot of the antenna at 24.068 GHz (2D).

Fig. 14. Radiation-Pattern in three dimensions at 24.068 GHz (Directivity).

Fig. 15. Radiation pattern in 2D at 24.068 GHz (Directivity).

Fig. 16. Gain vs. Frequency Curve of the antenna in free space.

D. Overall and Radiation Efficiency

From Fig.17, the overall efficiency is -2.57 dB, while the radiation efficiency is -2.568 dB. The ratio of gain to directivity can be used to calculate antenna efficiency.

Fig. 17. Radiation and Total Efficiency Curve of the designed antenna in free space.

E. Surface Current

The definition of surface current is the electric current induced in a metallic antenna due to an enforced electromagnetic field that drives charges at its surroundings [13]. Here, the surface current has shown in fig.18 which is 1360 A/m.

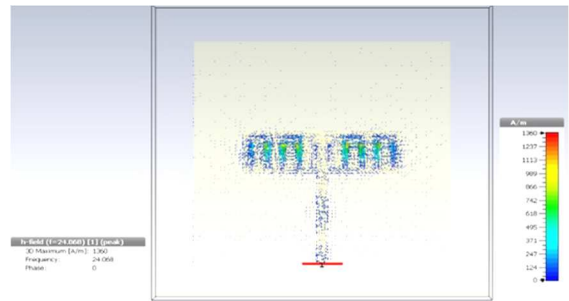

Fig. 18. Surface current.

F. Smith Chart

Smith's chart illustrates the relationship between transmission line impedance and antenna via frequency. This helps to understand more about changes in transmission line impedances [14]. Smith chart for this antenna is 49.8 ohm shown in Fig. 19. Impedance mismatches are noticed as a result of shape complexity. Finally, Table II gives the parameters summary of the proposed designed antenna.

Fig. 19. Smith chart of the antenna (Impedance View).

TABLE II. OBTAINED PARAMETER'S SUMMARY OF THE DESIGNED ANTENNA.

Specifications of Antenna	Values
$S_{1,1}$	-28.96 dB
Bandwidth	0.769 GHz
VSWR	1.08497
Gain	5.152 dBi
Directivity	7.699 dBi
Efficiency	67.026%
Surface Current	1360 A/m
Radiation Efficiency	-2.569 dB
Total Efficiency	-2.574 dB

V. COMPARATIVE STUDY

Table III summarizes and compares different parameters of the antenna. Different antenna characteristics are compared and examined with other research articles, including $S_{1,1}$, operating frequency, bandwidth, band, gain, and efficiency. Circular Polarization Antenna Array is designed for 24 GHz wireless communication and has 42% efficiency and a high gain of 20dBi, according to ref. [15]. The array antenna for 24 GHz has been presented in the majority of research articles. In ref. [6], a Microstrip patch antenna was built for 24GHz, although it has a return loss of -22dB.

TABLE III. COMPARATIVE ANALYSIS WITH OTHER RESEARCH PAPERS

Ref.	$S_{1,1}$	Resonant Frequency	Bandwidth	Band	Gain	Efficiency
[15]	-19 dB	24.5 GHz	2 GHz	-	20 dBi	42%
[6]	-22.1 dB	24.2 GHz	1.2 GHz	ISM	5.95 dBi	-
[7]	-25dB	2.4Ghz	160 MHz	ISM	-	-
[16]	-24 dB	24 GHz	-	-	13.5 dBi	-
[17]	-23dB	24.15 GHz	(24.07-24.27) GHz	ISM	18 dBi	-
This work	-28.96 dB	24.068 GHz	0.769 GHz	ISM	5.220 dB	67.02 6%

In contrast to other research papers, this article has a better return loss, a better gain, and a higher efficiency. An array antenna's design is complicated, but a Microstrip patch antenna's design is simple and easy to fabricate. This research has resulted in improved simulated findings for the 24GHz (ISM band), which will be advantageous for wireless communication and medical applications.

TABLE IV. COMPARISON OF OBTAINED RESULTS WITH RECENT RESEARCH PAPERS.

Ref.	Architecture of ground (length × width)	Substrate height (mm)	Substrate materials	Dielectric permittivity, ϵ_r	Software
[15]	30mm×30mm	-	Roggers/duroid 5880	2.2	HFSS
[6]	-	0.787	Roggers/duroid 5880	2.2	HFSS
[7]	30mm×40mm	1.63	FR04	4.4	HFSS
[16]	65mm×23mm	0.813	Rogers RO4003C	3.38	HFSS
[17]	-	0.508	Teflon - fiberglass	2.2	3D electromagnetic simulator
This work	20mm×20mm	0.257	Roggers 5880 (lossy)	2.2	CST

Table IV evaluates the ground architectures, substrate heights, materials, dielectric permittivity, and software applied in antenna design. The majority of research articles used HFSS software to build antennas, while this work has used CST software to simulate and design [15, 6]. Roggers/duroid 5880 was chosen as a substrate material in the majority of the research publications. Different substrate materials, such as Rogers RO4003C [16] and Teflon –fiberglass [17] have been implemented in numerous research publications. A very thin substrate is recommended for a low-profile construction and lightweight antenna; this paper has also proposed an antenna with thin substrate materials and a lower substrate height. [15] However, recent investigations have found that different substrate materials provide different results. As a consequence of the aforementioned comparisons, it can be determined that the projected antenna would be a preferable alternative for the wireless network to earlier versions.

VI. CONCLUSION

The proposed microstrip patch antenna can be considered to be compatible with forthcoming 5G wireless communication and medical applications. The recommended antenna's working frequency is 24.07GHz, with a return loss of -28.91 dB, a bandwidth of 0.769 GHz, a gain of 5.152 dB, directivity of 7.699 dBi, surface current of 1360 A/m, and 67.026% efficiency. The operational frequency of 24.07GHz is part of the ISM band, which spans 24 GHz to 24.25 GHz. Most of the researchers have focused on array antennas, but minorities have focused on Microstrip patch antennas, which is a novel idea in the 5G communication system. However, the proposed antenna in this study has a basic design that is easy to fabricate and improves overall simulation results. After analyzing all of the findings and simulations, it can be concluded that this study can

be used as a model for future communication and other research works.

Abstract—Coronavirus 2019, also known as COVID-19, has recently had a negative influence on public health and human lives. Since the second world war, this disastrous consequence has changed human experience by initiating an increasingly more devastating and unexpected health calamity. The world's condition has become a catastrophic epidemic due to uncontrolled infectious properties within society. Therefore, the initial stage and accurate identification of the virus may be a good strategy for tracking and suppressing the illness from spreading due to the lack of medication. During the pandemic, computed tomography (CT) imaging has been extensively used to detect the percentage of infection. Artificial intelligence-assisted CT- image analysis could be a better option which can be achieved using a convolutional neural network (CNN). This is one of the prominent modes that can be effectively used in such applications. In this paper, an artificial-intelligence-based approach has been presented to investigate the coronavirus infection in the human body. The various experiments are carried out on the freely available dataset. It has been observed that the results are better indicating adequate performance for prediction.

Keywords— *CT scan images; Convolutional neural network; Coronavirus; Dense-Net; Image Processing.*

I. INTRODUCTION

Recently, the coronavirus disease outbreak has already been identified as a significant worrying patient safety diversion. This virus is first discovered in late 2019 in Wuhan, China, and quickly spread to over 200 nations, prompting the Department of Health (WHO) to declare a pandemic emergency. Medical professionals, as well as regulations, were unable to control the spreading of the virus in the society which results in the quick death of individuals, due to significant infectious qualities among people in intimate contact. Since subsequent illnesses in communities are caused by close personal dealings, it is critical to quickly isolate and characterize the infectious disease and institute a social lockdown. As a result, early diagnosis of virus occurrences is critical for help in managing efforts to reduce infectious hazards and spreading, organize clinical treatment, and coordinate prompt care assistance. This could be crucial in improving national healthcare. This will have a direct impact on the virus's removal from the planet.

During the pandemic time, due to the lack of particular treatments and vaccinations, it was critical to identify the sick person so that prompt isolation can be taken. The real-time polymerase chain reaction analysis is widely adopted for the

identification of the virus in healthcare. Nevertheless, a low incidence of positive RT-PCR results and findings could be attributed to any evidence collecting and transportation bottlenecks, which are both time-consuming procedures. The patients with severe situations (those in the emergency ward (ICU)) may be missed by this method. An additional disadvantage of the RT-PCR evaluation methods is that traditional PCR tests take more time to detect disease. As this COVID-19 virus has a powerful transmitted character, an infected individual could become a carrier and pass the infection to other healthy, common citizens or medical practitioners. On the other hand, emerging economies have inadequate technical capabilities and a lack of healthcare technicians and specialists. Although there are few resources available to combat a pandemic, the COVID-19 performance indicators are a potential solution that reflects real requirements. Imaging techniques are a conventional technique for finding pneumonia that gives a more reliable judgement than RT-PCR. In this regard, CT image classification become a potential alternative approach for detecting viruses, particularly in patients with acute illnesses. According to the research, the accuracy of RT-PCR is lower than the accuracy of CT [1].

The major goal of this study is to develop an accurate method for identifying the coronavirus infection in the patients using CT images and a convolutional neural network (CNN). In recent days, several machine vision models using CNN presented good results [2-3]. Because of its opportunity for self-training, CNN has become more popular in medical image processing. Based on its superiority, several convolutional neural techniques for COVID- 19 detection have been presented in the literature [4-6]. Unlike all the other image datasets, the imaging techniques database uses a small number of training examples. CNNs have now been boosted with different techniques such as data augmentation to reach ground-breaking performance upon those datasets [7].

In this work, to investigate the patients with COVID-19, a relatively new strategy called CNN is used, wherein the process of learning is constructed using the interconnection of densely linked CNN architectures commonly called as Dense-Net. The fundamental justification for using DenseNet-121 is that it solves the degradation problem, increases feature reuse, and reduces variable usage, all of which are beneficial for creating deep learning algorithms.

DenseNet-121 has also been shown to be useful in identifying disorders using imaging technology [8]. To optimize the design flow, Dense-Net would've been driven by linking all components to just about every other layer below it. This method allows CNN to make judgements based across all levels rather than just one previous layer. In comparison to typical image recognition technologies, Dense-Net is much more advanced and can gather sensory information in a bigger sense.

II. CNN MODEL

A convolutional neural network (CNN) is a multilayer perceptron artificial neural network and it is superior in processing large dataset. It has structure consisting of different structures such as convolution, pooling, flattening, and connected layers. A generalized architecture of CNN is demonstrated in Fig.1.

Fig. 1. Convolution neural network architecture

In the CNN architecture, the learnable filters in the convolution layer plays an important role and demonstrate the learning skill of network. Fig. 2 explain the operation of convolution operation.

Fig. 2. An example of a convolution operation

In Fig. 2, the notations I , K and $I * K$ represent the pixel values of an image, filter and feature map, respectively. Another crucial component in a network architecture is pooling layer that lowers the computational issues. Here, average and minimum pooling are generally preferred in many applications. Fig. 3 depicts the operation of max-pooling.

Fig. 3. Max pooling operation

The next block after max-pooling in CNN architecture is fully connected layer. The previous layer neurons are fully interconnected to the next layer. In this, the input data need to be flattened before entering to this layer. Fig. 4 shows such data flattening operation.

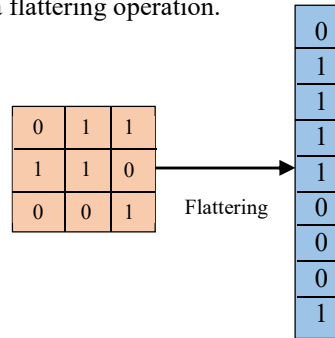

Fig. 4. Flattening operation

From literature, it has been observed that the development of CNN model is big challenge for researches and it is a time-consuming task. However, use of pre-trained network architecture may be a reasonable solution to these issues. The pretrained model can be effectively used for different applications particularly for feature extraction and classification applications. The pre-trained networks such as ResNet 18, GoogleNet and ResNet 50 are most comely used in the literature. The details pre-trained models are summarised in Table I.

TABLE 1: FEW FEATURES OF THE PRE-TRAINED MODELS FOR THE INPUT IMAGE SIZE 224x224 PIXELS

Model	Depth	Size (MB)	Parameters (Millions)
ResNet 18	18	44	11.7
GoogleNet	22	27	7
ResNet 50	50	96	25.6

III. PARAMETERS OPTIMIZATION ALGORITHM

In CNN, the various parameter needs to be optimized to the make the model more efficient for the particular application. The grid search (GS) approach is one of the effective techniques which can be used for the optimization of the parameters. In this approach, the different possible values of the parameters are calculated in the required or predefined range and feed to the defined model to start the optimization process [9].

Fig. 5. Parameter sets in the search space for GS

IV. GRID SEARCH BASED CNN ALGORITHM

An effective model based on the GS and CNN approach is shown in Fig. 6. It consists of image dataset, parameters set, pre-trained supported model, and evaluation phase.

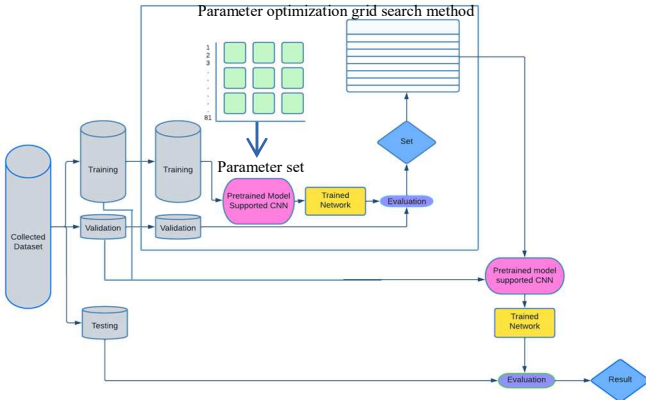

Fig. 6. GS and transfer learning supported CNN model

The first step in the presented model is the image data set collection. Here, freely data set available online websites like Kaggle or GitHub is used for the experimentations. The dataset needs to split into three subsets: training, validation, and testing and randomly percentage of each subset can be selected. The next task is the parameter sets optimization. It can be achieved using grid search algorithm. This step, help to optimized the parameters and can be used as an input to the CNN model. In the next phase, the CNN model is trained using the training data and optimized parameters. In the last phase, the trained CNN is evaluated on testing dataset and conclude the final results in the form of classification and confusion matrix.

Moreover, extensive work in literature depicts that most of the approaches to holding down a process before using the pre-trained models. As data augmentation is one of the important steps of the training procedure for profound learning models, it is used for our benefit and employed as an extra measure. In addition, the Dense-Net study obtained quality precision for CT images. Compared to other learning models, Dense-Net enhances a smaller set of parameters.

For greater accuracy, the Dense Net model with 121 perceptions can be used in the application [8]. It has been observed that the Dense Net-based CNN approach might be a useful detection approach for identifying infected patients using CT images. The CNN model could attain favorable outcomes. However, a CNN model-based application with sizeable training data for classification remains a challenge and hence, the motivation for the researchers. Therefore, Dense-net can be used as an alternative to achieve good results.

A. Dense-Net - A Pre-Trained Network

A Dense-Net is a modified CNN generally exploited in object identification [10]. It is somewhat analogous to Res-Net. Dense-Net combines the future layer and previous layer

output with its concatenated (\cdot) attributes. The conventional CNN aims to obtain the i^{th} output layers using a non-linear transformation $Q_i(\cdot)$ with respect to the previous layer $(P_i - 1)$ output [2].

$$P_i = Q_i(P_i - 1) \tag{1}$$

Dense-Net achieve an efficient information flow between the different layers. Eq. (1) can be modified [11]

$$P_i = Q_i[P_0, P_1, P_2, \dots, P_{i-1}] \tag{2}$$

where $[P_0, P_1, P_2, \dots, P_{i-1}]$ represents a concatenation of previous layer output maps [14].

Data augmentation is one of the approaches that facilitate the user to expand the diversity of data available for training sets, eliminating the need to acquire more data. Data augmentation is a strategy for increasing the number of training specimens by modifying photos whilst preserving semantic features, and it allows for bias-free image data. Basic changes such as horizontal flipping, random cropping, and color augmentations are generally used for model training. Further, data augmentation allows the designer to understand a more diversified set of characteristics, which expands the dataset and helps to keep the model from getting overfitted. The data augmentation to increase image categorization accuracy has also been made.

In this paper, image augmentation is employed to boost training benefits while reducing network regularization. A commonly known data augmentation method is used. Images were arbitrarily trimmed to the 64×64 original image size, with a random rotational range of 3600 pixels on each side. Horizontally and vertically duplicated images are mixed throughout.

B. Image Dataset

Large image datasets are available on websites like Kaggle or GitHub. This is an open source dataset that contain 349 Covid-19 CT images 463 non-Covid CT images from 216 individuals. These images are different in size and shapes and categorized into two types: effected and non-affected. Fig. 7 shows a few cases of CT images for patients that are COVID-19 positive/negative that compose the dataset. The patient with positive results has age, male and female information [16].

C. Model and Applied mechanism

In this work, to categorize corona using DenseNet-121 architecture-based CNN, a dataset comprising images of real patients is used in this study.

The pre-processing can be carried out by normalizing and changing the size of the image for further processing. There are many kinds of pre-processing techniques that can be used for developing our model. In the presented model, the process of image resizes, and normalization is being done on MATLAB through image processing techniques.

Fig. 7. An example of Covid 19 CT images

In the presented model, 36×36 pixel values are being used in the dataset. Typically, most of the dataset values lie between 0 and 255 but due to the network model, it is preferred to perform in the range 0 and 1 which will be the best fit for the model [2]. The technique helps in the reduction of the complexity of the model. Eq. (3) can be used to normalize the images [12-15].

$$I_{norm} = \frac{I - I_{min}}{I_{max} - I_{min}} \quad (3)$$

The presented COVID-19 classification model is designed using MATLAB software with required packages such as neural networks and image processing. The aim of COVID-19 patients' identification is to assure the positive/negative test. For experimentations, dataset is subdivided into validation (15%), training (70%), and testing (15%) [2]. The systematic procedure for COVID-19 prediction is presented in Fig. 8.

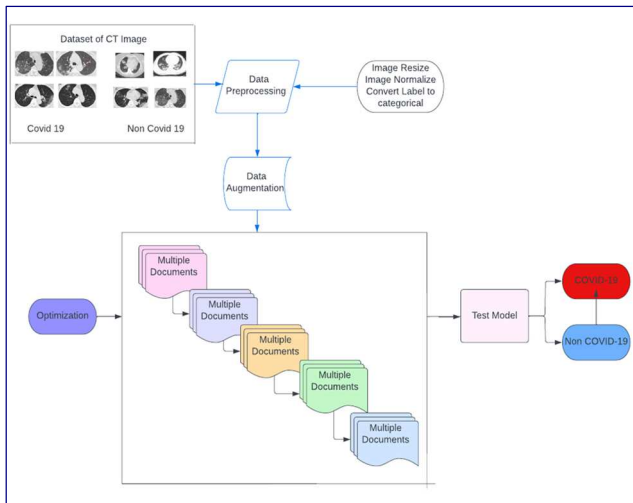

Fig. 8 procedure for predicting COVID-19 is presented

The results of specimens of each category correctly and incorrectly classified can be compiled as a confusion matrix. Accuracy can be determined based on the confusion matrix. The performance of the model is calculated using four performance parameters: recall, precision, G-Mean and F_1 -Measure. All these performance parameters are defined using the following equations.

$$Accuracy = \frac{T_p + T_N}{T_p + T_N + F_p + F_N} \quad (4)$$

where T_p , T_N , F_p and F_N represents true positive, true negative, false positive and false negative, respectively.

$$F_measure = \frac{2 \times Precision \times Recall}{Precision + Recall} \quad (5)$$

$$G_mean = \sqrt{\frac{T_p + T_N}{T_p + T_N + F_p + F_N}} = \sqrt{Precision \times Recall} \quad (6)$$

V. RESULTS AND ANALYSIS

The various experiments are carried out on the publicly available dataset. Each DenseNet-121-based CNN architecture is trained for various epochs on grayscale image data sets. Grayscale test images were used to evaluate DenseNet-121's performance. Table 2 shows the performance of the presented model.

TABLE 2: PERFORMANCE PARAMETERS FOR DENCENET

Data set	Accuracy	Recall	Gmean	F_Score
Non-covid	0.963	0.852	0.92	0.9
covid	0.857	0.953	0.9	0.89

Fig. 9 (a) and Fig. 9 (b) show the comparison of image prediction for COVID-19 along with non-COVID-19.

Fig. 9. (a) affected by Covid-19, (b) Non-affected by COVID-19

Generally, the performance calculation and the verification of the presented approach can be demonstrated using the concept of confusion matrix [17]. Thus, the confusion matrix can be used to show the accuracy of the presented approach. The confusion matrix is particular square table which demonstrates and visualized the classification accuracy of multiple classes. In this paper, two classes are classified: Covid positive and Covid negative, respectively. Fig. 10 shows classification accuracy based on the confusion matrix for 25 sample images. It is observed from Fig. 10 that

the DenseNet-121 performs better as classifier and achieved 96% to 100% accuracy.

Confusion Matrix

Output Class	Negative	23 46.0%	0 0.0%	100% 0.0%
	Positive	2 4.0%	25 50.0%	92.6% 7.4%
		92.0% 8.0%	100% 0.0%	96.0% 4.0%
		Negative	Positive	
		Target Class		

Fig. 10 confusion matrix.

Further, the evaluation of the proposed approach can be carried out using the Receiver Operating Characteristics (ROC) curve [12]. A binary classification is the basis for the ROC which results into four possibilities: true positive, true negative, false positive and false negative, respectively. Fig. 11 shows the results of four classes in the form of ROC curve.

Fig. 11. ROC curve.

The current techniques generally used a smaller dataset, whereas the applied DenseNet-121 model used a relatively

large dataset. Various photos and tactics have been validated using various state-of-the-art approaches. Some multi-class classification models achieved an accuracy of up to 95% or higher while being more difficult and computationally expensive. However, a fair comparison of performance evaluation results and validation is not possible due to the differences in data sets.

VI. CONCLUSION

In this paper, an efficient and systematic COVID-19 infection identification is presented. In this, the infected region can be identified from two different modalities of medical images. COVID-19 patients are identified based on the available CT image dataset. In addition, the qualitative results in the form of four performance parameters: recall, precision, G-Mean and F1-Measure as well as a confusion matrix. The results demonstrate higher accuracy in the classification and detection of infected COVID-19 in CT image datasets.

Abstract— This review covers the topics of cognitive dynamic systems and their definition following Simon Haykin's work in the field as well as their application through cognitive radar, cognitive radio and cognitive control. Furthermore, the article presents the topic of cognitive IoT and discusses it under the lens of cognitive dynamic systems referencing research in the field. It also discusses the needs for interoperability between IoT architectures and the need to integrate cognitive radio with future IoT frameworks developments.

Keywords—Cognitive Dynamic Systems, Cognitive IoT, Cognitive Radio

I. INTRODUCTION

The augmentation of physical objects with the power of the internet has become commonplace in the midst of the fourth industrial revolution. Many elements are becoming increasingly intertwined, including wearable technology, healthcare, home appliances, and transportation. The Internet of Things (IoT) has been characterised as a deeper integration of all physical objects with the digital realm, including the advancement from simple control systems sensing devices and effectors to more complex systems capable of exchanging data between devices connected to the internet for more timely and productive decision-making. The magnitude of today's IoT applications has posed several issues in terms of building a system-to-system interoperability framework. Developing IoT services that are intended to adapt to the circumstances and self-adjust in response to unforeseen situations through cooperation. These should also use the acquired data to extract semantic notations and optimize the system's effectiveness. In a general context, the IoT model has been defined as a globally connected network of uniquely addressable devices following established communication protocols. This term refers to a theoretical model of complex multidimensional systems made up of interconnected and interdependent items [6]. Smaller subsystems collaborate to achieve results in the most efficient way possible. Social network analysis is a study tool that is used to explain the network of relationships that exists among the numerous objects that make up the larger Internet of Things, as well as to investigate the effects on data processing, context extrapolation, and semantic

derivation. This is especially beneficial in time varying IoT systems like smart cities.

In a point-of-view essay published in the Proceedings of the IEEE in 2006, Dr. Simon Haykin initially suggested the concept of a dynamic cognitive system (CDS) [3]. He went on to write "Cognitive Radio: Brain Enabled Wireless Communication" [2] and "Cognitive Radar: A Way of the Future" [3], both of which were hugely significant. The author of these defines CDS as systems that learn from repeated enduring interactions with the environment to develop norms of behaviour over time, allowing them to deal with environmental uncertainty. Following Fuster's work on cognition, Haykin refined this concept in [4], outlining the distinction between adaptation and cognition by outlining the norms by which a cognitive dynamic system is defined, the perception action cycle (PAC), memory, attention, language, and intelligence.

Novel cyber-physical systems (CPS) are continually being launched in this new era of greater connectivity, upgrading things with the ability to control the world around them, compute the data acquired, and share it through the internet. This transformation affects a wide range of sectors and services, prompting the development of novel IoT architectures targeted at efficiently capturing and processing data to improve process efficiency. The concept of cognitive IoT (CIoT) has been introduced as a way to enhance current IoT systems with cognitive capabilities in order to better leverage the vast volumes of data being collected and tackle scalability issues. To better examine variables that impact functionality and data gathering, semantic computing, cognitive computing, and perceptual computing can be used [5]. The goal of CIoT is to make IoT systems capable of understanding environmental elements and capable of contextual awareness. This new paradigm aims to apply the principles of human cognition to IoT dynamic systems. The process of learning, reasoning, and understanding the physical and social environments by embedding cognition processes into IoT seeks to build a new class of systems capable of operating with minimal human intervention [7]. Some present obstacles for a scalable and reliable IoT must

also be faced and answered beforehand in order to build such systems. The existing constraints of wireless technology and mobile networks are the first major worry in terms of scalability of such systems. Regarding future large-scale IoT systems, the restricted range, data capacity, and spectrum availability are major concerns [8]. These difficulties will likely intensify in the coming years, given the rapid development of IoT.

Cognitive Radio (CR) and Cognitive Radio Networks (CRN) have sparked the interest of academic and business communities in recent years as a potential solution to many of these issues [8]. Spectrum sensing, spectrum decision, spectrum management, and spectrum mobility are the main processes of cognitive radio, with the goal of taking full advantage of licenced spectrum bands through the effective application of dynamic allocation to fill present spectrum gaps.

A further constraint in vast IoT network is the complexity of aggregating data from multiple sources. Since data collected in a multi-sensor IoT system can be heterogeneous, adaptive analytics approaches must be considered. Collecting such diverse datasets to get a holistic picture of the system can be difficult. The data collected can also be nonlinear, multidimensional, or partial, making its use for intelligent decision-making and services provisioning much more difficult [7][1]. This problem is addressed by Cognitive IoT, which adapts to the data type, situation, and setting, utilising techniques like association analysis, clustering analysis, and regression, for contextual data analysis. Big-data-driven applications, on the other hand, necessitate more intelligent decision-making to enable more efficient and flexible operations via cooperative self-organized and self-optimized behaviours. Moreover, for large-scale IoT systems, centralized data handling is a significant barrier. The challenges associated with central data processing include single-node failure, restricted scalability, and massive trade overhead [7].

II. RELATED WORK AND MOTIVATION

Because of the wide range of disciplines to which IoT may be applied, developments in architectural design for IoT systems have primarily been targeted to individual applications. As a result, cooperation amongst IoT systems is constrained, thereby restricting advancement toward a bridge architecture [9].

Although cognitive IoT is still a new topic, it is growing in prominence because of scientific research in cognitive dynamic system and cognitive control. This new paradigm could be used as a model for developing new IoT designs and as a framework for addressing specific IoT concerns. In principle, CIoT aspires to provide IoT systems with a cognition component that allows them to learn, reason, and comprehend both physical and social realms [7], bringing

together a variety of professions and areas such as computer science, mathematics, cognitive science, neurology, and engineering. CIoT may improve the interconnection of diverse IoT networks and be applied beyond disciplines and sectors, spanning the physical and cyber worlds to improve smart distribution of resources, autonomous process controls, and intelligent service provisioning.

The Internet of Things can be viewed as a macro-level development of ubiquitous computing combined with CPS. At the moment, IoT can only use permitted spectral bands, which are presumably already being used, posing an impediment for large-scale IoT implementation. As trillions of objects become more interconnected in the near term, we can anticipate the issue to intensify [14]. In turn, by significantly increasing IoT data transmission using cognitive radio and incorporating machine learning, signal processing, and other technologies, effective distribution of data transmission within 4G and 5G licenced available spectrum could be an answer [13].

Cognitive Radio is a promising enabling communication technology for IoT, dealing with issues such as wireless access network conflict and severe congestion, as well as automaticity, scaling, dependability, energy consumption, and service quality [14]. The most immediate advantage of CR for IoT is that it allows for more efficient spectrum allocation and administration, which improves accessibility, usability, flexibility, and interconnectivity. Addressing efficient and flexible networks and addressing heterogeneity concerns are the two types of CR techniques, with flexible networking referring to the optimal use of available spectrum via spectrum aware optimization to enhance QoS. While addressing diversity, the aim is to strengthen environment discovery, self-organization, adaptability, and nodal cohabitation.

Devices in both centralised and decentralised networks will require routing in order to convey data to a predetermined destination. However, traditional single-hop and multi-hop routing algorithms are incompatible with cognitive radio systems because they lack additional functions like flexible spectrum allocation. CR mesh networks (semi-static) and CR ad hoc networks (adaptable and self-reconfiguring using P2P interactions) have both been discussed in the literature [14]. By accessing data about interference zones and relaying this to the underlying common infrastructure or cluster leader, spectrum knowledge would be readily available to all nodes in centralised networks. Delay, hop count, energy usage, bandwidth, and route stability will be among the network parameters which will be collaboratively optimised. Simultaneously, single-hop, D2D networking will most likely be used in centralised networks provided that the transmitter's range is not surpassed.

A. Cognitive Dynamic Systems and Cognitive Control

Dr. Simon Haykin was the first to propose the concept of a cognitive dynamic system as an answer to the radio spectrum's utilisation inefficiencies. Prospective bandwidth users' capacity for using non - utilized bandwidths is constrained due to government organisations' control of electromagnetic bands in the nature of licences [2]. Cognitive radio was created to maximise the usage of existing radio frequencies by taking advantage of spectral gaps. The study describes it as a smart wireless communication technology that learns from the surroundings and adjusts its settings in real-time using the approach learning by building.

By assessing the electromagnetic environment, finding channels, and transmitting data through dynamic bandwidth control, cognitive radio seeks to maintain high reliability in connectivity utilising the radio spectrum efficiently. The radio scene analysis is performed by the receiver, which surveys the surroundings to detect spectrum holes and calculates the interference temperature. Dynamic beamforming is used for inference control in this passive activity, which requires interpreting non - stationarity temporal signals to accommodate for the spatial characteristics of radiofrequency inputs. This strategy relies on constant spectrum observation and the computation of alternate paths to recognised spectrum holes since it offers resilience whenever a main user requires the spectrum for its own purpose.

Difficulties in the channel estimation problem are solved by adopting semi-blind receiver training, resulting in a receiver with two modes: supervised learning and tracking. The first option acquires and estimates the channel value using a quick training cycle. The other, on the other hand, is intended to be used in operating condition and repeatedly evaluates the channel state. The computations are performed using a state-space model of the channel parameters, with the premise of linearity, utilising the process equation and measurement equation. Choosing an effective monitoring approach and filter choice addresses AR coefficients, dynamic noise, and measurement noise.

Cognitive radio might have to function in a distributed mode via a cooperative system that accomplishes collaboration among nearest neighbors in constant interaction, widening the reach of its application and making it easier for multiple users to adopt and implement the technology to existing networks. The challenge of transmit-power regulation for different users can indeed be viewed as a game-theoretic problem. The author suggested Nash equilibrium and water-filling procedures as remedies. The transmit-power regulation problem affects the dynamic spectrum management system in a similar fashion. The transmitter handles each of these components of the operation, thus it employs the very same methods to address it.

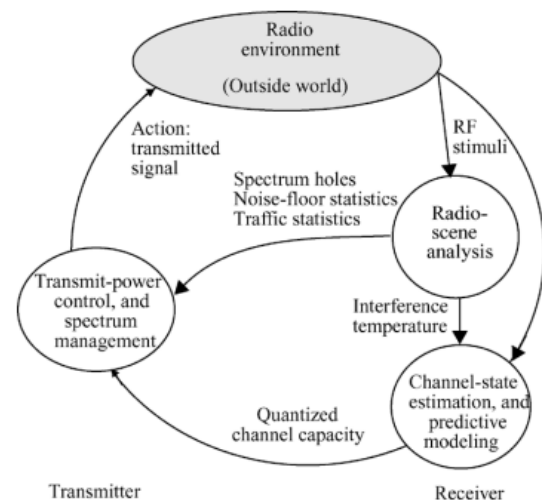

Figure 1: Cognitive Radio operational representation. [2]

In [15] authors considerations are raised regarding modulation techniques and traffic control, with a focus on OFDM. Orthogonal frequency-division multiplexing (OFDM) is a powerful modulation approach for cognitive radio and a cost-effective way to enable dynamic bandwidth allocation. Co-channel interference must be avoided when using an OFDM, which necessitates the inclusion of a traffic control system in the dynamic spectrum management algorithm. This system will be able to anticipate the length of time the spectrum gap would be empty, as well as predicting traffic patterns, based on previous data. More information regarding routing protocol, gateways and more can be found in [16]-[19]

Following the new paradigm outlined by the five principles of cognition, a system is deemed cognitive if it can perform the five basic cognitive processes: perception-action cycle (PAC), memory, attention, language, and intelligence. The perception-action's cycle concept ties to feedback loops, using sensing devices to extract data regarding the system's condition and functioning, which is then used to trigger predetermined events that affect the environment and the system itself within the context of the Internet of Things. To reach intelligent decision-making, this approach employs advanced data analytics and the other components of cognitive dynamic systems. Expanding on the PAC, by using relevant stored information about the surroundings, the system, and past behavior, which are stored in order to improve the system's reaction to hypothetical situations. perceptual, executive, and working memory are the three types of memory.

The PAC and memory elements of CDS are responsible for attention. This refers to the cognitive system's ability to comprehend data and properly optimise all preceding operations. In a cognitive dynamic system, attention is the systematic method for prioritising the distribution of

computational capabilities to alleviate the problem of information overload. As a result, dynamically filtering processed data by significance to aid learning and cognitive controller enhancement are employed. In CDS, attention is not defined by a physical state, but rather by an artificial process that shows itself within system. Network protocols used by devices to interact and send information to other systems represent speech in engineering systems. To share data, cognitive systems should be able to adjust to any communication protocol. Nevertheless, initiatives to standardise such protocols in the IoT are aimed at finding an easier solution. Intelligence is built on the preceding four cognitive operations and incorporates them into an analytical process capable of choosing the best decisions. Intelligence can carry out an assessment and develop appropriate action in the face of unanticipated conditions and uncertainty to then learn from it.

This innovative feature to Haykin's realisations sparked the special necessity to incorporate cognitive control further into conceptual frameworks of cognitive dynamic systems [10]. Fatemi et al. present a fresh perspective on cognitive control in this study, concentrating on two key components: training and planning, both of which are based on two basic ideas. Firstly, the global perception-action cycle, which in this case refers to a cyclic controlled stream of environmental information and is the basic premise of cognition. Secondly the two-state model is composed of the target state, or target of interest, and the current entropic state of the preceptor, which can be viewed as a measure of the lack of sufficient data in the cyclic flow of information from the global PAC. Mathematically it is represented by a state-space model of the environment defined by a process equation and a measurement equation. The target state, or target of concern, is made up of the goal state and the entropic state of the preceptor, which again can be thought of as a gauge of the insufficient data in the cyclical flow of information from the global PAC. A state-space model of the environment characterised by a process equation and a measurement equation is used to describe it analytically.

The purpose of cognitive control is to optimise cognitive strategy, which is defined as the probability density function of cognitive activities, such as the impact of past behaviour on present state, via learning and scheduling. The current state of the preceptor is described using Shannon's entropy notion, which quantifies the disturbance existing as a probability distribution depending on acquired data. The system attempts to estimate future entropic state of the system and apply it in the planning stage of the cycle through gradual variations, formalised by an automatic rewarding mechanism at the end of every iteration [10]. The core of the cognitive controller capabilities is the cognitive control algorithm, which is described in the article as a method to converge towards the optimal policy. This is defined and proved as a special example of dynamic programming that inherits the fundamental traits of convergence and optimality.

The authors explain a combined strategy of pure exploration and pure exploitation dubbed the $\epsilon - greedy$ strategy, which they adapted from Powell et al. [11], to accelerate the learning and convergence of the algorithm to optimized parameters. This balance among exploitation (selecting activities based on the highest value criterion) and exploration (purposeful sampling actions arbitrarily) could be considered as an attentiveness enhancer. Assigning computing resources to sustain developing awareness of the environment while avoiding local sub-optimal solutions [10]. Figure 2 depicts the global feedback loop as well as the interconnections between both the cognitive perceptor and the cognitive controller. The implementation of cognitive control studied in [10] uses this novel cognitive controller idea to solve a radar surveillance challenge. The cognitive controller adjusts the parameters in the system to enhance the prediction of the object's position, velocity, and ballistic coefficients. When contrasted to a static waveform radar, dynamically modifying the waveform led to a four-order-of-magnitude enhancement in performance.

Figure 2: Cognitive Control flow diagram. [10]

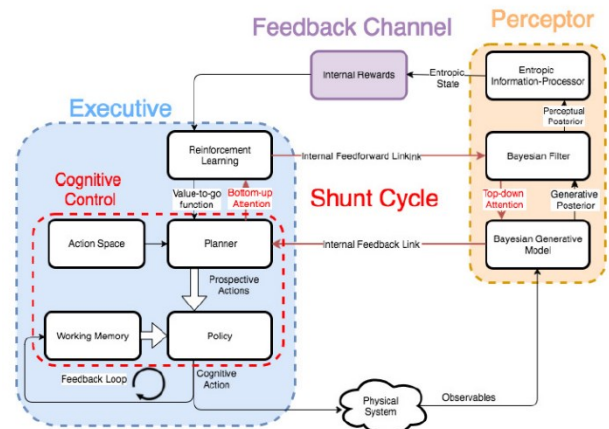

Figure 3: Architectural composition of CDS inclusive of Cognitive Risk Control mechanisms. [12]

In the face of future unforeseen uncertainty, cognitive control, as previously established, misses a strategy for anticipating undesirable outcomes or impediments, often known as risk. The researchers in [12] go even farther, recognising the necessity for a component able of interfacing with multiple parts of CDS, like the preceptor, working memory, and executive memory, in order to predictably adjust the system to the new unpredictable environment. To drive CDS via timely risk-avoidance actions, this redefined

subsystem employs a Bayesian filter algorithm and a Bayes generative model [12]. Figure 3 depicts the perceptor's engagement with the Bayesian-based subsystem. The posterior is calculated on the latest state derived from previous iterations in this generative model, with the caveat that each PAC cycle may have multiple repetitions.

The article's Bayesian filtering is the sub-optimal Kalman filter, which is applied under premise of a linear model. For nonlinear applications, the cubical Kalman filter is recommended. The screening phase' goal is to gather up valuable information from the generative model and discard useless details, all while refining the important information given to the entropic information processor in a top-down attention process. In addition, a shunt cycle is established to transfer bottom-up attention from the scheduler to that same reinforcement learning algorithm, culminating in localized feedback between the systems. The entropic state computation flows through into internal rewarding mechanism, which feeds into the executive for reinforcement learning and task switch control. This has two key qualities that let it distinguish between different scenarios: internal rewards are always positive in the absence of uncertainty and persistently negative in the presence of uncertainties. The reinforcement learning mechanism computes and transforms them into a value-to-go function, which is used as input to the cognitive controller. The action space (which contains all theorised activities), internal incentives, discount factor (a weight provided to progressively discount prior actions), and policy, all impact this.

The cognitive controller is made up of the planner and the policy, as defined earlier in this section (the function that leads to decision making) and of a classifier involved in decision-making, selecting risk-sensitive cognitive actions when there is ambiguity. The classifier assigns a specific posterior to prior disrupted cognitive activities stored in executive memory based on N past events. Moreover, a task switching mechanism is provided to avoid the disrupted cognitive operations from impacting executive memory; this directly connects with the internal reward systems' dual composition. Pre-adaptation is accomplished by correctly identifying events that took place in hazardous uncertain situations versus those that did not. In the CDS framework, a set of gates are employed to divert the flow of data to other regions, necessitating additional investigation if disruptive cognitive actions are required [12]. The implementation of effective policy decision is of major relevance in the administration of these systems, hence cognitive control is highly pertinent in the IoT field.

The following Section will discuss some attempts to apply the CDS framework to the IoT and more general trials to bring cognition into these systems.

B. Cognitive IoT

Incorporating a cognitive element to the Internet of Things advances existing studies in the areas, which is focused on enabling generic objects to detect their surroundings and share their findings with a central administrator. According to Wu et al. [7], simply being connected is insufficient. IoT systems should be able to learn,

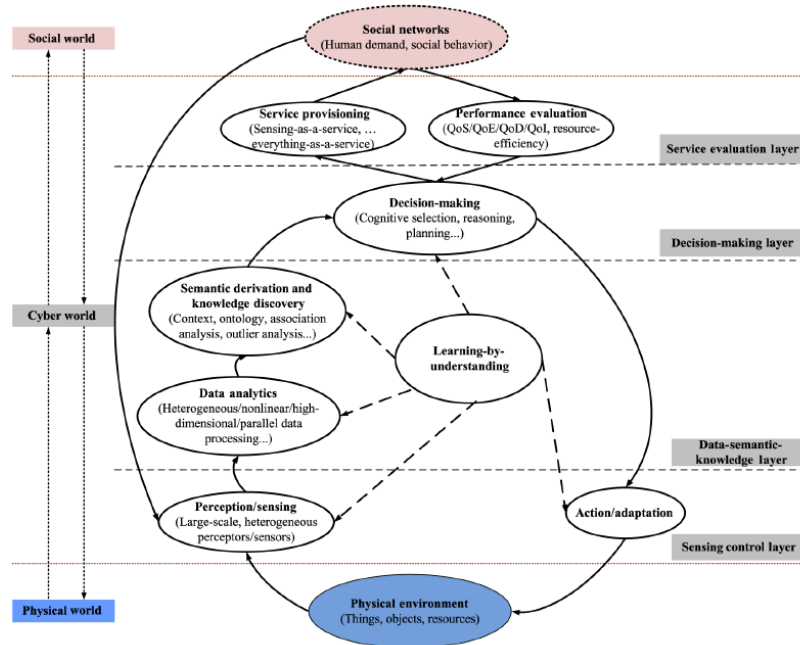

Figure 3: Cognitive Control flow diagram. [7]

think, and comprehend the physical and social world on their own, giving them "high-level intelligence" [7]. Based on past work by Haykin and Fuster, the study proposes a new concept, the Cognitive Internet of Things (CIoT). It presents a new implementation strategy based on interactions between five basic cognitive tasks: the perception-action cycle, large data analysis, semantic extraction, knowledge extraction, intelligent decision-making, as well as on demand resource provisioning [7].

By bridging the tangible, virtual, and social worlds and enabling smart distribution of resources, active network operation, and smart service provisioning, the researchers introduce a new network framework wherein physical/virtual objects are interconnected and act as autonomous agents with minimal intervention. The structure can be separated into layers. Through processing incoming inputs and feedback data, the sensory control layer, which is linked to the global PAC cycle, directly interacts with the surroundings. The semantic knowledge layer, which is concerned with semantic and ontological derivations, further analyses the input in order to provide context awareness. The decision-making layer reasoned, planned, and selected the best appropriate action for the interacting parts to take to use the information extracted from the preceding layer. The service evaluation layer evaluates the services provided and the feedback, using innovative social world-related performance measures.

Planning and choosing are the two aspects of decision-making generally. The article refers to the process of selecting an action from a range of options based on gathered data and deduced knowledge in Cognitive Radio Networks (CRN), which is driven by their learning capabilities. The ability to cognitively modify based on previous and present data is known as cognitive selection. The research highlights three types of cognitive selection: Markovian decision processes, multibandit armed problems, and multiagent learning. Since a distributed IoT architecture is likely to have a high number of decision-makers, the authors focus on the last described method, modelling it using game theory and studying the learning approach with ambiguous, volatile, and incomplete data [7].

Noncooperative game theories, which characterise exchanges between individual decision whereby each player optimises its utility function, are indeed a good fit for the challenge. The development of this systems is primarily concerned with constructing a utility function and achieving acceptable stable solutions. Local relationships amongst actors and spatial game models present additional hurdles in sizable CIoT systems. While global information exchange is impossible in a traditional large-scale IoT system, local interactions between agents can be achieved via regional collaboration, resulting in near-optimal solutions. The paper does not address whether blockchain may be a plausible solution for the worldwide flow of information in an IoT

ecosystem and could be a future topic for research in this field.

In CIoT, evaluating the overall system performance is a difficult operation that is reduced by classifying the data into two dimensions: cost and profit. Three primary measures are presented in the profitability dimension. The quality of data (QoD) is the initial parameter, which assesses the data gathering procedure as well as the reliability of sensed data. Furthermore, the QoD ought to be able to measure data completeness, veracity, and timeliness. The next indicator is quality of information (QoI), which reflects the amount of useful data obtained over a certain task based on precision, accuracy recall, and volume by the decision-maker. These specifics define the quality of the information presented. Finally, the profit dimension's quality of experience (QoE) indicator assesses customer experience relating to access, steady operation, speed, and requirements. Device usage performance, computational complexity, energy efficiency, and storage efficiency, on the other hand, are the cost aspect measures provided in the study.

Home automation provide an ideal platform for analysing the prospects of CIoT as a people centric IoT that enhances the quality of life by dynamically modifying the living spaces in the context of linking the cyber-physical and social worlds, as described in [21]. Additionally, the growing presence of intelligent sensors in households makes it feasible to introduce intelligence to today's smart homes, buildings, automobiles, and, eventually, cities.

In a larger sense, CIoT could be deployed to smart cities in a variety of ways. Feng et al. detail a test case employing the CDS concept towards the Internet of Vehicles (IoV) in smart cities in [22], claiming that modernising the transport network has the potential to decrease traffic, vehicle crashes, and commuting expenses. CAVs (connected autonomous vehicles) are ideal for this since they can change their activities in response to perceived environmental data. To keep up with recent advancements in the use of electric automobiles, the article expands this description to RACE vehicles. The adoption of vast CAV networks could help both commercial and public mobility but would also expose them to cyber-attacks. While delving into the CDS framework for smart vehicles, the authors explain the cyber dangers that such networks may face and recommend countermeasures to maintain the system's resilience, security, and privacy. This study looks at active attacks like jamming, binding, and FDI attacks, as well as passive attacks such eavesdropping and stalking [22]. Due to complex, variable, and hostile environment in which CAV function, adding CDS as a proactive supervisor of all components existing in a car is desired to improve risk management reduction via joint interoperability and adaptability. Relying on the context extrapolation features of CRC, operational sensors like LIDAR, video cameras, radio receivers, and radar receivers might be dynamically modified to the scenario, increasing

their functionality. The authors offer an improved CRC framework that is based on a Bayesian generative model and entropic information processing, which uses a task switch method of control to change mode of operation situationally. The reinforcement learning and scheduler, action library, policy, classifier, working memory, and executive memory all make up the executive element of CDS, that would estimate the optimum cognitive action or policy based on the adaptive and filtered feedback information. Further studies in the application of CIoT to smart cities, smart manufacturing and smart energy grids can be found in [23]-[25].

III. CONCLUSION

This article provides an overview of Cognitive Dynamic Systems and how they can be used in the Internet of Things. The standardisation initiatives aimed at expediting the creation of new IoT designs were also discussed in order to highlight the current issues with interoperability in IoT architectures, which is required to develop larger scale and comprehensive IoT and CIoT architectures. In addition, based on current research, the usage of Cognitive Radio for IoT was examined. Finally, IoT was used to improve cognitive policy selection and how CIoT is approached.

Abstract—Internet of Things (IoT) is a distributed communication technology system that offers the possibility for physical devices (e.g., vehicles, home appliances sensors, actuators, etc.), known as *Things*, to connect and exchange data, more importantly, without human interaction. Since IoT plays a significant role in our daily lives, we must secure the IoT environment to work effectively. Among the various security requirements, authentication to the IoT devices is essential as it is the first step in preventing any negative impact of possible attackers. Using the current IEEE 802.11 infrastructure, this paper implements an IoT devices authentication scheme based on something that is *in the IoT device's environment* (i.e., ambient access points). Data from the broadcast messages (i.e., beacon frame characteristics) are utilized to implement the authentication factor that confirms proximity between two devices in an ad hoc IoT network.

Index Terms—Internet of Things, IoT, ad hoc, proximity, Beacon Frame, IoT Authentication

I. INTRODUCTION

THE Internet over the last four decades has developed from peer-to-peer networking (P2P), world-wide-web (WWW), and mobile-Internet to the IoT. The IoT is a network that might consist of animals, people, objects, physical devices (e.g., home appliance sensors, actuators, vehicles, digital machines, etc.) that can collect and exchange data with each other without human intervention. The way of communication in an IoT network can be between people, between people and devices, and between devices themselves, also called machine-to-machine (M2M).

The IoT environment has three major components; IoT devices, Cloud, and Client applications. IoT devices are responsible for sensing and measuring the world around them, taking local action as necessary (turning off/on or opening/closing an object, sharing data, etc.). The cloud is where the powerful applications reside and can collect data from IoT devices, combine IoT device data with other data sources, perform data analytics to reveal trends, identify problems, and predict the future. The client applications enable users to access and view data processed in the cloud issue commands to remote IoT devices.

In 2015, approximately 15 billion IoT devices worldwide were in use [1], which was doubled in 2020 (approximately around 31 billion) and might be around 60 billion by 2024 [2].

In general, IoT is continuously evolving and has become an actual attractive area of attack for hackers. The number of cyber-attacks on IoT devices is raised by 600% in only one year, from 2016 to 2017, corresponding to 6000 and 50,000 reported attacks, respectively [3]. IoT devices are usually subject to Distributed Denial-of-Service (DDoS) and ransomware attacks due to the fact that these attacks take advantage of storage limitations and their internet-supported connectivity [4] which grants hackers the opportunity to interact with devices remotely.

One way IoT networks can mitigate cyber-attacks is to establish authentication, which is based on trusting the other end before communicating with. As of today, there is a number of ways to establish authentication in IoT networks:

- **On-way authentication:** in the case before two IoT devices start to communicate with each other, only IoT device authenticates itself to the other, while the other IoT device will not be authenticated.
- **Two-way authentication:** both IoT devices must authenticate themselves to each other prior to the communication.
- **Three-way authentication:** a service provider is involved in this type, which authenticates the two IoT devices and assists them to authenticate each other.
- **Distributed:** this method utilizes a distributed authentication technique between the IoT devices prior to the communication.
- **Centralized:** a trusted third end is utilized to distribute and manage the authentication certificates used.

IoT devices can be connected to a centralized network, in which all devices are connected directly the gateway. Alternatively, IoT devices can be connected to each other in ad hoc networks, where communications between IoT devices is used to relay information of other devices to

the gateway.

We propose a technique to authenticate IoT devices in ad hoc networks to verify proximity. This is done in a way that only devices within a certain distance from other authenticated IoT devices will be able to connect to the network. Meanwhile, devices that are far from an authenticated device or not physically in the area will fail in the proximity authentication. The proposed system enforces the security in ad hoc IoT networks.

II. CONTRIBUTION

Using the current IEEE 802.11 infrastructure, this paper implements an IoT devices proximity authentication scheme in IoT ad hoc networks. This based on something that is *in the IoT device's environment* (i.e., ambient access points). In this paper, data (a Wi-Fi *footprint*) from the broadcast messages are utilized to implement the proximity by determining whether two devices are within a certain range for an authenticated IoT device unobtrusively.

III. GUIDE TO PAPER

This paper is organized as follows; *Section IV* reviews the previous research on IoT devices authentication. *Section V* describes the proposed scheme system for beacon frame-based IoT devices authentication. The experiment of the proposed system and results are presented in *Section VI*. The proposed scheme is analysed in *Section VII*. Security analysis is discussed in *Section VIII*. Lastly, *Section IX* illustrates the conclusion for the proposed method.

IV. RELATED WORK

This section provides an analytical overview of the literature proposing proximity-based authentication. Some systems use GPS for proximity verification [5], [6]. This is mainly done by comparing the GPS location calculated at two device. Few researches propose using GPS for location verification. However, using GPS suffers from performance limitations indoors [7]. Other systems use wireless sensor network for localization [8]. Moreover, utilizing wireless sensor network requires additional hardware installed on IoT devices, which can be costly to deploy and maintain. On the other hand, Bluetooth had been a popular choice for proximity-based authentication [9], [10]. In addition, the weakness in these approaches is that Bluetooth typically has a short-range and requires additional hardware that is not always guaranteed to be in the infrastructure or in every user's device [7]. Wi-Fi is a popular solution for proximity-based authentication are ubiquitous and widely used for connectivity in many users [11]–[13] and IoT devices. A few works use channel characteristics to verify proximity using signal information received from access points such as SSID, MAC address, and Received Signal Strength Indicator (RSSI) [14], multipath profiles [15], or mathematical modeling

on channel characteristics [10], [16]. The proposed system uses Wi-Fi measurements to achieve authentication in the context of ad hoc IoT networks. This can be done by utilizing the role of Representational State Transfer (REST) API in the IoT Systems, which is able to record and count everything [17]. The proposed system provides a complete framework for IoT devices proximity verification and management, which is done by utilizing Wi-Fi Beacon frame information to perform proximity-based authentication.

V. THE PROPOSED SCHEME

In this section, we will present the proposed scheme in detail. The proposed scheme aims to authenticate new IoT devices joining and ad hoc network. The type of authentication that is carried out is proximity-based. This aims to prevent adding new IoT nodes that are outside the "allowed area". This would also eliminate adding fake IoT nodes, or adding IoT node outside the allowed physical boundaries. The proposed system utilizes Wi-Fi beacons in the area to achieve this goal. In general, Wi-Fi access points periodically broadcast their own beacon frame, including Service Set Identifier (SSID) and Basic Service Set Identifier (BSSID). Moreover, Using the Wi-Fi footprint, we can measure the RSSI value of every presented access point in the location.

Before a new IoT device joins an IoT environment, an authenticated IoT device must verify whether or not the new device is within the boundary of operations using their site following the steps below:

- 1) An authenticated IoT device in the system scan for the beacon frame of every Wi-Fi access point in the environment then collect it. Also, it measure the RSSI value of every presented access point as follows:

$$B_1 \begin{cases} Tuple_1 = \{SSID_1, BSSID_1, RSSI_1\} \\ Tuple_2 = \{SSID_2, BSSID_2, RSSI_1\} \\ \vdots \\ Tuple_n = \{SSID_n, BSSID_n, RSSI_n\} \end{cases} \quad (1)$$

- 2) When a new device wants to be added to the network the authenticated device verifies whether the new device is within the boundary of operations.
- 3) Similar to step, 1 the new device scan for the beacon frame of every Wi-Fi access point in the environment and then collect it. Also, it measures the RSSI value of every presented access point as

follows:

$$B_2 \begin{cases} Tuple_{e_1} = \{SSID_1, BSSID_1, RSSI_1\} \\ Tuple_{e_2} = \{SSID_2, BSSID_2, RSSI_1\} \\ \vdots \\ Tuple_{e_n} = \{SSID_n, BSSID_n, RSSI_n\} \end{cases} \quad (2)$$

Then it sends it to the authenticated device.

- 4) When the authenticated device receives the data in step 3, it calculates the Euclidean distance between the two data sets, B1 and B2, using equation 3:

$$D = \sqrt{\sum_{i=1}^n [B_1 Tuple_{e_i}(RSSI) - B_2 Tuple_{e_i}(RSSI)]^2} \quad (3)$$

Where D is the Euclidean distance.

If D is below a certain defined threshold, the proximity authentication is successful. If D is above this threshold, proximity authentication fails. The threshold is determined based on a calibration experiment. Such calibration can be done by the vendor for similar devices. Alternatively, it can be calculated at the area of operation for different devices.

The proposed system facilitates proximity authentication for multiple nodes. Authenticated devices are able to verify new device proximity before authenticating them to the network. This is done using the threshold, which is determined by the Euclidean distance in equation 3. When the calculated distance is below the threshold, it means that the accepted proximity reflects the most efficient data transmission in the ad hoc network. Also, it enforces security in the system to make sure far or imposter devices are not able to authenticate. Figure 1 shows how authentication works in the proposed system.

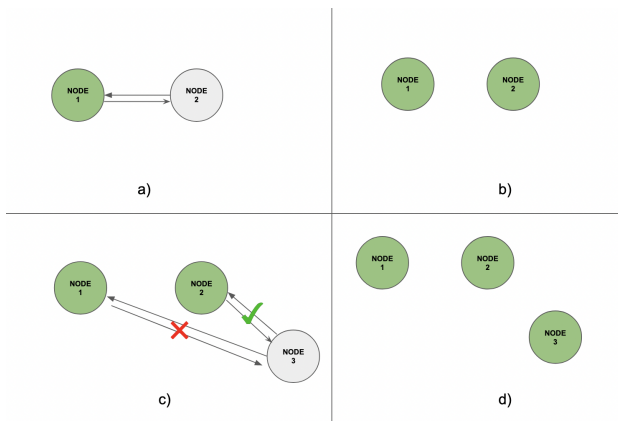

Fig. 1. Authenticating new IoT nodes

As can be seen in Figure1 (a). Node 1 is an authenticated node in the system. The color green denotes an authenticated node. Node2 enters the system and wants to be authenticated. It scans for Wi-Fi Beacon and broadcasts this data in the request to join the network. Node1 received this request along with the scan data. Node1 verifies whether Node2 meets the proximity threshold by calculating the Euclidean distance and comparing the distance with the pre-defined threshold. Figure1(b) shows that the authentication is successful. In Figure1 (c), a Node 3 enters the area. Node3 is more proximate to Node2 than Node1. Node 3 broadcasts the request to join the network along with the Wi-Fi scan data, which is received by Node1 and Node2. Both Node1 and Node 2 verify whether Node3 meets the proximity threshold in reference to these nodes. Figure1(d) shows that it met the threshold in reference to Node2 but not Node1. For this case, the new device meet the threshold with two devices. It connects to the device with the least Euclidean distance.

VI. EXPERIMENTS

To test the proposed system, two experiments were conducted. Experiment 1 calculates the accuracy of the proposed proximity-based authentication. Experiment 2 simulates the system operation with several nodes.

A. Two-device proximity authentication

In this experiment, two Raspberry Pis were placed within two meters of each other. Each Raspberry Pi scanned and collected the Wi-Fi beacon frames and RSSI in the area following equation 1 and equation 2. The collected data was used to calculate the value of the threshold using equation 3. In the experiment, the ten access points with the highest RSSIs were used in the equation. To test the proposed system, the two Raspberry Pis were placed at ten different locations around the building. Ten authentications were attempted at each location. Five of these attempts were conducted when the two devices were less than two meters apart. Then, five more times where the two devices are more than two meters apart. The data was collected for each attempt and the Euclidean distance was calculated using equation3. This distance was compared to the threshold to determine successful and failing authentications. The results of the experiment are shown in Table I.

TABLE I
SUCCESS RATE

N = 100	Actual	
	Success	Failure
True	TS = 45.54%	TF = 42.36%
False	FS = 4.46%	FF = 7.64%

The experiment returned authentication accuracy of 87.9%. The accuracy can be increased if the tolerance of the threshold value is increased. When 20% tolerance is considered, the accuracy jumps to 94.5%.

B. Several nodes simulation

This experiment is to simulate the system’s operations when several nodes are involved. The simulation was conducted utilizing python. The threshold calculated in the experiment above was considered. A function was written to perform the authentication following the steps above. The nodes in the simulation were configured with these Actual RSSI values at ten different locations collected in the experiment above. The simulation had each node to authenticate with the other through an iteration. Each node in the simulation would attempt to connect to the node where there are the nodes that meet the threshold and with the least Euclidean distance. In the simulation, each device is connected to a node with the least distance, as shown in figure 2. The experiment returned authentication accuracy of 90%, see Table II.

Fig. 2. Experiment 2: Ten nodes simulation

TABLE II
SUCCESS RATE

		Actual	
N = 10		Success	Failure
True		TS = 5	TF = 1
False		FS = 0	FF = 3

VII. SYSTEM ANALYSIS

A. Continuous Authentication

Continuous authentication is a feature where the authentication process every predefined time. The service provider will check continuously if the two communicated IoT devices are in the same IoT network in order to maintain the session. The frequency with which the IoT devices collect and send the new data (SSID, BSSID, RSSI values) can be varied based on requirements and/or an administration’s desire. The continuous authentication will check if both communicated IoT devices are still in the same IoT environment in order to keep the session alive. If not, the session can be automatically terminated. This feature could mitigate and, at some level, prevent

some types of cyber-attacks (more details are provided in the next section).

B. Usability

Due to the proposed scheme using the existing IEEE 802.11 infrastructure (i.e., Wi-Fi access points already in the IoT environment, network interface cards already in IoT devices), no new hardware is required to be installed. Moreover, the proposed scheme is considered to be readily applicable in a scalable manner because it relies on ubiquitous Wi-Fi access points. The internet can be found almost everywhere people live [18]. Due to its ubiquitous nature, the internet is an essential and robust platform for education, business, and entertainment. It has been noted that locations with reliable internet connectivity are also where access points are commonly established [19].

VIII. SECURITY ANALYSIS

A. Environment Simulation Attack

A chance of simulating the IoT Environment is possible. The attacker scans the IoT environment (i.e., beacon frame characteristics and RSSI value) and then replicates it elsewhere, where the attacker has full control of the simulated environment. In the proposed research, the IoT environment can be scanned and replicated; however, the attacker’s IoT device’s unique identifier (e.g., IMEI, UUID, MAC address, etc.) will not match the IoT’s unique identifier in the database. Moreover, the administration will be notified because the authentication entity will reject the request. Also, The continuous authentication feature will mitigate and, at some level, will prevent the attack.

B. Insider attacks

An attacker can be inside the IoT environment, which means he/she will be able to scan the IoT environment (i.e., beacon frame characteristics and RSSI value) and then utilizes it. Beginning inside the IoT environment and scanning it, is something easy to obtain. However, the continuous authentication feature will mitigate and, at some level, will prevent the attack. In addition, the service provider will notice that the malicious IoT device’s unique identifier does not match the one in its database, which results in rejecting the request and notifying the administrator.

IX. CONCLUSION

IoT is one of many buzzwords in Information Technology (IT), which will transform our daily lives into smart systems. To guarantee the security of the wireless communications in an IoT environment, devices must build trust in the identity of each other, *authentication*. This paper proposes a technique to authenticate IoT devices in ad hoc networks to verify proximity. This is done in a way that only devices within a certain distance from other authenticated IoT devices will be able to

connect to the network. Meanwhile, devices that are far from an authenticated device or not physically in the area will fail in the proximity authentication. The proposed system enforces security in ad hoc IoT networks. Also, it figures the more suitable device to connect to in an ad hoc network that would reflect the most suitable Radio frequency conditions to communicate. The experiment showed an adequate accuracy of proximity authentication that can be increased with configuring the tolerance in the threshold.

Abstract— While the global electric vehicle (EV) adoption is on rise, developing countries like Pakistan have been facing many obstacles in the face of EV adoption such as shortfall of electricity, high EV prices, low average income and absence of commercial and residential charging infrastructure. In this paper, we propose a design of a micro solar electric vehicle, which would help overcome all of these problems and provide an economical yet feasible solution. The design and system sizing of the micro solar EV was done in HOMER Pro. A dynamic model of the micro solar EV was created in MATLAB/Simulink, which implemented PV generation, maximum power point tracking, battery charging and discharging, DC-motor operation and speed control of the electric vehicle, while taking into consideration environmental factors like irradiance and temperature.

Keywords— solar EV, solar car, electric vehicle, EV design, dynamic modeling

I. INTRODUCTION

Climate change is one of the most pressing issues of the modern world and steps are being taken around the world to help slow down and mitigate climate change. The use of electric vehicles is one such bold step that helps reduce the GHG emissions of the global transport sector and slow down the impact of climate change. Global EV adoption has been growing at a rapid pace, in developed countries. However, the same cannot be said about developing countries, such as Pakistan.

The EV adoption in Pakistan is facing many obstacles including but not limited to electricity shortfall, high prices of electric vehicles, low average income, absence of commercial charging infrastructure and the inability of residential electrical infrastructure to charge an electric vehicle. At typical electrical service is 5A or 10A at 220V to supply house load, which is not enough to charge an EV at home.

Therefore, in this paper, we propose the design of a micro solar electric vehicle, which holds against all the above-mentioned challenges. This solar EV would have the ability to take power from the sun in the form of solar energy, throughout the daytime. It would also be very economical in price and would easily be charged from the existing residential electrical infrastructure.

II. LITERATURE REVIEW

While it has roughly been less than a decade since EV commercialization has become mainstream and automakers are selling fully functional EVs to consumers. There has been

plenty of research on EVs before that as well. During the literature review part of this research we came across multiple designs and dynamic models of all types of EVs from micro electric vehicles, to passenger sedans, vans, buses and other commercial vehicles.

Qingqing Xie et al. present a MATLAB/Simulink model for advanced vehicle dynamic model for EV emulation, while taking into consideration actual environmental conditions. The model also takes into account the rotational inertia of each component involved in developing the model [1]. Another research published in University of Washington discusses the dynamics of an electric vehicle by preparing a model which uses enhanced techniques such as torque vectoring [2]. Similarly, another research uses modelica methodologies to model EV pickup attributes to study the dynamic response of an electric vehicle [3]. Other such models for battery dynamics and solar hybrid vehicles have been given in [4] and [5] respectively. In conclusion, there is enough research material that can be found for developing a model to study the vehicle dynamics of an electric vehicle.

Talking about solar electric vehicles, there is limited research present on the design of solar electric vehicles, let alone, dynamic models of solar electric vehicles.

As outlined in [6] the research on solar electric vehicles can be divided into three major segments a) commercial solar cars, b) solar electric vehicles for solar races and c) small solar cars. Research groups and universities from all around the world take part in solar car design for solar races such as World Solar Challenge [7] and American Solar Challenge [8].

Talking about the second segment of solar electric vehicles, there are multiple automakers, who have undertaken the task of designing and selling commercial solar electric vehicles [9] [10] [11]. Finally some interesting designs have come forward for the small solar electric vehicle segment as well [12] [13].

However, there exists a huge gap, when it comes to developing and studying a dynamic model of a solar electric vehicle. In our previous research, we proposed a design for a micro-solar electric vehicle for application in Pakistan [6]. In this paper, we are going to develop a dynamic model of our micro-solar electric vehicle using MATLAB/Simulink.

III. DESIGN OF MICRO SOLAR EV

Before we talk about the dynamic model of our micro solar electric vehicle, we will briefly discuss the system design and PV sizing. The specifications of the vehicle used in the design are as following;

Table 1: Vehicle Specifications used for the design [6]

Item	Description
Max. Range	100 km
Dimensions	2450 mm*1350 mm*1750 mm
Wheelbase	1500 mm
No. of seats	3
Motor Size	1200 W
Total Motor Torque	100 Nm
Max Speed	43 km/hr

The design and PV sizing was carried out in HOMER Pro and the system can be seen in the figure below:

Figure 1: System Design of micro-solar electric vehicle in HOMER Pro [6]

The sizing of the system was as follows:

Table 2: System sizing carried out in HOMER Pro [6]

Item	Quantity
Solar Panels/ Advance Solar Hydro Wind Power API – 150 W	3
24V, 1kWhr Li-Ion battery, 72V bus	3
Cost/NPC (Rs)	177013.7
Cost/COE (Rs)	54.62492
Cost/Operating cost (Rs/yr)	961.2305
Cost/Initial capital (Rs)	184128
System/Ren Frac (%)	100
Kyoc145/Capital Cost (Rs)	21000
Kyoc145/Production (kWh/yr)	766.9749
Dis1.0/Autonomy (hr)	57.6
Dis1.0/Annual Throughput (kWh/yr)	392.1335
Dis1.0/Nominal Capacity (kWh)	2.88

Based on this system design and sizing, we have developed a detailed dynamic model of our solar electric vehicle.

IV. DYNAMIC MODELING OF MICRO SOLAR ELECTRIC VEHICLE IN MATLAB/SIMULINK

Electrical dynamic modeling is an important part of research and helps us understand how a system would be working in real-life. A dynamic model of a PV system would not only help us understand how the system would perform, but also how it would reach to the changes in the environment. This dynamic model would also help us simulate the system in various conditions that an electric vehicle has to go through during its course of operation.

Figure 2 shows a block diagram of the dynamic model of our system. As shown in the figure, our system consists of seven major blocks, which are further made of tens of components, all coming together to form a dynamic model of our micro-solar electric vehicle. The first block i.e. PV arrays generate power by converting solar energy into electrical energy, which is then supplied to the DC-DC converter. This converter is then connected to the battery storage block of our system, which not only stores this power, but also supplies to the DC motor, when in operation. The battery storage block can also be charged by an external AC source i.e. the electrical grid. There are two control blocks used in our system, one is an MPPT controller, which helps the system extract the maximum amount of power from the PV panels, and the second one is a speed controller, which helps the DC machine operate at desired speeds, as per the speed reference provided.

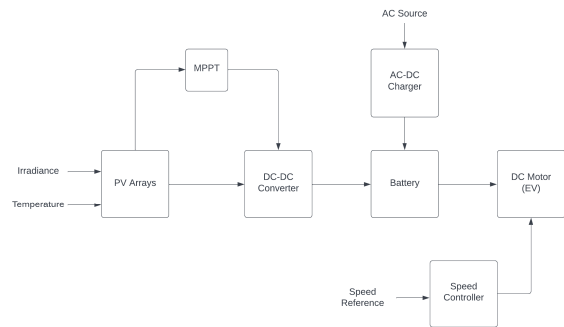

Figure 2: Block Diagram of the dynamic model

A. PV Array

PV arrays are the most fundamental part of our dynamic model, as we are developing a micro solar electric vehicle, meaning our focus is on extracting the most amount of power from the PV array, given the available space to mount PV panels. It is important to note that the non-linear output of PV modules is affected by environmental parameters such as irradiance, temperature, clearness index, dust, cloud and other shading effects etc. However, in this model, we are only taking into account irradiance and temperature.

A PV array can be made up of multiple PV modules, which in turn consist of series of PV cells. To better understand the performance of a PV module, we will take a look at the equivalent circuit of a PV module as show in figure 3.

Figure 3: Equivalent circuit of a PV module

This equivalent circuit gives us some basic equations to help calculate the values of current and voltages under consideration.

$$I_d = I_o \left[\exp\left(\frac{V_d}{V_T}\right) - 1 \right] \quad (1)$$

$$V_T = \frac{KT}{q} \times A \times N_{cell} \quad (2)$$

$$V_d = V_{PV} + R_S I_{PV} \quad (3)$$

$$I_{PV} = I_{ph} - I_D - \frac{V_D}{R_{sh}} \quad (4)$$

In the above equations Eq. (1) to Eq. (4) [14], I_d is the diode current, I_{ph} is the light-generated current, I_o is the diode saturation current, V_T is thermal voltage equivalent, V_d is the diode voltage, V_{pv} and I_{pv} are module voltage and current, respectively, K is the Boltzman constant equal to $1.3806 \times 10^{-23} \text{J/K}$, A is the diode ideality factor, T is the cell temperature, q is the electron charge equal to $1.602 \times 10^{-19} \text{C}$, and N_{cell} is the number of cells connected in series in a module. As evident, from equations 1 to 4, almost every parameter of the PV module is subject to change as per the variations in temperature and irradiance.

Based on the results from HOMER Pro [6] the model consisted of three 24V, 150W solar PV (Advance Solar Hydro Wind Power API – 150) modules connected in series, making the bus voltage to be 72V.

B. Maximum Power Point Tracking (MPPT) Controller

As discussed before, the performance of a PV module is very much dependent on environmental factors like irradiance and temperature. For each PV module, there is a point in the P-V curve, where the PV module is giving the maximum amount of power. This point is called Maximum power point, and it can be different for different condition. This can be observed in figure 4, where two different temperatures result in two different MPPs.

Figure 4: PV Curve of our chosen PV Module

Maximum power point tracking is a process, controls the power generation from a PV panel in a manner that it is always operating at maximum power point. There are numerous techniques to achieve maximum power point tracking such as incremental conductance method, perturb and observe (P&O) method etc. In this model, we are going to use the perturb and observe (P&O) method, in order to implement maximum power point tracking.

The way P&O technique is used is that a minor perturbation is introduced into the system, which causes the power of the PV module to vary. After the perturbation is introduced, the algorithm then observes the output power periodically and compares it with previous power. A similar perturbation is introduced to vary the voltage of the PV array. By doing so, the algorithm identifies, where the system is lying on the PV curve. Depending on that, the duty cycle is either increased or decreased.

Figure 5: P&O algorithm working principle [15]

As seen in the figure 5, our system can have two operation points. The first one is indicated as point 1 and the second one is indicated as point 2 on the graph. In the case that the system was on point 1, the voltage needs to be increased. Similarly, if it was on point 2, the voltage need to be decreased. In order to implement this operation, we used a code-based function, according to the flowchart shown in figure 6.

The MPPT starts by measuring the current and voltage of the PV modules using sensors, and outputs a duty cycle. This duty cycle is going to be used to generate a PWM signal, which will enable or disable the switch used in our DC-DC converter. A change in the duty cycle generated by the MPPT means that the voltage of the module would change and subsequently, the power of the PV module would also change. The P&O algorithm can be best described by the flowchart given in figure 6.

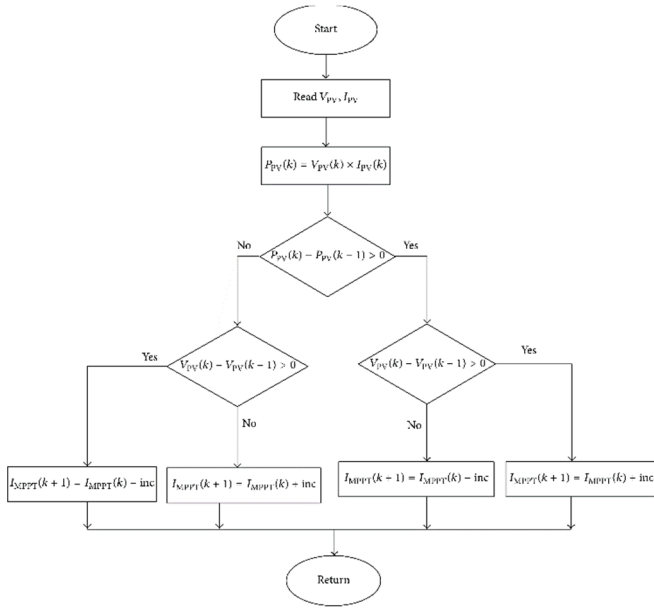

Figure 6: P&O Algorithm flowchart

C. DC-DC Converter

As evident from the name, DC-DC converters are used where both the input voltage and output voltage are in DC. The main purpose of using a DC-DC converter is to produce a regulated voltage from an uncontrolled source to a load that may or may not be constant, in a manner that is efficient. A DC-DC converter is a high-frequency power conversion circuit, which makes use of high-frequency switching, transformers, inductors, and capacitors.

There are many different topologies of DC-DC converter including buck, boost, buck-boost and SEPIC converters. A buck converter is used in applications where the output voltage needs to be lower than the input voltage, boost converter is used when output voltage needs to be higher than input voltage, whereas, buck-boost and SEPIC can be used in both situations. In this model, we are going to use a buck converter since the input voltage or PV module voltage in our case is higher than what is needed at the battery terminal. Figure 7 shows the circuit of a buck converter.

Figure 7: DC-DC Converter (Buck Converter)

The buck converter operates in two steps. The first step of operation is when the switch is turned ON. During this step, the current is flowing to the output capacitor, thus charging it up. Since the voltage of a capacitor does not rise instantly, as well as the inductor limiting the charging current, the capacitor voltage is not the full voltage of the source during the switching

cycle [16]. This is depicted in figure 8, the highlighted part of the circuit shows the flow of current.

Figure 8: Buck Converter Operation (Switch ON)

During step two, the switch turns off and a voltage is created across the inductor due to the fact that inductor cannot change current suddenly. This voltage allows the capacitor to charge and power the load when switch is off [16]. This can be seen in figure 9.

Figure 9: Buck Converter Operation (Switch OFF)

Now in order to design the buck converter, we need to calculate the values of the components used to form the buck converter [17]. Following are the mathematical equations that help design a buck converter.

$$D_{max} = \frac{V_{OUT}}{V_{IN(max)} \times \eta} \quad (5)$$

Where, $V_{IN(max)}$ = maximum input voltage

V_{OUT} = output voltage

η = efficiency of the converter

$$L = \frac{V_{OUT} \times (V_{IN} - V_{OUT})}{\Delta I_L \times f_s \times V_{IN}} \quad (6)$$

Where, f_s = minimum switching frequency of the converter

ΔI_L = estimated inductor ripple current

$$\Delta I_L = (0.1 \text{ to } 0.4) \times I_{OUT(max)} \quad (7)$$

$$C_{OUT} = \frac{\Delta I_L}{8 \times f_s \times \Delta V_{OUT}} \quad (8)$$

Where, C_{OUT} = minimum output capacitance

ΔV_{OUT} = desired output voltage ripple

$$\Delta V_{OUT} = ESR \times \Delta I_L \quad (9)$$

Where, ESR = equivalent series resistance of the used output capacitor [17].

The buck converter design is complete once we have calculated the values for the inductance and the capacitance to be used.

D. Li-Ion Battery

For the battery storage system of our PV system, we used a Li-Ion battery. The model present in Simulink is called a generic battery model, which allows you to mimic the charging and discharging characteristics of any rechargeable battery. Figure 10, shows the equivalent circuit of the rechargeable battery model [18].

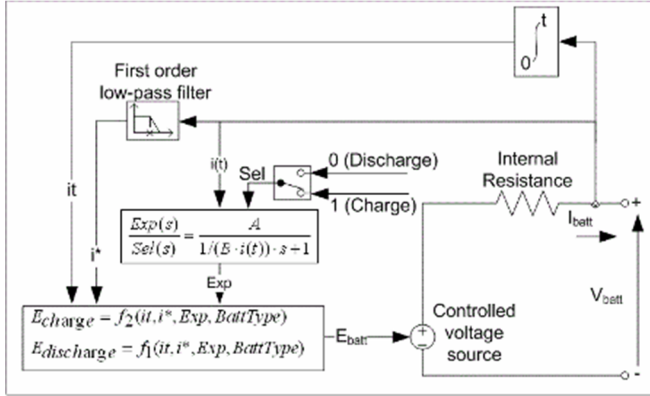

Figure 10: Equivalent circuit of a rechargeable battery model

The battery model has three observable parameters i.e. battery voltage, battery current and SOC. As evident from the name, battery voltage is the rated voltage of battery. A positive battery current represents that the battery is discharging, whereas a negative battery current represents that the battery is charging. Similarly, SOC is the battery state of charge, and gives information about the state of charge of the battery at any given moment. An increasing SOC represents battery charging and a decreasing SOC represents battery discharging.

E. AC-DC Charger

In addition to the battery being able to charge from the PV panels, the micro solar electric vehicle would also have the ability to charge from an AC source, if needed. This represents the time of the day when there is no sun, and the vehicle needs charging. In such a case, the car battery could be directly plugged into an AC wall outlet. This is where the AC-DC charging block comes in handy. Figure 11, shows the equivalent circuit of an AC-DC charging block [19].

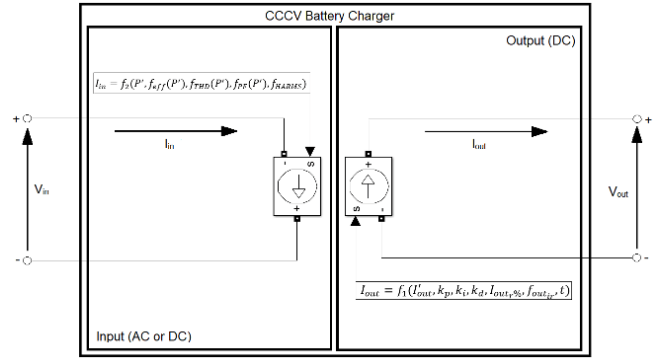

Figure 11: AC-DC Charging Block

F. DC Machine

Since our micro solar electric vehicle would be running a DC motor, in order to develop the model of such a motor, we have used the DC machine block in Simulink. The DC machine block allows us to implement both a wound-field or permanent DC machine. However, in our case, we are using a wound-field DC machine in series configuration.

The armature circuit of the DC machine consists of an inductor L_a and resistor R_a in series with a counter-electromotive force (CEMF) E , which is proportional to the machine speed.

$$E = K_E \omega \quad (10)$$

Where, K_E is the voltage constant and ω is the machine speed.

$$\text{Electromechanical Torque} = T_e = K_T I_\omega \quad (11)$$

Where, K_T is the torque constant.

There is a mechanical part of the DC machine, which is used to calculate the speed of the machine from the net torque applied to the rotor.

$$J \frac{d\omega}{dt} = T_e - T_L - B_m \omega - T_f \quad (12)$$

Where, J = inertia,

B_m = viscous friction coefficient, and

T_f = Coulomb friction torque.

G. Speed Controller

The last block of our model is a speed controller, which is being used in order to regulate the speed of the motor. The speed controller is a simple PWM Chopper circuit. Figure 12, shows the model of the circuit

Figure 12: Voltage to PWM Signal Converter Block

By taking into account the reference voltage set on the input side of this circuit, it generates a PWM signal, which operates a high-frequency switch thus changing the average value of current supplied to the motor, which results in an increase or decrease in the motor speed as required.

V. SIMULATION RESULTS AND DISCUSSION

A dynamic model of the block diagram shown in figure 2, was implemented in Simulink, which consisted of all the major blocks discussed in the previous section. The detailed model can be seen in figure 13.

A. PV Operation

Now let us take a look at the results of each part of the simulation. First of all we have the PV array, the output of which is very much dependent on the irradiance values. We are going to introduce a variable irradiance curve, to see how PV output varies accordingly. Figure 14, shows the changing irradiance values. At these values, the PV is generating the amount of current and voltage shown in figure 15. Notice, how the voltage and current values change with the irradiance values.

B. Battery Operation

Now let us move on the battery parameters, when PV modules are in operation and actively generating power, this power is being directly transferred and deposited into the battery. This is being demonstrated in figure 16. Notice that the SOC of the battery is increasing over the course of the simulation, and the battery current is in negative, which shows the influx of current into the battery.

Similarly, when the PV is disconnected due to any reason including bad weather or absence of sun during night time, the PV panels will not be producing any power. Hence, the EV

motor will be drawing power from the battery. If we look at figure 17, we can see that the SOC of the battery is decreasing and the battery current is also positive, which shows the outflow of current from the battery.

In the last scenario, we will be charging the battery directly from the AC source, through the CCCV charging block. In this scenario, once again the battery SOC is positive and the battery current is in negative as shown in figure 18.

C. DC-Machine Operation

In this section, we are going to observe the operation of the DC machine, which represents the electric vehicle motor. The DC machine operation can be observed in two different modes.

The first one is the normal mode, in which the DC machine is drawing power from the battery and generating a normal response. This can be seen in figure 19, from the armature current, field current and electrical torque values.

The second mode of operation is when the DC machine is put in reverse, which represents the electric vehicle moving in reverse direction. In a DC series machine, in order to reverse the direction of motion, we have to change the polarity of field windings. In this model we have achieved this by using ideal relay modules, which can be switched at any instant at the start of, or during the simulation to reverse the direction of the vehicle. Figure 20 shows the vehicle direction changing at the 5 second mark during the simulation. This change is denoted by a change in the direction of field current.

D. DC-Machine Operation under variable load

In order to understand the response of our electric vehicle over uneven or steep roads, we are going to run the simulation for 60 seconds, introduce a variable load profile and see how that affects the dynamics of our electric vehicle. Figure 21, shows the dynamic load profile used in the simulation. Figure

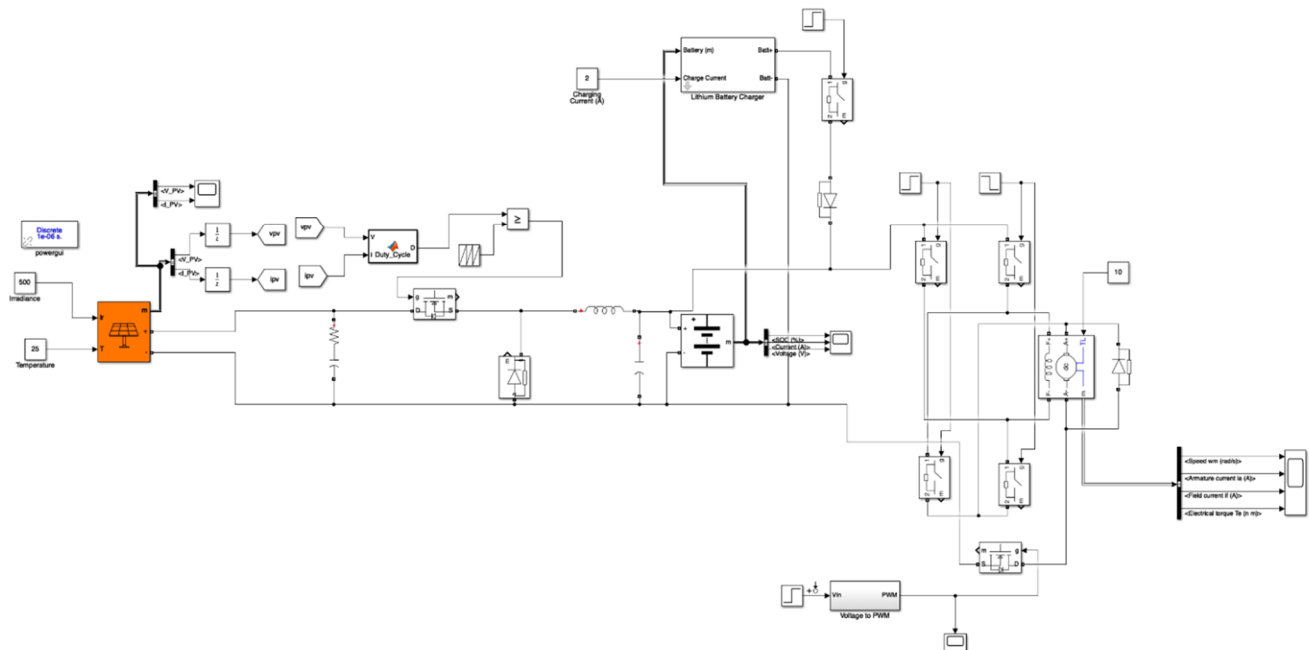

Figure 13: Simulink Model of the proposed micro solar electric vehicle

22, shows DC Machine dynamics under that changing load profile. The electrical torque and armature current of the DC-machine varies accordingly to keep up with the uneven roads.

E. Speed Control

Finally, we are going to observe how our speed control circuit works. In this case, we are running the simulation for 60 seconds, and we have introduced a signal which changes the speed reference every 10 seconds. Figure 23, shows the changing speed reference. Figure 24, shows the dynamic response of the DC-machine to keep up with the changing speed reference.

VI. CONCLUSION

A novel design for a micro solar electric vehicle for application in Pakistan has been presented in this paper. Not only does this micro solar electric vehicle provide the basis for the design of a new class of cars, but it also helps solve almost

all of the problems that are currently slowing the growth of EV market share in Pakistan and other developing countries.

The said micro solar electric vehicle was designed in HOMER Pro, and a system sizing was done. According to this system sizing, the micro solar electric vehicle would require 3, 24V, 150W PV modules (Advance Solar Hydro Wind Power API – 150) to add a range of approximately 30 KMs to the pre-existing battery range of the electric vehicle.

The electric vehicle can also be charged from a 220V AC outlet with the help of the onboard AC-DC charging block, which allows the electric vehicle to charge at extremely low currents, easily supported by the current residential electricity infrastructure in Pakistan.

In addition, a dynamic model of the micro solar electric vehicle was developed to be studied in much more details. The dynamic model focused on three different aspects of the systems i.e. power generation by PV modules that are to be mounted on top of the vehicle, battery charging from PV modules as well as an external AC source, and finally DC-motor operations in forward and reverse mode. Other notable features of the model include a maximum point power tracker and a PWM chopper based speed control circuit.

The dynamic model of the system not only helped us fully understand the working of the system in different modes, conditions and situations, but also helped us understand how the system will react to any variations in the environmental factors such as irradiance and temperature etc.

Abstract— Solar water pumps must be the most optimum size to work efficiently and be at a reasonable price. The storage system can play a main role in both system reliability and the total cost of a solar water pumping project; thus, it should be designed carefully. Traditionally, only batteries or water tanks are used as primary storage system; each of them has its benefits and drawbacks. In this research, a new approach to a storage system is proposed, consisting of both batteries and water tanks at the same time. Such hybrid storage can decrease project cost and increase system reliability. To find the most optimum size for such a hybrid system an optimization algorithm named “Imperialist Competitive Algorithm (ICA)” is used to minimize the Life-Cycle Cost Analysis (LCCA) of the storage system. In this paper, a hybrid storage configuration for solar water pumping for a site in Iran is proposed, and results of the optimum size for that system using ICA are expressed. It is shown that the configuration is more feasible compared with many other configurations.

Keywords— Solar water pump, Energy storage, Hybrid storage system, Optimization, ICA, Life-cycle cost analysis

I. INTRODUCTION

These days, conventional pumping systems are replaced with solar water pumping in remote areas, especially in Middle East countries. The most significant issue with solar-based systems, including solar water pumping, is storage systems, which increase solar projects' cost [1].

In the authors' previous work [1], two configurations of storage systems, battery storage and water tank, were proposed, and the advantages and disadvantages of each system were discussed. It is wise to design a hybrid storage system consisting of batteries and water tanks to take advantage of both systems. In addition, the system's reliability will be increased because in case of failure in either water tank or battery bank, another one can cover partial needed storage.

Apart from what is said, the most motivation to have a hybrid storage system is that if only batteries are used as a storage system, it will be pricy, or if only a water tank is used as a storage system, an amount of produced solar energy will be missed because PV output should reach to a specific power to run the pump in the morning, and when the output power drops below a threshold point, the pump will be stopped. So, the produced

power in the early morning and late afternoon will be missed as shown in figure 1 below.

Figure 1: Nominal output array power for the site in Iran (for June 17th)

Since a hybrid system consists of both battery and water tank, conventional design software like Homer pro or PVSYS cannot be employed. Thus, an optimization method should be employed to calculate the optimum size of battery storage or water tank storage system in this hybrid system. Due to complications of this optimization problem and storage constraints, the “Imperialist Competitive Algorithm (ICA)” is used; this evolutionary algorithm is more efficient and straightforward to implement in comparison with typical optimization methods.

In this paper, first, an overview of hybrid storage systems is given; then, the optimization problem is defined in detail. After expressing the ICA, it is shown how to implement this algorithm to reach an optimum size of hybrid storage for solar water pumping for a site in Iran. In the end, a conclusion of the results of the proposed systems are given.

II. HYBRID STORAGE SYSTEM

The proposed hybrid system consists of a few strings of batteries and a water tank. The batteries can be charged during the early morning and late afternoon, save any excess energy during the day and provide power to the water pump whenever needed. The water tank is used to store excess pumped water and discharge water in case of pump failure or unexpected

water demand. A simple schematic of this hybrid storage system is depicted in figure 2.

Figure 2: Schematic of a water pumping system with a hybrid storage

This system is proposed for a site near Mashhad in northeastern Iran; this site's approximate area is two hectares, which is divided into 20 cherry and apple gardens with shared water well [1]. Currently, they use diesel generators (figure 3) to provide power to the water pump which this research aims to replace it with an affordable and efficient solar water pumping.

Figure 3: Primary diesel generator which is used in this site

III. DEFINE OPTIMIZATION PROBLEM

The advantage of a hybrid storage system is expressed above. The question has still remained what is the most optimum size of the battery bank and what is the best capacity for the water tank to reduce the system cost while meeting the minimum needed back-up for solar water pumping to guarantee the system reliability; clearly, this is an optimization problem. Like any other optimization problem, first, it is necessary to determine the objective function (which can be called cost function because here is a minimization problem) and constraints that might be

linear, nonlinear, equal, or unequal. In the following, the optimization problem is expressed for a hybrid storage system of solar water pumping for the site under study.

A. Cost function

In this research, like some other work such as [2], Life-Cycle Cost Analysis (LCCA) is considered as the cost function:

$$LCCA = C_C + C_{O\&M} + C_R$$

Where:

- C_C =Capital cost
 - $C_{O\&M}$ =Operation and maintenance expenses
 - C_R =Replacement cost during the project lifetime
- *Note 1:* According to Homer pro simulation for this site in Iran, the mean battery depth of discharge is approximately %15. Also, based on the battery manufacturer company, if %15 of battery capacity is used, the battery lifetime will be more than 2000 cycles (figure 4). Since the operation period in this site is about five months per year, there is no need to replace the batteries during the project lifetime, as shown in Homer pro results in figure 5.

Figure 4: Life characteristics of cyclic use for Euronet Gel Battery

The water tanks are last long, and there is no need to replace them during the project lifetime. Thus, the term C_R can be omitted in the LCCA function.

Quantity	Value	Units
Autonomy	68.5	hr
Storage Wear Cost	0.133	\$/kWh
Nominal Capacity	263	kWh
Usable Nominal Capacity	210	kWh
Lifetime Throughput	228,510	kWh
Expected Life	54.7	yr

Figure 5: Results of Homer pro battery analysis

- *Note 2:* the used batteries are gel batteries which unlike the conventional lead-acid batteries, they do not need to charge after each period of use. In addition, the water tanks have no specific operation or maintenance cost. As a result, the term $C_{O\&M}$ is relatively small, so that it can be omitted as well.

For this specific site in Iran, the sum of the capital cost of water tanks and batteries is considered as a cost function:

$$\text{Cost function} = P_B + P_T ; \begin{cases} P_B = \text{Price of batteries} \\ P_T = \text{price of water tanks} \end{cases}$$

B. constraints

The only constraint in this problem is that there should be enough stored energy, whether in the form of chemical energy in batteries or potential energy of stored water in tanks, to ensure the reliability of the solar water pumping system during the operation period on the site in Iran. The best source to find this minimum needed energy is Homer pro simulation because Homer calculation is based on accurate data for the ambient condition on the site in addition to battery specifications. Based on Homer simulation, the minimum stored is calculated:

- 1) Homer suggestion for total size of the battery bank for the site in Iran is 240 KWh
- 2) Just 80% of the battery capacity is allowed to use (min SoC is 20%); also, the efficiency of this battery is 85%; so the minimum needed stored energy is:

$$\begin{aligned} \text{minimum needed stored energy} \\ &= 240 \text{ KWh} \times 0.80 \times 0.85 \\ &= \mathbf{163.2 \text{ KWh}} \end{aligned}$$

It is found that this solar water pumping in Iran needs at-least 163.2 KWh of stored energy. As a result, the constrain for this optimization problem is:

$$((E_B + E_T) - 163.2) \leq \varepsilon$$

Where:

- E_B is the stored energy in batteries
- E_T is the stored energy in water tank
- ε is a small positive number. In this paper, it is considered as five percent of the minimum needed energy to ensure daily water demand is satisfied.

$$\varepsilon = 163.2 \times 0.05$$

The following procedure is taken to calculate the stored potential energy in the battery and water tanks:

Stored energy in battery: To calculate the total stored energy in batteries, simply can multiply number of used batteries to the ampere-hour of each battery times voltage of each battery:

$$E_B (\text{Wh}) = \# \text{ of batteries} \times 100 \text{ Ah} \times 12 \text{ V}$$

Stored energy in water tank: The potential stored energy in water tank can be obtained based on injected water into the tank by water pump. To do so, first, divide tank capacity by rated water flow to see how many hours it takes to fill this water tank; then, multiply the water pump's nominal power to calculate hours to obtain the energy consumed by pump to pump sufficient water to the tank. This energy is called the *stored capacity* of the tank [3]:

$$E_T (\text{KWh}) = \text{Tank capacity} (\text{m}^3) \div 27 (\text{m}^3/\text{h}) \times 22 (\text{KW})$$

IV. IMPERIALIST COMPETITIVE ALGORITHM (ICA)

Imperialist Competitive Algorithm (ICA) is an evolutionary algorithm which is proposed by Esmail Atashpaz-Gargari in the year 2007 [4]. This optimization algorithm is inspired by imperialist competition on their properties. This algorithm starts with a random initial point called "country"; countries are divided into two groups, imperialists and colonies which each colony belongs to an imperialist. During the run of this algorithm, imperialists start a competition with other imperialists to take power over more colonies. In the end, the most powerful imperialists take control over all countries and converge them to an optimum global point. In this section, an overview of ICA is expressed, and flowchart of this algorithm is shown in figure 6.

A. Initialization

In the beginning, the algorithm generates Npop (number of total countries in the world) random initial countries which each country is defined as a $1 \times Nvar$ array where Nvar is the number of variables of intended optimization problem; each element of this array represent a property of that country like race, language, and so on [4].

$$\text{country} = [P_{\text{race}}, P_{\text{language}}, \dots, P_{Nvar}]$$

The algorithm calculates the power of each country by evaluating the objective function and then ranks the countries according to their power (a country with higher fitness is more powerful).

$$\begin{aligned} \text{fitness} &= \text{objective function}(\text{country}) \\ &= f(P_{\text{race}}, P_{\text{language}}, \dots, P_{Nvar}) \end{aligned}$$

Then Nimp (number of imperialists) of most powerful countries are selected as imperialists and the rest of the population (Ncol) as colonies. Afterward, all colonies are divided among imperialists such that an imperialist with a higher power must have more chances to get more colonies[4].

$$N_{\text{col}} = N_{\text{pop}} - N_{\text{imp}}$$

In this research, to divide colonies among imperialists, the Roulette Wheel selection is used; casinos' roulette inspires this method. This wheel is like a pie divided into different partitions, representing the normalized power of an imperialist.

$$\begin{aligned} \text{Normalized power of imperialist } k^{\text{th}} \\ &= 1 - \frac{\text{Cost}(\text{imperialist } k^{\text{th}})}{\sum_{i=1}^{N_{\text{imp}}} \text{Cost}(\text{imperialist } i^{\text{th}})} \end{aligned}$$

A random number between 0 and 100% is generated to select an imperialist and allocate a colony to that imperialist. In this way, an imperialist with a higher power has a higher chance to be selected; as a result, an imperialist with a higher power has more colonies. Figure 7 is an example that shows the second imperialist is the most powerful imperialist; as a result, it has the most share in nominalized probability.

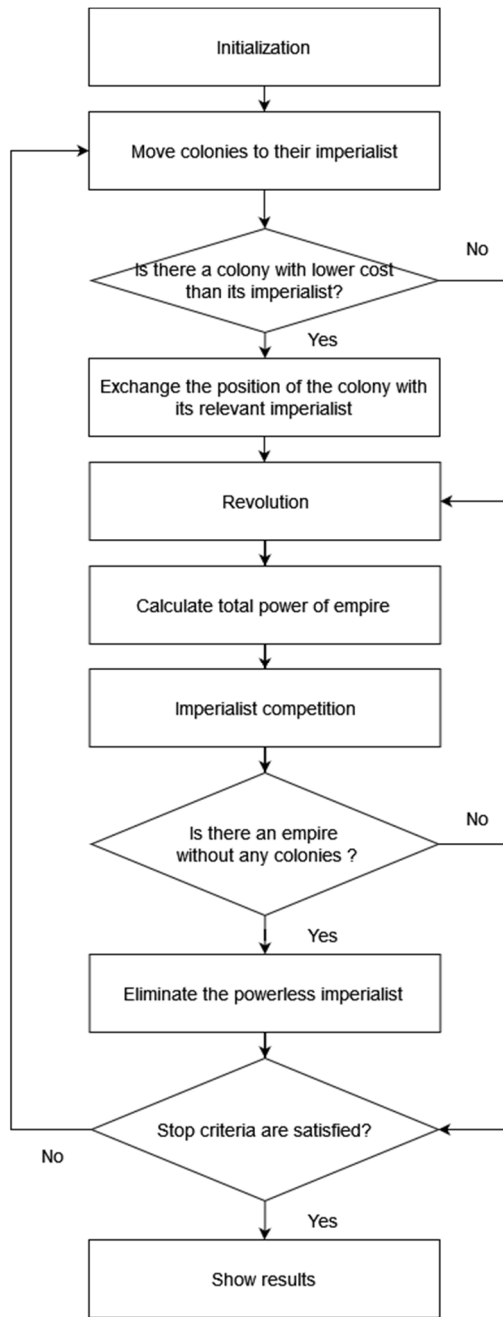

Figure 6: ICA flowchart

B. Colonies moving toward their imperialist

Imperialists try to make their empire more powerful by moving their colonies toward themselves; in this way the total power of the empire will rise, so the chance of winning that imperialist in the competition will be increased, which will result in empire expansion.

To move a colony toward its imperialist the following function is defined:

$$x = \beta \times rand \times d ;$$

- $\beta =$ moving coefficient
- $d =$ distance between imperialist k^{th} and colony h^{th}

$$new\ position\ of\ colony\ h^{th} = old\ position\ of\ colony\ h^{th} + x$$

Figure 7: The nominalized probability of imperialists

C. Exchange the position of a colony with its relevant imperialist

After a colony moves toward its imperialist, it may find a better location in the search area with higher fitness than the imperialist; in this scenario, the position of the imperialist and that colony will be switched [5].

D. Total power of an empire calculation

The total power of an empire is defined as the sum of the power of the imperialist of the empire and a coefficient of the mean power of all colonies of the empire[4]:

$$\begin{aligned}
 Total\ Power\ of\ Empire\ k^{th} &= power\ imperialist\ k^{th} + \zeta \\
 &\times \left(\frac{\sum_{i=1}^{N_{col}} Fitness(colony\ i^{th})}{N_{col}} \right)
 \end{aligned}$$

ζ is a constant coefficient ($0 < \zeta < 1$) that determines the share of colonies' power in the empire's total power. Small zeta means imperialist power has the most effect on total power and large zeta means the effect of colonies' power is considered.

E. Imperialist competition

As is clear from the name of this algorithm, this step of the algorithm is the most important step. In the competition among imperialists, they try to take control over more colonies in other empires to increase their empire power. During this competition, the weakest empire has the most likelihood of losing colonies and the most powerful empire has more chance of owning more colonies.

In this algorithm, the weakest colony in the weakest empire is picked. It is given to the selected empire using the roulette wheel, which means that an empire with the most total power has more probability of owning the weakest colony [4].

F. Eliminating the powerless imperialist

During the run of the algorithm and after a couple of loops, an imperialist might lose all of its colonies; in this case, the relevant empire will be collapsed, then imperialist will be considered a colony and it will be assigned to one of the rest empires with roulette wheel selection [4].

G. Stop criteria

Stop criteria can be defined in different ways depending on the nature of the optimization problem. In this research, reaching a specific number of algorithm loop (generation) is considered a stop criterion.

V. IMPLEMENTATION OF ICA FOR OPTIMUM SIZE OF HYBRID STORAGE FOR SOLAR WATER PUMPING IN IRAN

In this section, the properties of used ICA are presented, and the result of optimum sizing is expressed.

A. ICA initial parameters

The ICA algorithm for this research is programmed and run in MATLAB R2021a. The initial parameter of used ICA is mentioned in the following table:

Table 1: The initial parameter of employed ICA in this research study

Parameter	Value	Note
Number of countries' property	2	There are two variables: battery and water tank
Number of countries	30	
Number of Imperialists	5	
Lower and Upper Bound of Battery Value	[0 200]	# of batteries
Lower and Upper Bound of water tank Value	[0 200]	In m3
Moving coefficient (β)	2	
Weight of mean cost of Colonies (ζ)	0.1	
Maximum number of iterations	10000	
Percent of Revolution	0.2	
probability of revolution operation	0.2	
probability of revolution on each colony	0.4	

The initial population is generated uniformly randomly.

B. Search area

In this research, a lookup table consisting of prices of batteries and water tanks in different capacities is given to the algorithm as input; the algorithm performs a linear interpolation method to build a continuous search area.

C. Cost function and constrain

The cost function in this research is the summation of the price of batteries and water tanks:

$$Cost = price\ of\ batteries + price\ of\ water\ tanks$$

A penalty function is defined in order to apply the constraint:

$$if \left[\left(\frac{stored\ energy}{in\ water\ tanks} + \frac{stored\ energy}{in\ batteries} \right) - \frac{min\ needed}{stored\ energy} \right] \geq \frac{min\ needed}{stored\ energy} \times 0.05$$

then

$$Cost = (price\ of\ batteries + price\ of\ water\ tanks) + penalty$$

According to section III, the minimum needed stored energy for the under-study site in Iran is 163.2 KWh. Also, the penalty should be a large number, in this research, it is CA\$9,000,000.

D. Revolution

This auxiliary operation for ICA mimics the mutation operation in the Genetic Algorithm (GA)[6], [7]. This operation takes one colony and moves that randomly in the searching area. Revolution might slow down the algorithm, but it ensures that the ICA will not be stuck in the local optimum.

E. Results

The algorithm suggestion for optimum size of storage system for this specific solar water pumping system in Iran is as follows:

Table 2: the output results of ICA

storage	Value
Number of batteries	40
Water tank (m ³)	140

Figure 8 illustrates how the best country in the world improved during the algorithm's run; at first, the algorithm found a system size with a cost of more than CA\$28,000, and after a couple of loops, it tried to optimize the size of hybrid storage. This improvement happened step by step during the algorithm run, and after the loop 1000, the algorithm reached a steady-state, which means that the most optimum size of the hybrid storage system is found.

Figure 8: The cost of best imperialist during the run of algorithm

The following calculation can be done to show that the found size of the system can satisfy the constraint:

$$V_{Bus} = 12V \times 10 = 120V$$

Ah of each string is 100 Ah, so total bank Ah= 4×100= 400

Energy in batteries (Wh) = 400×120= 48000= 48 KWh

Energy in batteries (consider energy lost and depth of charge) = 48×0.8×0.85= 32.64 KWh

With 40 batteries, the pump with 22KW power can run for about 1.5 hours (32.64 /22).

This pump can pump about 40.5 m³ of water (1.5hr × 27(m³/hr)).

Also, there is a tank with 140 m³ of water storage.

As a result, this system has 180.5 m³(40.5+140) water storage This site in Iran needs about 180 m³ (188.6 ± 5%) of water as a back-up for one day. So, this system satisfies the water requirement as back-up for this site in Iran.

To justify the output result of ICA, the following table is prepared with a couple of battery and water tank combinations. As can be seen in table 3, if battery is used more, the total cost is high, as the number of batteries decreases and the capacity of water tank increases, the total cost starts to drop. At the minimum point it reaches to lowest cost and after that the cost start to increase. As a result, the optimum size for this specific site in Iran is supposed to be around this point that the ICA found it correctly.

Table 3: Some feasible size of the hybrid storage system

# of batteries	Water tank capacity (m ³)	Total Price (CA\$)
130	9	26562
120	24	25509
110	39	24483
100	55	23757
90	68	22760
80	82	21860
70	97	21366
60	112	20699
50	128	20448
40	140	20041
40	141	20342
40	142	20644
40	143	20945
30	156	22862
30	158	23464
20	170	24905
20	171	25188
10	184	26540
10	185	26740

F. Comprasion

As expressed in table 4, using a hybrid storage system with 40 batteries (each battery 100 Ah) and a 140 m³ water tank, the total cost is approximately CA\$20,000, which is cheaper than the two other configurations.

Table 4: comparison of storage methods

Storage type	capacity	Cost (CA\$)
batteries (Number of 100 Ah battery)	200	40,000
Water tank (m ³)	180	23,800
Hybrid	Batteries: 40 × 100Ah and Water tank: 140 m ³	20,041

Although the difference between hybrid storage and only water tank storage is not significant, the hybrid system boosts system reliability and can provide sufficient water during the hours of operation.

VI. CONCLUSION

In this paper, a hybrid storage system is proposed for a site in Iran. It is discussed that a hybrid storage system can take advantage of both battery and water tank at the same time, resulting in lower cost and higher system availability.

Also, ICA is employed to find an optimum size of the system. It not only guarantees the minimum needed storage, but also reduces the cost of the storage system. The algorithm suggests a hybrid storage system consisting of 40 batteries and 140 m³ water tank; this is the cheapest configuration for the site in Iran, which can satisfy the minimum needed storage.

This research shows that a hybrid storage system can be more economical in comparison to conventional configurations for storage systems in solar water pumping.

ACKNOWLEDGMENT

The authors kindly thank Roshana Gostar Shargh Barsava for providing funding for this research.

Abstract— A camera is a tool to record visual footage in the form of photographs, film or in video format. However, a smart camera can be recognized as a device to retrieve application-specific information from the recorded footage. In this paper, we have proposed a solution to detect parking lot occupancy status using deep learning model and commercially used CCTV cameras in real time. Our implemented solution is decentralized and efficient in terms of light-weight deployment to low powered devices like Raspberry Pi. Our proposed solution is compared with the existing approaches. Our deep learning model is also tested on other datasets having images taking from multiple CCTV camera implemented in different height. Along with this, we have tested our model on indoor both outdoor parking garages in low light conditions during day and evening. Result of the performed experiments shows that our model is operable in low-powered embedded devices with effective accuracy.

Keywords — Deep Learning, Machine Learning, Convolutional Neural Networks, Classification, Embedded Device

I. INTRODUCTION

Automated parking lot occupancy status detection in real time is important for managing parking lots effectively. This should be also scalable and able to reduce the time to find the parking lot occupancy status in real-time. Traditionally sensors are installed in every parking spot to detect if an individual spot is being occupied or not. The main drawback of this approach is the maintenance cost, although the detection accuracy is higher providing that the installed hardware is in working order. In addition to that, this approach needs additional cost at the hardware installation phase, and regular maintenance is required for the system up and running in normal and extreme weather conditions specially in rainy and winter season. For additional parking spot in a given parking space new hardware needs to be installed. In this scenario, the total cost of the system piled up exponentially as the number additional of parking spot is added to the system.

In recent years, there are many applications which are developed to serve the purpose to detect parking spots in a parking space at comparatively low cost and maintenance. Our proposed approach is using a decentralized system where no central server will not be used to perform computational tasks for detecting if a parking spot is occupied or not considering different lighting conditions and obstacle presence like shadow, human interference etc. We have designed our model on Deep CNN (Convolutional Neural Network). [1][2] However, the used CNN model needs to be modified in such a way so that it runs fast enough on low

powered devices like Raspberry PI. This decentralize approach solves the computational bottleneck that is normally faced in centralized systems and ensure better scalability with respect to the cost of installation and maintenance, because to add a new parking lot to the system, we need not to install additional sensors. A single camera can monitor multiple parking locations.

However, the problem to detect multiple parking spot occupancy status using video footage is not new. Several researches have been performed in this regard. The authors in [3] [4] [5], detected occupancy status using only visual information like using only image or video footage is done with case-specific contexts and scenarios. This means that model is being trained with the specific parking space context-based data. These approaches can not easily be generalized to parking lots in other parking spaces.

To make our application more generic and robust deep CNN is used for our approach. Our solution provides better accuracy in presence of shadows, other kind of obstacles and human presence. With this model training phase is less expensive in terms of using computational resources than the classification steps. For this reason, this model can be handled using low powered and embedded devices. In addition to that, this model performs even better if few context-specific training data related to the specific parking lots are provided along with generic training data. To validate the robustness of our deep CNN model in other approaches, we have used two additional parking spaces datasets. One is CNRPark-Ext, another one is PKLot [5]

These two datasets contain the images from two different and independent parking spaces, and images from different viewpoints, weather conditions and presence of obstacles. These conditions are considered as the presence of these conditions makes the detection task of the parking lot occupancy more challenging. These datasets are annotated manually. More of the datasets are discussed in Section 4. In addition to that, we trained the model on one scenario and test the model on different scenario, and then compare the results found in different approaches to find how our model performs in generalized conditions.

II. RELATED WORK

In the very first attempts to detect occupancy status one paper takes help of SVM(Support Vector Machine) classifier to separate the occupied spot from the unoccupied spot in a

parking space. In summary, this classifier just differentiates the car regions with the parking space region to detect the occupancy status [6]. This approach has lower accuracy in presence of shadow, different light and weather conditions. Later [3] another approach was made to overcome the low accuracy due to the presence of various kinds of obstacle by considering the three neighboring parking lots. The state and color histogram of the neighboring parking lots are considered as the feature in SVM classifier. In this method, situations like changes of light were not addressed properly causing lower accuracy.

Another study was conducted to address the light change [7]. The authors trained a classifier based on Bayesian to detect the occupancy status. Corners, edges and wavelet are considered as features for the classifier. Another study used Bayesian hierarchical framework to detect empty spot based on three-dimensions of the given parking space that operates day and night. Similar method was followed in another study [8] that models available parking spots as a single pack in the three-dimensional space. This model can provide higher accuracy comparatively than previous approaches addressing obstacles like light changes. Another study [9] is conducted that used customized trained neural network model that can detect occupies or not occupied based on extracted visual feature from specific parking space. For this study, 126 parking spots in a single parking space in considered. This method provides robust result than other models in considering the lighting condition.

Recently another study is conducted that addresses this problem is machine learning approaches. This study uses around 700,000 images taken using three different cameras. These images are used to train the SVM classifiers where multiple texture features are considered. Although they have used similar kind of classifier but this study provides better accuracy in terms of detection performance as then used simple aggregation function either max or min to the confidence values.

There are also other studies found based on temporal analysis of video frame. This study [4] uses this method by subtracting background with Gaussians to detect the vehicles that are parked or that are being leaving. Another study [10] focused in considering obstacles considering that many parking spaces can be hidden by another vehicle that is parked in neighboring parking lot. In this study tracking is performed considering two events: vehicles that are leaving and entering in parking lot. There are also other approaches that consider both features extracted from footage and sensors. This study [11] proposed an approach to detect parking lot occupancy status with the help of vehicle navigation system. Another study [12] proposed a solution that collects real-time occupancy status based on smartphone sensors.

In recent time this study [13] addresses our problem by using deep CNN to build generic model to detect open parking spaces. Our study is the extended version of their study to build a generic model that can detect occupancy status of a

parking lot in indoor parking spaces where obstacle in term of shadow and absence of daylight is comparatively higher.

III. DATASETS

1. *PkLot*

PKLot dataset consists of around 700,00 images of parking lots. Images are organized by the weather condition and the date of capture. Only sunny, cloudy and rainy weather conditioned in considered. PKLot dataset is comparatively larger than both CNRPark and CNRPark_EXT.

2. *CNRPark-Ext*

CNRPark-Ext is the extended version of CNRPark [14] which is a small dataset compare to CNRPark-Ext consists of around 12,000 labeled images. Images of CNRPark is captured in different situations of light including considering different kind of obstacle like shadow, human presence and trees. CNRPark_EXT dataset contains the images collected using nine cameras. The images are taken considering different perspective and angle of views. Different light conditions and the including obstacles like tree, human interference, shadow, presence of other cars in neighboring parking spaces are also being considered while selecting images for this database. This dataset also contains the images partially shadowed vehicles. This kind of dataset trains our model to perform with better accuracy as this is the real scenario in most of the cases. All of these three datasets images are being cropped with the help of masks to smaller one. Each smaller images contains only single parking lot. Those smaller images are referred as patches. The resolution of these patches is 150px*150px. Each patch is labeled as 0 if the parking spot is not occupying and 1 if it is occupied. Finally Patches of these datasets are groups together into subsets based on weather condition, camera ID, image taken date. We have trained our model on these different subsets to justify which one provides better accuracy.

CNRPark and CNRPark_EXT both datasets cover the real-life scenarios more accurately other than PKLot. So, it is expected that CNRPark will train the datasets for real-life scenarios with better accuracy in testing period.

3. *Indoor and Outdoor*

We have collected 60 minutes footage of both indoor and outdoor parking spots. Those footage are being recorded using commonly used CCTV cameras in apartments. The resolution of the captured footage is 1280px*720px at 30fps. After each 5 seconds or 150frames, each image is being extracted for testing purpose. Both footage for indoor and outdoor is captured using single camera covering three parking slots. We built masks that allow cropping the full pictures into smaller ones. Each smaller one contains single parking spaces. These smaller images are labeled for validation purpose. Scenario of our testing dataset matches with the used training dataset CNRPark and CNRPark_EXT.

In terms of obstacle presence both test datasets are matched with the extreme scenarios. For Indoor dataset (Figure 01) have higher obstacle presence in terms of presence of shadow, comparatively low presence of day light or artificial source of light. For outdoor dataset, due to high amount of camera view, the adjacent vehicle occupies a small portion of neighboring parking spaces. In both cases, detection occupancy status is quite challenging.

Fig 01: Overview of PkLot and CNRPark-EXT

Fig 02: Overview of Indoor and Outdoor Datasets.

Fig 03: Overview of Segmented Images from datasets.

IV. METHODS AND APPROACH

In order to enable the model to track down the occupancy status of slots in a given parking space, we need to follow following steps. However, before deploying the model to the embedded Raspberry PI, we need to pretrain the model. Based on the pretrain model segmented images will be classified.

Fig 04: Work Flow of the System

1. Capture Image from Footage

The method to capture image from the video footage in every 5 seconds. In this process, image extraction depends on the frame rate of fps of the CCTV camera. Our tested CCTV camera delivers footage at 25fps. For this reason, we extract each image after closely 125frames. This Image extraction process can be changed based on the camera configuration. Each Image is extracted automatically for the next step to be segmented, and resized.

Fig 04: Extracted Image from CCTV after each ~ 5 seconds.

2. Define ROI and Prepare Patches

The captured images are filtered by Mask. The Mask identifies each and every parking spots in the given space. For our application, mask is implemented in case specific manner. This means that for every new parking space this Mask is needed to be redefined according the image resolution and location of the parking lot in the parking space.

For example, in Figure 4 the given parking space has three parking spots. The mask will segment the images into 3 parts. These segmented images are marked as patches.

Fig 05: Segmented Patches from the Image by Mask.

3. Prepare Patches for Input to Model

Our CNN Model take 224*224 RGB image as input for performing classification. In this stage we resize the image into the following format and prepare for the next step which is to feed the resized images to the pre-trained model for making a decision.

Fig 06: Resized image to 224*224.

4. Deep Convolutional Neural Networks (CNN)

We have tested deep CNN architectures. One is mini-AlexNet and another one is miniLetNet. Those are reported in [15] [16] These architectures have higher accuracy rate in extracting features using visual recognition. Both mini-AlexNet and mini-LetNet have five trainable layers. Lower number of layers ensures feasible computational capability in real-time, also ensures to be runnable on low powered embedded devices. This architecture is inspired from AlexNet. AlexNet is a large CNN architecture to decide multiple decisions. As we need to decide binary decisions, the architecture is reduced to be run on real-time. AlexNet is trained on million datasets and task was to recognize 1000 different classes.

Both mini-AlexNet and mini-LetNet takes an image of 224*224 as input. We have prepared the segmented patches for input in previous step.

Mini – LetNet has total four layers including the output layer. Out of these four layers first two are Convolutional layer. These two convolutional layers is followed by two fully connected layers including a max-pooling layer. The first layer is similar to the layer of AlexNet [15]. Thus, it is suitable for the resized segmented images in previous step. Number of neurons in last convolutional layer and last fully connected layer is reduced to meet the classification dimension for detecting two classes. Reduced number of neurons and filters does not overfit in the testing phase. In this study [16] Gaussian Radial Bias Function is used in the last layer. For mini-LetNet this is replaced by 2-way SoftMax classifier.

Mini-AlexNet CNN architecture that is defined for classifying the occupancy status for a parking spot is inspired from the AlexNet[7]. Five trainable layers are used in this architecture, among them three layers convolutional layer. Last two layer are fully connected layer. Two fully connected layer are followed the convolutional layers, and the fully connected layer is considered as the output layer. First and second convolutional layer is followed by *max – pooling* and *local rectification* (ReLU). Third and last convolutional layer follows the same architecture. Only first two convolutional layer implement *local normalization* (LRN).

The final architecture of miniAlexNet with reduced number of neuron and filter have roughly $\frac{1}{1340}$ parameters than AlexNet[7]. In the last two fully connected layer, drop out regularization method is followed. Same as mini LetNet, mini AlexNet takes 224*224 RGB image as input for classification.

In the training phase, for data augmentation purpose *random – crop* and *horizontal – flip* technique is followed. Each horizontally image is assigned with the probability of 0.5.

However, in training phase, no horizontal flipping is applied. Only resized images 224 * 224 are feed for the input to the architecture.

$$size\ of\ the\ filter = number * width * height + stride$$

$$Max - pooling = width * height + stride$$

Net	Conv 1	Conv 2	Conv 3	Fc – 4	Fc – 5
miniL Net	30 * 11 * 11 + 4 pool 5 * 5 + 5	20 * 5 * 5 + 1 pool 2 * 2 + 2	-	100 ReLU	2 Soft – max
miniA Net	16 * 11 * 11 + 4 pool 3 * 3 + 5 LRN, ReLU	20 * 5 * 5 + 1 pool 3 * 3 + 2 LRN, ReLU	30 * 3 * 3 + 1 pool 3 * 3 + 2 ReLU	48 ReLU	2 Soft – max

Table 01: CNN Architectures

Both mini – AlexNet and mini – LetNet architecture has densely connected convolutional layer. Details of the layers are represented in the above table.

V. EVALUATION

To assess the performance of proposed CNN based on existing architecture, *miniAlexnet* and *miniLetNet*, we considered two cases:

- i. Train and Test CNN model on same dataset
- ii. Compare accuracy with existing approaches and datasets

1. Train and Test CNN model on Same Dataset

Both Indoor and Outdoor dataset contains the images taken from one camera. For both datasets images are in roughly 50%~50% split. All patches are horizontally flipped and resized to 256*256 pixels. Each image is classified independently. No previous model is used for testing purpose. Each time for every dataset the model is trained again. Overfitting of the model will be limited as training and testing dataset is different and there exist sufficient amount of data for the training purpose.

Datasets	Unoccupied Slots	Occupied Slots	Total
Indoor Garage	310	230	540
Outdoor Garage	312	246	558

Table 2: Details of datasets used for training and testing purpose in (i)

We trained and tested our model on multiple splits to limit the problems of overfitting. The model is trained on Split A and tested on Split and vice versa.

Datasets	Unoccupied Slots	Occupied Slots	Total
Indoor Split A	150	110	260
Indoor Split B	160	120	280
Outdoor Split A	160	120	280
Outdoor Split B	152	126	278

Table 3: Splits of datasets used for training and testing purpose in (i)

Train Dataset	Test Dataset	Model	Base Learning Rate	Accuracy
Indoor Split A	Indoor Split B	miniAlexNet	0.01	0.861
Indoor Split B	Indoor Split A	miniAlexNet	0.01	0.833
Outdoor Split A	Outdoor Split B	miniAlexNet	0.01	0.905
Outdoor Split B	Outdoor Split A	miniAlexNet	0.01	0.911

Table 4: Accuracy in different splits for miniAlexNet

Train Dataset	Test Dataset	Model	Base Learning Rate	Accuracy
Indoor Split A	Indoor Split B	miniLetNet	0.001	0.845
Indoor Split B	Indoor Split A	miniLetNet	0.001	0.822
Outdoor Split A	Outdoor Split B	miniLetNet	0.001	0.897
Outdoor Split B	Outdoor Split A	miniLetNet	0.001	0.874

Table 5: Accuracy in different splits for miniLetNet

Fig 06: Representation of accuracy for various splits

2. Compare Accuracy with Other Approaches

To compare the accuracy among other approaches we have followed the techniques discussed in this paper [5]. The discussed classification techniques on this paper are based on SVM trained on textural of features. A study [17] [18] used LBP and their variations to detect occupancy status like taking

binary decisions. Our model is compared with various variations of LBP used in study [19]. In this experiment, we also CNRPark, PkLot, indoor and outdoor datasets.

CNRPark is divided into two partitions named as CNRPark-Even and CNR-Park. CNRPark-Even consists of even number of parking lots and CNRPark-ODD consists of odd number of parking lots. PkLot is divided into two subsets named as PkLot2days and PkLotNot2Days. Indoor and Outdoor datasets are in two split A and B like in previous experiment. To compare mAlexNet with study [4], extracted features of LBP-type ranges *radius* 1~8. SVMs in this study is trained using *grid – search* and cross validation on training set. With selected parameters SVM is then trained on entire training dataset. The final probabilistic output of the SVM is obtained with the help of posterior probability using sigmoid function. These same steps are followed in this study [4].

Method	Variation	Input dimension	Description
mAlexNet	-	224	224*224 resolution of inputted patch
SVM	LBP	256	Classical LBP [12]
SVM	LBPu	59	Uniform LBP [12]
SVM	LBPuri	10	Uniform and Rational invariant LBP [12]

Table 6: Accuracy in different splits for miniAlexNet

Dataset	Unoccupied	Occupied	Sub-Total
CNRPark A	2549	3622	6171
CNRPark B	1632	4781	6413
CNRPark	4181	8403	12584

VI. CONCLUSION

We have presented a model for make a decision of occupancy status in parking lots of a parking space. Our model is based on deep Neural Network. As we need to only take binary decision either occupied and not occupied, our CNN architecture is robust enough to take decision on real time on embedded device.

In our study we have tested our CNN architecture on different scenarios to test the generalizability to justify how this system will perform if specific parking space related data is not provided in the training phase. To justify this, we considered both of the splits Indoor and Outdoor as training data, and test the model on our test dataset Indoor and Outdoor. Indoor and outdoor data are divided roughly 50%~50% split. In every case, the accuracy is equal and above of 80%. However, for dataset Outdoor, the accuracy is higher than Indoor as Indoor Dataset consists of segmented images

covers obstacles like light lamp, human interference, shadow, variation of light, adjacent vehicle presence, where Outdoor dataset does not address light changes. These scenarios are close to real-life scenarios.

We also tested our model with other approaches based on SVM. In those cases, our proposed CNN model performed higher accuracy than other models based on SVM. For Intra database experiment (Table 08), highest accuracy of mAlexNet is ~96%, and the lowest accuracy is ~86%, where for SVM based approaches, highest accuracy is ~92% and lowest accuracy is ~78%. This can be concluded that on generalized approaches where park space specific training data will be absent, mAlexNet based on CNN architecture will also perform better than other approaches like SVM and their variations.

This research can be extended to implement ANPD (Automatic Number Plate Detection) system. Implementing a system to detect vehicle number plate, we can more accurately pinpoint which vehicles are staying or leaving. Furthermore, this can be implemented for commercial use to replace centralized parking spots. However, this is quite challenging to perform OCR (Optical Character Recognition) on noisy and low resolution images.

Abstract—Although Bangladesh has a total of 19 solar power projects of total 1070 MW capacity which generate 10 percent electricity from renewable energy source by 2020, PV technology is still not widely used in many parts of the country. This research focuses on using simulation tools to build and estimate the efficiency of a solar PV system for self-consumption at a region with a high solar potential that is currently underutilized. To learn more about the field and the grid local regulations in Bangladesh, a thorough review of photovoltaic search was reviewed. After that, this research supports in order to choose the best area for the installation. After that, a load profile is constructed to determine the energy consumption of the specific location, and ultimately, the technology to be implemented is chosen and characterized. An AutoCAD 3D modeling of the worksite and supporting components is put into a simulation software Pvsyst version 7.2 based on a particular premise. This enables the development of the PV scheme, the determination of the most appropriate values for the system's characteristics (tilt angle, azimuth, and row spacing), and the advancement of a shading and loss study. Finally, an economic analysis is conducted. The study finds the service to be efficient, cost-effective, and useful, as well as providing a design reference for solar PV self-consumption systems.

Keywords— Pvsyst, Solar PV panel, Inverter, Azimuth angle

I. INTRODUCTION

Energy is a crucial component of human growth. The world's population is expected to increase to more than 11.2 billion by the end of the century and world energy consumption should increase by approximately 1.7 billion tons of oil equivalent per year by 2025. This means that maintaining an oil energy share of around 33% (2015 levels) would require increasing current oil production by more than 11 million barrels per day [1]. However, fossil resources are not only limited, but they also produce greenhouse gas emissions that contribute to climate change, which can have destructive consequences for the ecosystem. The most abundant source of energy that comes straight from the Sun is solar energy. According to NASA calculations, the Sun still has 6500 million years of life left and, every hour, it throws onto Earth more of the energy necessary to supply the global demand of a whole year [2]. Solar photovoltaic (PV) panels use the photovoltaic effect to convert solar energy into electrical energy.

The advantages of photovoltaic energy is given below

- Solar energy is 100 percent renewable and will continue to radiate the earth for millions of years.
- It is environmentally friendly because it produces no greenhouse emissions or other pollutants.
- It may be utilized anywhere on the planet, reaching areas where power lines do not reach.
- Maintenance is inexpensive and straightforward, and there is no noise pollution.

The disadvantages of photovoltaic energy is given below

- Requires a high initial investment.
- Sufficient area is required for installation.
- The solar panels' efficiency is bounded.

This research considered some specific goals, such as:

- a. More efficient PV modules with cutting-edge technologies used in design consideration
- b. Reduced dependency on power utility and produce power from renewable sources
- c. Proposed system is designed with consideration of load profile analysis. So, that it can reduce purchase energy from the grid
- d. PV technology uses contribute in reducing pollution and emission to the environment
- e. capex/opex model analysis of PV system
- f. Implement simulation tools to optimized PV system design which reduce cost

Research work is divided into the following steps:

1. Design/Calculations Phase: Theoretical basic concepts considering legislation, regulations & grid-code
2. Development Phase: Data analyzed; load profile analyzed
3. Chosen Technology: Type of modules, voltage sizing, minimum and maximum number of panels per string, number of modules and inverters
4. Simulation with specialized software

II. RELATED WORKS

Very few works have been done related to this field in Bangladesh. Among them Kaptai 7.4 KWP (6.63 MW AC) grid connected solar PV power plant is the challenging one. Over 3 million house hold are now covering by solar PV system which is 8 to 20 watt per day. There some grid based project are under implementation such as Dharala 30MW and Panchagar 10 MW(IPP) which will cover the rural area’s daily need. There is another undergoing implementation project which is Rangunia’s 60 MW solar park [3].

In Bangladesh, 147 billion KW/S of solar electricity is required, which is well beyond our current projects. The Bangladesh Power Development Board (BPDB) has approved a 50 MW (AC) Solar Park by the HETAT-DITROLIC-IFDC Solar Consortium, which will cover the country's Mymensingh division. Electricity Generation Company of Bangladesh Ltd. (EGCB) is building a 50 MW solar power plant in Sonagazi, Chittagong [4].

Evacuation of power to grid will increase because of the short distance, load flows, short circuit, stability and harmonic distraction will decrease the loss of the main grid. Energon Technologies FZE and China Sunergy Co.Ltd (ESUN) are developing a 100 MW (AC) solar park, which will be sponsored by the Chinese government. The purpose of this project is to be aware of the grid voltage level and to re-project the desired capacity. These two projects, 3.28 MWs at Sharisabari Jamalpur and 25 MWk at Teknaf, are the most dependable and long-term projects [5]. Those projects necessitated the hiring of EPC contactor experts, the majority of whom came from the EU.

Another disadvantage of our geographical location is the fact that we are in the middle of nowhere. Global horizontal irradiance (GHI) is 6 KWH/M/day on average. The PPA of a 2x120 Mw peaking power plant in Siddirgonj solved this problem and used less land to achieve the best results. Among all of this labor, each power grid employs different strategies, but the unifying thread is that they are all attempting to keep their losses below 8%, which is a significant amount for every grid. The 109.77 MWp (82.5 MW AC) Solar Photovoltaic Grid Connected Power Plant at Sonagazi, Feni is now under construction. The project's goal is to reduce grid loss to 4.7 percent, which is the lowest in the field. Rather, more projects of this nature are swiftly being built in Germany and Denmark, with 346 GWh under development and another 525 GWh set to come online in 2023 [6].

III. CIRCUIT DIAGRAM AND PV POWER VARIES

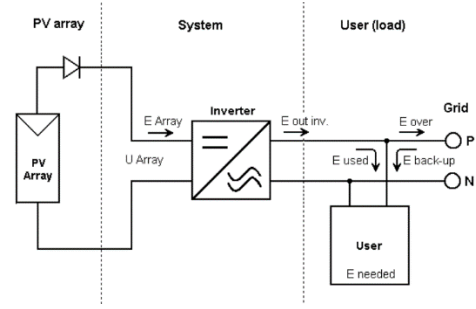

Fig. 1. Components of the System

A typical circuit diagram of PV system is given in Figure 1. In the PV installation, whenever there is an excess of energy production not used for the self- consumption needs of the household, that energy surplus will be injected into the grid. Otherwise, when there is not enough energy to cover the demand of the user, such as during night time, the energy consumed by the load will be extracted from the grid as back-up energy. For now, no storage system is going to be implemented in the first simulations. Thus, with all this explained, several simulation scenarios can be defined. To start, the inter-row spacing or pitch distance is going to be compared in different layouts to minimize the shadings. From the minimum distance calculated in section 9.2.4, with a value of 2,31m rounded to 2,3m a first scenario (Scenario A) will be built with the 35o tilt and a 0o azimuth orientation. That layout will allow the installation of 30 panels in the building rooftop in a configuration of up to 4 panels per string and 8 strings. It is represented in Section IV.

Then, the pitch distance will be increased to 3 m and to 3,3 m (Scenarios B and C), without modifying the tilt nor azimuth angles. The loss percentage is going to be evaluated at this point. Nonetheless, the number of PV modules is subsequently going to decrease as the pitch distance rises, so a whole assessment is required to find a balance point between losses and energy production. Once the best pitch distance is chosen, regarding as well the number of PV modules that fit into the rooftop, a change in tilt will be performed in the next simulation (Scenario D), in order to gauge the beneficial or detrimental effect of seasonal tilt adjustment. The PV modules in this scenario will remain oriented to the southern direction.

Afterwards, having already determined the optimal pitch distance, the number of panels, and whether the tilt should be fixed or adjustable, different tilt angles will be studied, by means of trying the initial tilt and adding and subtracting 10o from that value Scenarios E and F. Moreover, two simulation scenarios G and H with a different azimuth orientation for the modules are going to be compared as well. The modules in these scenes will be oriented south west and south east and aligned with the building orientation, maintaining the best tilt found in the previous scenarios.

V. METHODOLOGY

The basic design of a PV solar plant is divided into several stages. Firstly, before pre-design we studied the basic theoretical concepts, regulations of grid-connected electricity systems.

In the development phase solar potential, plant site location is selected through detail data analysis. Then a specific area measured because solar panel will be mounted there. We have taken the load profile and account all the energy consuming devices during each hour of the day.

Then we take into consideration new types of modules with higher efficiency and I-V characteristics parameters. PV system electrical configuration based on: voltage sizing, minimum and maximum number of panels per string, number of modules and inverters. This will give us a gross estimation of the produced energy.

Specialized simulation software (PVsyst 7.2) simulates the electrical behavior and performance of this pre-design PV system. Different scenarios created with diverse

orientations and tilts angle. The final design derived after several iterative processes of comparing, discarding and changing parameters on the simulations. Losses due to shadings and electrical connection also examine on this step. The best layout design with application of a storage system is now optimized which produce the maximum energy. Our studied research is based on efficiency and performance.

Design/Calculation Phase

Theoretical Concepts---- At a temperature of 5778 K, the Sun is an element that behaves like a blackbody. Through fusion reactions, it is an excellent absorber and emitter of a relatively constant amount of radiation from its surface. When solar radiation reaches the atmosphere, it is influenced by a number of significant mechanisms that reduce its power and split it. These are radiation absorption (by dust and air molecules), scattering, and reflection [6]. As a result, solar radiation is broken down into three types: direct, diffuse, and reflected [7]. The Sun's azimuth, and hence its radiation, varies constantly based on the season of the year and the hour of the day. The deflection angle is the angle measured between the Earth's axis and a straight line connecting the Earth's center and the Sun's center. It is given in Figure 2.

Figure 2: Angles considered for solar orientation

Regulations---- When we design the self-consumption PV system for household or commercial space, there are some object we need to think about which can make the whole system more efficient. First we have to consider the solar module type. Multiple solar cells are grouped and linked by bus bar connectors to increase their output power, resulting in a PV module. Similarly, when modules are joined in series, PV panels are formed, which are then connected to form solar strings or arrays. The majority of PV modules are stable units with a non-reflective front surface to absorb the most amount of sunlight possible. The angle between two PV panel and cells are more important for solar module which can make the system 2% more efficient. Power rating, power tolerance and temperature coefficient also can change the PV module connection more efficient and productive.

Then we have to consider the quality and durability. This is the most important part to choose a PV module system. A 250W and 150W panel produce two different amounts of voltage but if we maintain the quality then both of them will provide same kind of efficiency which is almost 16.2%. Its compulsory to know the irradiance data evolution for sunlight and locate the area where the power of the ray is higher. For this measurement we did use the latest Meteonorm 8.0 which show us the perfection location for the setup based on an area. It is also shows us the worldwide data so that we can change the location and identify the more productive region for this area. This graph shows us the maximum and minimum radiation around the globe.

Data Analyzed-----In development phase of our project, details and data are analyzed in order to find the suitable location for building that can make the most out of the solar potential of the region. Our designed PV system is located in Dhaka. We have taken the average solar potential map by Solargis tools. GHI data available over long period 1999-2018. In Dhaka region the daily and yearly GHI is 4.5 and 1643 kW/m² respectively. It is represented in Figure 3.

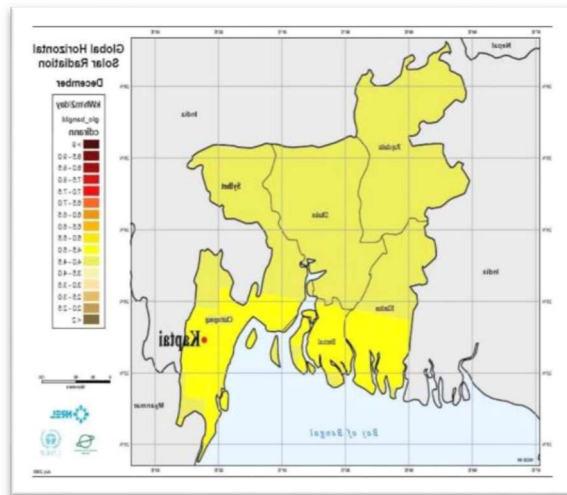

Figure 3: Global Horizontal Solar Radiation Map [7]

From the map (Fig.3) we can see the ray of sun is much higher in the north of the country which means the temperature is 1 or 2 degrees above compare to south. In that case we can consider north side more effective rather than south.

Till now Bangladesh is not much more dependable on solar power system because of the initial costing but scenario will change with time being. Almost 50-60% of the country power supplies from the coal, gas and oil those are responsible climate change and world temperature, so the world is thinking some other option like solar PV system.

For Bangladeshi perspective northern side of the country is produce more sunlight compare to other area. From the

PVsys website map we can see the effective region for solar PV installation. Recently, Bangladesh also implement a 1 MW solar PV system in Kaptai, we will try to reduce the costing such big project. Bangladesh has the longest sea beach; we can make that more productive by implementing more power plant based on nature.

We know the monthly solar irradiance, temperature. Irradiance and other meteorological data are obtained for Dhaka found in Meteonorm 8.0, a meteorological database containing worldwide weather data (1991-2010).

Site Studied-----The Site of study for this project is a Grid-Connected Solar PV Power Plant placed in Kaptai, Kaptai Upazilla. The exact location of this site is given in Fig. 4.

Figure 4: Kaptai proposed site and 11kV power evacuation line [7]

Load Profile-----The measurement of electrical demand across time is represented by load profiles. When developing a self-consumption system, it is critical to understand the user's load profiles in order to scale the system and calculate factors like performance and level of independence. Furthermore, these profiles provide information on the load's highs and lows.

The load profile (Figure 5) will always be determined by the user type, the region, local vacations, and so on. As a result, identifying the electrical load data is critical for measuring and assessing equipment requirements, servicing, and modifications, as well as determining when the device can serve the user and when it cannot.

An initial load profile will be developed for the chosen property. The site we looked at would most likely have peaks in the morning and afternoon, because everyone will be at residence during working hours, and just standby usage will be recorded on the profile.

Figure 5: Load Profile of Site [10]

Chosen Technology-----Silicon-based solar cells remains the most popular type of solar panel, despite being the first generation of PV technology. Although it is not yet outdated, it has undergone additional development, and the number of technological types available today is extremely diverse. However, silicon is the most prevalent solid element on Earth [8], accounting for nearly 28% of the planet's total mass. This, combined with the fact that it is processed and manufactured, creates a powerful combination. After more than 30 years of use, technology is now quite sophisticated and widely established. Silicon-based solar cells are still the most efficient and have the lowest failure rate (less than 1%) with a market share of around 87 percent of PV technologies in 2019, it is the most appealing.

The second generation of PV technology is referred to as Thin-film technology. This technology is developed from a desire to make equipment thinner and inexpensive in order to save money, as well as to use greener and more environmentally friendly procedures. The open-circuit voltage of a solar cell increases as the thickness of the cell is reduced due to the drop in the saturation current [9]. One or more thin layers of light-absorbing substance are applied to a metal, plastic, or crystal backing support to generate these cells. They are, however, less effective. Inverters are required to change the kind of output current depending on the application. Photovoltaic systems or installations, on the other hand, generate a direct current. Distribution is also accomplished out by using DC inside the installations, but when sent to the grid, it must be in the form of alternating current, which requires the use of an inverter to convert it into oscillating compatible and synchronized with the electrical grid [10].

Simulation----- Once an estimated pre-design is done, then it can be modelled into the specialized software that will help to simulate the electrical behavior and performance of the PV system installed at the plant site. We are using simulation software PVsyst version 7.2 which allowed creating the PV layout to find the most accurate values for the parameters to the system and developing a shading and loss analysis. By using this

software various simulations will be run so that we can compare each value, hence the system design can sequentially be optimized.

Design Process-----At **first**, we have specified the desired power or available area. Then we chose the PV module from the internal database. For this we had to import PAN file to the software. Then we chose the inverter from the internal database. For this we had to import dot OND file to the software. Inverters are necessary to change the output current according to its end use. Then the software PVsyst proposed an array/system configuration that will allow us to conduct a preliminary simulation.

In the **second** stage we import the location in PVsyst because the location of the site is not on the software's database. A Meteo file for Kaptai is created using the latitude and longitude of the place, and irradiance and temperature data are imported from Meteonorm 8.0.

Data source: Meteonorm 8.0 (1991-2019), Sets=100%

	Global horizontal irradiation kWh/m ² /mth	Horizontal diffuse irradiation kWh/m ² /mth	Temperature °C	Wind Velocity m/s	Linke turbidity []	Relative humidity %

Global horizontal irradiation year-to-year variability 4.9%

Figure 6: Meteorological Data introduced on PVsyst

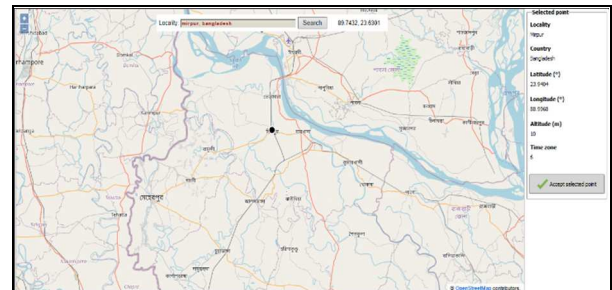

Figure 7: Interacting Map on PVsyst

The **third** stage is about module tilt and orientation. In our case we have used fix modules for economic reasons. The amount of diffusion of radiation from Sun is depending on tilt angle of the module and also the type of plane. For this we use the Albedo option into the software. Here, we have to set a common value 0.30 because our plane is concrete and the value given for concrete is 0.25 - 0.35. The installation of tracking system reduces in short period of time. Therefore, given a fixed structure for the panels, their tilt angle shall be defined. After that we must set a common value for that we have to select "copy" monthly values in copy from. MET file.

That is how we get the same value for every month of the year. We also set project site- Meteo default maximum search area 10km. So that if the software can not find the exact location it will provide temprature information for nearest 10km from our desired location. Then we set Design Conditions. Here, we input the lower temperature of Kaptai for last 5 years which is 26°C. We set winter operating temperature for Vmpp Max design is 28°C. The other 2 values are default values in this software. Those values are fixed. Then we chose IEC (1000 V) in the Array Max voltage which is the International Standard. Also, we have chosen μ Voc value from Specification, because we are not using one-diode model. Transposition Model for this project will be sophisticated. For Circumsolar treatment we chose Separate treatment because in PVsyst the circumsolar is treated the same way as the sunbeam which is coming from the direction of the Sun. This also means that the shading loss on isotropic diffuse is lower, so the shading loss on beam and the circumsolar is higher. Since our aim is to decrease the amount of loss. So, we set Limits overload loss for design is 1%. Since all places does not have same orientation so the azimuth angle varies from building to building. For that we set tilt plane angle to 25°C so that the loss with respect to optimum is 0%. If we change the plane angle the percentage of loss will increase. Also, we set azimuth angle to 0°C. If we want to tilt it to West we have to change the azimuth angle to negative value and if we want to tilt it to East we have to change the azimuth angle to positive value.

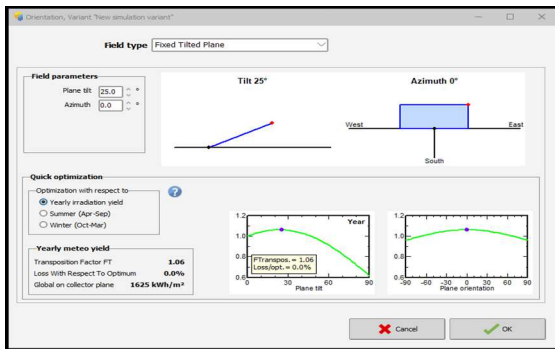

Figure 8: Orientation, variant of Azimuth angle

From the above figure we can see that the Transposition Factor FT is only 1.06. We can also see that there are 2 graphs, one is for Plane Tilt and another one is for Plane Orientation.

The **final** stage is the Row spacing. First of all, for an optimal layout of the PV modules, we have to implement the right minimum inter-row distance, so there are no desired shadows between them. The power that reaches a PV module depends not only on the power of the sunbeams but also the tilt angle between the panel and the Sun. Power density will reach a maximum peak whenever the panel is totally perpendicular to the sunlight. So the angle between the panel and the sun have to be 90°C. If

there is no losses the power density of the absorbing surface would equal the one from sunlight but due to Sun's constantly changing position and to various types of other losses this power density is always less than the incident one.

After completing all the stages, we can "Run Simulation".

VI. RESULT ANALYSIS

Three different scenario A B and C were tested 3D scene and software data and each parameter were run according the table shown as below which is our initial step for the result analysis, for first three cases the angle 0 degree to 35 tilt angle were changed. The distance was given below 2.3 m to 3.3 m continuous process. Rest parameters were constant as before to reduce the loss of the system.

Energy production represent the total effective energy from the system output. Yearly production is the total outcomes without losses from the grid which will be counted on the grid connected calculation. PR is the difference between the input and output energy ratio and finally the losses from the total system is consider as the shading loss.

Figure 9: ISO-Shadings Diagram

According to the shading diagram different scenario create different losses from the angle. From the figure particular months shows the different shading loss. According to this more panel is installed in the area will give the more energy performance ration and global system efficiency values which means less harmful for nature.

Storage System Operating---There two different modes for different times when PV system feeds the battery and the sun goes down to back up the system and complete the user demand. Once the PV system is fully charged the system supply the users demand and it surplus the grid.

Figure 9: simplify scheme for charging mode

Figure 10: Storage mode during night mode

When the sun sets, there will be no other means to acquire energy from the sun, leaving the grid and batteries to satisfy the demand of the consumers. Grid storage and battery provide direct energy to users. We chose a 12.84 KW lithium battery with a storage capacity of 252 Ah and a voltage of 51.2v, and we linked the lithium batteries in parallel to ensure optimal charging capacity.

Figure 11: P-V Curve

Figure 12: Comparison of charging and supplying the energy to the grid

Consider it as 20.35 MW inverter output which generate 22.7% is stored 4.36 Mw yearly to supply the family demand and rest are used to fulfill the demand of hydro based power grid in Kaptai. Only 7.6% time needs users purchase to bring outer energy. That means 346.2 Kw yearly purchase energy from outside means only 5.3% loss from the system. This outcome considers as the less possible loss from the system.

Sub-variant Result

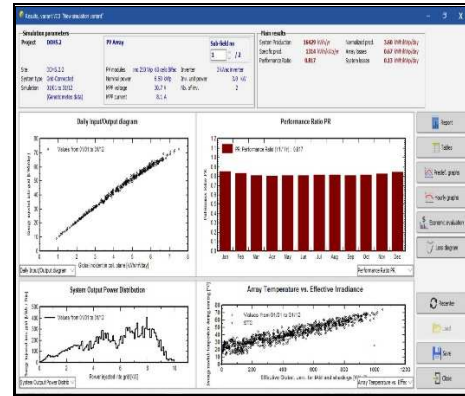

Figure 13: Simulation-1

Figure 14: Main simulation results

This data chart shows us every monthly production of the year based on different variable and set the variable differently how the losses change. For example, if we choose the June which is produce the 227.7 GHI (Global Horizontal Irradiance) 68.2 DFI (Horizontal diffusion irradiation) and rapidly energy use by the consumer and energy injected in the grid and supplies from the grid. From this we can calculate the monthly and yearly losses and efficiency from the system.

Loss Diagram Report

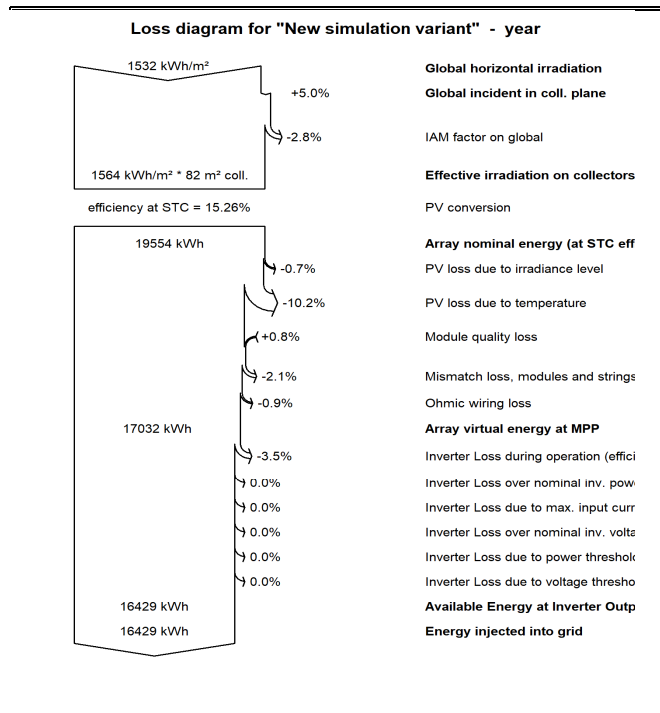

Figure 15: Loss Diagram

From the loss diagram we can observe that the PV loss due to irradiance level is -0.7%, the PV loss due to temperature is -10.2%, and the mismatch losses are fixed at the default value of a power loss at MPP of -3.5%. In terms of unavailability of the system, a constant loss of 5% is assumed. We can also see that there are Ohmic wiring loss on the DC circuit are set to a loss fraction at STC of -0.9%, while the voltage drops across the diodes and the losses on the AC circuit after the inverter are not considered.

VII. FUTURE WORK

Since the construction of the Kaptai Dam began in 1962, the site for this project has been unoccupied. As a result, there will be no loss of livelihood or agricultural land to relocate or assign as a result of this project. The system lacks a sensitive environment as well as historical or cultural significance, both of which are considered

additional value. The 7.4 MWp will be added to the national grid, resulting in only 5.3 percent system loss, which is the lowest loss from a PV system-based grid in Bangladesh [11].

We did work on the tilt angle, stability and consults time of 7.6% during the discharge period. How will the photovoltaic technology work for the solar cells such as thinner film cells can meet the silicon crystalline and reduce the system loss upto 3.6% which is close to the ideal grid system for the solar PV. Also the costing, grid connection or transportation of the energy will lot less then now. Sizing AC and DC wires, loads and installing the sun tracking system or other Nano technologies for solar cell also consider the system more affordable.

Finally, this kind of energy we can install in household building and commercials building to reduce the need of energy consumption come from non-renewable sources such as oil, gas and nuclear system.

Abstract—This current work proposed the system of detection and information delivery on accident locations to related parties in order to get medical aids punctually. This system was based on three major components as the data source inputs, namely the sensors of tilt/slope, vibration, acceleration, and coordinate locations. The data was then processed through Arduino microcontroller by applying a fuzzy logic algorithm using Tsukamoto method as a supporting system for accident status decision. The results of the decision were then transmitted to the data center in real time using the Wi-Fi module, and then send notifications to related parties. The test results revealed that the slope sensor accuracy was about 96.1%. Additionally, the use of fuzzy logic via Tsukamoto method was successfully implemented to determine the accident status by an accuracy value of 85.18%.

Keywords—*detection system, accident detection of tilt sensor, vibration sensor, location and acceleration sensor, fuzzy logic.*

I. INTRODUCTION

The sale number of two-wheeled motorcycles year by year is almost no less than 5 million units each year. Based on information gained from the Indonesian Motorcycle Industry Association (AIS), the accumulated number of two-wheeled motorcycle sales from 2009 to 2019 reached 75 million within 10 years. The large number of vehicle sales each year has triggered problem related to the highway traffic system. Such mentioned number can affect the traffic flow on the highway. In addition to the traffic factor, the drivers' undisciplined driving attitude has also caused accidents

The data by the Traffic Center of the Indonesian National Police (locally known as *Korlantas Polri*) recorded that there were 100,028 traffic accidents over 2020 in Indonesia. This number decreased approximately 14% from the previous year's record, by 116,411 cases. The Traffic Center of the Indonesian National Police also recorded that there were 113,518 minor injuries due to traffic accidents in 2020, declining about 45% from 206,447 victims in 2019. Meanwhile, the number of seriously injured victims was 10,751 in 2020, falling 14% from 12,475 in 2019. The number of deaths due to traffic accidents reached 23,529 cases in 2020, decreasing 8% from the previous year by 25,671 victims. Therefore, the average death cases due to

traffic accidents was 1,960 people per month whilst the average death was 65 people each day, or 2-3 people per hour. Surprisingly, these accidents were dominated by two-wheeled motorcycles [1].

The accident victims are defined as not merely those who died at the time of the incidents, but also those suffering from many serious injuries and minor injuries as a result of a traffic accident, which if they do not get safety and medical assistance quickly, it will end up with death or lifelong disability [2].

The traffic accidents also caused very high costs. Such loss due to traffic accidents in Indonesia during 2002 was estimated at IDR 41.4 trillion, which was 2.91% of gross Domestic product (GDP). Notwithstanding, the number of accidents recorded in Indonesia was merely about 8%, and most of unrecorded cases were accidents without death cases [3].

To deal with the problem of traffic accidents, the Government has already established an integrated service unit in handling traffic accidents. According to the existing system, there were still fundamental weaknesses needed to be addressed. The accident information system still required eye witnesses as senders of information to the related parties, in this case the police, hospitals, and family/relatives. Following this, other factors of delays in handling accidents also often occurred due to delays in information received by the police and the nearest hospital.

This study thereby aimed to establishing an analysis system for early detection of accidents on two-wheeled motorcycles that is able to report quickly and automatically, in order to assist handling accidents more responsively, and further to minimize the impact of accidents.

II. LITERATURE REVIEW

In this given section, I compared multiple studies related to accident detection systems. Several methods had been previously used by some researchers to detect accidents. These systems included location and accident detection utilizing smartphones, VANET (Ad-hoc network), mobile applications, gyroscopes, accelerometers and deep learning.

In [12], this current work used arduino, accelerometer (ADXL336), GSM and GPS as modules to detect accidents and send accident location information automatically. The specified threshold value was $x < 70$ so that if the slope of the vehicle was less than 70 degrees, the system would detect a severe accident and would automatically send an accident location message. This detection system did not analyze the fatality rate due to accidents such as considering the acceleration and collisions that occurred. Thus, this can cause bias detection.

A. Censor MPU-6050

The MPU-6050 is a censor module which has two functions namely, an accelerometer with a micro-electromechanical system (MEMS) and a gyroscope with a micro-electromechanical system (MEMS) on a chip. There are about 16 analog pins converted first to determine the axis, so that this censor can work optimally. The values of the x-axis, y-axis, and z-axis on this censor can be taken simultaneously at one time. This censor applies an Inter Integrated Circuit (I2C-bus interface) as a connection between the censor and Arduino [4].

Figure 1. Titlt position or rotation of MPU-6050 module.

As seen in Figure 1, it depicts the location of the rotation or tilt of the MPU-6050 censor. Roll, pitch, and azimuth are reference points for the tilt of the system. The movement of turning upward and downward is known as roll. Then the downward and upward circular motion is called pitch. Moreover, the rotation of sideways horizontally is labelled azimuth

B. Global Positioning System (GPS)

GPS stands for Global Positioning System. It is a system for determining the position and global navigation using satellites. The system was first developed by The United States Department of Defense used for military and civilian purposes [5]. This module has a better performance as it has features of a data backup battery, a built-in electronic compass, and a strong signal catcher using the built-in antenna [6].

This existing study used the NEO-6M GPS module which could generate the data of coordinate locations and speed with an accuracy of 0.1 m/s [7].

C. Fuzzy Logic Algorithm

This kind of fuzzy logic method is a method developed based on the language of human reasoning, so that it can be utilized into several fields. Basically, this fuzzy logic method has a way to map an input space to an output space [8].

D. Fuzzy Tsukamoto

Fuzzy Tsukamoto is one of the methods of the Fuzzy Inference System. In the Tsukamoto method, every consequence of the if-then rule must be represented by a fuzzy set with a monotonous membership function [9].

- 1) *Fuzzification*: is the process carried out to change the system input that has a firm or crisp value into a fuzzy set, and determines the degree of membership in the fuzzy set
- 2) *The Formation of IF-Then rules*: is the process carried out to form rules that will be used in the form of IF-THEN stored in a fuzzy membership base.
- 3) *Inference* is the process of converting the fuzzy input into the fuzzification output of each predefined rule (IF-THEN).
- 4) *Defuzzification* is the process used to change the fuzzy output obtained from inference to a firm or crisp value. The final result is obtained by using the average weighting equation using the Average Weight Average method as shown in (1) as follows.

$$Z = \frac{\sum(\alpha_i \times z_i)}{\sum \alpha_i} \tag{1}$$

Notes : Z= Output Variable
 α_i = Value of α predicate
 z_i = Value of output Variable

III. METHODOLOGY

This accident detection system consists of two primary infrastructures, namely hardware and software interconnected with each other.

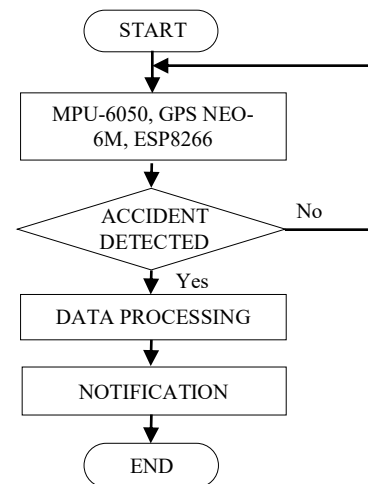

Figure 2. The Diagram Block of Accident Detection System of two-wheeled motorized vehicles.

In Figure 2, the block diagram consists of a hardware module as a data input source. The system will read the slope input data on the vehicle. If the slope exceeds the specified limit, the system will continue such process to data processing in order to find out the accident status and then send information via WhatsApp notification to related parties.

A. Hardware Design

In the hardware design, there are censors MPU-6050, Arduino Uno, GPS NEO-6M and ESP8266 as shown in Figure 3 below.

Figure 3. The design of Accident Detection System.

The MPU-6050 sensor was mainly used to detect tilt and vibration on a motorcycle. There was also a NEO-6M GPS sensor to detect the location of the coordinates and speed of the vehicle. Additionally, there was an ESP8266 module used as wifi. So it could be connected to a smartphone hotspot in order to send information.

B. Software Design

This system was designed by taking data values of slope, vibration, acceleration, and coordinate location. The slope value from the sensor was then analyzed using an Arduino Uno microcontroller with a maximum slope angle of 30°. If the slope angle exceeded this limit, the system could detect an accident [10]. Then, the system would continue the process into data processing.

Data processing used the fuzzy logic algorithm by applying the Tsukamoto method in order to get a more accurate accident status with the flow shown in the following Figure 4 as follows.

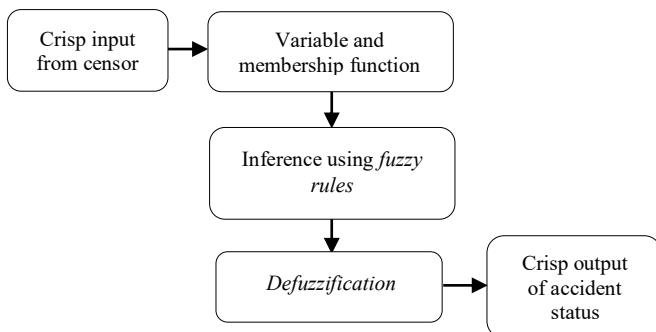

Figure 4. The System of fuzzy logic.

1) The Variable of fuzzy

In this study, the variables were divided into two, namely input variable and output variable. Each variable consisted of

three fuzzy sets. Each variable can be seen in the following Table I.

TABLE I. TABLE OF INPUT AND OUTPUT VARIABLE

Variable	Types	Values
Acceleration	Input	low, medium, high
Vibration		low, medium, high
Accident Level	Output	light, medium, heavy

2) The function of membership degree

a) Acceleration

Acceleration has three fuzzy sets, namely: $0 < \text{low} < 1.23$, $1.20 < \text{moderate} < 2.00$, $\text{high} > 1.90$ [11].

a. Low = $0 - 1.22$.

b. Medium = $1.21 - 1.90$.

c. High = $2.00 - 10.00$.

For each membership function, the degree of validity can be seen in Figure 5.

Figure 5. The function of membership acceleration.

In Figure 5, the membership of the acceleration variable indicates the membership function formulated with the following eqs. (2)-(4):

$$\mu_{PR}[x] = \left\{ \begin{array}{l} 1; \rightarrow x \leq 1.22 \\ \frac{1.90-x}{1.90-1.22}; \rightarrow 1.22 \leq x \leq 1.90 \\ 0; \rightarrow x \geq 1.90 \end{array} \right\} \quad (2)$$

$$\mu_{PS}[x] = \left\{ \begin{array}{l} 0; \rightarrow x \leq 1.22 \text{ atau } x \geq 10.00 \\ \frac{x-1.22}{1.90-1.22}; \rightarrow 1.22 \leq x \leq 1.90 \\ \frac{10.00-x}{10.00-1.90}; 1.90 \leq x \leq 10.00 \end{array} \right\} \quad (3)$$

$$\mu_{PT}[x] = \left\{ \begin{array}{l} 0; \rightarrow x \leq 1.90 \\ \frac{x-1.90}{10.00-1.90}; \rightarrow 1.90 \leq x \leq 10.00 \\ 1; \rightarrow x \geq 10.00 \end{array} \right\} \quad (4)$$

Notes : PR = Low Acceleration
PS = Medium Acceleration
PT = High Acceleration

b) Vibration

Vibration has three fuzzy sets, namely: low, medium, high.

a. Low = $15 - 30$ N.

- b. Medium = 30 – 45 N.
- c. High = 45 – 60 N.

For each membership function, the degree of reliability can be seen in the following Figure 6 as follows.

Figure 6. The function of vibration membership.

As seen in Figure 6, the membership of the vibration variable showed the membership function formulated with the following eqs. (5)-(7):

$$\mu_{GR}[x] = \begin{cases} 1; \rightarrow x \leq 30 \\ \frac{45-x}{45-30}; \rightarrow 30 \leq x \leq 45 \\ 0; \rightarrow x \geq 45 \end{cases} \quad (5)$$

$$\mu_{GS}[x] = \begin{cases} 0; \rightarrow x \leq 30 \text{ atau } x \geq 60 \\ \frac{x-30}{45-30}; \rightarrow 30 \leq x \leq 45 \\ \frac{60-x}{60-45}; 45 \leq x \leq 60 \end{cases} \quad (6)$$

$$\mu_{GT}[x] = \begin{cases} 0; \rightarrow x \leq 45 \\ \frac{x-45}{60-45}; \rightarrow 45 \leq x \leq 60 \\ 1; \rightarrow x \geq 60 \end{cases} \quad (7)$$

Notes : GR = Low vibration
GS = Medium vibration
GT = High vibration

c) Accident Status

The accident status output has three fuzzy sets, namely: light, medium, and heavy.

- a. Light = 15 – 30 N.
- b. Medium = 30 – 45 N.
- c. Heavy = 45 – 60 N.

For each membership function, the degree of reliability can be seen in the following Figure 7.

Figure 7. The membership function of accident status

As in Figure 7, the membership of the accident status variable showed the membership function formulated with the following eqs. (8)-(9):

$$\mu_{SKR}[x] = \begin{cases} 1; \rightarrow x \leq 30 \\ \frac{45-x}{45-30}; \rightarrow 30 \leq x \leq 45 \\ 0; \rightarrow x \geq 45 \end{cases} \quad (8)$$

$$\mu_{SKS}[x] = \begin{cases} 0; \rightarrow x \leq 30 \text{ atau } x \geq 60 \\ \frac{x-30}{45-30}; \rightarrow 30 \leq x \leq 45 \\ \frac{60-x}{60-45}; 45 \leq x \leq 60 \end{cases} \quad (9)$$

$$\mu_{SKT}[x] = \begin{cases} 0; \rightarrow x \leq 45 \\ \frac{x-45}{60-45}; \rightarrow 45 \leq x \leq 60 \\ 1; \rightarrow x \geq 60 \end{cases} \quad (10)$$

Notes : SKR = Low Accident Status
SKS = Medium Accident Status
SKT = High Accident Status

3) Fuzzy Rule

This stage contains rules generated based on two input variables, with the maximum number of rules is 9. Such rules state the input and output relations. The operator connecting both inputs is called AND. The implemented rules can be seen in Table II as follows.

TABLE II. TABLE OF FUZZY RULES

No	Variable		Accident Status
	Vibration	Acceleration	
1	Low	Low	Light
2	Low	Medium	Light
3	Low	High	Light
4	Medium	Low	Light
5	Medium	Medium	Medium
6	Medium	High	Medium
7	High	Low	Light
8	High	Medium	Medium
9	High	High	Heavy

C. The Testing of Detection System

The system testing was carried in order to obtaining data samples. Moreover, it as to measure the sensitivity level of each sensor. The sample data of research can be used as a reference to show the level of stability, accuracy, and feasibility of using the tool. This test included accelerometer testing, slope testing, GPS module testing, fuzzy logic algorithm testing, and information delivery testing respectively.

1) Vibration testing

Vibration is an input variable in the fuzzy logic analysis process that determines the accident status. This vibration testing was done by converting the accelerometer value into vibration, in order to get the vibration threshold value of the vehicles. The following Table III is the data generated from the accelerometer test when there was no accident which resulted in the resultant value working on each axis without a significant change.

TABLE III. THE TABLE OF ACCELEROMETER DATA WITHOUT ACCIDENT CASES

Time (s)	Acc-x	Acc-y	Acc-z	Resultant
1	0.08	1.62	9.08	9.22
2	0.32	1.82	9.95	10.12
3	0.45	1.74	9.88	10.04
4	0.12	1.23	10.87	10.94
5	0.15	1.45	9.89	10.00
6	0.22	1.34	9.88	9.97
7	0.34	1.88	10.89	11.06
8	0.45	1.98	11.89	12.06
9	0.55	1.99	10.89	11.08
10	0.43	1.78	9.88	10.05

Following this, the testing of the accelerometer was also carried out as an accident occurred. Table IV below revealed result data when an accident occurred causing the values in the 4th and 5th seconds of the y-axis and z-axis of the accelerometer. It experienced a significant change from the average value of each axis. Such change in value caused the resultant value becoming high.

TABLE IV. TABLE OF ACCELEROMETER DATA WITH ACCIDENT CASES

Time (s)	Acc-x	Acc-y	Acc-z	Resultant
1	0.08	1.62	9.08	9.22
2	0.32	1.82	9.95	10.12
3	0.45	1.72	9.88	10.04
4	0.12	3.23	18.76	19.04
5	-1.15	2.45	17.89	18.09
6	1.22	1.34	11.88	12.02
7	0.34	1.88	10.89	11.06
8	0.45	1.98	9.89	10.10
9	0.55	1.99	9.89	10.10
10	0.43	1.78	9.88	10.05

2) Slope/Tilt Testing

The slope data was obtained from the MPU-6050 module consisting of 3 axes, namely the x-axis, y-axis, and z-axis. To get slope data, the sensor was placed in the trunk of the motorbike, and then tilted the vehicle. The system detected the slope before further proceeding to the data processing in order to determine the accident status.

TABLE V. TABLE OF DATA AS MOTORBIKE FELL TO RIGHT SIDE

Time (s)	Pitch	Roll
1	-0.4°	-6.4°
2	-0.5°	-6.5°
3	-0.6°	-9.5°
4	-0.4°	-9.5°
5	-0.5°	-35.5°
6	-0.6°	-40.4°
7	-0.4°	-48.4°
8	-0.5°	-55.4°
9	-0.6°	-55.4°
10	-0.4°	-56.4°

The slope test on the vehicle in Table V shows a negative roll. Based on the data above, it can be concluded that the negative value on the roll surely indicated that the vehicle was falling to the right side.

Figure 8. The slope change of X-axis, Y-axis, and Z-axis as motorbike was falling to right side .

As seen in previous Figure 8 above, the graph as the vehicle had an accident and tilted to the right side beyond the maximum slope limit. In addition, the testing was also carried out when the vehicle fell to the left as shown in table 6 below. When it fell to the left, the roll value showed a positive value. Moreover In Figure 9, the graph indicates the slope of the vehicle when it fell to the left side.

TABLE VI. TABLE OF DATA AS FALLING TO LEFT SIDE

Time (s)	Pitch	Roll
1	-0.4°	8.4°
2	-0.5°	6.5°
3	-0.6°	9.5°
4	-0.4°	10.5°
5	-0.5°	35.5°
6	-0.6°	40.4°
7	-0.4°	48.4°
8	-0.5°	55.4°
9	-0.6°	55.4°
10	-0.4°	56.4°

Figure 9. The slope change of X-axis, Y-axis, and Z-axis as motorbike was falling to left side .

3) GPS Testing

GPS testing aimed to determine the accuracy of GPS showing the location coordinates of the accident victim as compared to google maps. In addition, it was used to determine the speed of the vehicle.

4) Testing of Information delivery

Information delivery was the end point of the accident detection system. This test was carried out to ensure that the system could send information after an accident had been detected. Information was sent/transmitted in the form of short messages via WhatsApp.

IV. RESULTS AND DISCUSSION

After having tested the accident detection system for 26 trials, this system is regarded to be able to detect accidents with the results of slope testing by an accuracy of 96.1%. Furthermore, testing was also carried out towards the algorithm, namely fuzzy logic with the Tsukamoto method in order to determine the accident status with an accuracy value of 85.18%. Finally, the accident status information was successfully sent to the relevant parties.

V. CONCLUSION

In this current research, the detection and delivery system a two-wheeled motorcycle accidents had been carried out using Arduino Uno hardware, MPU-6050, GPS NEO-6M, ESP8266 hardware and a fuzzy logic system by using the Tsukamoto method to support the system of the accident status decision-making. Several stages of this research consisted of hardware design, software design and system testing. According to the test results, the slope sensor accuracy was by 96.1%, and the use of fuzzy logic with the Tsukamoto method was successfully applied to determine the accident status with an accuracy value of 85.18%. The information of both coordinate location and accident status were successfully transmitted using the ESP8266 module which was connected to a smartphone hotspot via a WhatsApp notification to related parties for quick response.

Some challenge faced in this research was, for instance, the limitation of testing on vehicles with higher speeds to get a better level of detection accuracy. In addition, this study used the wi-fi module to transmit accident information. So, in

such certain locations with poor internet connections there would be delays or failures in sending information.

Abstract—Exploration plays a key role in the performance of metaheuristics. An algorithm should perform more exploration when reaching the “ideal search scale”; this happens when solutions are regularly sampled from different attraction basins. The moment this search scale is reached depends on the topological features of the objective function and the inherent randomness of the heuristic optimization process. Previous work on adjusting exploration have mostly used fixed rules based on fitness improvement, in this paper, we model it as a supervised machine learning problem. We apply a data-centric approach to understand whether variations in the data are more relevant than variations in the classification models. For our study we use the Estimation Multivariate Normal Algorithm with Threshold Convergence, which provides an ideal framework as it allows us to directly control exploration through the γ parameter. Optimization results show that the machine learning hybrid significantly outperforms the baseline algorithm.

Index Terms—metaheuristics, machine learning, data centric, threshold convergence, estimation multivariate normal algorithm

I. INTRODUCTION

The optimization of multimodal problems involves two distinct tasks: identifying promising attraction basins (exploration) and finding the local optima in these basins (exploitation). However, many metaheuristics were initially conceptualized for unimodal search spaces. For example, Particle Swarm Optimization (PSO) begins with a cornfield vector (see Section 3.2 in [1]) and Differential Evolution (DE) builds its foundation from a simple unimodal cost function (see Figure 1 in [2]). As a consequence, the primary search mechanisms of these metaheuristics are biased towards converging on local optima rather than searching for the best attraction basins.

Estimation of Distribution Algorithms (EDAs) are faced with a similar challenge [3]. In EDAs, the best solutions are used to estimate the parameters of the distribution, thus rapidly focusing on the best found attraction basins. The efficacy of exploration in EDAs relies strongly on the diversity of their populations. However, once the algorithm starts to converge, the variance of the distribution functions becomes smaller. With a smaller variance, new candidate solutions

are generated closer to each other, which in turn, leads to even smaller variance, which leads to a rapid convergence. As a consequence Estimation Distribution Algorithms may converge prematurely [4]. A variety of techniques have been developed to avoid premature convergence, including mechanisms such as diversification, speciation and sub-population formation [5], restarts [6], Threshold Convergence [7] and niching [8].

Threshold Convergence (TC) has been used to avoid premature convergence in an Estimation Multivariate Normal Algorithm (EMNA) [4]. The proposed algorithm, named Estimation Multivariate Normal Algorithm with Threshold Convergence (EMNA-TC), led to an improvement of approximately 50% in performance compared to the original EMNA. One of its key contributions was the design of an adaptive threshold function for controlling the transition from exploration towards exploitation, based on the results gathered by the algorithm during the optimization. In this paper we take the design of adaptive threshold functions for TC a step further, by designing a machine learning based adaptive threshold function. Such a function uses a classification model to determine how to adjust the threshold given the topological features observed during the optimization process.

The combination of metaheuristics with machine learning is currently one of the most successful trends in optimization [9]; in this paper, we continue this trend by designing a machine learning based hybrid of EMNA-TC that leads to a significant improvement in performance. However, the key contributions of this paper go beyond the mere improvement in performance, on one hand, we present a novel way of modelling the problem of controlling exploration as a supervised learning problem and we use a trained model for adjusting exploration directly during the optimization process. On the other hand, we pursue a data-centric approach when solving the classification problem. Such an approach has been promoted by Andrew Ng, the cofounder of DeepLearning.AI, Coursera, and LandingAI, who recently launched a campaign to support data-centric Artificial Intelligence [10].

This paper begins with a background on EMNA, Threshold Convergence and the hybridization of machine learning with metaheuristics. The problem of controlling exploration is then defined as a classification problem in Section III. Section IV presents the classification results for a variety of models on the different datasets. Section V presents the machine learning based optimization hybrid. Optimization results, including an analysis of how the models influence the hybrids, are presented in Section VI. The paper then concludes with a discussion of current results and future work in Section VII.

II. BACKGROUND

Estimation of distribution algorithms (EDAs) are metaheuristics that guide the optimization by building and sampling explicit probabilistic models of promising candidate solutions. Thus, EDAs transform the optimization problem into a search over probability distributions; in the specific case of the Estimation Multivariate Normal Algorithm (EMNA) a multivariate normal distribution is used for sampling the search space. In every iteration the mean μ and co-variance matrix Σ are calculated for the subset of best solutions in the current population. The next population is then calculated by sampling an inverse multivariate Gaussian function using μ and Σ [3].

A. Estimation Multivariate Normal Algorithm with Threshold Convergence

In globally convex search spaces, promising solutions tend to cluster around the best attraction basins and, as a result, with every iteration the variance of the estimated distribution will become smaller. New solutions sampled from a distribution with a smaller deviation will be closer to each other. Such close solutions will have an even smaller variance, which subsequently leads to even closer solutions in the next iteration. This auto-catalytic process is an important mechanism which allows EMNA to converge; however, it can also lead to a ‘‘cascading convergence’’ and cause premature convergence [4].

Premature convergence can be limited through the use of the Threshold Convergence (TC) technique. TC modifies the sampling strategy so that new solutions are created at least a ‘threshold’ distance away from its reference solution(s). This controlled sampling strategy allows management of the transition from exploration to exploitation, convergence is thus ‘held’ back until the last stages of the search process [7]. The name *Threshold* is a combination of the words threshold and held.

Threshold Convergence has been incorporated into multiple metaheuristics, significantly improving results when optimizing multi-modal functions. In most metaheuristics, TC has been used to control the distance among existing and new solutions directly in the search space (e.g. Differential Evolution [11], Particle Swarm Optimization [12] and Evolution Strategies [13]). However, in the case of EMNA, Threshold Convergence was used to control the Σ parameter of the distribution function. The resulting algorithm, EMNA-TC,

was presented in [4]. The application of TC in the parameter space did not only report state of the art performance, but also opened a new line of research into the application of TC to combinatorial optimization problems [4].

$$\Sigma_{norm} = init_ \Sigma_{norm} \times \left(\frac{totalFEs - FEs}{totalFEs} \right)^\gamma \quad (1)$$

In EMNA-TC the value provided by the threshold function is used to set the (Euclidian) norm of the Σ matrix. This is done by normalizing Σ and then multiplying it by the threshold value. Initially the norm is set to be equal to the norm of Σ calculated from initial population of randomly sampled solutions ($init_ \Sigma_{norm}$), and it is updated over the execution of a metaheuristic by following the decay rule shown in Equation 1. In this equation, $totalFEs$ is the total number of function evaluations, and FEs is the amount of evaluations performed so far. The parameter γ controls the decay rate, and thus controls the convergence rate in EMNA-TC.

Algorithm 1 EMNA-TC

```

Randomly initialize population  $P$ 
while  $FEs \leq maxFEs$  do
     $best\_solutions \leftarrow select\_best(P)$ 
     $[\mu, \Sigma] \leftarrow estimate\_parameters(best\_solutions)$ 
    if first iteration then
         $\Sigma_{norm} \leftarrow init\_ \Sigma_{norm} \leftarrow norm(\Sigma)$ 
    else
        if best solution has improved then
             $\gamma \leftarrow 0.95 \times \gamma$ 
        else
             $\gamma \leftarrow 1.05 \times \gamma$ 
        end if
         $\Sigma_{norm} \leftarrow init\_ \Sigma_{norm} \times \left( \frac{maxFEs - FEs}{maxFEs} \right)^\gamma$ 
    end if
     $\Sigma \leftarrow \Sigma_{norm} \times \frac{\Sigma}{norm(\Sigma)}$ 
     $P \leftarrow sample\_normal\_multivariate(\mu, \Sigma)$ 
end while
return  $best\_solution$ 

```

B. Controlling Exploration in EMNA-TC

An advantage of controlling the convergence rate is that convergence can be held to a pause when an ‘ideal search scale’ is reached. Arguably, this ideal search scale happens when solutions are regularly sampled from different attraction basins. If the distance between different attraction basins could be known *a priori*, then the norm of Σ could be held longer at this scale, allocating more function evaluations to this threshold level and thus increasing the chances of finding the best regions before performing local search [14].

Previous work has shown the challenges of determining the ideal search scale, focusing on the number of solutions that are kept from one iteration to the next, as an indicator of whether this ideal search scale has been reached [11]. However, because in EMNA the population is entirely replaced by the new solutions, a different strategy was used in EMNA-TC. This strategy used as a criterion whether the

best new solution improves over the best solution from the previous population [4]. Thus, if the best solution is improved, then γ is decreased by multiplying it by 0.95 (which slows convergence); otherwise, γ is increased by 1.05. A general outline of EMNA-TC algorithm with adaptive threshold is presented in Algorithm 1.

C. Machine Learning for Improving Metaheuristics

In this paper we present a novel way for adjusting γ using supervised machine learning models. The combination of metaheuristics with machine learning is currently one of the most successful trends in optimization [15]. There are a variety of approaches that use machine learning techniques for improving metaheuristics, e.g. machine learning methods can be used to cleverly generate the initial population [16], for building approximate models of the fitness function and replacing function evaluations [17], for setting up parameters [18] or managing the population of evolutionary algorithms [19]; among other applications [9].

In this paper we focus on a broader approach, where optimization can be understood as a decision-making process. In such an approach, the best search strategy needs to be chosen for a particular search region and moment during the optimization [20]. Such decisions must be made as the optimization proceeds, taking into account information gathered during the search. As discussed in [21], two distinctive factors influence these decisions:

- **The topology of the objective function:** different characteristics such as unimodality, multimodality, separability, deceptiveness, etc. are better optimized by different search strategies.
- **The optimization process:** given the stochastic nature of the heuristic optimization process, the same decision may be optimal at different moments, even for the same objective function.

The first step towards applying machine learning techniques in this approach is to model the decision problem as a machine learning problem, either supervised [20], unsupervised [22] or reinforcement problem [23]. Then, a model can be trained to identify the function's topological features, learn to generate a sampling sequence associated with a given search strategy, determine which strategies are better fitted for a given topology, and deciding when to apply them. In the case of this paper, a strategy refers to either decreasing γ to promote more exploration or increasing γ for a faster convergence.

III. CONTROLLING EXPLORATION AS A SUPERVISED LEARNING PROBLEM

In EMNA-TC the parameter γ determines the norm of Σ (Equation 1), thus by adjusting γ during the optimization process it is possible to indirectly control the exploration of EMNA-TC. The problem of finding the best value for γ at any given point during the optimization can be modeled as a supervised learning problem, in this paper, we will specifically focus on modelling it as a classification problem.

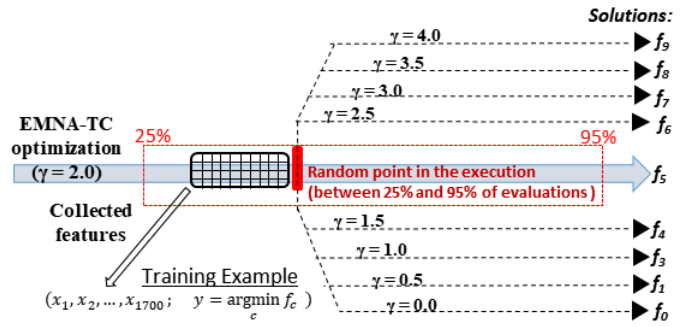

Fig. 1. Procedure for creating a training example for the V_0 dataset.

We modeled the problem as a multi-class classification problem, with 9 different output classes associated to different values for the γ parameter. As shown in Figure 1 classes 0, 1, 2, ..., 7, 8 correspond to the values of $\gamma = 0, 0.5, 1.0, \dots, 3.5, 4.0$, respectively. To create one training example we execute EMNA-TC starting with $\gamma = 2$, then at a random point of the execution between 25% and 95% of the total budget of function evaluations, EMNA-TC is branched out with all the 9 possible values for γ . The final result for each branch is obtained by completing the optimization with the remaining evaluations.

Information regarding the optimization status of the algorithm is collected before branching EMNA-TC. The collected features are intended to capture knowledge about the function topology and the optimization process itself. Seventeen features are collected in every other iteration of the 200 iterations prior to the branching point, thus leading to a total of $100 \times 17 = 1700$ features; the collected features are:

- Feature 1: The function evaluations used so far.
- Feature 2: The function evaluations available.
- Feature 3: The current value for the gamma parameter.
- Feature 4: The current threshold value.
- Feature 5: The standard deviation of the fitness in the current population.
- Feature 6: The average fitness of the current population.
- Features 7-17: The 0%, 10%, 20%, ..., 100% percentiles of the fitness of the current population.

As illustrated in Figure 1, we create a training example by associating the vector of collected features to the class that led to the best final result. As part of our data-driven approach, we decided to create different variations of the original dataset in order to assess the effect on the classification and optimization process.

A. Dataset variations

In the original dataset, which we denoted as V_0 , training examples that had multiple γ values producing the exact same final result were excluded. However, V_0 does include training examples which have a very small difference in the final results among the γ branches (i.e. between f_0, \dots, f_8 in Figure 1). Such training examples may mislead the classifier into learning decisions that are not relevant in practice.

Fig. 2. Distribution of classes among training examples in the different datasets.

To tackle this issue the following variants used a “gamma index strategy” based on the difference between the best and worst final result achieved after branching. The strategy varies depending on the variant, but the decisions were based on whether the relative difference between the best and worst branching results were larger than 1%, 3%, 5%, 7%, 9% or 11%.

- Variant 1 (V_1): This variant uses the strategy of not including a training example if the difference between the best and worse results was less than the previously mentioned percentages. We denote each of these subtypes as $V_{1p1}, V_{1p3}, \dots, V_{1p9}$ and V_{1p11} .
- Variant 2 (V_2): A disadvantage of V_1 is that it removes training examples, thus reducing the size of the dataset. V_2 uses a different strategy, instead of removing the training example, it keeps the training example but indicating that no relevant action is required. This is done by setting the prediction class to 5, i.e. $\gamma = 2.5$, which is the median value among all the collected γ values in the dataset. Similarly to V_1 , variants subtypes are denoted as $V_{2p1}, V_{2p3}, \dots, V_{2p9}$ and V_{2p11} .
- Variant 3 (V_3): Variant 3 uses a similar gamma strategy as V_1 , but it only uses three classes, for $\gamma = 0.5, 2$ and 3.5 , selecting the best option (of the three) which had the best average result between it and its two nearest neighbours (eg. Average of results from $\gamma = 0, 0.5, 1$ for $\gamma = 5$).

The training data was gathered using the 28 functions from the IEEE CEC’13 benchmark [24]. This benchmark consists of a set of 28 unimodal and multi-modal functions with various characteristics. The process of creating one training examples is computationally expensive, as it requires completing a full execution of EMNA-TC plus the 8 branches. We were able to collect slightly over 1400 training examples per function, resulting in a total of 39382 examples in the V_0 dataset.

The number of training examples and the class predictions varied depending on the dataset variant. Figure 2 shows how

the number of training examples distributes along each class on each dataset. It can be noticed how the overall number of examples is reduced in datasets V_1 and V_3 as the percentages for the gamma strategy are increased. A surge of examples towards larger γ values can also be observed, which indicates a bias towards faster convergence. In multi-modal functions training examples are balanced, but in multi-modal functions training examples are skewed into increasing γ , and thus convergence. Future data collection should focus more on multi-modal functions.

IV. CLASSIFICATION RESULTS

We tested over 20 different classification models, more data and the project code can be found in the Github repository [25]. In this paper we focus on the most relevant and best performing models; six of those models are classic machine learning models from the Sklearn library, and two are deep neural networks implemented using TensorFlow Keras. These models are:

- Decision Trees (DT): Sklearn implementation with default settings.
- K Nearest Neighbour (KNN): Sklearn implementation with the number of neighbours set at 20, the weights set to distance, otherwise default settings.
- Radial Nearest Neighbour (RNN): Sklearn implementation with default parameters, the radius was set to 2600.
- Linear Discriminant Analysis (LDA): Sklearn implementation with solver set to ‘svd’ and otherwise default settings.
- Quadratic Discriminant Analysis (QDA): Sklearn implementation with default settings.
- Logistic Regression (LR): Sklearn implementation with the solver set to ‘sag’, the maximum number of iterations set at 100000, and otherwise default settings.
- Deep Neural Network (TF3): a Sequential Keras model with five layers. Output dimensions 64, 32, and 9 for the first, third and fifth layers. The second and fourth layer being Dropout Layers with a 0.1 dropout rate. The

first layer has a *relu* activation function the last having a *sigmoid* activation function.

- Deep Neural Network (TF4): a Sequential Keras model with three layers. Output dimensions 256, 128, and 9; the first layer has a *relu* activation function, the last layer has a *softmax* activation function. Both TF networks use Adam optimizer with a learning rate of 0.01 and a categorical crossentropy loss function.

For testing the classifiers we used a holdout-validation set with 25% of the dataset. Table I shows the accuracy of the different models for the best dataset subtypes; we choose the subtype based on the overall performance when we applied the hybrid to the optimization benchmark (see next section). Accuracy for Variant 3 is higher because it has only 3 classes, while Variants 0, 1 and 2 have 9 classes. It is noticeable that the average accuracy for all the models doesn't vary much among the different datasets, with V_1 and V_2 having an almost identical average. The average per model shows that RNN, DT and LOG perform slightly better than the rest.

When looking at individual models it can be appreciated that some models such as RNN and LOG show a good performance for all the dataset variants. Other models, such as DT and QDA, seem to be more sensitive to the different datasets. Despite being one of the best performing models overall, DT performs rather poorly in V_3 , while QDA (the worst performing model), performs very poorly in V_0 and V_3 . It is also noticeable that the Deep Network models don't perform as well as other models, this could be due to the relatively small size of the datasets. Although the TF3 model does perform reasonably well and with a stable performance among all the datasets. In the following sections, we will analyze how these accuracies correlate to the optimization performance.

TABLE I
CLASSIFICATION ACCURACY FOR VARIANT TYPES WITH BEST OPTIMIZATION PERFORMANCE

Model	V_0	V_1p_5	V_2p_3	V_3p_9	Model Average
RNN	0.182	0.188	0.182	0.656	0.302
TF4	0.151	0.167	0.164	0.660	0.286
TF3	0.167	0.167	0.164	0.660	0.290
DT	0.184	0.201	0.187	0.638	0.302
KNN	0.153	0.172	0.161	0.630	0.279
LOG	0.185	0.186	0.185	0.659	0.304
LDA	0.180	0.191	0.179	0.609	0.290
QDA	0.116	0.181	0.131	0.466	0.224
Dataset Average	0.165	0.182	0.169	0.622	

V. THE MACHINE LEARNING HYBRID

The EMNA-TC machine learning hybrid starts the execution of EMNA-TC with $\gamma = 2.0$. At every other iteration the algorithm collects the features described in Section III; this information is then used to build the input features required by the classifier. Once the algorithm reaches the 10% of function evaluations the trained classifier is called regularly every 10 iterations. The classifier is used to make a prediction

of what the optimum value for γ is at that given time in the optimization; then γ is set to this value and the optimization resumes.

These regular updates of the γ parameter allow EMNA-TC to adjust its exploration directly from information gathered during the optimization process. Ideally, γ would be decreased (which means the threshold will decay more slowly) when the algorithm reaches a threshold size that promotes the sampling of solutions from different attraction basins. To guarantee a final convergence, the hybrid stops calling the classifier once 70% of the function evaluations are reached, and γ is set to 4 to promote a fast convergence during the final iterations. A pseudocode of the machine learning hybrid is shown in Algorithm 2.

Algorithm 2 EMNA-TC-ML(classifier)

```

Randomly initialize population  $P$ 
while  $FES \leq maxFES$  do
     $best\_solutions \leftarrow select\_best(P)$ 
     $[\mu, \Sigma] \leftarrow estimate\_parameters(best\_solutions)$ 
    if first iteration then
         $\Sigma_{norm} \leftarrow init\_Sigma_{norm} \leftarrow norm(\Sigma)$ 
    else
         $input\_data \leftarrow collect\_features()$ 
        if  $0.1 \times maxFES < FES < 0.7 \times maxFES$  then
            if every 10 iterations then
                 $\gamma \leftarrow classifier.predict(input\_data)$ 
            end if
        else
            if  $FES > 0.7 \times maxFES$  then
                 $\gamma \leftarrow 4.0$ 
            end if
        end if
    end if
     $\Sigma_{norm} \leftarrow init\_Sigma_{norm} \times \left( \frac{maxFES - FES}{maxFES} \right)^\gamma$ 
     $\Sigma \leftarrow \Sigma_{norm} \times \frac{\Sigma}{norm(\Sigma)}$ 
     $P \leftarrow sample\_normal\_multivariate(\mu, \Sigma)$ 
end while
return  $best\_solution$ 

```

A. Machine Learning Based Adaptive Threshold Function

As stated in [7] "The ideal case for Threshold Convergence is to have one sample solution from each attraction basin, and for each sample solution to have the same relative fitness with respect to its local optimum". To achieve this ideal case, an adaptive threshold function should flatten once the algorithm reaches a scale that allows sampling random solutions from different attraction basins. This scale is directly related to the size and shapes of attraction basins.

In the Rastrigin function, where local optima are located at the integer values of a regular grid of size 1, we know that the minimum distance between adjacent local optima is 1 and the maximum distance is \sqrt{n} (n being the number of dimension) [14]. In such case, the threshold function should have a smaller γ and thus a slower decrease, when the threshold value is in the $[1, \sqrt{n}]$ interval. Because in EMNA-TC the threshold value is set over the parameter space and not over the search space, it becomes more difficult to determine

when the average sampling distance of new solutions is within a given search interval. However, it is still possible to illustrate how different models vary the threshold decay.

Figure 3 shows the threshold values for the best two models (RNN and TF4, both shown here for V_0) and for the worst performing model (QDA) on the Function 12 of the CEC'13 benchmark, i.e. the Rotated Rastrigin function. The figure also shows the fixed threshold decay as a baseline comparison. Because the Rastrigin function is a sinusoid super-imposed on a quadratic base function, a fixed threshold decay with $\gamma = 2$ provides a good convergence schedule. However, delaying convergence when solutions are sampled in the $[1, \sqrt{n}]$ interval can still lead to a slight improvement in performance. This logic is captured differently by the different models, RNN for instance, deviates little from the very effective quadratic decrease, it converges slightly faster up to the iteration 150, and at that point reduces the convergence speed. The TF4 model delays convergence earlier with a faster decrease in the second half of the optimization. The QDA model delays convergence far too much and convergence is only achieved once the model stops being used and γ is set to 4 in the final iterations.

Fig. 3. Adaptive threshold functions.

Even though the accuracy among some models doesn't seem to vary much, there is a clear difference among the adaptive threshold functions each model has learned. This difference is the underlying reason behind the significant variations in optimization performance observed among the machine learning hybrids in the next section.

VI. OPTIMIZATION RESULTS

In this section we present and analyze the optimization performance of the EMNA-TC machine learning hybrids. Results are presented using the 28 functions from the IEEE CEC'13 benchmark suite [24]. This benchmark consists of a set of 28; these are divided into three sets: unimodal functions (1 to 5), basic multi-modal functions (6 to 20) and composite multi-modal functions (21 to 28).

The experimental setup consists of 30 independent runs on each function on 30 dimensions with a maximum of 300,000 function evaluations, as recommended in the benchmark description [24]. Performance is measured by comparing the mean error. The relative difference in performance between

two given algorithms a and b is also presented using equation: $100(b - a) / \max(a, b)$. These values indicate by what amount (percentage) algorithm a outperforms algorithm b .

A. Best Optimization Performance on the Dataset Variants

Table II shows the improvement (relative difference) of the machine learning hybrids when compared to EMNA-TC over the entire benchmark. As in Table I, results are presented for the best subtype of each dataset. It is noticeable that the RNN-hybrid shows a steady performance, clearly outperforming EMNA-TC on every dataset. These results are consistent with RNN's strong accuracy performance in Table I. Conversely, the TensorFlow models, which weren't among the best classifiers, achieve the second and third best average optimization results. It is less surprising to notice that models such as QDA and LDA, which performed poorly as classifiers, also perform poorly when integrated into the optimization hybrid.

TABLE II
RELATIVE IMPROVEMENT OVER EMNA-TC FOR BEST VARIANT TYPES

Model	V_0	V_{1p5}	V_{2p3}	V_{3p9}	Model Average
RNN	21.67%	18.04%	13.06%	15.32%	17.02%
TF4	2.79%	18.58%	13.66%	22.70%	14.43%
TF3	7.07%	5.87%	7.53%	6.79%	6.82%
DT	4.08%	3.82%	4.84%	6.03%	4.69%
KNN	-0.09%	4.35%	0.76%	13.27%	4.57%
LOG	2.35%	0.32%	4.44%	4.63%	2.94%
LDA	3.69%	-9.53%	5.50%	2.97%	0.66%
QDA	2.26%	-10.02%	5.48%	-20.68%	-5.74%
Dataset Average	5.48%	3.93%	6.91%	6.38%	

Perhaps the most noticeable result comes from looking at the individual differences of each model for specific dataset variants. Table I didn't show much variation in classification accuracy across the datasets, however, the optimization performances vary more significantly. For instance, the RNN-hybrid performs very well across all the dataset variants and achieves the overall second best performance in the V_0 dataset with an improvement of 21.67%. The TF4-hybrid, on the contrary, varies its performance significantly depending on the dataset. This hybrid achieves the best overall improvement of 22.70% when trained on the V_{3p9} dataset, while performing quite poorly (2.79%) when trained on the original V_0 dataset. In a similar note, some hybrids perform very badly at specific datasets, e.g. the LDA-hybrid when trained with the V_2 variant and the QDA-hybrid for V_3 .

B. Effect of the Classification Accuracy on the Optimization Performance

To better illustrate how the accuracy of the classifiers relates to the optimization performance we have plotted both values in Figure 4 for the whole rank of dataset variations. The accuracy plot for the RNN model is very similar to that of other models, with a stable accuracy around 0.2 for all the variants and subtypes with 9 classes, and then an increase to approximately 0.65 for the V_3 subtypes. The

relative difference for the RNN-hybrid also shows a very stable performance, outperforming EMNA-TC in the range of 10% to 20% in all of the dataset variants.

Because RNN achieves a relatively high accuracy, and the highest average optimization improvement among all the models, we could hypothesize that there is a direct correlation between both measures. However, when looking at the plot for Logistic Regression (LOG) we can see that even though the accuracy plot is very similar (just slightly lower values), the optimization performance is clearly worse for the LOG-hybrid; the DT plot is similar to the LOG plot (not included for space reasons). This observation may lead us to the conclusion that there is either a weak correlation between classification accuracy and optimization performance, or that the optimization performance is very sensitive to small variations in accuracy.

The plots for the two TensorFlow models (TF3 and TF4) favour the hypothesis of a weak correlation between accuracy and relative difference. It can be noticed that while the accuracy plot is similar to that of most models, the optimization performance varies significantly: from performing slightly worse than EMNA-TC for some datasets (e.g. TF3 for V_1p_1 and V_1p_9) to achieving the overall best result (TF4 for V_3p_9). Meanwhile, the plots for QDA and KNN show a different story. Both these plots suggest a correlation between accuracy and performance, however, they suggest opposite relationships. In the case of QDA the plot seems to suggest an inverse correlation: the relative performance worsens when the accuracy improves. The KNN plot shows what would have been the most natural result to expect: optimization performance improving as classification accuracy improves.

Figure 5 presents a scatter plot for all the models, correlating the relative difference in optimization vs the classification accuracy. This figure confirms that there is no relationship between both measures for the V_0 , V_1 and V_2 datasets. But, it also shows that the relative performance for V_3 is overall better when compared to the other datasets. It also confirms that results of the QDA classifier are outliers with respect to the other classification models. It can also be noticed that 4 hybrids achieved an improvement of over 20% when compared to EMNA-TC, with the TF4-hybrid as the best performing one.

C. Full Optimization Results for the TF4-hybrid

Table III presents the optimization results for the TF4-hybrid on the entire CEC'13 benchmark. Results are compared against the EMNA-TC algorithm, for determining the effectiveness of the machine learning based adaptive threshold function. Table III also includes some well-known population-based metaheuristics such as PSO, DE and the Covariance Matrix Adaptation Evolution Strategy (CMA-ES). CMA-ES is a state of the art algorithm, which uses a multivariate normal distribution for generating new solutions, default parameters were used as recommended in [26]. The PSO implementation is a standard version with a ring topology, zero initial velocities, "Reflect-Z" for particles that exceed

the boundaries of the search space and a population size of 50 individuals [27]. The DE algorithm is based on a DE/rand/1/bin version with a population size of 50, crossover $Cr = 0.9$, and scale factor $F = 0.8$ [2]. Results include the mean error over 51 runs and the relative difference (%-diff) in performance between a given algorithms vs. the TF4-hybrid; positive percentages indicate by what amount the algorithms outperform the hybrid, negative values indicate the hybrid performs better.

Results in Table III show that compared to EMNA-TC the hybrid achieves an overall improvement of 22.70% over the entire benchmark. It is noticeable that much of that improvement comes from the unimodal functions, this is due to the classifier's ability to promote convergence in this set of functions (as mentioned in Section III-A). However, because EMNA-TC is originally designed for optimizing multi-modal functions, it is no surprise that the set of unimodal functions is where the hybrid performs the worst when compared to CMA-ES, DE and PSO.

In the set of classic multimodal functions is where the TF4-hybrid performs the best when compared to other metaheuristics, achieving improvements of 61.31%, 66.09% and 61.54% when compared to CMA-ES, DE and PSO, respectively. When compared to EMNA-TC, the hybrid achieves an improvement of 16.88%, confirming the effectiveness of the adaptive threshold for controlling exploration in multimodal search spaces. In the set of composition multi-modal function, the TF4-hybrid achieves the highest improvement when compared to CMA-ES (37.65%) but almost no improvement (0.79%) when compared against EMNA-TC. This result indicates that most of the improvement comes from applying TC for controlling convergence, rather than from an adaptive threshold function. Also suggesting that for this type of functions, the quadratic threshold decrease from the baseline EMNA-TC algorithm is the most appropriate convergence schedule; probably due to the globally convex structure that many of these function have.

Overall, the TF4-hybrid's adaptive threshold function leads to a significant improvement over EMNA-TC, with most of this improvement coming from the unimodal functions. It also shows a significant improvement over CMA-ES, DE and PSO, with most of that improvement coming from both sets of multi-modal functions. It is also relevant to notice that there are 8 multi-modal functions, for which the TF4-hybrid achieves results that are at least 10% better than all of the other algorithms (bold results in Table III)

VII. CONCLUSIONS

This paper presented a novel way of controlling exploration by modeling it as a supervised learning problem that outputs an adaptive threshold function. Computational results (Table III) confirm the effectiveness of the approach, which can be easily adapted to other metaheuristics that use Threshold Convergence.

An analysis of the classification models and the corresponding hybrids (Tables I and II; Figures 4 and 5) suggests that

Fig. 5. Scatter plot of accuracy vs. optimization performance for all the models.

the correlation between the classification accuracy and the optimization performance is weaker than expected. However, the adaptive threshold functions produced by each model illustrate the contrast among the different models (Figure 3). These differences are reflected in the optimization results of the corresponding hybrids, even though they are not captured by the classification accuracy. Future work should dig deeper into this analysis and potentially suggest alternative metrics that could better correlate the classification and optimization results.

The data-centric analysis suggests that the difference among the machine learning models is more relevant than the variations in the data. Although slightly superior results for V_3 indicate that reducing the number of output classes leads to a better performance of by the hybrids. Future work should focus on further varying the datasets, e.g. by reducing dimensions through Principal Component Analysis or modelling γ output as a regression problem. Future work should also focus on compiling a larger dataset, which could significantly improve the performance of the Deep Learning models. Another promising line for future research is modelling the machine learning problems as a reinforcement learning problem. This would remove the need to collect a dataset, and would allow the metaheuristic to learn as it optimizes.

Abstract— In power system analysis, sometimes the combined influence of a part of the network is desirable/investigated instead of the dynamics of the individual components therein. For such studies, aggregated models of system components would become beneficial when obtaining the equivalent circuits for the subject part of the network. This paper presents an aggregation method for modeling a cluster of synchronous generators (SGs) connected to a common bus in a power grid. First, it is shown how the so-called transfer matrices can be used for equivalent dynamic modeling of the system components, e.g., SGs with field and damper windings. Then, the transfer matrix-based models of SGs are aggregated to obtain an equivalent dynamic model for the cluster of SGs. The proposed aggregated model of SGs is then validated compared to their full-order qd models using computer simulations. It is verified that the proposed aggregation technique can preserve the dynamic behavior of parallel SGs very accurately for low- and high-frequency electromagnetic oscillations while being computationally more efficient than their classical full-order qd model counterparts.

Keywords— *Aggregated model, equivalent dynamic modeling, impedance-based modeling, synchronous generator (SG), transfer matrices.*

I. INTRODUCTION

Modeling large-scale power systems considering the details of all the components to analyze their dynamic behavior would be cumbersome and computationally demanding, especially in pace with the growth of switching converters [1]. As a matter of fact, the detailed dynamic behavior of all the internal states of some parts of the grid might be unnecessary in some studies [1]. In addition, with the rapid growth of distributed energy resources (DERs) in power grids, new dynamic behaviors and stability issues are emerging [2]. Thus, new and computationally efficient modeling methods are appreciated by planners and operators when conducting analyses to improve the stability and resiliency of the power grids considering the new dynamic behaviors [2]. Traditionally, the state-space modeling [3], [4] and impedance-based modeling [5], [6] were the two main approaches for considering the dynamic behavior of the system components. In the state-space modeling technique, all the system states are required to model the dynamic behavior of the whole system [6]. However, some manufactures may only provide the black-box model of their products [where enough information may not available for obtaining the details of all the states], or the parameters of some components cannot be measured using field tests [4], [5]. In such cases, the impedance-

(and/or admittance-) based modeling approach can be utilized in the form of a transfer function, from input voltages/currents to output currents/voltages [6], [7]. This modeling approach only includes the states corresponding to the input/output voltages/currents to the equivalent impedances/admittances. Consequently, such methods can predict only the dynamic behavior of the states at the interfacing points/connections [6].

One advantage of the impedance/admittance-based modeling technique is that it can provide the possibility of aggregation of the system components [5], [8]. Recently, various aggregation and reduction techniques have been introduced for DERs [1], [7], [9], and wind turbine generators (WTGs) [10], [11], due to their distributed nature. Even with the fast-growing DERs, synchronous generators (SGs) are still pivotal components of power systems as they constitute the dominant share of power generation. Therefore, leveraging aggregated models for SGs can alleviate the computational burden in dynamic simulations of large-scale power systems [5], [12].

Conventionally, modeling SGs in the rotating rotor reference frame (RRF) is more convenient as the varying rotor-position-dependent machine parameters become constant and their implementation for computer simulations would be more efficient and straightforward [3]. However, using RRF in SG modeling would encompass the inevitable dynamics of the reference frame, aka frame dynamics [5]. This introduces a significant challenge in using the impedance-based modeling techniques to aggregate SGs [5], [13]. Particularly, in wind farm studies where the same issue exists, two aggregation approaches have been introduced [11]–[14]. The first method [11], [14] assumes that the rotor speeds of all the SGs are equal, e.g., for those groups of wind turbines that receive equal wind speed. The second method [11]–[13] considers the differences in the rotor speeds of various SGs, which requires appropriate modeling of their mechanical system individually. However, for WTGs the investigations in the literature were mainly focused on the aggregation of doubly-fed induction generators (DFIGs) or permanent-magnet SGs (PMSGs), and the aggregation of wound-field SGs with damper windings has not been explored [11]–[14]. Furthermore, a reduced single equivalent machine model has been reported in [15] for aggregating coherent groups of SGs (which show similar rotor angle swings following a fault) for system-level studies. However, this reduced/aggregated model [15] cannot accurately predict the exact low- and high-frequency electromagnetic oscillations of the original system.

This paper proposes an aggregation technique for incorporating the dynamic models of wound-field SGs with damper windings (which are dominantly used in power systems) into a single transfer matrix-based equivalent dynamic model. With the assumption of a constant synchronous rotational speed, the transfer matrices are employed first for modeling each SG separately. Then, the parallel-connected SGs are transformed into an intermediary reference frame between individual machines where they are aggregated using simple mathematical operations. It is verified that the proposed method results in an aggregated transfer matrix model for a cluster of SGs which not only preserves the exact dynamic information of all the SGs for a wide range of frequencies, but also improves the computational performance in dynamic simulations compared to using multiple classical full-order qd models for SGs.

II. PROPOSED AGGREGATED MODELING METHOD FOR SGs

To present the transfer matrix modeling of an individual SG, and later the aggregation of transfer matrices for a cluster of parallel SGs, the full-order qd model of an SG is considered first. Here, RRF is used and it is assumed that the rotor variables are referred on to the stator side. Also, for simplicity but without loss of generality, only the field winding is considered on the d -axis (denoted by fd) and one damper winding is considered on the q -axis (denoted by kq). The procedure of calculating the equivalent parameters of the field and the one damper winding based on the machine time constants is described in Appendix A.

A. State-Space Model of the SGs in qd Reference Frame

The voltage equations of SGs can be expressed in the qd reference frame as [3, Ch. 5]

$$v_{qs} = r_s i_{qs} + \omega_r \lambda_{ds} + \frac{d\lambda_{qs}}{dt}, \quad (1)$$

$$v_{ds} = r_s i_{ds} - \omega_r \lambda_{qs} + \frac{d\lambda_{ds}}{dt}, \quad (2)$$

for stator windings, and as

$$v_{fd} = r_{fd} i_{fd} + \frac{d\lambda_{fd}}{dt}, \quad (3)$$

$$v_{kq} = r_{kq} i_{kq} + \frac{d\lambda_{kq}}{dt}, \quad (4)$$

for the field and damper windings. The flux linkages can also be expressed as

$$\lambda_{qs} = L_q i_{qs} + L_{mq} i_{kq}, \quad (5)$$

$$\lambda_{ds} = L_d i_{ds} + L_{md} i_{fd}, \quad (6)$$

$$\lambda_{fd} = L_{fd} i_{fd} + L_{md} i_{ds}, \quad (7)$$

$$\lambda_{kq} = L_{kq} i_{kq} + L_{mq} i_{qs}, \quad (8)$$

where

$$L_{mq} = L_q - L_{ls}, \quad L_{md} = L_d - L_{ls}, \quad (9)$$

$$L_{kq} = L_{mq} + L_{lkq}, \quad L_{fd} = L_{md} + L_{lfd}, \quad (10)$$

ω_r : rotor electrical rotational speed,

v_{qs}, v_{ds} : q - and d -axes stator voltages,

i_{qs}, i_{ds} : q - and d -axes stator currents,

$\lambda_{qs}, \lambda_{ds}$: q - and d -axes stator flux linkages,

r_s, L_{ls} : stator resistance and leakage inductance,

L_q, L_d : q - and d -axes stator inductances,

L_{mq}, L_{md} : q - and d -axes magnetizing inductances,

v_{fd}, i_{fd} : field winding voltage and current,

λ_{fd}, L_{fd} : field winding flux linkage and self-inductance,

r_{fd}, L_{lfd} : field winding resistance and leakage inductance,

v_{kq}, i_{kq} : q -axis damper winding voltage and current,

λ_{kq}, L_{kq} : q -axis damper winding flux linkage and self-inductance,

r_{kq}, L_{lkq} : q -axis damper winding resistance and leakage inductance.

B. Transfer Matrix Model of a Single SG

Here, it is considered (as a commonly used assumption) that all parallel SGs have a constant and equal rotational speed (i.e., $\omega_r = \omega_b$ for all SGs where ω_b is the nominal/base rotational speed). This can be a fair assumption considering the slower dynamics of the mechanical subsystems compared to the electromagnetic phenomena of interest. Yet, it facilitates the derivation of transfer matrices for SGs in the Laplace domain. Specifically, considering constant rotational speed for SGs avoids the convolution operation occurring in the frequency domain from the multiplication of two varying state variables in the time domain (i.e., the products of $\omega_r \lambda_{qs}$ and $\omega_r \lambda_{ds}$ in the qd model of SGs). Consequently, (1), (2) become linear ordinary differential equations with constant parameters, and the formulation of the SGs in the Laplace domain would be straightforward.

The field and the damper winding currents can be expressed in Laplace domain based on (3), (4), (7), (8) as

$$i_{fd}(s) = \frac{1}{r_{fd} + sL_{fd}} v_{fd} - \frac{sL_{md}}{r_{fd} + sL_{fd}} i_{ds}(s), \quad (11)$$

$$i_{kq}(s) = -\frac{sL_{mq}}{r_{kq} + sL_{kq}} i_{qs}(s), \quad (12)$$

where v_{fd} is assumed to be constant for SGs in this paper, and v_{kq} is equal to zero for the damper winding. Using (11), (12), the q - and d -axes stator voltages can be expressed in Laplace domain based on (1), (2), (5), (6) as

$$v_{qs}(s) = A(s) \cdot i_{qs}(s) + B(s) \cdot i_{ds}(s) + C(s) \cdot v_{fd}, \quad (13)$$

$$v_{ds}(s) = D(s) \cdot i_{qs}(s) + E(s) \cdot i_{ds}(s) + F(s) \cdot v_{fd}, \quad (14)$$

where

$$A(s) = \left(r_s + sL_q - \frac{s^2 L_{mq}^2}{r_{kq} + sL_{kq}} \right), \quad (15)$$

$$B(s) = \left(\omega_b L_d - \frac{s\omega_b L_{md}^2}{r_{fd} + sL_{fd}} \right), \quad (16)$$

$$C(s) = \left(\frac{\omega_b L_{md}}{r_{fd} + sL_{fd}} \right), \quad (17)$$

$$D(s) = \left(\frac{s\omega_b L_{mq}^2}{r_{kq} + sL_{kq}} - \omega_b L_q \right), \quad (18)$$

$$E(s) = \left(r_s + sL_d - \frac{s^2 L_{md}^2}{r_{fd} + sL_{fd}} \right), \quad (19)$$

$$F(s) = \left(\frac{sL_{md}}{r_{fd} + sL_{fd}} \right). \quad (20)$$

Based on (13), (14) and considering the voltages as inputs and currents as outputs, the SG model in the Laplace domain can be expressed in transfer matrix form as

$$\begin{bmatrix} i_{qs}(s) \\ i_{ds}(s) \end{bmatrix} = \overbrace{\begin{bmatrix} Y_{qq}(s) & Y_{qd}(s) \\ Y_{dq}(s) & Y_{dd}(s) \end{bmatrix}}^{\mathbf{Y}_{qd}} \begin{bmatrix} v_{qs}(s) \\ v_{ds}(s) \end{bmatrix} - \overbrace{\begin{bmatrix} G_{qfd}(s) \\ G_{dfd}(s) \end{bmatrix}}^{\mathbf{G}} v_{fd}, \quad (21)$$

where

$$\begin{bmatrix} Y_{qq}(s) & Y_{qd}(s) \\ Y_{dq}(s) & Y_{dd}(s) \end{bmatrix} = \begin{bmatrix} A(s) & B(s) \\ D(s) & E(s) \end{bmatrix}^{-1}, \quad (22)$$

$$\begin{bmatrix} G_{qfd}(s) \\ G_{dfd}(s) \end{bmatrix} = \begin{bmatrix} A(s) & B(s) \\ D(s) & E(s) \end{bmatrix}^{-1} \begin{bmatrix} C(s) \\ F(s) \end{bmatrix}. \quad (23)$$

Here, the \mathbf{Y}_{qd} matrix with Y_{ij} ($i,j=q,d$) entries is the admittance matrix specifying the relationship between q - and d -axes stator currents and voltages, and the \mathbf{G} matrix with G_{ik} ($i=q,d$, and $k=fd$) entries specifies the relationship between q - and d -axes stator currents and the field voltage.

C. Aggregation of SGs with Transfer Matrices

To demonstrate the general concept of aggregation of the transfer matrix-based models of SGs, it is assumed that N parallel SGs are connected to a power grid, as depicted in Fig. 1. It is assumed that the rotor angle (δ) of each SG can be obtained from a power flow analysis. Knowing the rotor angle of SGs, the variables can be transformed between different qd reference frames as

$$\begin{bmatrix} u'_q \\ u'_d \end{bmatrix} = \overbrace{\begin{bmatrix} \cos(\varphi) & \sin(\varphi) \\ -\sin(\varphi) & \cos(\varphi) \end{bmatrix}}^{\mathbf{T}_{qd}} \begin{bmatrix} u_q \\ u_d \end{bmatrix}, \quad (24)$$

where u is a system quantity, e.g., voltage or current, and φ is the angle difference between the two qd frames which is assumed to remain constant through the system dynamics [5]. It should be noted that transforming between qd frames using the \mathbf{T}_{qd} matrix leads to an alteration of transfer matrices of (21) as

$$\begin{bmatrix} Y'_{qq}(s) & Y'_{qd}(s) \\ Y'_{dq}(s) & Y'_{dd}(s) \end{bmatrix} = \mathbf{T}_{qd} \begin{bmatrix} Y_{qq}(s) & Y_{qd}(s) \\ Y_{dq}(s) & Y_{dd}(s) \end{bmatrix} \mathbf{T}_{qd}^{-1}, \quad (25)$$

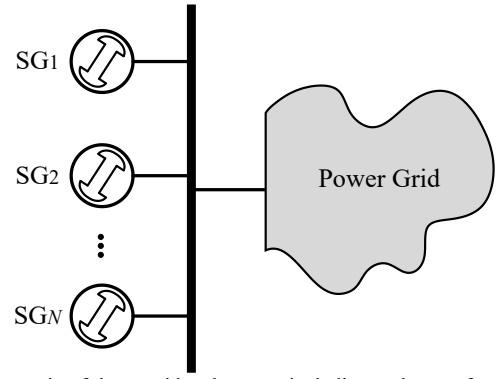

Fig. 1. Schematic of the considered system including a cluster of parallel SGs connected to a power grid.

$$\begin{bmatrix} G'_{qfd}(s) \\ G'_{dfd}(s) \end{bmatrix} = \mathbf{T}_{qd} \begin{bmatrix} G_{qfd}(s) \\ G_{dfd}(s) \end{bmatrix}. \quad (26)$$

Without loss of generality, it is assumed that SG1 remains in its qd reference frame (i.e., RRF1), and the qd equations of all other SGs (i.e., SG n with $n \in \{2, \dots, N\}$) are transformed from their qd reference frame (i.e., RRF n) to RRF1. Therefore, the transfer matrices of the first and n -th SGs can be expressed as

$$\begin{bmatrix} i_{qs1}(s) \\ i_{ds1}(s) \end{bmatrix} = \begin{bmatrix} Y_{qq1}(s) & Y_{qd1}(s) \\ Y_{dq1}(s) & Y_{dd1}(s) \end{bmatrix} \begin{bmatrix} v_{qs1}(s) \\ v_{ds1}(s) \end{bmatrix} - \begin{bmatrix} G_{qfd1}(s) \\ G_{dfd1}(s) \end{bmatrix} v_{fd1}, \quad (27)$$

$$\begin{bmatrix} i'_{qsn}(s) \\ i'_{dsn}(s) \end{bmatrix} = \begin{bmatrix} Y'_{qqn}(s) & Y'_{qdn}(s) \\ Y'_{dqn}(s) & Y'_{ddn}(s) \end{bmatrix} \begin{bmatrix} v'_{qsn}(s) \\ v'_{dsn}(s) \end{bmatrix} - \begin{bmatrix} G'_{qfdn}(s) \\ G'_{dfd n}(s) \end{bmatrix} v_{fdn}. \quad (28)$$

where $v_{qs1} = v_{qsn} = v_{qs}$ and $v_{ds1} = v_{dsn} = v_{ds}$ due to their parallel connection.

Finally, the transfer matrices of all the SGs, which are referred to as RRF1 can be aggregated by adding their stator currents [e.g., adding (27) to (28)] and obtaining the combined currents as

$$\begin{bmatrix} i_{qs}(s) \\ i_{ds}(s) \end{bmatrix} = \begin{bmatrix} i_{qs1}(s) \\ i_{ds1}(s) \end{bmatrix} + \sum_{n=2}^N \begin{bmatrix} i'_{qsn}(s) \\ i'_{dsn}(s) \end{bmatrix} \\ = \begin{bmatrix} Y'_{qq}(s) & Y'_{qd}(s) \\ Y'_{dq}(s) & Y'_{dd}(s) \end{bmatrix} \begin{bmatrix} v_{qs}(s) \\ v_{ds}(s) \end{bmatrix} - \begin{bmatrix} G'_{qfd1}(s) & \dots & G'_{qfdN}(s) \\ G'_{dfd1}(s) & \dots & G'_{dfdN}(s) \end{bmatrix} \begin{bmatrix} v_{fd1} \\ \vdots \\ v_{fdN} \end{bmatrix}, \quad (29)$$

where

$$\begin{bmatrix} Y'_{qq}(s) & Y'_{qd}(s) \\ Y'_{dq}(s) & Y'_{dd}(s) \end{bmatrix} = \begin{bmatrix} Y_{qq1}(s) & Y_{qd1}(s) \\ Y_{dq1}(s) & Y_{dd1}(s) \end{bmatrix} + \sum_{n=2}^N \begin{bmatrix} Y'_{qqn}(s) & Y'_{qdn}(s) \\ Y'_{dq n}(s) & Y'_{ddn}(s) \end{bmatrix}, \quad (30)$$

$$\begin{bmatrix} G'_{qfd1}(s) & \dots & G'_{qfdN}(s) \\ G'_{dfd1}(s) & \dots & G'_{dfdN}(s) \end{bmatrix} = \begin{bmatrix} G_{qfd1}(s) & \dots & G_{qfdN}(s) \\ G_{dfd1}(s) & \dots & G_{dfdN}(s) \end{bmatrix}. \quad (31)$$

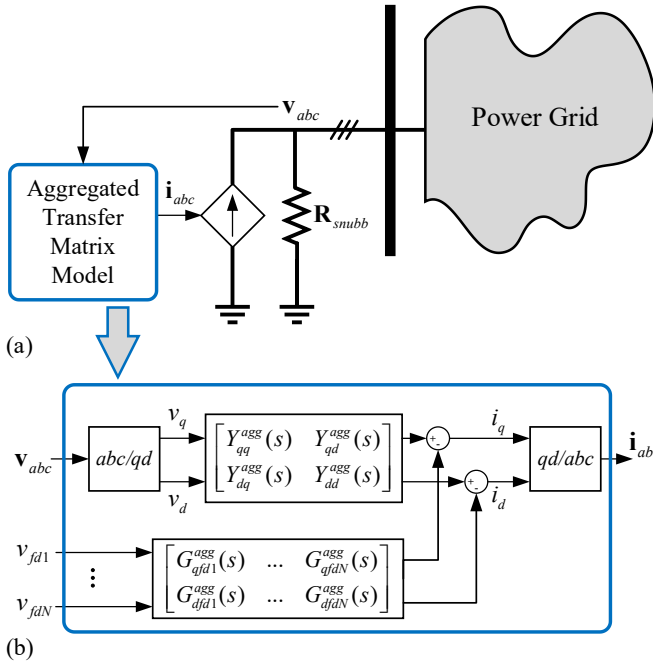

Fig. 2. Implementation of the proposed aggregated transfer matrix model of the parallel SGs: (a) interfacing with external network using voltage-controlled current sources, (b) implementation of the transfer matrices.

Fig. 3. Schematic of the case-study system consisting of two parallel SGs supplying a dc system through a rectifier.

Based on (29), the cluster of SGs can be modeled as an aggregated transfer matrix, as illustrated in Fig. 2(a). As seen, the inputs of the aggregated transfer matrix model of the SGs are the terminal and field voltages and the outputs are the injected stator currents of SGs. Therefore, similar to the qd models of SGs, a three-phase dependent current source (with possibly a three-phase snubber resistance (R_{snubb}) in case of connection to an inductive or a power-electronic-based network [16]) can be used for circuit implementation of the proposed aggregated transfer matrix model of the SGs.

III. COMPUTER STUDIES

Here, the accuracy and computational performance of the proposed aggregated transfer matrix model of the SGs, formulated in Section II, are investigated for a representative case study shown in Fig. 3. Therein, two SGs are connected in parallel and supply a dc load through a six-pulse diode rectifier. The SGs are connected to the rectifier through a transmission line (represented by R_{line} , L_{line}). A low-pass filter (represented by L_{filter} , C_{filter}) is also used to smoothen the dc voltage supplied to the dc load. Without loss of generality, it is also assumed that

Fig. 4. Waveforms of the system variables in steady-state obtained by the classical qd state-space model and the proposed aggregated transfer matrix-based model for: (a) phase a voltage at Bus-PCC, (b) total injected phase a current to Bus-PCC by the two SGs, (c) dc load voltage, and (d) rectifier dc current.

the dc load can be represented by a resistor consuming the required power. The parameters of the case-study system are summarized in Appendix B.

To verify the proposed transfer matrix-based modeling technique, two different approaches are considered for modeling the parallel SGs: First, as the reference model, the two SGs are implemented individually using their classical qd state-space models in MATLAB/Simulink. Secondly, the proposed aggregated model of the two SGs has been implemented using the transfer matrices following the procedure explained in Section II. Both the reference and the proposed aggregated models are interfaced with the external network using 100 pu (with base $S_b = 105$ MVA and $V_b = 560$ V) artificial snubbers connected across the terminals of the SGs [see Fig. 2(a)].

A. Steady-State Operation with High-Frequency Harmonics

Here, it is assumed that the field voltages (E_{xfdn}) of both SGs [i.e., $E_{xfdn} = (X_{mnd}/r_{fdn}) v_{fdn}$ with $n \in \{1, 2\}$], are held constant at 2.30 pu. As a result, at the rated line-to-line voltage (i.e., 560 V), SG1 delivers 52 kW with rotor angle $\delta_1 = 32.94^\circ$ and SG2 delivers 22 kW with rotor angle $\delta_2 = 26.02^\circ$. This corresponds to 74 kW (neglecting the losses in the transmission line) consumed by the dc network, which is modeled as a resistive load of 10 ohms. The system variables obtained by the subject models in steady-state are shown in Fig. 4. As it can be observed in Figs. 4(a) and 4(b), the proposed aggregated model provides

consistent results with the qd state-space model for the ac-bus (Bus-PCC) voltage and the combined current of the two SGs, including their harmonics. Also, as seen in Fig. 4(c) and 4(d), the proposed aggregated model provides very accurate results for the dc-side variables, compared to the reference model, including the switching ripples.

B. Transients Following a Short-Circuit Fault

Here, it is assumed that the system initially operates in a steady-state condition as specified in Section III-A. Then, at $t = 1$ s, a three-phase short-circuit fault occurs on the transmission line and is very close to Bus-PCC (as indicated in Fig. 3). The fault is removed at $t = 1.1$ s. The system variables obtained by the subject models for the duration of the transient are depicted in Fig. 5. As it can be observed in Figs. 5(a) and 5(b), the voltage at the ac-bus becomes zero after the short-circuit fault, resulting in a very high current due to the high voltage at the terminals of the SGs (the field voltages were assumed to be constant). It can also be seen in Fig. 5(d) that the dc current becomes zero following the fault. This is due to the fact that the diodes in the rectifier become reverse biased after the fault. Consequently, the dc voltage starts to decrease (with the time constant of the dc subsystem). It is also seen in Figs. 5(a)–(d) that the system starts to recover after removing the fault.

In the meanwhile, it is verified in Figs. 5(a)–(d) that the proposed aggregated model is very accurate (compared to the qd state-space model as the reference) in predicting the system variables even in such large-signal transients.

C. Predicting the Operational Impedances

The so-called operational impedances [3, Ch. 7] can be analyzed to verify the accuracy achieved by the proposed aggregated model in steady-state and transient studies in Sections III-A and B. For this purpose, the q - and d -axes stator flux linkages per second can be written in the frequency domain as [3, Ch. 7]

$$\psi_{qs}(s) = X_{qs}(s)i_{qs}(s), \quad (32)$$

$$\psi_{ds}(s) = X_{ds}(s)i_{ds}(s) + K_{fd}(s)v_{fd}. \quad (33)$$

Here, $X_{qs}(s)$ and $X_{ds}(s)$ are the operational impedances [3, Ch. 7], and $K_{fd}(s)$ is a transfer function that expresses the relationship between the d -axis stator flux linkage per second and the field voltage. Comparing (5), (6) with (32), (33), and using (11), (12), the operational impedances for an SG can be expressed as

$$X_{qs}(s) = \omega_b \left(L_q - \frac{sL_{mq}^2}{r_{kq} + sL_{kq}} \right), \quad (34)$$

$$X_{ds}(s) = \omega_b \left(L_d - \frac{sL_{md}^2}{r_{fd} + sL_{fd}} \right), \quad (35)$$

and $K_{fd}(s)$ is defined as

$$K_{fd}(s) = \frac{L_{md}}{r_{fd} + sL_{fd}}. \quad (36)$$

The operational impedances can also be calculated using the proposed transfer matrix-based model of the individual SGs based on the Y_{qd} transfer matrix in (21). This is achieved by

Fig. 5. Waveforms of the system variables when a short circuit occurs at $t=1$ s (and cleared at $t=1.1$ s) as obtained by the classical qd state-space model and the proposed aggregated transfer matrix-based model for: (a) phase a voltage at Bus-PCC, (b) total injected phase a current to Bus-PCC by the two SGs, (c) dc load voltage, and (d) rectifier dc current.

setting r_s and ω_r equal to zero [3, Ch. 7] for computing the impedances as

$$X_{qs}(s) = \frac{\omega_b}{s} \left. \frac{v_{qs}(s)}{i_{qs}(s)} \right|_{r_s=0, \omega_r=0} = \frac{\omega_b}{s} \left. \frac{1}{Y_{qq}(s)} \right|_{r_s=0, \omega_r=0}, \quad (37)$$

$$X_{ds}(s) = \frac{\omega_b}{s} \left. \frac{v_{ds}(s)}{i_{ds}(s)} \right|_{r_s=0, \omega_r=0} = \frac{\omega_b}{s} \left. \frac{1}{Y_{dd}(s)} \right|_{r_s=0, \omega_r=0}. \quad (38)$$

Similarly, aggregated operational impedances can be calculated for the cluster of SGs using the proposed aggregated model based on the transfer matrix in (29) and following the procedure in (37), (38).

The bode plots for the operational impedances of the two parallel SGs in Fig. 3 are obtained using their proposed aggregated model [based on (37), (38)] and compared with their exact (reference) values [i.e., $X_{qs}(s) = X_{qs1}(s) \parallel X_{qs2}(s)$ for the q -axis and $X_{ds}(s) = X_{ds1}(s) \parallel X_{ds2}(s)$ for the d -axis, based on (34), (35)] in Figs. 6 and 7. As observed, the proposed aggregated model can be effectively utilized for predicting the magnitude and phase of the d - and q -axes operational impedances of the parallel SGs with very high accuracy over a wide range of frequency spectrum. This also verifies and explains the high accuracy observed in Figs. 4 and 5 for the steady-state and transient response of the proposed model.

Fig. 6. Magnitude and phase of the q -axis operational impedance of the two parallel SGs over a wide range of frequency as predicted by the proposed aggregated model.

Fig. 7. Magnitude and phase of the d -axis operational impedance of the two parallel SGs over a wide range of frequency as predicted by the proposed aggregated model.

D. Comparison of Computational Performance

Finally, the computational performance of the proposed aggregated model of the parallel SGs is benchmarked against their counterpart qd state-space model. For consistency, both models are simulated in MATLAB/Simulink [17] using the stiff solver *ode23tb* as well as the non-stiff solver *ode45* with maximum and minimum time-step of 0.1 ms and 0.01 μ s, respectively. The absolute and relative errors are chosen to be 10^{-4} . The simulations are executed on a personal computer with Intel® Core™ i7-10750H CPU @ 2.60 GHz processor.

Here, the same short-circuit fault transient study explained in Section III-B is conducted on the case-study system of Fig. 3 and simulations are continued for 5 seconds. The computational performance of the two subject models is tabulated in Table I and Table II with the stiff solver *ode23tb* and non-stiff solver *ode45*, respectively.

As can be seen in Tables I and II, the two models require approximately the same number of time steps. Therefore, one can deduce that the two models have essentially similar eigenvalue structures. However, with the *ode23tb* solver, the proposed aggregated model shows a marginal improvement of 14.7% in the CPU time compared to the qd state-space model (i.e., 25.37 s vs. 29.77 s), as seen in Table I. Meanwhile, when

both models are run with the *ode45* solver, the proposed aggregated model outperforms the qd state-space model by decreasing the CPU time by 39.9% (i.e., 300.25 s vs. 499.85 s), as seen in Table II. This verifies that simulating the system using the proposed aggregated transfer matrix-based model is computationally more efficient (i.e., less complex) for the solver than computing the system variables using multiple qd state-space models for SGs.

TABLE I. COMPUTATIONAL PERFORMANCE OF THE SUBJECT MODELS FOR THE CONSIDERED 5-SECOND TRANSIENT STUDY WITH THE STIFF SOLVER *ode23tb*

Model	Number of time steps	CPU time
Classical qd State-Space Model	97,520	29.77 s
Proposed Aggregated Model	99,465	25.37 s

TABLE II. COMPUTATIONAL PERFORMANCE OF THE SUBJECT MODELS FOR THE CONSIDERED 5-SECOND TRANSIENT STUDY WITH THE NON-STIFF SOLVER *ode45*

Model	Number of time steps	CPU time
Classical qd State-Space Model	2,500,643	499.85 s
Proposed Aggregated Model	2,500,501	300.25 s

IV. CONCLUSION

This paper presents an aggregation technique for equivalent dynamic modeling of a cluster of synchronous generators (SGs). The proposed method exploits the so-called transfer matrices in the Laplace domain, where the equivalent transfer-based models are aggregated. It has been shown for a cluster of wound-field synchronous generators (SGs) with damper windings that the proposed aggregated model can follow their classical full-order qd models very accurately for a wide range of electromagnetic transients, e.g., for high-order harmonics and/or short-circuit dynamics. Furthermore, it was verified that the proposed aggregated model of the SGs is computationally more efficient than their classical full-order qd state-space models.

APPENDIX A

The magnetizing and subtransient reactances of an SG with a field and one damper winding on its d -axis as well as two damper windings on its q -axis are expressed as [3, Ch. 7]

$$X_{mq} = X_q - X_{ls}, \quad (\text{A.1})$$

$$X_{md} = X_d - X_{ls}, \quad (\text{A.2})$$

$$X_q'' = X_{ls} + \frac{1}{\frac{1}{X_{mq}} + \frac{1}{X_{lkq1}} + \frac{1}{X_{lkq2}}}, \quad (\text{A.3})$$

$$X_d'' = X_{ls} + \frac{1}{\frac{1}{X_{md}} + \frac{1}{X_{lfd}} + \frac{1}{X_{lkd}}}. \quad (\text{A.4})$$

Also, the SG's open-circuit time constants can be expressed as [3, Ch. 7]

$$\tau_{qo}'' = \frac{1}{\omega_b r_{kq2}} \left(X_{lkq2} + \frac{X_{mq} X_{lkq1}}{X_{mq} + X_{lkq1}} \right), \quad (\text{A.5})$$

$$\tau'_{do} = \frac{1}{\omega_b r'_{fd}} (X_{jfd} + X_{md}). \quad (A.6)$$

To calculate the parameters of an equivalent SG with only the field winding on the d -axis and only one damper winding on the q -axis, it is desired that the subtransient reactances of the equivalent machine remain unchanged (to keep the short-circuit subtransient peak current magnitude of the equivalent machine in the same level) [3, Ch. 7]. Therefore, using the magnetizing and subtransient reactances in (A.1)–(A.4), the leakage reactances of the equivalent field winding and one damper winding for the equivalent SG can be obtained as

$$X_{jfd}^{equ} = \frac{1}{\frac{1}{X_d'' - X_{ls}} - \frac{1}{X_{md}}}, \quad (A.7)$$

$$X_{lkq}^{equ} = \frac{1}{\frac{1}{X_q'' - X_{ls}} - \frac{1}{X_{mq}}}. \quad (A.8)$$

Then, to maintain the same open-circuit time-constants as the original SG, the transient d -axis open-circuit time-constant (τ'_{do}) is used as the field winding time-constant (τ_{fd}), and the subtransient q -axis open-circuit time-constant (τ''_{qo}) as the q -axis damper winding time-constant (τ_{kq}) for the calculation of machine winding parameters [18]. As a result, the field and the one damper winding resistances are calculated based on (A.5), (A.6) as

$$r'_{fd} = \frac{X_{jfd}^{equ} + X_{md}}{\omega_b \tau'_{do}}, \quad (A.9)$$

$$r_{kq} = \frac{X_{lkq}^{equ} + X_{mq}}{\omega_b \tau''_{qo}}. \quad (A.10)$$

In this paper, the superscript “ equ ” denoting the parameters of the equivalent SG has been removed from notations for simplicity.

APPENDIX B

Parameters of the Case-Study System in Fig. 3:

TABLE III. PARAMETERS OF SG 1 [19]

Parameter	Value	Parameter	Value
Rating	105 kVA	Voltage	560 V
r_s	0.137 Ω	X_{ls}	0.338 Ω
X_d	16.624 Ω	X_q	8.180 Ω
r_{fd}	0.0266 Ω	X_{jfd}	1.270 Ω
r_{kd}	0.120 Ω	X_{lkd}	0.062 Ω
r_{kq}	0.120 Ω	X_{lkq}	0.131 Ω

TABLE IV. PARAMETERS OF SG 2 [20]

Parameter	Value	Parameter	Value
Rating	59 kVA	Voltage	560 V
r_s	0.09 Ω	X_{ls}	1.276 Ω
X_d	29.507 Ω	X_q	17.226 Ω
r_{fd}	0.0195 Ω	X_{jfd}	2.1852 Ω
r_{kd}	0.42 Ω	X_{lkd}	5.33 Ω
r_{kq1}	25.26 Ω	X_{lkq1}	2.3287 Ω
r_{kq2}	1.07 Ω	X_{lkq2}	5.2635 Ω

Abstract—Non-destructive mapping of underground utilities is one of the fundamental concepts of subsurface imaging technology that has a great contribution to the improvement of many infrastructure concerns. It is incorporated with electrical resistivity measurement of various ground conditions through electrodes with functional geometric configuration. Due to the presence of an electrical field, electromagnetic noise and interference will likely occur and might cause inaccuracy of data. On that note, it is vital to understand the different factors affecting the system and its impact as the initial step in the development of an effective filtering and shielding mechanism. Thus, this paper discusses the possible impacts of parasitic inductance and capacitance affecting the performance of low and very low-frequency antennas, and the collection of various optimization methods as well as the tools and software used in the mitigation of parasitic elements in an electronics system found in different research publications and journals. Furthermore, an AI-based framework was also provided as an initial step in the development of a parasitic antenna filter that performs well for underground imaging single antenna array. Genetic algorithm is the AI technique proposed for the optimization of the antenna filter by providing the best combination of material by considering its conductivity and thickness.

I. INTRODUCTION

Subsurface imaging technology has been known for its functional detection of utilities underground [1]. In the Philippines, it has a huge potential in solving infrastructure problems through the non-destructive mapping of underground utilities as there are more investments in infrastructure projects since 2017 [2]. In putting up an underground imaging system, there are transmitter and receiver circuits as well as capacitive electrodes that have functional geometrical arrangements that are capacitively coupled to the ground. They are used in the recording of electrical resistivity measurement which depends on varying ground conditions. Thus, it is inevitable to encounter challenges such as close levels of electrical and electromagnetic noise and interference due to the presence of the electrical field [3].

It is eminent that electromagnetic interference (EMI) brings disruption to the electrical circuit because of the presence of electromagnetic radiation coming from an outer source [3]. Relatedly, the noise all around the EMI frequency spectrum is caused by impedances and current/voltage sources [4]. The increasing use of electromagnetic transmission systems for information technology applications in the surroundings caused the electromagnetic spectrum to be congested that resulting in EMI which affects the normal function of a certain system [3]. In addition, this disturbance was caused by electromagnetic energy called environmental interference (EI) which is categorized according to its sources such as environmental, incidental, or intentional [3]. Also, the spectrum is crowded in low-frequency bands [5]. Hence, an effective EMI shielding mechanism is vital for the protection of a sensitive frequency-operated system such as in the mapping of underground utilities.

In power electronics, electrical circuits usually contain parasitic elements due to the coupling of electromagnetic and electrostatic between different components of the circuit [6]. Truly, it is difficult to obtain a unified and accurate model to characterize noise emissions due to varying speed, configuration, and information of a particular system in power electronics [4]. With that, this research addresses the conventional sources of electromagnetic interference and the impacts of parasitic inductance and parasitic capacitance affecting the performance of very low and low frequency antennas. It aims to discuss how parasitics may possibly influence and contribute to the disturbance of systems. Furthermore, this study contributes to the: (1) discussion and emphasizing of the tools and software used by different studies in this field and the optimization methods done to establish an effective mitigation mechanism for parasitic elements in an electronics system, and (2) formulation of an innovation framework for the use of AI-based techniques in mitigating parasitic elements that could be used for further development of a shield or filter mechanism for VLF-LF antenna operation for subsurface imaging.

II. ACTIVE PARASITIC ELEMENTS IN ANTENNA

Self and mutual parasitics are the two types of parasitic parameters in a particular electronic circuit. The self-parasitics basically covers the parasitic components of inductors while the

mutual parasitics usually occur between the layout of printed circuit board (PCB) and its traces [7]. Additionally, pertaining in the analysis of electromagnetic compatibility, there are factors to contemplate, such as distinguishing the EMI sources, locating the crucial signal paths and coupling loops, and applying EMI mitigation techniques, especially in designing EMI filters [8].

Undeniably, parasitic elements are present in any frequency spectrum, and it just varies on how it affects the circuit system. It is interesting to unveil how parasitic elements deal with low and very low-frequency ranges. It is known that underground and underwater are two difficult environments to deal with when it comes to radio frequency communications since the incorporation of high-frequency electromagnetic waves is rejected in concentrated media [9]. Hence, stray inductance and stray capacitance in antennas with low and very low frequencies were attempted to tackle. This will help in establishing an EMI filter that could potentially be used in an underground imaging application operating in a very low and low-frequency range.

III. STRAY INDUCTANCE AND CAPACITANCE IN ANTENNA OPERATIONS

Stray inductance can be defined as unavoidable inductance present within a circuit which disrupts the normal flow of the current. The basic concept of stray inductance is when wires or any other electronic components conceived magnetic fields around them producing an inductive effect that must be avoided. The goal of minimizing the parasitic inductance is a great challenge to engineers and circuit designers as it contributes to difficulties in the field of power electronics. Some problems related to it are the rise of unwanted overshoots and ringing after switching transients [10]. Likewise, stray capacitance is incorporated into unnecessary capacitance in an electronic system. Capacitance can be produced if there are any two elements at different electric potentials that are near to each other. Those elements could generate an electric field and become like capacitors [11]. It must be considered also that any wire used in the circuit can contain limited capacitance concerning the ground. Likewise, a sensor that acts as a capacitor could also contribute to the additional capacitances in the circuit due to its obtained wires [12]. Changes in capacitance such as capacitance fluctuations are considered one source of error due to the said circumstances [12]. Hence, one important way of minimizing the stray capacitance is through the separation of sensor elements and the rest of the circuit [12].

A. Impacts of Stray Inductance and Capacitance

The inductance is not of great concern in low-frequency circuits as well as with the lower HF band circuits [13]. Strays become crucial when passing frequencies from upper HF to the VHF region. At those frequency ranges, the stray inductance becomes a significant component of the total circuit inductance [13]. In regards to the VLF range, the authors have difficulty gathering research papers about the effects of stray inductance and capacitance in VLF. To the best of the researchers' knowledge, most of the studies found that are related to the VLF antennas are very outdated [14-16]. Thus, it can be concluded that most of the authors studying the field of parasitics are not

exploring too much VLF compared to a high-frequency range which has a huge impact on this matter.

On the other hand, stray capacitance has a notable impact on the common-mode noise in conductive electromagnetic interference (EMI) [17]. However, stray capacitance should not give special attention to dc and low ac frequencies [13]. It is mentioned in [18] that in dealing with high-frequency, the effects of such unwanted capacitance are amplified. Capacitive effects are more dynamic at higher voltages in low frequency than inductive effects [18]. However, it should also be noted that as the frequency increases, those parasitic elements obtained a massive proportion of their totality [13].

B. Factors Affecting Stray Inductance and Capacitance

Proper circuit layout is an important factor in RF circuits as it can reduce the effects of parasitic elements [13]. Stray inductance is mainly incorporated into metal connecting wire where the distance, diameter, type of material, shape, and linking methods are factors to be considered for a change in electrical characteristics of a certain power module [19]. For stray capacitance, it is also noteworthy to consider the use of broad printed circuit tracks for connection rather than wires [13]. Air as an excellent dielectric is a most renowned contributor to stray capacitance [20]. Evidently, one or more dielectrics can be incorporated into stray capacitances. Hence, its magnitude will vary depending on the location of the main capacitor [20]. Resistors also exhibit a few amounts of parasitic capacitance due to their connecting leads and certain parts that have the capability to store charge [18].

IV. MITIGATION STRATEGIES FOR PARASITIC ELEMENTS

There are stray couplings between components that are more challenging to classify, so the development of a mitigation model that incorporates the identification of magnetic and electric fields around certain parts components were employed to control its parasitic elements [21]. Efficient EMI mitigation strategies have gained increasing interest as EMI designing and simulation enable the estimation of the emf performance of a certain circuit system before prototyping [22]. It is known that the sole objective of noise filters is to reduce the unnecessary electrical waves to the electronically powered equipment and propagates via alternating current lines and to the nearby devices [22]. Thus, EMI filters must be properly designed according to the need and complexity of an electronic system [22].

A. Tools and Software

In developing an EMI filter, one important thing to consider is the tools and software used in measuring current flows in components and other parasitic elements. For an antenna model estimation, a study used an LCR meter that functions in frequencies between 12 Hz and 187 Hz to measure the electrical circuit of a loop antenna [23]. On the other hand, an oscilloscope and a function generator were established to measure lower frequencies that are < 12 Hz [23]. In [24], ANSYS HFSS 3D finite element electromagnetic solver was used for measuring current scattering within two AI blocks that resemble the inner capacitors' form (Fig. 1). It was used to confirm the suggested concept of the proximity effect, while the electrical flow in the anti-parallel arrangement will approximate each other, thus,

based on the simulation the expected phenomenon happened [24].

In terms of measuring the stray inductance and capacitance of an Integrated Power Electronics Module (IPEM), Maxwell Q3D Extractor was used in [25] and Agilent 4294A precision impedance analyzer for verification of the simulation results. Using these tools, impedance measurement confirmed the loop inductances when the switching to on and off is employed as well as the capacitances between three terminals and the ground. Hence, this was done to measure the parasitic inductance. Relatedly, another tool for impedance measurement was mentioned in [22]. The OMICRON Bode100 vector network analyzer was used to verify measurements, thus, upon comparing the simulations and measurements, it conceived a good match that operated in a frequency of 10 Hz to 40 MHz [22].

One tool for measuring insertion gains and network criteria in an EMI filter structure is the Agilent four-port balanced network analyzer E5070B which was utilized in [11]. It is known that the effects of stray capacitance can be illustrated through numerical simulations using finite element analysis (FEA) [18]. Thus, to execute the modeling, a Comsol Multiphysics® software package was utilized in a study to develop FEA models used to calculate the charge distribution of conductors with an operating frequency of 50 Hz [18]. Apparently, voltage noise measurement is important to consider in exploring the effects of parasitic elements as it also leads to the mitigation of those strays. In [26], the Hewlett-Packard 35665A dynamic signal analyzer was utilized in calculating all the voltage noise incorporated in the study that is open from the test circuits output. The modulation frequency used in the experiment is 100 kHz [26]. Overall, these tools and software mentioned in different studies were able to establish an important initiative to mitigate the known parasitic elements and analysis of various electronic systems. Hence, the summary of these tools and software with a measured frequency range between <12 Hz and 110 MHz were presented in Table 1.

TABLE I. SUMMARY OF THE TOOLS AND SOFTWARE USED IN MITIGATING PARASITIC ELEMENTS.

Tools / Software	Function	Measured Frequency Range
LCR meter [23]	measure a loop antenna electrical circuit	12 Hz -187 Hz
Oscilloscope and a function generator set-up [23]	measure a loop antenna electrical circuit	< 12 Hz
ANSYS HFSS 3D finite element electromagnetic solver [24]	compute the current distribution	50 MHz
Maxwell Q3D Extractor [25]	calculate the parasitic elements of an Integrated Power Electronics Modules (IPEM)	-
Agilent 4294A precision impedance analyzer [25]	measure IPEM for verification of Maxwell Q3D simulation results	40 Hz – 110 MHz
OMICRON Bode100 vector network analyzer [22]	verify impedance measurements of the L-shaped conductors of Partial element equivalent circuit (PEEC) model	10 Hz – 40 MHz
Agilent four-port balanced network analyzer E5070B [11]	measure all insertion gains and network criterions	-
Comsol Multiphysics® software package [18]	develop FEA models used to calculate the charge distribution of conductors	50 Hz
Hewlett-Packard 35665A dynamic signal analyzer [26]	calculate the voltage noise coming from the circuits' output	100 kHz

B. Optimization Methods

Over the years, there are various techniques and optimization methods that were developed by researchers for the attenuation of noise and performance improvement for EMI filters. One simple technique used in [24] is placing two or more capacitors in two positions which are parallel and anti-parallel arrangements (Fig. 2). Using these, it significantly reduced their equivalent parasitic inductance, which increases the level of reduction of a filter at the HF range [24]. The proposed anti-parallel arrangements of capacitors can also enhance the behavior of EMI filters in HF range [24].

Cancellation techniques were utilized in various research papers, one is the ESL cancellation technique which basically uses an X-capacitor-inductor structure [8]. In Fig. 3(a) and 3(c), the ESL cancellation concept was presented where two capacitors are connected diagonally. It can be seen that two inductors, L, are attached on the upper and lower sides. Thus, if the total value of inductance is the same as the ESL (Fig. 3(b) and 3(d)), then the reaction of ESL on the diverted path are canceled as well as the cancellation resistance and ESR [8]. However, ESR and ESL cannot be completely canceled, but they can be successfully lessened and improve the capabilities of the capacitors [8].

In mitigating parasitic capacitance, a great work of estimating it applicable to CM noise in actual time was employed using the Unscented Kalman Filter (UKF) [17]. The UKF was used as a state simulator and the complement circuit of CM noise. Together, they were able to determine the effective parasitic capacitance. Thus, the proposed method used a typical

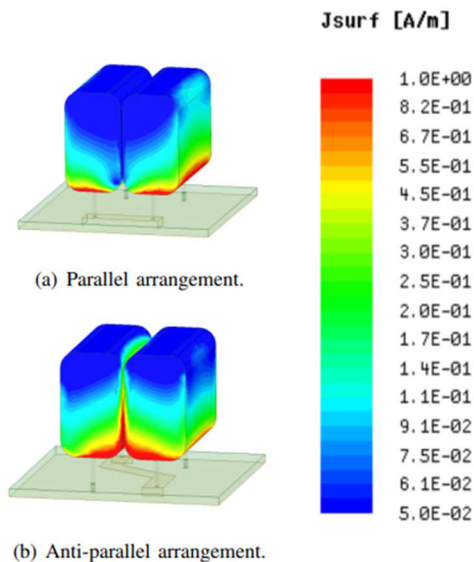

Fig. 1. The current surface density of two aluminum blocks was calculated with ANSYS HFSS at 50 MHz [24].

Fig. 2. Two smart arrangements applied in two capacitors that serve as diverted filters together with their incorporated circuit representation: (a) parallel and (b) anti-parallel [24].

Fig. 3. ESL cancellation for capacitors: (a) two capacitors were connected diagonally, (b) resultant circuit of (a), (c) two small inductors L , are attached to the upper and lower sides, and (d) resultant circuit of (c) showing that inductance is equal to equivalent series inductance (ESL) showing no effect [10].

DC-DC buck converter in various working set-ups for testing [17].

Another study was conducted [18] where the effects of dispersed parasitic capacitance have been examined by conducting assessments through 3-D Finite Element Analysis (FEA). This allows the calculation of the parasitic capacitance and the alteration in the divider voltage output [18]. Additionally, the use of grading electrodes to alleviate the results of stray capacitance was utilized. It found that only limited correction and enhancement in the function of the resistive divider was gained when the toroidal grading rings were employed while grading hollow cylinders that function as a Faraday cage for the electrical lines, showing an excellent improvement in the response of the divider [18].

Another application that accumulates stray capacitance is in a cryogenic experimental set-up where it uses long coaxial

cables for the minimization of heat leak [26]. Unfortunately, these cables have a huge amount of capacitance per unit and a lock-in amplifier can be utilized to get rid of the outcome of the demodulator at around 100 kHz [26]. The effectivity of the coax cable and the vessel in terms of disallowing EMI should be considered in noise performance. Thus, an optimized trans-impedance capacitive sensor circuit was utilized that obtained functional noise operation and an allowable rejection of RFI [26]. This circuit introduced a capacitor that is in series with the stray capacitance and this greatly resulted in reduced noise gain in comparison to other test circuits employed [26].

A summary of the various optimization methods was presented in Table 2. However, the frequency range utilized in those methods is mostly for high-frequency operations as research papers incorporated from LF to VLF range is very limited to none. Thus, it can be concluded that parasitics in high frequency really gained a lot more interest and exploration compared to low frequencies.

TABLE II. SUMMARY OF THE OPTIMIZATION METHODS FOR MITIGATION OF PARASITIC ELEMENTS

Method / Technique	Function	Frequency Range
Parallel and antiparallel arrangement of thin-film capacitors [24]	Significantly decrease the equivalent inductance	high frequency
X-capacitor-inductor structure [8]	ESL cancellation technique for HF noise suppression	high frequency
UKF (Unscented Kalman Filter) algorithm [17]	Estimates parasitic capacitance in real-time	very high-frequency processing unit (250 MHz)
Three-dimensional FEA simulations [18]	Allows calculation of both the parasitic capacitance and output voltage	high frequency
Grading hollow cylinder [18]	Provides excellent performance in the reduction of stray capacitance in a resistive divider.	high frequency
Proposed noise gain modification method [26]	Reduces the noise gain from the shield's low impedance	100 kHz

V. PROPOSED AI-FRAMEWORK IN MINIMIZING THE BUILD-UP OF ANTENNA PARASITICS FOR SUBSURFACE IMAGING

Among the various mitigation techniques from different literature, another possible application is underground imaging antenna operations. It is known that geophysical imaging technique such as electrical resistivity tomography (ERT) has been of great use in the identification of underground utilities [27]. On that note, it can be functional in an infrastructure problem such as in the instances of 'hits' or phenomena that unintentionally damage utility lines or even worksites due to a lack of information on existing utilities and entities located underground.

In creating a subsurface imaging system, it is also important to consider that it requires high sensitivity in the recording of electrical resistivity during land surveying. Thus, the initial development of a parasitic antenna filter will be of great help in

securing the subsurface imaging antenna array against unnecessary noise or parasitic elements. Moreover, the authors have proposed a framework using the AI technique that can be utilized as an initial step in the development of a parasitic antenna filter for an underground imaging array (Fig. 4). The framework is divided into two phases, the first one is the design and modeling of the underground imaging antenna array and the parasitic antenna filter up to their data acquisition process and the second is the application of AI technique for optimization. Thus, after considering the best material selection and parameters for the parasitic antenna filter, simulations will take place and the gathering of data. Then, it will undergo the second phase which starts with data analysis. This is where AI techniques such as genetic algorithms and evolutionary computing can be applied. Genetic algorithm (GA) is incorporated into an optimization algorithm that is influenced by natural selection [28]. Various research papers used GA as an optimization technique in designing and modeling shields related to electromagnetic waves [28-35]. Hence, it is evident that this AI technique can be functional in the development and optimization of a parasitic antenna filter.

To assess the proposed AI based-framework, initial simulations of single pair (transmitter and receiver electrodes) antenna array for an underground imaging system showing with and without the application of parasitic antenna filter were conducted to prove its functionality. In Fig. 5(a), a single pair antenna including the transmitter and receiver circuits and their electrodes was simulated using Altair Feko software operating in 1 MHz frequency. The pattern of radiations in Fig. 5(a) are all coming from the transmitter and flow continues to the receiver as expected since there is no added filter yet in the system. Since the circuits and electrodes are near field locations, the generation of electromagnetic waves can be observed which

employs the presence of parasitic elements. The reading of the receiver below the ground could be affected by the generated electric field above that could result in inaccurate data in surveying.

On the other hand, another simulation was conducted, this time with a parasitic element filter as presented in Fig. 5(b). The parasitic antenna filter used in this simulation is in the form of box enclosures. The electrodes and circuits are secured with enclosures to filter unnecessary electromagnetic waves in the system. It can be seen that the radiations from the transmitter did not continuously flow in the receiver circuit as compared with the scenario in Fig. 5(a). The box enclosure in the receiver circuit was able to absorb and reflect the radiation and function well as a shield. To verify the result of the shielding mechanism, a near field graph that corresponds to the electric field around the enclosure can be observed (Fig. 6). The blue line in the graph represents the circuit without a filter which shows a continuous line with increasing value of the electric field. This indicates that the receiver circuit can also acquire direct signals which could affect the reading of data. However, in the green line that is incorporated into the circuit with filter, it displays its peak in the -0.73 m position and decreased intensely from -0.7 m to -0.61 m, then afterward started to increase again. It can be perceived that the location where the line was in the lowest position is the area where the box enclosure is located, meaning it successfully blocks and absorb the electromagnetic waves coming to the receiver circuit.

Furthermore, AI techniques such as the genetic algorithm using MATLAB can be applied for the optimization of the best combination of thickness and material of the parasitic antenna filter that is ideal for the underground imaging antenna array. This can help in identifying the best alloy mixture of materials considering their conductivity and thickness. However, in the simulations conducted in Altair Feko, a graphite material was used as a metal shield since it is the best option for a filter enclosure due to its dense quality and conductivity, but it is rarely used because it's expensive [36].

One of the limitations that can be perceived in using GA is the premature convergence due to the early completion of exploitation. This is incorporated into the loss of population diversity [37]. With that, other bio-inspired optimization algorithms should be explored using the same dataset. Conversely, the main advantage of the proposed technique is providing an accurate and optimal combination of a material that can be functional for the development of the parasitic antenna filter. This can be applied in land surveying on roads or even in uneven terrain through an underground imaging system apparently being towed with a small vehicle for economic improvement [38]. The filter will be a great help in securing the accuracy of data acquired by blocking unnecessary signals or EM waves as the imaging operation requires high sensitivity to soil resistivity readings. The success of employing this parasitic filter can guarantee a good result in generating maps of utilities underground.

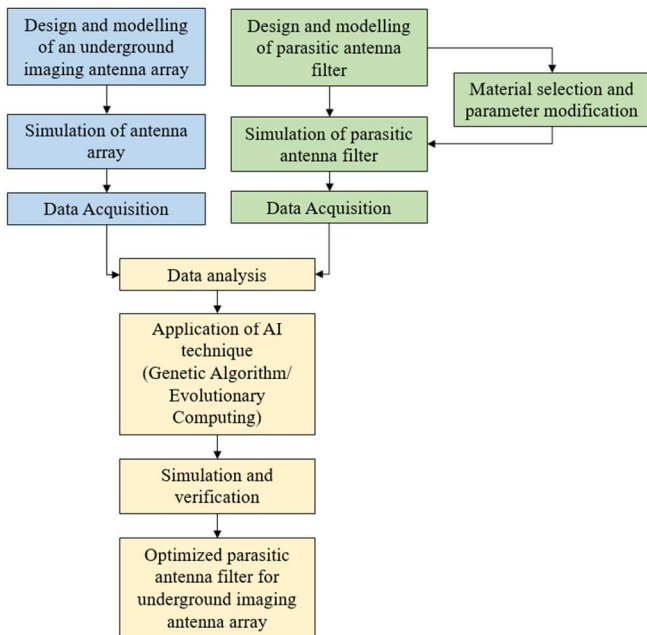

Fig. 4. Proposed framework in using AI technique in the initial development of parasitic antenna filter for the underground imaging antenna array.

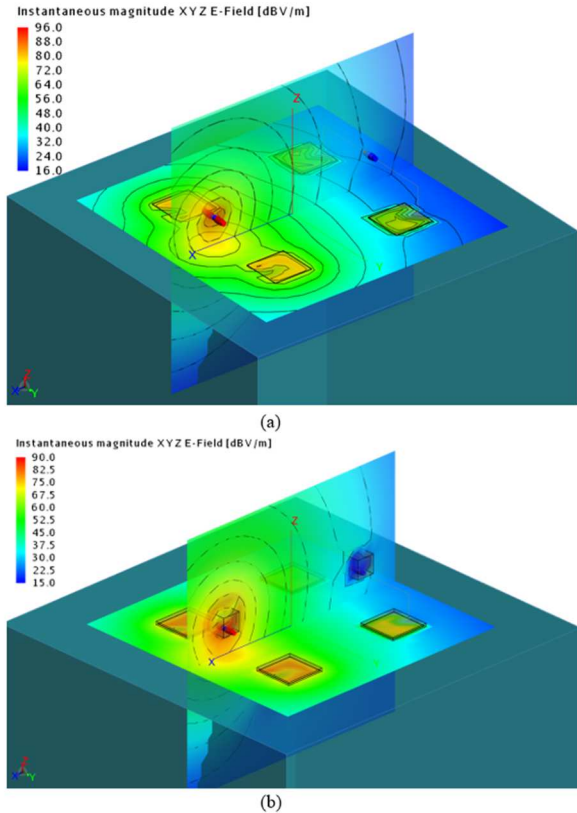

Fig. 5. Single pair antenna array simulation using Altair Feko software (a) without and (b) with parasitic antenna filter.

Fig. 6. Near-field comparison of with and without parasitic antenna filter.

CONCLUSION

This paper gives rise to the initial establishment of an effective filtering and shielding mechanism for an underground imaging system as it focused on the systematic analysis of parasitics in the low and very low-frequency range. We also proposed a framework for using the AI technique to reduce antenna parasitic in a subsurface imaging application. However, based on gathered literature, it found that in low-frequency circuits, the inductance is not of great concern in low frequency as strays become crucial when passing frequencies from upper

HF to the VHF region. At those frequency ranges, the stray inductance becomes a significant component of the total circuit inductance. On the other hand, the effects of such unwanted capacitance are amplified with HF compared to the LF. Moreover, as the frequency increases, those parasitic elements obtained a massive proportion of their totality. In terms of very low-frequency range, most of the studies found that are related to the VLF antennas are very outdated which can be perceived that researchers are not exploring too much in VLF especially in parasitics compared to high-frequency range that has a huge impact on this matter. Furthermore, the proposed AI-based framework was employed, and a simulation of a single pair antenna array was conducted to assess it. Genetic Algorithm as an AI technique can be utilized to provide the best combination of alloy material that could ideally perform as a parasitic antenna filter. Mitigation techniques and optimization methods from other research papers as well as the functional tools and software were also presented to give insights into the current strategies for the attenuation of EMI noise.

ACKNOWLEDGMENT

The researchers would like to express gratitude to the DOST-PCIEERD and Intelligent Systems Laboratory of De La Salle University-Manila for their support and motivation to complete this research work and pursue the technological advancement of a subsurface imaging system in the Philippines.

Abstract: Renewable energy sources have been proven to be reliable, and they are also thought to be the best way to meet our growing energy needs. The rising interest in solar power, increasing costs and functional expenses are led to a few convincing explanations behind the requirement for energy monitoring. Today, Solar Photovoltaic (PV) power is the newest and brightest advancement in the renewable energy market that reduces the requirement of fossil fuel by-products. To get the most out of solar power generation, it's important to pay a lot of attention to how it's kept and how it's used. The purpose of this project work is to display real-time PV parameters on mobile or computer remotely, manage the data and load which is connected with the PV panel and examine the statistics via graph. In this work 20-watt solar panel is used as a PV module, Boltuino (Bolt IoT+ Arduino) device is used as a controller circuit and Current sensor, Voltage sensor, Temperature & Humidity sensor are used for solar parameter collection. The Arduino Uno collects the current sensor, voltage sensor, temperature & humidity sensor data and sends it to the BOLT via serial communication. Following receipt of the statistics in BOLT, it displays all of the solar parameters and generates a graph, which stores all of the information. The alert message will be sent to the registered mobile phone through SMS, and be able to monitor the data from the PV module and remotely operate the system in the event of any unwanted situation like a short circuit or voltage cut out.

Keywords – Renewable energy, solar photovoltaic, cloud computing, internet of things, remote monitoring

I. INTRODUCTION

In today's world, innovation has effectively taken the place of civilisation as the supercurrent. Numerous advancements are taking place in the electrical and hardware domains, which are resulting in more recent and significant revelations and discoveries. The primary difficulty facing all developing countries is the production of large amounts of electrical energy. Since the rise of industry and business, power request arrives at their pick. Henceforth all are aiming towards environment-friendly power sources to meet the energy needs in a sustainable manner. Solar power station

production requires astute observation and activity in moving toward breakthroughs in low-energy engineering that is oriented toward zero-energy engineering. [1].

Internet of Things (IoT) is a fast-developing invention [2], that when connected through the correspondence convention and cloud stage, makes things more intelligent and easier to utilise. In order to determine the PV module's efficiency, parameters such as current, voltage, power, and temperature must be considered [2] [3]. Consequently, a real-time photovoltaic module monitoring system is essential for increasing the reliability of solar modules by comparing the results of the test to begin a preventative activity [4].

Deficient PV modules, dust on solar panels that lowers the efficiency, connection of the system [5], and other factors affecting plant execution are monitored by this system.

Using the Internet of Things [6], a remote real-time monitoring system for solar power plants allows for the monitoring of solar parameters from anywhere and at any time. It controls the system for execution at the solar power plant level and promotes the decisional interaction for the main control station.

The Internet of Things (IoT) allows objects to be controlled and detected remotely [7] [8], allowing for easier integration of the real world into a programmable system, reducing human intervention and increasing efficiency, precision, and economy. Real-time monitoring [9], control, and maintenance of a solar power plant can be made possible via IoT technology.

For monitoring all PV module data, an internet-based programmable graphical user interface is designed [10]. In order to improve the data characteristic of the solar module, Arduino is utilised as a controller to display and analyse collected data. It will be a future accountable technique for large PV power plants using the IoT-enabled smart solar panel monitoring system using the Boltuino platform [11].

II. LITERATURE SURVEY

When it comes to increasing the quality of life for individuals, the Internet of Things (IoT) has emerged as a reliable partner in recent years.. The Internet of Things (IoT) is a network of physical devices that connect to the internet. Due to the fact that it allows sensing and specialised devices to interact with one another in order to meet the specific requirements of individuals. It bridges the gap between the advanced virtual and physical world. The Internet of Things (IoT) is replacing human interventions with machine-to-machine communication to screen and manage the borders of the PV board.

In the year of 2021 N. A. b. Anang Othman et. al [12] designed an IoT-based Solar Battery Monitoring System utilizing two microcontrollers, Node-MCU and Arduino Uno. The information acquired will be put away in the nearby data set and can be seen over an individual website that fills in as an information log and through a representation apparatus utilizing Grafana. All through the framework, the sun-powered PV framework can be effortlessly followed by the client utilizing the internet.

Kanaga Durga D. et. al [13] in 2020 revealed a paper that proposes an installed framework to support the remote observing of inverters in a photo-Voltic power generating station. The information is a complete power created and usual parts of the framework execution must be gotten physically in the Solar power generating station. This proposed framework involves Raspberry pi as the regulator circuit. The inverters are associated with a Daisy chain style and the last inverter is associated with the Raspberry Pi. The absolute power and five safeguard boundaries grid fault, high-current, high-temperature, and short-circuit are gotten from the inverters utilizing the Modbus convention. Sensors are utilized to gauge Wind speed, Temperature, and Solar Irradiance.

R. I. S. Pereira et.al [14] in 2019 published a paper detailing about plan, improvement, execution, and approval of an Internet of Things (IoT) circuit with sensors signal melding network for observing decentralized photo-voltaic plants. The framework expects to diminish expenses of business information lumberjacks and detecting devices which necessary to control information stockpiling utilizing restrictive programming.

An IoT-based far-off ongoing energy observing network is created to display the solar power generation in 2019 by Mohd Sajid Khan et. al [15]. Several voltage and current sensors are connected with a versatile micro-controller for amassing the data. An Internet of Things research stage is adjusted to envision the amassed data and assess the energy generate for a given dispersed age structure. This aids in nonstop remote

monitoring and brings about superior productivity of the power plants.

In the year 2018 Prakhar Srivastava et. al [16] published a paper where they focused on controlling crossbreed energy frameworks utilizing IoT. The primary rules are exchanging within the two sources of energy which are solar and wind-based power with no burden by a site using the ESP8266 Wi-Fi module. The data is transferred remotely by the site to the ESP8266 Wi-Fi module that controls the wellsprings of energy. The sent data is controlled remotely using the Internet of things (IoT). This allows clients to have versatile control tools via a secured internet connection. The system assists the energy client in remotely and physically monitoring the sources parameters via an advanced mobile or computer. This system is somewhat effective, cheap, and versatile in action.

III. OPERATION, BLOCK DIAGRAM & CIRCUIT CONNECTION

This system works with the following connection displayed in Fig 2. The BOLT module and Arduino Uno get power from an external source using a USB cable. Interface the pins Rx and Tx of the BOLT module to connect the 8 and 9 digital I/O pins of the Arduino Uno. The PV module is connected with the demo load through the relay and current sensor, the single-channel relay is used as a system relay, a voltage sensor is connected with the PV module in parallel, also two loads are connected with a dual-channel relay which is used as a load relay. The current sensor, Voltage sensor, OLED display, and DHT11 (Temperature & Humidity sensor) +ve and -ve terminal which is VCC and GND connect with Arduino UNO 5V and GND pin. The data pin of the current and voltage sensor is connected with Arduino UNO A0, and A1 analog pin respectively. Pin A0 and pin 3 of the BOLT module are connected with the voltage data pin and digital pin 10 of Arduino Uno. The SCL and SDA of OLED are connected with Arduino Uno A5 and A4 analog pins. DHT11 (Temperature and humidity sensor) is connected with Arduino Uno of digital pin 2.

All relay is connected with BOLT GPIO pin system relay is connected with BOLT pin 0 and load 1 and load 2 relay data pin is connected with BOLT pin 1 and 2. The VCC and GND pin is connected with Arduino Uno 5V and GND pin.

In this proposed system relay connect with the PV module positive terminal as a switch. In the BOLT cloud system, ON and OFF switches are present which is for turning on the system relay.

At the first system, the relay gets turned on through press the button in the BOLT cloud platform and the system gets started. The prototype of the system is shown in Fig. 3.

BOLT request data from Arduino Uno and it collect data from all the sensor. Collect data from the current sensor, voltage sensor, and DHT11 (temperature & Humidity sensor). Process the data and send it to the BOLT device through serial communication. BOLT shows the data in the BOLT cloud platform. If any data get high or low, if the voltage and power of the solar panel are low and the current are high, so we can manage the load to turn OFF through the load relay which is controlled by the Lad ON and Load OFF button of the BOLT cloud plate from. If the temperature rises and touches the threshold value, press the button system OFF. So, all system is turned off.

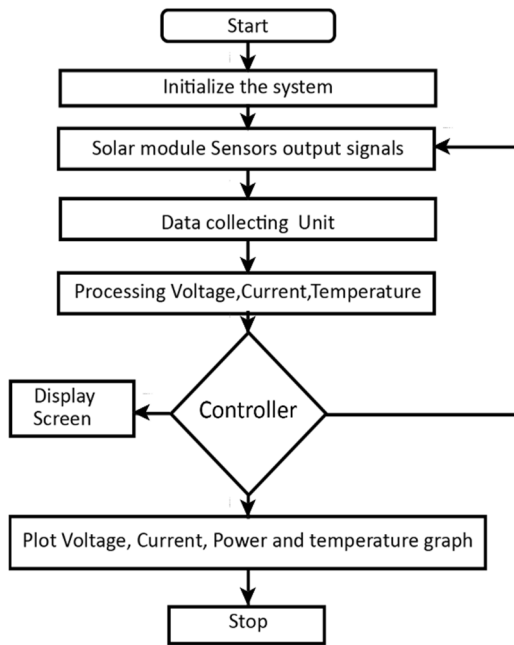

Fig.1: Flowchart of Operation

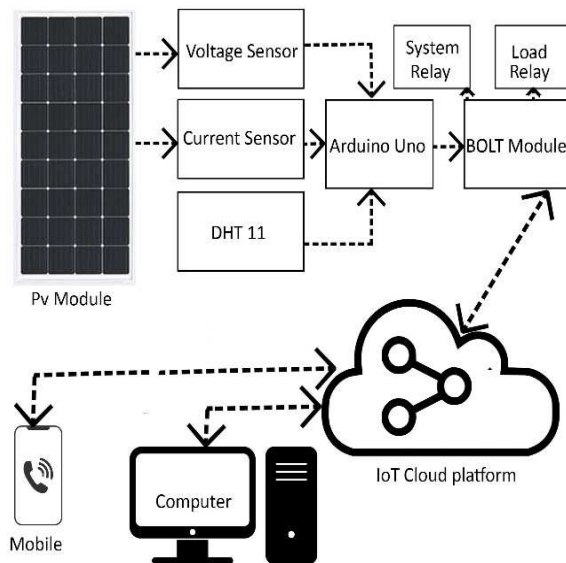

Fig 2: Block diagram of the proposed system

Fig 3: Prototype of the proposed system

All the data show in the OLED display near the system which is shown in the IoT cloud platform. If unwanted things happened like a line cut out, a short circuit, voltage drop near to zero, or current fallen down to zero the alert message is sent to the mobile.

IV. HARDWARE ARCHITECTURE

A. BOLT IoT Device

BOLT IoT module is a Wi-Fi cloud computing-based module [17]. This device has Wi-Fi connectivity based on the ESP8266 module. It collects data from any sensor or device and sends it to the cloud also shown in graphs various from [11]. With BOLT Cloud you have some control over and screen them over the web, make customized dashboards to picture the information, screen the gadget's wellbeing, run AI calculations, and part more. It has one analog pin, 5 digital input/output pins, one 3.3 Volt power pin, 5 Volt power pin, one GND pin, and also RX and TX pin for serial communication from another device. ML (Machine Learning) algorithms are simply consolidated with BOLT IoT projects to work for recognizing anomalies in the sensor information.

B. Arduino Uno

The Arduino Uno is an open-source microcontroller board in base on the microchip ATmega328P microcontroller [18] and created by Arduino. cc. The board is equipped with sets of advanced and simple input/output (I/O) pins that might be communicated to various extension sheets (safeguards) and different circuits. The board has 14 input/output (I/O) pins (six fit for PWM), 6 simple I/O pins, and Arduino IDE (Integrated Development Environment) is used to program for different purposes and projects, by a USB cable. The power source of the Arduino is through a USB cable or by an outside 9-volt DC battery, but it acknowledges voltages somewhere that vary between seven and twenty volts. Arduino Uno is used in this project to collect the data from all the sensor, display the data on the OLED screen, and when the data requested Arduino sends it to the BOLT.

C. Current Sensor (ACS712ELCTR-30A-T)

The ACS712ELCTR-30A-T current sensor is a totally integrated, linear current sensor IC in 8 pins SOIC package which has a hall effect [19]. The sensor consists of an accurate, low-offset, copper conduction path with a linear hall IC circuit which is located near the surface of the die. It generates a magnetic field for flowing through the applied current to the copper conduction path which is sensed by the integrated Hall

sensor and converted into a proportional voltage. It has a low-noise analog signal path. Its reaction time is 5 μ s to step input current and 1.5% at TA = 25 $^{\circ}$ C complete result blunder. It has 1.2 ohms inside guide opposition. 66mV/A result responsiveness. Incredibly steady result offset voltage. Almost Zero Magnetic Hysteresis. This current sensor is used in this system to measure the current flow from the solar panel to the load is loaded condition also no-load condition.

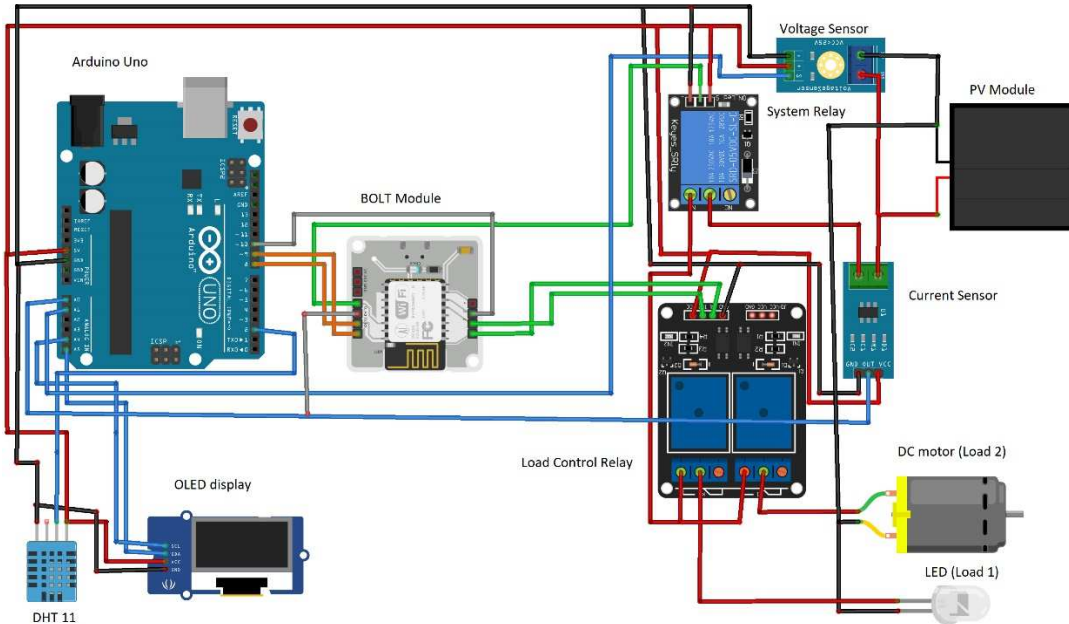

Fig 4: Circuit & connection diagram of the proposed system

Fig 5. Actual prototype of the proposed system

D. Voltage Sensor

The voltage Detection sensor module [15] [19] could be a straightforward and extremely helpful module that uses a possible divider to reduce any input voltage by an element factor of five. This permits us to use the input pin which is an analog pin of a microcontroller to detect the potential difference higher than it is capable of sensing. For example, with a 0 Volt to 5 Volt input limit which is analog, you can sense a voltage up to 25 Volt. In this framework voltage sensor use to measure the voltage of the solar panel. It connects parallel with the terminal of the solar output.

Fig 6: Details of solar panel

Fig 7: Output of organic light-emitting diode (OLED)

Fig 8: Output from BOLT IoT Module

E. Temperature & Humidity Sensor (DHT11)

The Temperature & Humidity Sensor (DHT11) is a necessary, chipset and advanced digital temperature and humidity sensing device [20]. It measures humidity through a capacitive sensor and temperature through a thermistor of the surrounding environment and sends a digital data signal on the input/output (I/O) pin of the microcontroller (no analog pins are used for this device). It's easy and simple to use but requires careful timing to collect the data. This device's working voltage is 3 to 5 Volt and 2.5 mA maximum current use during transformation (while mentioning information). Great for 20% to 80% dampness readings with 5% exactness. Great for 0 to 50°C temperature data readings with ±2°C accuracy.

F. Photo-Voltaic (PV) module

A solar panel, or photograph voltaic (PV) module, is a gathering of photograph voltaic cells mounted in a system for a creating functional solar panel. PV panels utilize sunlight as solar power which is a source of energy to produce DC electricity. A collection of Photo-Voltic modules is known as a Photo-Voltic panel or solar panel, and a framework of solar panels is known as an array [7] [21]. The collection of arrays of a photo-voltaic system produces solar electricity for

various electrical hardware. We use a 20-Watt max power solar panel whose max voltage is 17.0 V and current in max power is 1.18 Amp.

G. OLED Display

The OLED (Organic Light-Emitting Diode) show is an option for the LCD show. The OLED is super-light, nearly paper-slight, adaptable, and produces a more brilliant and crisper picture.

V. RESULTS

The solar parameter is seen through BOLT IoT and also see-through OLED. Voltage, Current, Power & temperature is showing BOLT IoT clouded through graph for remotely use and analysis purpose also showing in OLED. We can see the data through a laptop or Mobile. When any fault occurs or unwanted things happened, we can get an alert message [22] on mobile.

Fig 9: Line graph obtain from BOLT IoT Module

VI. CONCLUSION

The purpose of this project is to monitor real-time solar parameters from any location at any given time and also to control the system and load through a relay that is used as a switch. The proposed system has the capability to display the present and past recorded data. It has also an emergency alerting system when a fault occurs or voltage and current drop dangerously and also when the temperature crosses the threshold value. Moreover, the proposed system has the ability to remotely start and shut down the overall system and also ON/OFF the load with respect to the generation and demand. The Current Sensor, Voltage sensor, and relay are interfaced with Arduino Uno and BOLT IoT devices. The Voltage, current and DHT 11 sensor sense the data and send Arduino Uno, Arduino communicates BOLT device through serial communication and sends the data to the BOLT device. Arduino IDE is used for writing and compiling the program in C language and the BOLT device uses

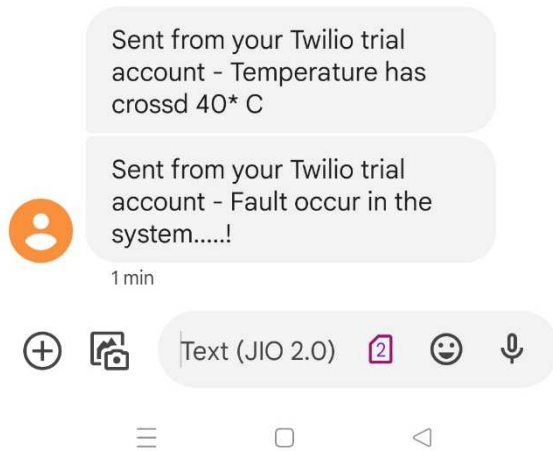

Fig 10: Fault alert SMS

JavaScript to collect data from the BOLT serial pin that is TX and TR and show the data through the graph. This proposed system will be beneficial for research objectives as well as for industrial applications. When the temperature exceeds the threshold value, it can shut down the entire system; likewise, when the voltage and current are inappropriate, the operator will be able to halt the load whenever deemed necessary. In addition, the system shows the data in a variety of ways, such as a bar graph or a line graph, in an excel datasheet that can be studied anytime for further research.

Abstract—This paper presents the result of the approach to the development of a decision support system (DSS) to improve the chosen location of base stations (BS) of mobile systems. The system is designed to improve the reliability of the decision-making and forecasting of the dynamics of the mobile transceiver systems and devices based on the uncertainty influences of a different nature. Analysis of these problems shows that an effective solution to this issue is to use the principles of the fuzzy set theory (FST) and modern geographic information systems (GIS) taking into consideration the geographically distributed topology of the information and telecommunications systems (ITS) elements. As a tool, a neuro-fuzzy inference system (ANFIS) in a Matlab environment is used to develop the decision support system and to select an optimal place geographical information system (GIS) is applied to find installation places of base stations of mobile companies taking into consideration geographic characteristics of the region. It also has been found that effective monitoring of the ITS in such information provision conditions primarily depends on the degree of compression of the input information.

Keywords— *Telecommunication systems, monitoring, fuzzy models, neural networks, Geographic information systems, decision making system.*

I. INTRODUCTION

This Modern rates of development of information and telecommunications systems (ITS) puts new demands on the development of the existing and new design of ITS, including the optimization of the existing ITS, and can significantly improve the quality of various types of information services. This is a priority task for many information and telecommunications sector enterprises that provides various services to the population [1,2,3,4].

The possibilities of existing research methods and decision-making for ITS solutions in case of territorial distribution of topological elements of ITS are limited.

The basis of the ITS is a spatially-distributed telecommunications infrastructure and to continuously monitor the status of ITS is necessary to conduct operational monitoring of ITS, which is the subject of this article.

Methodological bases used for the design, development, and optimization of the existing ITS have some disadvantages.

For statistical analysis of network characteristics, usually classical mathematical models are used, and largely focused on the use of numerical information, thus the information of fuzzy character is determined by the influence of various external factors used indirectly and insufficiently [5].

There are many methods to process data from the various type of information and telecommunications systems, which are using data mining technologies. The modern approach to processing data using data mining technologies allows the use of all types of data in modern information and telecommunications systems. Traditional methods of optimization and planning on the basis of their organizational arrangements for the maintenance and keeping gave the level of all the network resources required to provide quality services in the ITS due to industry dynamics and dominance of information heterogeneous nature does not allow a sufficient degree of control over all the resources.

Telecommunications infrastructure is distributed over large areas, thus there is the need to consider a variety of factors that characterize certain areas (topography, distance, construction, and so on.), and all needed information contained in the digital terrain models and digital maps. The main tool for working with these maps and models is the geographic information systems (GIS) [6].

GIS in the field of ITS may be used for:

- Strategic planning, demand analysis, and forecasting market development of telecommunication networks;

- Design and development of telecommunication networks, including spatial analysis and modeling of the network:
 - selection of locations for the antennas, repeaters with the relevant calculations of service areas, from certain points of view (antenna location), modeling propagation, etc.
 - determine the optimal cable routing based on the location of streets, highways and railways, various underground utilities, as well as data about the owners of the land, etc.
- The inventory of telecommunication networks of distributed infrastructure companies, technical documentation, including graphical, for a variety of distributed, often over a considerable area, and difficulties associated with the environment and each other object.
- Organization of a network of customer service and payments for delivered services.
- Analysis of the company and the quality of delivered services to the customer. Operative response to accidents and emergencies.
- Monitoring of networks and prevention of emergencies.
- Analysis of correspondence of boundaries and service area attributable to her workload, redefining areas.
- Optimization of travel and transportation, routing of official vehicles.
- Providing additional services using communication devices (Value-added services).

II. MATERIALS AND METHODS

To take into account the dynamic variability and Decision-making under conditions with the prevalence of heterogeneous information, and to obtain an adequate assessment of the status of ITS in time and space, appropriate to integrate geographic information systems modeling, as well as the application of the principles of fuzzy set theory (FST) in the decision-making process.

A complex assessment of the status of ITS should include an analysis of the topology of the network, channel capacity based on modern information visualization, and organizing interactive interfaces. The implementation of these approaches based on modern geo-information modeling technology is relevant and poorly investigated.

Realization of this approach is performed based on a considered hypothetical object – the town “Nurafshon” with an installed base station (BS). (Figure 2).

BS - complex radio transmitters and the main element of the mobile network. It is necessary to ensure that delivering affordable, high-quality mobile communications to all users in the territory of the district in which is installed. During making a call, the mobile phone is connected through a radio

channel to the nearest base station, and then on the base station network connection is established with the called party. The more stations, the better the communication quality [4].

Generally, a set of base station equipment is placed on the roofs of buildings (antenna device) and in technical areas (channeling equipment). Considering the complexity of the radio frequency (RF) environment, topology construction, and high population density in the “Nurafshon” area base stations (radio waves of low power) are placed not only on the objects that dominate the building areas but also on low buildings, including road transport infrastructure (installation on outdoor lighting, traffic lights, etc.).

The concrete location of base stations is determined by the communication operator independently as a result of complex technical calculations and radio measurements, based on the need to provide quality and security of services to:

- covering by qualitative radio signal of certain territory;
- provide electromagnetic compatibility with other radio electronic facilities;
- provide sanitary zones and set acceptable standards of radio emission levels.

Figure.1 Mounting the BS locations. (vrednost.ru)

Figure 2. Hypothetical map of the town "Nurafshon".

The main characteristics of the BS can be listed as:

1. The height of the BS - H_{BS} (in meters)
2. The signal power - P_{BS} (dBm)
3. The number of subscribers - C_n (numbers)

Planning a cellular network starts with a plan that shows the estimated location of the installation of base stations in the territory, which are expected to deploy in the network. Such a plan is little tied to the area characteristics and existing objects in this infrastructure and is usually called a nominal plan. After forming the requirements designer must conduct a preliminary calculation of the coverage area. At this stage performed searching appropriate areas for placing the BS.

III. RESULTS

In order to analyze the place of installation of BS antennas in the district area, we need specific details about antenna suspension heights and the structure of the BS location in the areas. Further must be specified the type of user equipment and formed a detailed design of the future network.

Installation, configuration, and upgrading of the base stations are performed based on the following algorithm (Figure 3).

In addition to technical aspects of planning must be considered an important economic component of the process to minimize cellular facilities at an appropriate level of coverage and quality of services.

Further follows the construction of the BS and all the key elements of the network. Before the commercial launching, from the operator side a frequency plan, setting up hardware and software complex base stations of the system, and the test of the systems must be performed.

Many factors affect the quality of signals (for example, it may overlap the surrounding tall buildings and interfere with other radio signals), since the radio signal is distributed not in a straight line. All these factors are taken into account during planning radio networks and accordingly locations for base stations.

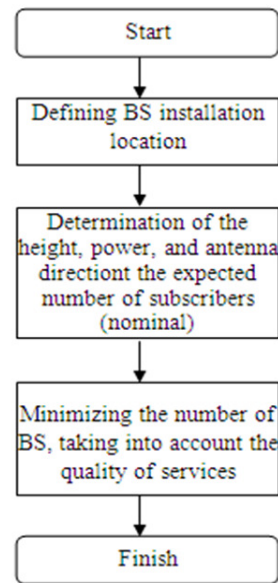

Figure 3. The algorithm of designing and construction of the BS mobile systems

The main tasks of the mobile operator is providing reliable communications to their subscribers, by placing and maintenance of the BS and prevent electromagnetic energy flux density level not more than $10 \text{ mW} / \text{sm}^2$ for most countries. In the Uzbekistan $2,5 \text{ mW} / \text{sm}^2$ is allowed. Because the last research shows that, this level of electromagnetic fields can not have a negative impact on the human body.

Antenna height varying between 20 meters to 100 meters (in case antenna installed on the roof of high-rise building). The rule is, the closer to the telephone BS is located, and the cellphone spend less radiation on setup and maintaining communication with the base station.

So the more base stations, the smaller the distance from the cellular phone to the subscriber station, the lower level of electromagnetic radiation field a subscriber cellular phone.

As analysis shows in order to find best location to install BS must be considered different internal and external factors where heterogeneous information is exists. In this case to obtain best location and adequate assessment location of BS in time and in space can be used approach by integrating geographic information systems modeling, as well as the application of the principles of fuzzy set theory (FST) [8].

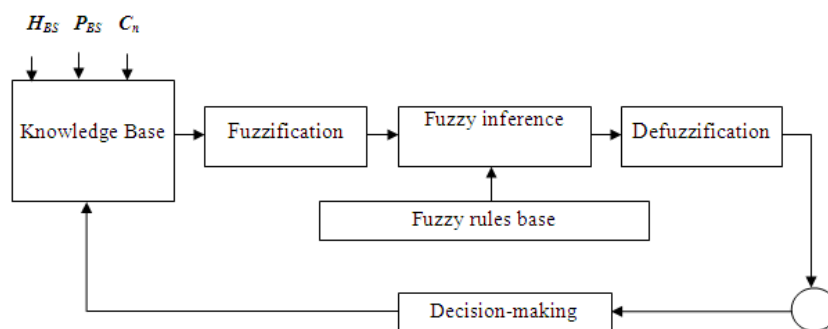

Figure.3.Fuzzy model

ITS optimization performed based on the construction of neuro-fuzzy model, on the this basis conducted a series of

numerical experiments in order to select the optimal functioning of the ITS and location of elements.

$$C_n = f(H_{BS}, P_{BS}) \quad (1)$$

Where, H_{BS} - BS elevation (in meters), P_{BS} - Signal strength (in dBm) and C_n - Number of subscribers (number).

Table 1. Rule Base

Rules №	Elevation, m		Signal power dBm		Number of Subscribers	
	H_{BS}	P_{BS}	P_{BS}	C_n	C_n	C_n
1	Very low	1	Significantly Below Normal	1	Significantly few	1
2	Low	32	Below normal	2	Few	25
3	Average	53	Normal	5	Average	74
4	High	85	Above norm	9	Big	153
5	Significantly High	100	Significantly higher than normal	10	Significantly Big	200

In the calculations, the parameters H_{BS} , P_{BS} and C_n are accepted as fuzzy values, which allows us to compress the information, which involves taking into account linguistic estimates of fuzzy variables of H_{BS} , P_{BS} and C_n .

CONCLUSION

Decision support systems for the operation of ITS depend on the use of diverse information about network topology and capacity of communication channels, subscriber access, and others. Effective monitoring of the ITS in such information provision conditions primarily depends on the degree of compression of the input information. An effective solution to this problem is to integrate the principles of the FST and modern GIS to account for the geographically distributed topology of the ITS elements. The location of the base stations of the telecommunications system is mainly determined by many characteristics, which can be taken as a time factor, changes in the terrain, the height of the transmitting antennas, and their radiation. Further research is planned as follows, including into model the results of an expert survey and adding other factors that affect the location of the Base stations, taking into account the electromagnetic radiations of the area, where the telecommunications network is deployed.

Abstract— This paper presents a universal algorithm for solving boundary value problems of bending plates of arbitrary shape. To solve the problem of bending, the method of sources and sinks is used. According to this method, sources and sinks are distributed continuously along a line located outside the area occupied by the plate and similar to the contour of the original plate. By choosing their powers, the conditions at the plate boundary are satisfied.

In this paper, we use an elementary solution for the problem of bending a round supported plate and fundamental solutions from a unit transverse force and moment concentrated at a point. Mathematical expressions corresponding to various boundary conditions are given. The boundary value problem is reduced to a system of integral equations. To obtain a stable solution to the system of integral equations, the regularization method with minimization of the Tikhonov functional is applied, the numerical implementation of which will lead to systems of algebraic equations. An algorithm for solving the problem in the MATLAB system is proposed.

Keywords— boundary value problem of thin elastic plate bending, source and sink method, regularization method, fundamental solutions from concentrated forces.

I. INTRODUCTION

The study of the stress-strain state of plates is carried out on the basis of general methods for solving boundary value problems of the technical theory of elasticity and is reduced to the integration of differential equations in high-order partial derivatives. The problems of plate bending are so complex and diverse that almost all the main methods of mathematical physics have been used with varying degrees of efficiency to solve them.

Despite the presence of a large number of works devoted to the theory of calculation of plates, the problem of bending still requires further study, since interest in the diversity of the shape of buildings, structures and technical products grows over time. And most parts of the structures consist of thin plates, with a decrease in material consumption and labor intensity of manufacturing, which requires the

study of the stress-strain state. Therefore, a single algorithm is needed to create a computer tool that allows solving this problem under arbitrary loadings of a complex configuration with any fastenings, and this work is devoted to this.

Formulation of the problem. Let us consider the problem of the stress-strain state of a thin elastic plate, which occupies a region G , with a boundary G . As is known, a small transverse deflection of a thin elastic plate that satisfies the Kirchhoff-Leyva hypothesis is determined by the differential equation [1]:

$$\frac{\partial^4 w}{\partial x_1^4} + 2 \frac{\partial w}{\partial x_1^2 \partial x_2^2} + \frac{\partial^4 w}{\partial x_2^4} = \frac{\rho}{D} \quad (1)$$

$$D = Eh^3/12(1 - \nu^2), x = (x_1, x_2) \in G$$

where $w = w(x) = w(x_1, x_2)$ – plate deflection, ρ – transverse load intensity, D – bending stiffness of the plate, E – is the modulus of normal elasticity of the plate material, ν – is its Poisson's ratio, h – is the plate thickness.

The deflection $w(x_1, x_2)$ must satisfy the boundary conditions:

$$L_i w = 0, \quad i = 1, 2 \quad (2)$$

L_i – boundary condition operator.

The most common conditions on the contour are as follows [1] if the edge is pinched,

$$w(x_1, x_2) = 0, \quad \frac{\partial w}{\partial n_x} = 0$$

if the edge is freely supported, then:

$$w(x_1, x_2) = 0, \\ M_{n_x}(x_1, x_2) = 0$$

if the edge is free, then:

$$M_{n_x}(x_1, x_2) = 0, \\ Q_{n_x}^*(x_1, x_2) = 0$$

where $M_{n_x}, Q_{n_x}^*$ – respectively the bending moment and the reduced transverse force, n_x, s – the corresponding outward normal and tangent to the boundary Γ , in accordance with the assumptions made in Fig. 1 rule signed bending moment and reduced shear force

Figure. 1. Outer normal and tangent to the boundary Γ

$$\begin{aligned} \frac{\partial w}{\partial n_x} &= \frac{\partial w}{\partial x_1} \cos \psi + \frac{\partial w}{\partial x_2} \sin \psi \\ M_{n_x} &= M_{x_1} \cos^2 \psi + M_{x_2} \sin^2 \psi \\ &\quad + 2M_{x_1 x_2} \sin \psi \cos \psi \\ M_{n_{xt}} &= M_{x_1 x_2} \cos 2\psi + \frac{1}{2}(M_{x_1} - M_{x_2}) \sin 2\psi \\ Q_{n_x} &= Q_{x_1} \cos \psi + Q_{x_2} \sin \psi \\ Q_{n_x}^* &= Q_{n_x} - \frac{\partial M_{n_{xt}}}{\partial s} \\ \frac{\partial M_{n_{xt}}}{\partial s} &= \frac{\partial M_{n_{xt}}}{\partial x_1} (-\sin \psi) + \frac{\partial M_{n_{xt}}}{\partial x_2} \cos \psi \\ &\quad + \frac{1}{\rho} \frac{\partial M_{n_{xt}}}{\partial \psi} \end{aligned}$$

Where s – tangent to contour; ρ – contour curvature, $\psi = (\widehat{n_x, x_1})$, $M_{x_1}, M_{x_2}, M_{x_1 x_2}, Q_{x_1}, Q_{x_2}$ – are expressed through deflection according to known formulas [1]:

$$M_{x_i} = -D \left(\frac{\partial^2 w}{\partial x_i^2} + \nu \frac{\partial^2 w}{\partial x_j^2} \right), \quad i = 1, 2, \quad j = 1, 2, \quad i \neq j$$

$$M_{x_1 x_2} = -M_{x_2 x_1} = D(1 - \nu) \frac{\partial^2 w}{\partial x_1 \partial x_2}$$

$$Q_i = -D \frac{\partial}{\partial x_i} \left(\frac{\partial^2 w}{\partial x_1^2} + \frac{\partial^2 w}{\partial x_2^2} \right), \quad i = 1, 2$$

For example, consider a mixed boundary value problem for plates having the shape shown in Fig. 2.

Figure. 2. Mixed boundary value problem for thin plates.

$$\begin{aligned} w(x_1, 0) &= 0, \quad \left. \frac{\partial w}{\partial n_x} \right|_{x_2=0} = 0, \quad -a \leq x_1 \leq a \\ AB \text{ и } EF &\text{ – freely supported boundaries:} \\ w(a, x_2) &= 0, \quad M_{n_x}(a, x_2) = 0 \\ w(-a, x_2) &= 0, \quad M_{n_x}(-a, x_2) = 0 \\ 0 \leq x_2 &\leq c \\ BC &\text{ – free edge, etc.} \end{aligned}$$

for CD edge: $M_{n_x}(x_1, b) = 0, Q_{n_x}^*(x_1, b) = 0, -a + r \leq x_1 \leq a - r$, here $r = b - c$

for BC edge: $M_{n_x}(x_1, x_2) = 0, Q_{n_x}^*(x_1, x_2) = 0, a - r \leq x_1 \leq a; c \leq x_2 \leq b$ for DE edge: $M_{n_x}(x_1, x_2) = 0, Q_{n_x}^*(x_1, x_2) = 0, -a \leq x_1 \leq -a + r; c \leq x_2 \leq b (x_1 - (a - r))^2 + (x_2 - c)^2 = r^2$,

II. METHODOLOGY

The solution $w(x_1, x_2)$ of equation (1), due to the linearity of the differential operator, can be represented as $w(x_1, x_2) = w_0(x_1, x_2) + \bar{w}(x_1, x_2)$ (3)

here w_0 – is a particular solution of equation (1) with the right side, and the function \bar{w} is a general solution of a homogeneous equation in the domain G .

As w_0 , you can take any function that satisfies (1). Here we use an elementary solution for the problem of bending a round supported plate [2].

$$w_0(x_1, x_2) = \frac{\rho r^4}{64D\pi}, \quad r = \sqrt{x_1^2 + x_2^2} \quad (4)$$

As \bar{w} , we take the solution from the transverse force and moment distributed continuously along the line G' (Fig. 3), located outside the region $G (G' \in \mathbb{R}^2/G)$ and similar to the contour of the original plate. In this case decision is

$$\bar{w}(x) = \int_{G'} [W_1(x, y)q(y) + W_2(x, y)m(y)] dl_y \quad (5)$$

where $y = (y_1, y_2) \in G', W_1(x, y), W_2(x, y)$ – fundamental solutions from a single transverse force and moment concentrated at the point y , respectively $q(y), m(y)$ – (source power), located along G' .

Fig 3. Auxiliary circuit for applying the method.

Fundamental solutions are known in [3].

$$W_1(x, y) = \frac{1}{16\pi D} \bar{r}^2 \ln \bar{r}^2, \quad W_2(x, y) = -\frac{\partial W_1(x, y)}{\partial n_y} \quad (6)$$

here $\bar{r} = \sqrt{(x_1 - y_1)^2 + (x_2 - y_2)^2}$, n_y – outward normal to Γ' .

From (3)-(6) it follows that the solution of equation (1), expressed through the unknown functions $q(y)$ and $m(y)$, has the form

$$w(x) = w_0(x) + \int_{\Gamma'} [W_1(x, y)q(y) + W_2(x, y)m(y)] dl_y, \quad (7)$$

The function $w(x)$ exactly satisfies equation (1). The unknown functions are determined from the conditions that the given relations (2) hold on the boundary Γ . At the same time, no restrictions are imposed on the forms of the boundaries Γ and on the type of fastening, they can be liked, i.e. the algorithm of this method is universal.

Applying to $w(x)$ in (7) the corresponding differential operators L , we obtain the expressions $\frac{\partial w}{\partial n}$, M_n , Q_n , Q_n^* . As is known, these differential operators are linear: $L[w(x)] = L[w_0(x)] + L[\bar{w}(x)]$ or by (7) we have

$$L[w(x)] = L[w_0(x)] + \int_{\Gamma'} [L[W_1(x, y)]q(y) + L[W_2(x, y)]m(y)]dl_y \quad (8)$$

With this in mind, below are the expressions for each

$$L[W_i(x)], \quad i = 0, 1, 2$$

These expressions were used the following notation:

$$r^2 = x_1^2 + x_2^2, \quad \bar{r}^2 = (x_1 - y_1)^2 + (x_2 - y_2)^2$$

$$\begin{aligned} (x_1, x_2) \in \Gamma, & \quad (y_1, y_2) \in \Gamma', \\ \theta = (\widehat{y_1, n_y}), & \quad \psi = (\widehat{x_1, n_x}), \\ S(a, b, \alpha) = a \cos \alpha + b \sin \alpha, & \quad C_1 = \\ S(x_1, x_2, \psi), & \\ C_2 = S(x_2, x_1, \psi), & \quad S_1 = \\ S(-x_2, x_1, \psi), & \\ S_2 = S(x_1, -x_2, \psi), & \quad C_\theta = S(x_1 - y_1, x_2 - \\ & \quad y_2, \theta), \end{aligned}$$

$$\begin{aligned} S_\theta = S(x_1 - y_1, -(x_2 - y_2), \theta), \\ C_\psi = S(x_1 - y_1, x_2 - y_2, \psi), \\ S_\psi = S(x_1 - y_1, -(x_2 - y_2), \psi), \end{aligned}$$

A. Expressions for $w(x)$

$$1^\circ) w_0(x) = \frac{pr^4}{64\pi D}$$

$$2^\circ) W_1(x, y) = \frac{\bar{r}^2 \ln \bar{r}^2}{16\pi D}$$

$$3^\circ) W_2(x, y) = \frac{(\ln \bar{r}^2 + 1)C_\theta}{8\pi D}$$

B. Expressions for $\frac{\partial w}{\partial n_x}$

$$1^\circ) \frac{\partial w_0}{\partial n_x} = \frac{pr^2 C_1}{16\pi D}$$

$$2^\circ) \frac{\partial W_1}{\partial n_x} = \frac{(\ln \bar{r} + 1)C_\psi}{8\pi D}$$

$$3^\circ) \frac{\partial W_2}{\partial n_x} = \frac{(-C_\psi C_\theta (\ln \bar{r}^2 + 3) + S_\psi S_\theta (\ln \bar{r}^2 + 1))}{8\pi D \bar{r}}$$

C. Expressions for M_n

$$1^\circ) M_n^0 = \frac{p}{16} (r^2(-1) + 2(S_2^2 + \gamma C_2^2))$$

$$2^\circ) M_n^1 = -\frac{1}{8\pi} \left\{ (1 + \nu)(\ln \bar{r}^2 + 1) + \frac{2}{\bar{r}^2} [C_\psi^2 + \nu S_\psi^2] \right\}$$

$$3^\circ) M_n^2 = \frac{1}{4\pi \bar{r}^2} [C_0(1 + \nu) + 2S_\psi C_\psi S_\theta(1 - \nu)]$$

D. Expressions for Q_n

$$1^\circ) Q_n^0 = -\frac{pC_1}{2}$$

$$2^\circ) Q_n^1 = \frac{-1}{2\pi \bar{r}^4} C_\psi$$

$$3^\circ) Q_n^2 = -\frac{1}{2\pi \bar{r}^4} [C_\theta C_\psi - S_\theta S_\psi]$$

E. Expressions for Q_n^*

$$1^\circ) Q_{0n}^* = \frac{p}{8\pi} (\rho(\nu - 1)[C_1^2 - S_1^2] - (5 - \nu)C_1)$$

$$2^\circ) Q_{1n}^* = \frac{1}{4\pi \bar{r}^2} \left[(1 - \nu)(C_\psi^2 - S_\psi^2) \left(\rho - \frac{C_\psi}{\bar{r}^2} \right) - 2C_\psi \right]$$

$$3^\circ) Q_{2n}^* = \frac{1}{4\pi \bar{r}^4} \left[(C_\theta C_\psi - S_\theta S_\psi) \left((1 - \nu) \frac{1}{\bar{r}^2} (S_\psi^2 - C_\psi^2) - 2 \right) + 4S_\theta C_\psi S_\psi \left(\frac{C_\psi}{\bar{r}^2} - \rho \right) \right]$$

Using 1^o), 2^o), 3^o) it is easy to obtain representations of the components of the stress-strain state $\frac{\partial w}{\partial n}$, M_n , Q_n , Q_n^* of the plate in terms of arbitrary functions $q(y)$, $m(y)$.

Substituting expression (7) into the boundary conditions, we obtain a system of two integral equations of the 1st kind with respect to q , m with continuous kernels:

$$\int K(x, y)z(y)dl_y = u(x), \quad x \in \Gamma \quad (9)$$

or in operator form

$$Kz = u,$$

here $K(x, y)$ – matrix with elements $K_{ij}(x, y) = L_i W_j$, $i = 1, 2$, $j = 1, 2$; $z(y)$ – unknown vector with components q , m ; $u_i(x) = -L_i[w_0(x)]$; L_i – differential operator of boundary conditions.

Having solved system (9) and substituting the found functions $q(y)$, $m(y)$ into formula (7), we obtain the solution of this boundary value problem.

The solution of the system of integral equations is unstable. It was shown in [4] that the stability of the approximate solution of system (9) depends on the distance

$$d = \rho(\Gamma, \Gamma')$$

In [5], a technique was developed for obtaining a stable solution using the regularization method. In this technique, the approximate solution of system (9) is obtained by minimizing the Tikhonov functional [6]:

$$M_\alpha(z) = \|K_h z - u_\delta\|_\Gamma^2 + \alpha \|z\|_{\Gamma'}^2, \quad \alpha > 0$$

with the choice of the regularization parameter α from the «principle of least residual».

$$\|K_h z_\alpha - u_\delta\|_\Gamma + h \|z_\alpha\|_{\Gamma'} \rightarrow \min$$

here K_h – numerical analogue of the integral matrix K , u_δ – numerical analogue of the vector $u(x)$

$$h > 0, \quad \delta > 0, \quad \|K_h - K\| \leq h, \quad \|u_\delta - u\| \leq \delta$$

With the help of quadrature formulas, we replace the system of integral equations (9) with a system of linear algebraic equations (SLAE) and from the condition of the minimum of the functional

$$\frac{\partial M_\alpha(z)}{\partial z} = 0$$

We obtain a system of algebraic equations

$$(A'BA + \alpha D)z = A'Bu \quad (10)$$

here A – order matrix $2n_1 \times 2n_2$; n_1, n_2 – the number of nodes on Γ, Γ' , respectively; B and D – symmetric positive definite matrices of square forms of discrete analogs of scalar products in spaces L – a vector of functions on the curves Γ, Γ' , respectively; u, z – vectors with components $u(x_i), z(y_i)$. at the split points of the curves Γ and Γ' .

Solutions to system (10) are obtained using MATLAB, with the choice of the regularization parameter from the conditions

$$(B(Az_\alpha - u_\delta), Az_\alpha - u_\delta)^{\frac{1}{2}} + h(z_\alpha, z_\alpha)^{\frac{1}{2}} \rightarrow \min_\alpha,$$

at

$$(B(Az_\alpha - u_\delta), (Az_\alpha - u_\delta)) \leq \varepsilon,$$

where ε – accuracy.

According to the obtained values of z and according to the numerical analogues of formula (7):

$$\tilde{w}(x) = w_0(x) + \sum_{j=1}^{n_2} C_j [W_1(x, y_j)q(y_j) + W_2(x, y_j)m(y_j)]$$

It is possible to approximately determine the value of the deflection at arbitrary points of the plates.

Solution algorithm. We solve this problem numerically in MATLAB.

When programming, there is no need to write equations for each edge separately. It is enough to assign a parameter for the boundary condition and compose the algorithm so that the above expressions are selected by the value of this parameter. The parameter values are the boundary condition code.

For a complete solution of any considered bending problem, it is necessary to specify the following information:

LF – number of edge rows, separated by boundary conditions and by curvature;

B1(I), B2(I) – coordinates of the starting point of the 1st side;

O1(I), O2(I) – center of curvature of the 1st curved side;

KK(I) – view of the I-th side of the edge of the plate:

KK(I)=0 – straight edge,

KK(I)=1 – curvilinear edge convex down,

KK(I)=2 – curvilinear edge convex up;

L(I) – type of boundary conditions specified on the 1st side:

1 - pinched,

2 - freely supported,

3 - free;

MN(I) – number of nodes of points on the 1st side;

AN – parameter determining from $AN = h_2/h_1$,

h_2 – step on the additional contour,

h_1 – on the main line;

D(I) – the distance between the additional and main circuits on each I - th side;

Q – external load intensity;

(M,N) – dimension of the resulting system of linear algebraic equations;

HP – plate thickness;

E – elastic modulus;

ν – Poisson's ratio.

The implementation of this method is carried out according to the following algorithm:

1. Entering and printing data;

2. Geometry subroutine;

3. Organization of calculations $\frac{\partial w}{\partial n}, M_n, Q_n, Q_n^*$ by L(I) using the formula A)-E);

4. Formation and solution of SLAE (10);

5. Calculation and verification of residual $\|Kz - u\| \leq \varepsilon$;

6. Selection of the regularization parameter;

7. Calculation of the stress-strain state;

8. Print results.

III. CONCLUSION

This paper proposes a technique for numerically solving basic and mixed linear boundary value problems in the theory of thin plate bending. The resulting expressions are presented, which make it possible to write out a complete system of relations describing the bending of thin plates. Algorithms for the implementation of the developed methodology are proposed.

Here, a small transverse deflection of a thin elastic plate is considered, the equation of state of which is described by a linear differential equation. The linearity of the equation of state made it possible to reduce boundary value problems to integral equations. This method can be applied to any linear boundary value problem, only in this case it is necessary to have a particular solution and fundamental solutions for the differential equation under consideration. When choosing these solutions, it is necessary to take into account the differentiability of the required degree, otherwise integral equations will not be obtained.

Solving a system of integral equations is not always possible. Therefore, here we use numerical methods. The numerical solution is ill-conditioned, since the smaller the step of partitioning the interval, the closer to zero the determinant of the matrix of the numerical analogue of the problem. Therefore, the regularization method is used, which minimizes the Tikhonov functional [6] with the choice of the regularization parameter. In this case, we obtain a system of algebraic equations with the regularization parameter (10). We solve this system with different values of the regulation parameter until the accuracy of the calculations is satisfied. To form and solve a system of algebraic equations, we consider it more practical to use the MATLAB system. It is also convenient for the graphical representation of the result. Therefore, an algorithm for implementing the method in the integrated MATLAB environment has been developed.

DEVELOPMENT OF STOCHASTIC DISTRIBUTION MODEL OF CONTAMINATED WATER TREATMENT COMPLEX

1st Bakhadir Begilov

Faculty of Computer Engineering

Nukus branch of Tashkent University of

Information Technologies named after Muhammad al-Khwarizmi

Nukus, Uzbekistan

bakhadirbegilov@gmail.com

Abstract—The object of the research is the treatment facilities of the city of Nukus.

Purpose of the study. The aim of the study is to develop and analyze mathematical models and algorithms for solving deterministic problems of polluted water purification, establishing the ratio of duality and optimality conditions, as well as establishing a marginal ratio for these tasks and determining the optimal size of costs for the purification of polluted water with various technological treatment schemes, development of a software package for solving deterministic problems of the complex for the purification of polluted waters.

In general, on the research topic under study, theoretical studies were carried out to determine the optimality conditions for solving optimization problems and the stability of the deterministic model of the complex for the purification of polluted waters.

The results of the study allow, determine the optimal size of the cost of treating polluted water with various technological treatment schemes.

Index Terms—Stochastic, water, treatment, model

I. INTRODUCTION

Water is the most valuable natural resource. It plays an exceptional role in the metabolic processes that form the basis of life. Water is of great importance in industrial and agricultural production. It is well known that it is necessary for the everyday needs of man, all plants and animals. For many living creatures, it serves as a habitat [1], [2].

The shortage of fresh water is already becoming a global problem [3]–[5]. The ever-increasing needs of industry and agriculture for water are forcing all countries and scientists of the world to look for various means to solve this problem.

At the present stage, the following directions of rational use of water resources are determined: more complete use and expanded reproduction of fresh water resources; development of new technological processes to prevent pollution of water bodies and minimize the consumption of fresh water.

The main schemes of treatment facilities were described back in 1949 by Professor, Doctor of Technical Sciences B.O.

Botuk [6]. In his book Domestic Wastewater Treatment, he describes the first laboratory studies on the use of an aeration tank for biological wastewater treatment, carried out in 1912 [7]–[11].

The authors of the article Formation, treatment and use of wastewater gave the following definition to the biological treatment process: Biological treatment involves the purification of the dissolved part of wastewater pollution (organic pollutants - COD, BOD; biogenic substances - nitrogen and phosphorus) with special microorganisms (bacteria and protozoa) or earthworms, which are called activated sludge or biofilm [12].

Ts.I. Rogovskaya in her 1967 work "Biochemical method of industrial wastewater treatment" writes about the development of industry, in particular chemical, and changes in the composition of wastewater, which led to changes in the composition and characteristics of activated sludge biocenoses [13]–[22]. It is unacceptable to discharge un-treated industrial wastewater into water bodies; it is necessary to intensify the purification process. With this information, it is possible to speed up and reduce the cost of the biological treatment process. The author also gives the maximum allowable concentrations of some compounds for adapted microflora when they enter aerobic treatment facilities operating for complete purification [23].

In 1977, in the reference manual Methods of industrial wastewater treatment, the authors (A.I. Zhukov, I.L. Mongait, I.D. Rodziller) noted that various types of aerotanks are most often used for biological treatment of large volumes of wastewater, one of the important advantages of which is the ability to effectively influence the speed and completeness of the process of biochemical oxidation occurring in them. That the processes occurring in the aerotank are controllable [20].

Doctor of Technical Sciences E.D. Gelfand in the textbook "Fundamentals of Biological Wastewater Treatment" highlights some parameters of biological treatment [21]–[26].

Tukalevsky Sergey Leonidovich in 1992 in his dissertation work "Economic and mathematical models and methods for solving special classes of nonlinear distributive problems" proposed for a discrete-continuous goal with a concave function

of the distribution problem of optimizing the water treatment process, a new two-stage approach to finding a solution was proposed, which consists in determining the lower estimate of the minimum and the optimal values of the dual estimates at the first stage and the algorithm for obtaining a feasible solution close to the optimal one at the second.

In Uzbekistan, scientists academician M. Mirsaidov, Sh.Kh. Rakhimov, I.K.Khuzhaev, E.I. Makhmudov, S.I. Khudaykulov, O. Golovatsky, A.V. Kabulov, N. U. Uteuliev, A. Zh. Seitov, D. Sh. Bazarov, E. Shermatov and others.

Purpose of the study. The aim of the study is to develop and analyze mathematical models and algorithms for solving deterministic problems of polluted water treatment, establishing a duality ratio and optimality conditions, as well as establishing a marginal ratio for these tasks and determining the optimal cost of polluted water treatment under various treatment flowsheets, development a software package for solving deterministic problems of a polluted water treatment complex [27]–[29]. Research tasks:

- Development of mathematical models that optimize costs in the treatment of polluted wastewater;
- Development of an algorithm for solving the problems of contaminated water treatment complex;
- Establishment of secondary relations and optimal conditions for the optimization of wastewater treatment;
- Development of software to solve the problem of optimization of wastewater treatment;

Object of research. The object of research is the treatment of polluted wastewater in municipal wastewater treatment plants.

Subject of research Mathematical model and numerical methods of optimizing the cost of wastewater treatment.

Research methods. The study used mathematical programming theories and methods and discrete optimization methods.

II. SETTING OF DETERMINISTIC DISTRIBUTION PROBLEM OF COMPLEX OF CONTAMINATED WATER TREATMENT

This part discusses the deterministic distribution problem of the contaminated water treatment complex.

A. Statement of the problem

Thus, the objective is to select such an acceptable combination of technologies and such a distribution of the volume of contaminated water between them so that the cost of purification is minimal and at the same time the concentration of impurities after purification at the control solution does not exceed the specified maximum permissible values. In reality, the problem of water treatment is solved for a certain water treatment complex in the presence of several spillways and the concentration of controlled impurities at the control range depends on the quality of water protection events at all spillway facilities.

Enter the following symbols:

– q_k volume of contaminated water supplied to the treatment complex on the k - volume of the spillway;

– x_{ki} amount of contaminated water to be treated on i cleaning process diagram on k - volume of the spillway. Thus, $X_k = \{x_{ki}\}, i = \overline{1, N}$, vector of the distribution of the total amount of contaminated water between treatment technologies on the k - th of the spillway;

x_{ki}^- and x_{ki}^+ - values limiting production capacity i process diagram during volume discharge cleaning q_k ;

C_{0kj}, C_{kj} - concentrations of j -type impurities before purification and maximum permissible concentrations (MPC) after purification, respectively;

P_{kij} - degree of cleaning of j -th impurity according to the i -th cleaning technology on k -volume spillway;

A_{ki}, λ_{ki} - coefficients of approximation of the function of costs for treatment of contaminated water according to the i -th process diagram on k - volume of the spillway ($A_{ki} \geq 0; 0 \leq \lambda_{ki} \leq 1, k = \overline{1, L}, i = \overline{1, N}$).

Then the mathematical model of the contaminated water treatment complex, reflecting the process of finding the best treatment method with minimal costs, has the following form:

$$F(x) = \sum_{k=1}^L \sum_{i=1}^N A_{ki} x_{ki}^{\lambda_{ki}} \rightarrow \min \quad (1)$$

$$\sum_{i=1}^N B_{kij} x_{ki} \leq C_{kj}, \quad k = \overline{1, L}; j = \overline{1, M}, \quad (2)$$

$$\sum_{i=1}^N x_{ki} = q_k, \quad k = \overline{1, L}; \quad (3)$$

$$x_{ki}^- \leq x_{ki} \leq x_{ki}^+, \quad k = \overline{1, L}; j = \overline{1, M}, \quad (4)$$

$$A_{ki} \geq 0, \quad 0 \leq \lambda_{ki} \leq 1, \quad k = \overline{1, L}, i = \overline{1, N}$$

The problem in which it is necessary to distribute wastewater to process schemes in such a way that the limitations of the balance and process type are fulfilled, and at the same time obtain the optimal value of the objective function, is called a non-linear problem of the distribution type.

It should be noted that the set mathematical problem arises not only in connection with the use of equipment, but also in many other issues. Such a model and problems on the rational use of water resources are considered in special studies by L.V. Kantorovich and V.A. Zalgaller [4], reflecting both the mathematical and purely technological aspect of the question. In addition to the distribution problem of optimal load of equipment, following the transport problem and assignment problem, one of the first detailed problems of the distribution type studied was the linear problem of optimal distribution of interchangeable resources.

B. Now let us dwell on the economic content of the model (1) – (4).

The objective function (1) reflects the total cost of the water user to carry out water treatment events. It will be appreciated that the dependencies reflecting the relationship

of cleaning implementation costs to the loading volume of cleaning technologies are concave functions. Minimizing the objective function even on the convex region presents increased complexity.

Constraints (2) to (4) specify the best solution search area. Limitation (2) means that in the control solution the concentration of j- of this type of impurity should not exceed the permissible one.

“Cleanability” factor denoted by B_{kij} , calculated as follows:

$$B_{kij} = C_{0kj}(1 - P_{kij}) \quad (5)$$

Limitation (3) requires that the entire volume of k- of this discharge on that spillway be distributed according to process diagrams.

Limitation (4) means that the amount of contaminated water to be treated shall not exceed the production capacity of the process diagrams.

III. ALGORITHM FOR SOLVING DETERMINISTIC DISTRIBUTION PROBLEM OF CONTAMINATED WATER TREATMENT

In this part we will give the algorithm of solution of the deterministic and limiting problem of the complex of contaminated water purification, reflecting the process of search for the best method of purification with minimum costs (1) - (4), proposed in work [2].

To justify the procedure proposed in work [2], write down the Lagrange function for problem (1) - (4), which has the form:

$$L(x, u) = \sum_{k=1}^L \sum_{i=1}^N A_{ki} x_{ki}^{\lambda_{ki}} + \sum_{k=1}^L \sum_{j=1}^M u_{kj} C_{kj} + \sum_{k=1}^L u_k q_k \quad (6)$$

If we know u^* - the optimal solution of the dual problem to the problem (1) - (4), then one can consider its equivalent setting:

$$L(x, u^*) \rightarrow \min_{x \in X} \quad (7)$$

where X is a set of vectors satisfying the conditions (2), (4).

From problem (7) we obtain, taking into account (7), k-independent subproblems for each catchment

$$\sum_{k=1}^L \sum_{i=1}^N A_{ki} x_{ki}^{\lambda_{ki}} - \sum_{k=1}^L \sum_{i=1}^N \left(\sum_{j=1}^M u_{kj}^* B_{kij} - u_k^* \right) x_{ki} \rightarrow \min_{x \in X} \quad (8)$$

Problem (8) is a problem of geometric programming with a concave nonlinear objective function and it can be solved by the conditional gradient method.

Thus, with the known solution u^* The problem (1) to (4) is decomposed. The same will be the case with arbitrary u , only then the solution of problem (8) obtained in this case will not be the optimal solution of problem (1) - (4).

Let us now give the algorithm for solving the deterministic distributive problem (1) - (4):

In fact, the exact optimal solution to the dual problem is unknown. However, you can build a definition procedure u^* , which has the form:

1) As an initial approximation $u^{(0)}$ we take an arbitrary number. Let us know $u^{(s)}$, $s = 0, 1, \dots$ Then we determine $x^{(s)}$, solving a problem

$$\begin{cases} \sum_{i=1}^N (A_{ki} x_{ki}^{\lambda_{ki}} - u_k^{(s)} x_{ki}) \rightarrow \min \\ x \in X \end{cases} \quad (9)$$

2) New value $u^{(s+1)}$ is defined using the formula

$$u_k^{(s+1)} = \max\{0, \rho_s (q_k - \sum_{i=1}^N x_{ki}^{(s)})\} \quad (10)$$

where ρ_s - some step factor.

3) The step factor is defined as follows:

$$\rho_s \geq 0, \quad \rho_s \rightarrow 0 \quad \text{at} \quad s \rightarrow \infty, \quad \sum_{s=0}^{\infty} \rho_s = \infty, \quad \sum_{s=0}^{\infty} \rho_s^2 < \infty \quad (11)$$

These conditions are satisfied, for example, by the following step factor value

$$\rho_s = \frac{1}{(1+s)^\alpha}; \quad \frac{1}{2} < \alpha \leq 1 \quad (12)$$

It should be noted that $q_k - \sum_{i=1}^N x_{ki}^{(s)}$ is the (10) generalized gradient of the objective function $\varphi(u) = \min_{x \in X} L(x, u)$ a dual problem. Under the assumptions made, this function will not be differentiable under those $u^{(s)}$, when at least one of the problems (9) has more than one optimal solution. The procedure (10) itself will be a general gradient descent method (8) for solving the dual problem.

IV. STOCHASTIC DISTRIBUTION PROBLEM OF COMPLEX FOR TREATMENT OF CONTAMINATED WATER

In this part, let's talk about the problem of distributing a certain amount of contaminated discharge water to the process treatment schemes. By cleaning process circuit is meant a set of some cleaning devices arranged in series. The part of the discharge allocated for cleaning according to some scheme should not go to the cleaning devices of another scheme in the future.

It should be noted that in the problem according to the available literary sources [5], dependencies reflecting the relationship of the water user's costs for the implementation of water protection events with the load volume of purification process circuits are concave functions and are well approximated by power functions with a fractional indicator. In addition, the coefficients of the objective function may depend on random factors, then we will obtain a stochastic model of the complex for treating contaminated waters.

Here is a stochastic version of the distribution problem of the contaminated water treatment complex:

The objective is to select such an acceptable combination of technologies and such a distribution of the volume of contaminated water between them so that the media total purification costs are minimal and the concentration of impurities after purification at the control solution does not exceed the specified maximum permissible values. In reality, the problem of water treatment is solved for a certain water treatment complex in the presence of several spillways and the concentration of controlled impurities at the control range depends on the quality of water protection events at all spillway facilities.

Enter the following symbols:

$A_{ki}(\theta)$, λ_{ki} - coefficients of approximation of the function of costs for treatment of contaminated water according to the i -th process diagram on k -th of the spillway, θ - random number ($A_{ki}(\theta) \geq 0$; $0 \leq \lambda_{ki} \leq 1$, $k = \overline{1, L}$, $i = \overline{1, N}$).

Then the stochastic distribution model, reflecting the process of finding the best cleaning method with average total minimum costs, has the following form:

$$F(x, \theta) = \sum_{k=1}^L \sum_{i=1}^N MA_{ki}(\theta)x_{ki}^{\lambda_{ki}} \rightarrow \min \quad (13)$$

$$\sum_{i=1}^N B_{kij}x_{ki} \leq C_{kj}, \quad k = \overline{1, L}; \quad j = \overline{1, M}, \quad (14)$$

$$\sum_{i=1}^N x_{ki} = q_k, \quad k = \overline{1, L}; \quad (15)$$

$$\begin{aligned} x_{ki}^- \leq x_{ki} \leq x_{ki}^+, \quad k = \overline{1, L}; \quad j = \overline{1, M}, \\ A_{ki} \geq 0, \quad 0 \leq \lambda_{ki} \leq 1, \quad k = \overline{1, L}, i = \overline{1, N} \end{aligned} \quad (16)$$

Problems (13) - (16) are problems of stochastic convex programming.

To solve the problem (13) - (16), the algorithm proposed in operation [2] is used.

This algorithm is applicable to solve the problem (13) - (16). To do this, we construct the Lagrange function for problem (11) - (14)

If we know u^* - the optimal solution of the dual problem to the problem (13) - (16), then one can consider its equivalent setting:

$$\begin{cases} L(x, u^*, \theta) \rightarrow \min \\ x \in X \end{cases} \quad (17)$$

where X is a set of vectors satisfying the conditions (14), (16).

From problem (17) we obtain, taking into account (??), k -independent subproblems for each catchment

$$\begin{cases} \sum_{i=1}^N (MA_{ki}(\theta)x_{ki}^{\lambda_{ki}} - u_k^*x_{ki}) \rightarrow \min \\ x \in X \end{cases} \quad (18)$$

We do not know the exact solution to the dual problem. But instead, you can use the approximation obtained, say, by the method of stochastic generalized gradient descent.

Based on this, we give the following algorithm for solving the stochastic problem (13) - (16) and the dual to it:

1) As an initial approximation $u^{(0)}$ we take an arbitrary number. Let us know $u^{(s)}$, $s = 0, 1, \dots$. To calculate $u^{(s+1)}$ perform the following actions:

2) We solve the following problem using one of the methods of stochastic programming [?].

$$\sum_{i=1}^N (MA_{ki}(\theta)x_{ki}^{\lambda_{ki}} - u_k^*x_{ki}) \rightarrow \min_{x \in X} \quad (19)$$

solution of the problem we denote $x^{(s)}$;

3) Find the gradient of the Lagrange function (16) by the dual variables u ;

4) we calculate $u^{(s+1)}$ by formula:

$$u_k^{(s+1)} = \max\{0, \rho_s(q_k - \sum_{i=1}^N x_{ki}^{(s)})\} \quad (20)$$

where ρ_s - some step factor. Selection of step multiplier is determined by conditions (13) - (14).

It should be noted that $q_k - \sum_{i=1}^N x_{ki}^{(s)}$ is the (20) generalized gradient of the objective function $\varphi(u) = \min_{x \in X} L(x, u, \theta)$ a dual problem. Under the assumptions made, this function will be undifferentiated under those $u^{(s)}$, when at least one of the problems (19) has more than one optimal solution. The procedure (20) itself is a method of stochastic quasi-gradients [?] for solving a dual problem.

V. NUMERICAL EXPERIMENT OF ENVIRONMENTAL-ECONOMIC MODELS OF CONTAMINATED WATER TREATMENT COMPLEX

Numerical experiment of the calculation of MPD (maximum permissible discards) substances for a water stream and a water body. We consider the river basin section (Figure 1), which includes 3 water quality control sections, 2 wastewater discharges, 2 water intakes and 1 reservoir. The volume of filling the reservoir is $1km^3$. Water quality is estimated by 6 indicators biochemical oxygen consumption (BOD), BOD_{full} (complete oxidation) or BOD_{20} (almost complete oxidation is achieved within 20 days), ammonium nitrogen, nitrite nitrogen, nitrate nitrogen, dissolved oxygen and petroleum products. Initial data for MPD calculation are given in table 1-2.

Let us introduce the following notation. Complete biological treatment - 101, complete biological purification with simultaneous precipitation to improve the purification of phosphorus - 102, complete biological purification with nitrification-denitrification to improve purification by impurities of the nitrogen group - 103.

Realization. The operation diagram of the treatment facilities is as follows: from the receiving chamber, waste water enters the pond as a settling tank for deposition of suspended

Fig. 1. Linear diagram of the river basin section: 1, 2, 3 check doors; p1, p2 wastewater discharges; 1, 2 water intakes.

substances and processing of sediment. To increase stability and reliability of the effect of clarification, the sump is divided into two consecutive stages, the interruption of the effluents of each of them is 3 or 2 days, respectively.

TABLE I
CHARACTERISTICS OF THE WATER BODY

	Activities	Reset conditions	
		mg/liter	MPD g/hour
1	suspended substances	140.0	53050.4
2	BOD ₅	5.0	1894.3
3	mineral composition	2000.0	757720.0
4	Chlorides	350.0	132601.0
5	Sulfates	500.0	189430.0
6	Fats	5.5	2083.73
7	Nitrate nitrogen	—	—
8	Nitride nitrogen	—	—
9	Ammonium nitrogen	—	—

To improve reliability of compliance with KMK requirement 2.04.02-97 (Water supply External networks and structures), it is also envisaged to divide all earthen capacitance structures into two parallel operating sections, each of which is designed to pass 50% of the design flow in normal operation mode and 100% in forced operation.

Lean liquid clarified during 5 days is divided into two streams in accordance with 30% or 70%. A smaller flow is passed through the cultivator pond for 6 days for the development of algal biomass and the accumulation of the sum of oxidants, after which it is mixed with the main flow. To accelerate cultivation, 10% of the flow is supplied to the cultivator - starter pond, from which it enters the cultivator after 4.5 days.

The resulting mixture continuously enters the biocogulator pond, where during 2 days a complex biocogulation process occurs, as a result of which the content of suspended and dissolved contaminants is reduced.

Next to the pond biocogulator treatment stage is aerobic treatment stage under flow conditions in the pond insulator, the main process of which is bacterial oxidation of dissolved organic and mineral components of waste water.

In the flow pond waste liquid is 2 days, BOC (biochemical oxygen consumption) brought to 15mg/liter. After biological treatment, water enters post-treatment ponds with the highest water vegetation, where the quality of the treated effluents

is brought to the requirements that meet the rules of the Protection of Surface Waters from Pollution by Waste Water.

Approved MPD and waste water composition (discharge of substances not specified below is prohibited) according to the table.

Water protection measures according to formulae (1) to (4) are described as follows:

$$f_1 = 9,67 \cdot 365 \cdot (x_{10} + 602,9 \cdot x_{11} + 741,5 \cdot x_{12} + 1083,6 \cdot x_{13}) = 3530 \cdot x_{10} + 2128237 \cdot x_{11} + 2617495 \cdot x_{12} + 3825108 \cdot x_{13};$$

$$C_{11} = 193,7x_{10} + 103,1 \cdot x_{11} + 34,4 \cdot x_{12} + 20,6 \cdot x_{13};$$

$$C_{12} = 7,6 \cdot x_{10} + 4 \cdot x_{11} + 1,4 \cdot x_{12} + 0,8 \cdot x_{13};$$

.....

$$x_{11} + x_{12} + x_{13} + x_{10} = 1;$$

Results of solution of formed problem of calculation of MPD of substances and optimal water protection measures for their achievement obtained with the help of OCHISTKA software complex are given in Table 2.

TABLE II
OPTIMAL WATER CONSERVATION MEASURES TO ACHIEVE MPD

Dumping	Event cipher without cleaning	Waste water flow rate			Reported costs, thousand sum/year
		thousand m ³ /day	in %	x _{ii} - decisions	
	202	—	—	—	—
	206	8.9177	92.22	0.9222	2413792

TABLE III
OPTIMAL WATER CONSERVATION MEASURES TO ACHIEVE MPD

No.	Components	Without cleaning	Complex cleaning by permissible concentration
1	suspended substances	193.7	140.0
2	BOD ₅	7.6	5.0
3	mineral composition	2769.0	2000.0
4	chlorides	712.5	350.0
5	sulfates	404.4	500.0
6	fats	1	5.5
7	nitrate nitrogen	47.1	20
8	nitride nitroge	0.08	0.04
9	ammonium nitrogen	0.91	0.4
10	costs, thousand of units per day	0	6613.7

It should be understood that in order to achieve acceptable pollutant concentrations, it is necessary to clean mainly the process some allowable values are not achieved, for example, mineral composition, chlorides and nitrogen. Comparison of cleaning costs by different process diagrams and complex cleaning is given in Table 3.

VI. CONCLUSION

In the proposed work, we considered the deterministic and stochastic distribution problems of the contaminated water treatment complex, consisting in the distribution of a certain volume of contaminated discharge water through treatment schemes, and we also proposed algorithms for solving these problems.

We also presented the results of a numerical experiment with the task of choosing such an acceptable combination of technologies and such a distribution of the volume of polluted water between them that the average total cost of cleaning is minimal and at the same time the concentrations of impurities after cleaning at the control site do not exceed the specified maximum permissible values. All possible types of visualization of the results of a computer experiment, as a rule, are reduced to the representation of tabular dependencies of a function of one variable, a function of two variables, as well as lines of the level of fields of vector functions.

The results of the study in the form of software, algorithms, and methods for the purification of polluted waters have been implemented: a software tool for calculations on deterministic and stochastic ecological and eco-nomic models of the complex for the purification of polluted waters has been introduced in the purification plant of the city of Nukus. The implementation made it possible to obtain and determine the optimal costs for the treatment of polluted waters with various technological treatment schemes; An improved mathematical model of the process of the polluted water treatment complex was used in the purification plant of the city of Nukus. The results of scientific research made it possible to save costs several times less than the previous one (by 15%).

Abstract—To maximize efficiency, quality of products, and profits, it is important to maintain machine tools to reduce downtime and maximize output. Predictive maintenance is the most efficient method of condition monitoring and maintenance. An Internet of Things approach can help implement an autonomous predictive CM system in manufacturing facilities. The critical parameters of sensor selection, communication, and data analysis have been examined. The components that make up an effective IoT CM system have been discussed and analyzed. An IoT approach has been shown to eliminate the disadvantages of traditional manual CM approaches.

Index Terms—Feed drives, Machine tools, Condition monitoring, IoT, Internet of Things, Industry 4.0.

I. INTRODUCTION

The manufacturing world has entered the fourth industrial revolution, often referred to as *Industry 4.0*. The fourth industrial revolution builds upon the automation and digitization of the third industrial revolution. It includes the implementation of the Internet of things (IoT), machine to machine communication, and improved communication and condition monitoring (CM).

The manufacturing sector is one of the most competitive sectors in developed nations. They must compete not only with other firms in developed nations but also with developing nations, which have the advantage of lower wages and less strict labour and environmental laws. To remain competitive, firms must embrace industry 4.0. Embracing Industry 4.0 can help to reduce costs, reduce errors, increase efficiency, and improve throughput. These advantages can help firms propel themselves above the local competition and compete with the prices of firms in developing nations. Advanced manufacturing is very capital dependent. Expensive machine tools such as CNC lathes, mills, laser cutters, and grinders are staples of modern manufacturing facilities. It is of utmost importance to maximize the output of these machines. Substantial costs are accrued if machines are not working at high levels of output.

It is in the best interest of these manufacturing facilities to maintain these machines adequately. Machines are maintained through maintenance and CM.

Maintenance and machine condition has several associated costs: Expected downtime, unexpected downtime, quality, and replacement parts. The cost of expected downtime is the lost production due to the machine being down for scheduled maintenance. Unexpected downtime is the cost of lost production and damage due to sudden failures and crashes. The cost of quality is the cost of defects that arise due to poor machine conditions, such as not meeting dimensional tolerance. Replacement part cost is the cost associated with replacing a part before it has reached the end of its useful life.

Predictive and prognostic maintenance is the latest evolution of maintenance paradigms. The first level of maintenance paradigms is reactive maintenance. Reactive maintenance is simply fixing machines as they break. This is the least effective form of maintenance. Reactive maintenance increases unexpected downtime as unexpected failures arising from neglect force the machines down. The next level of maintenance is planned maintenance, where maintenance occurs at set intervals. This is a better method compared to reactive maintenance but is still not ideal. Doing maintenance at set intervals increases the cost of expected downtimes and can mean replacing parts that are still far away from the end of their life. Predictive maintenance involves analyzing data from the machine and predicting when it requires maintenance. This paradigm can reduce expected, and unexpected downtime costs as machines are serviced only when necessary and before critical failures occur. Cost of quality and replacement part costs can be reduced as well as parts are used for the majority of their useful life and not past the point where the cost of quality begins to rise. A summary of the relative costs of each paradigm is seen in Table I below.

Predictive maintenance requires a great deal of data to

TABLE I
COSTS OF MAINTENANCE

Paradigm	Associated cost			
	Expected downtime	Unexpected downtime	Quality	Replacement parts.
Reactive	Low	High	High	Moderate
Scheduled	High	Low	Low	High
Predictive	Moderate	Low	Low	Low

analyze. Traditional CM is labour intensive and prone to human error. It often requires a worker to inspect and test machines over time individually. This approach is too expensive to inspect at a high enough frequency, and inspection is done too infrequently, therein faults and wear are detected too late. IoT can facilitate autonomous CM. Sensors can be installed on machines to collect a large stream of data in real-time. Data collected from the machines can be analyzed to determine the machine’s condition. This information can be used to take corrective action if required. Autonomous CM will maximize machine performance and up-time, which will, in turn, maximize manufacturing efficiency.

Machine tools have several components whose condition is worth monitoring. The primary investigation of this paper will be on machine tools with ball screw feed drives. Machine tools feed drives and spindles are typically run by AC servo motors. Ball screw feed drives are the most common feed drive for machine tools. The main components of a ball screw system can be seen below in Fig.1. Ball screws are normally supported on either end by fixed and free ball bearings. A table is connected to the ball nut, and this table is a set of linear guides that support it to slide back and forth with minimal friction.

This paper will cover the following: Section II will cover the current literature on the subject of CM. Section III will cover the sensors used in the machine tool CM system. Section IV will cover the communication within the system. Section V will cover the data analysis used for CM. Finally Section VI will cover the conclusion and future work.

II. STATE OF CONDITION MONITORING IN THE LITERATURE

Condition monitoring has been a field that has been studied extensively in the literature. A paper by Martin [2] covered machine tool CM and fault detection technology. Numerous

Fig. 1. Ball Screw System [1]

CM analysis methods for bearings and other moving parts exist in the literature. A survey by Zhou, Habetler, and Harley [3] outlines many common methods for CM. Many of these methods will be outlined in section V. A journal by Tandon, Yadava, and Ramakrishna [4] compared four methods for CM to determine which was most effective at detecting a fault in a bearing. They examined velocity vibration, motor stator current, acoustic emission and shock pulse method. They found that acoustic emission and shock pulse methods were the most effective method in detecting a bearing fault. In another study by Tandon [5] several vibration analysis techniques were compared to determine which was the most effective at detecting a bearing failure. It was found that peak vibration and vibration power were good predictors of wear. Temperature is another method for CM. A study by Touret et al. [6] reviews sensors and methods involving temperature for detecting faults. An IoT system for CM of CNC machine was proposed in a paper by Al-Naggar et al. [7].

There are several studies to detect wear in machine tools. In a study by Pichler, Klinglmayr, and Pichler-Scheder [8] they examined methods such as vibration, temperature and current to detect wear in a ball screw system. In one study by Verl et al. [9] they used information from the CNC controller to measure positioning error, repeatability and reversal error to determine if the system had encountered a fault. In a study by Huang, Tan, and Lee [10] they used Kalman filtering to detect mechanical and sensor failure in a ball screw system. Methods for detecting preload loss and determining levels of preload in a ball screw have been covered by several studies. In a study by Frey, Walther, and Verl [11] they inserted a force sensor between nuts in a system preloaded with a double nut setup. By doing this, they were able to determine the force of preload and measure changes over time and over the stroke of the screw. Studies by Feng and Pan [12] [13], Chang et al. [14], Tsai, Cheng, and Hwang [15], and Nguyen, Ro, and Park [16] used ball pass frequency, temperature, motor current and vibration analysis to detect preload loss.

IoT approaches to CM exist in the literature. Machine learning has become a popular data analysis method over the past decade. In a study by Ayvaz and Alpay [17] they implemented an IoT system and used machine learning to predict the time until failure for machine equipment. In another study by Kanawaday and Sane [18] they could predict a bad production cycle with a high degree of accuracy using machine learning. Both edge computing [19] and cloud computing [20] approaches to IoT CM have been proposed in two studies.

III. SENSORS AND DATA COLLECTION

Sensors on a machine tool can broadly be categorized into *integrated sensors* and *external sensors*. Integrated sensors are sensors that are built into the CNC controller or are required for normal operation. External sensors are sensors not normally included with the CNC controller or required for normal operation. External sensors can collect information from many different components such as the bearings, spindle, motor, and linear guides.

A. Integrated Sensors

Integrated sensors are the sensors and information that are required for the normal operation of the machine tool. These typically include both linear and rotary encoders for measuring the position of the worktable in each axis, as well as the torque signal which is sent to the motor from the CNC controller.

1) *Encoders*: Position measurements are performed using linear and rotary encoders. Encoders can either be incremental or absolute encoders. Absolute encoders do not require a reference position, while incremental encoders do. As a result, incremental encoders need to have zero points established after being powered down. Glass scale encoders are the most common type of linear encoder used, as seen in Fig. 2.

Most servo motors are equipped with optical rotary encoders to measure the rotational position of the output shaft. The derivation of readings from encoders can be used to determine velocity and acceleration. Disagreement between the two encoders can be used to detect faults. If there is disagreement during changing of directions, it could mean there is substantial backlash in the system. Constant disagreement between the two encoders could represent miscalibration or misalignment of the system.

2) *Measuring Torque and Current*: The torque input signal of the system and motor current information can be retrieved from the CNC controller. These can be used to determine the torque applied to the system. If torque is greater or less than expected, it could represent a fault [16]. Analyzing the torque signal behaviour [22] or motor current behaviour [23] can also provide useful analysis.

B. Temperature Sensors

Temperature can be a useful characteristic to measure. Heat is normally generated as a result of friction. Excess heat can result in increased wear in both mechanical and electronic components. It can indicate faults in components such as bearings and motors. When selecting a sensor, it is important to consider what temperature range will be examined, the sensitivity, response time, and linearity of measurement. Temperature sensors are either contact or non-contact. A summary of popular temperature sensors can be seen below in Table II.

A comparison of the performance of popular contact temperature sensors can be seen below in Table III. Contact temperature measurement sensors are ideal if it is possible to make a solid physical connection without interfering with the operation of the machine.

Fig. 2. Glass scale linear encoder [21]

TABLE II
COMMON TEMPERATURE SENSORS

Contact	Non-Contact
Thermistor	Radiation thermometer
Resistance temperature detectors	Optical pyrometer
Thermocouple	Fiber optic sensors
Semiconductor thermometer	

TABLE III
COMMON CONTACT TEMPERATURE SENSORS

Sensor type	Thermistor	RTD	Thermocouples
Range (C°)	-55 to 125	-200 to 850	-600 to 2000
Sensitivity	High	Low	Medium
Response time	Fast	Slow	Fast to Slow
Linearity	Exponential	Fairly linear	Fairly linear

Thermocouples are one of the most common contact temperature sensors. They can sense a large range of temperatures, have linear sensing of temperatures, and can have fast response times. They do not require an external power supply. Contact sensors may be useful to measure non-moving objects such as the bearings and motors. The expected temperatures for these in normal operating conditions are around 50° to 80° Celsius. IoT specific thermocouple exist and have built-in communication capabilities.

Non-contact sensors may be more useful in situations where contact with the object is not feasible or easy, the object is moving, or there are multiple objects to be measured at once. The most common of these sensors are radiation thermometers. These sensors measure the infrared radiation emitted from objects. They are often used for measuring the temperature of electronic components, and bearings [24].

C. Vibration Sensors

Vibration sensors are sensors that measure the mechanical vibrations of components. Papers by Goyal and Pabla [25], and Xu et al. [26] provide an overview of sensors used to detect vibrations. Vibration sensors can mostly be categorized into displacement, velocity, and acceleration sensors. An overview of these sensors can be seen below in Table IV. These sensors can also be categorized as contact and non-contact.

Certain characteristics must be considered when selecting a vibration sensor [27]. Some of these characteristics include Level of vibration, the frequency range of interest, environmental conditions, size constraints, contact type, and linearity of measurement.

Anticipating the expected sensitivity and frequency range of the vibrations is important. With high vibration amplitudes, low sensitivity sensors are preferable. The expected frequency of vibrations must reside within the range of the sensor. Different frequencies can represent different faults, as discussed in section V-A. Environmental conditions such as humidity, extreme

TABLE IV
COMMON VIBRATION SENSORS

Type of sensor	Common sensors	Frequency range
Displacement	Eddy current	Low frequency
	Inductive proximity	
Velocity	Coil and magnet	Low to mid
Acceleration	Piezoelectric accelerometer	All frequencies
	Capacitive MEMS	

temperatures, hazardous chemicals, and corrosion must be considered. Machine tools can expect a great deal of exposure to metal chips and lubrication fluid. Shielding the sensor from these is important to ensure accurate measurement. Sensors must fit into the machine tool without interfering with moving parts. For non-moving components such as bearings or motors, wired contact sensors are adequate. For moving components such as the cutting tool spindle or ball nut, it may be necessary to use a wireless and/or non-contact sensor. Otherwise, special considerations may be needed for cable management so that interference does not occur. Linearity of sensor measurements makes vibration analysis easier.

The piezoelectric sensor and the capacitive micro-electromechanical system (MEMS) are two very common sensors used for vibration sensing. They are useful for a wide range of frequencies and have low noise characteristics. They also boast high linearity over a large range. MEMS sensors are usually incredibly small. A study compared the performance of each of these two sensors and found that they had similar performance in metrics such as maximum load before failure, peak amplitude and linearity. [28]. A 3 axis IoT vibration sensor can be seen in Fig. 3.

D. Other Useful Sensors

Other than vibration and temperature sensors, there are a few other external sensors which can provide useful data. Oil quality sensors are useful devices for analyzing the quality of lubricants. Sensors are available which can provide information about the oil such as pH, temperature, capacitance [30].

Sound pressure sensors can be used to measure the sound energy emitted from moving parts. Components such as bearings will emit more noise as they wear or in the cases of

Fig. 3. Wireless 3 axis vibration sensor [29]

misalignment. One study used sound to detect faults in machine tool carbide inserts during facing operations [31]. They are not often used for CM because there is a great deal of background noise during the use of the machine.

Force sensors are useful for measuring process forces such as cutting or drilling as well as component forces such as the preload of the ball screw [11]. Common force sensors include load cells, strain gauges, and force-sensing resistors.

Cameras are useful for collecting visual data such as wear on the components like the ball screw. Many low cost cameras for IoT exist, such as the camera module available for the Raspberry Pi as seen in Fig.4.

IV. COMMUNICATION AND NETWORKING

Two key levels of communication exist in a CM system: the machine sensing level and the decision making factory level. A system overview which shows the interaction between the nodes can be seen in Fig. 5 below. The machine-level consists of individual machine tools with CNC controllers and external sensors. The factory level consists of all the machines, a central data analysis node, data storage, and nodes for each department. This is a similar framework as proposed in papers by Yaseen, Swathi, and Kumar [33], and Takemura et al. [34].

Four communication technologies are considered for IoT CM: Wired, Bluetooth, Wi-Fi, and Zigbee. An overview is seen below in Table. V. Zigbee is a popular communication technology used in literature. In one study by Lee et al. [35] they prototyped a smart factory to simulate measuring plastic extrusions. They used Zigbee with star topology for their communication. In another study, Zigbee was used for CM of motors [36]. Bluetooth technology was used in a study for the CM of welding stations [37] and a study on an IoT monitored factory [38]. In one study, the performance of Wi-Fi 2.4 GHz was examined for use in an IoT factory [39].

A. The Machine Level Communication

The machine level is the interaction between the sensors, CNC controller and machine computing and communication unit. This level represents a single machine. Table VI outlines

Fig. 4. Raspberry Pi camera [32]

the key considerations when selecting communication technology. The subsections below cover communication technology recommendations based on each design factor. Some computation occurs on this level for applications requiring low latency or immediate corrective action.

1) *Range*: Machine tools are typically never larger than a few meters. Sensors in the system can either be wired or wireless, depending on the sensor and application. If a sensor can be cannot be wired, Bluetooth or Zigbee wireless connection makes the most sense.

2) *Latency*: Certain analysis and control methods such as Kalman filtering may require low latency. Sensors for methods requiring very low latency should use a wired connection. For analysis methods with more lenient latency requirements such as temperature analysis, Bluetooth or Zigbee would be adequate.

3) *Throughput*: Certain types of sensors, such as cameras, will require a large throughput; these sensors should be wired if possible. Sensors with lower throughput, such as temperature sensors which may only pass on a single value every few seconds, can use either Zigbee or Bluetooth.

4) *Scalability*: Sensors may need to be added or removed. If a large number of sensors are required, issues may arise with the number of physical connections for wired sensors. Bluetooth has a maximum of 7 devices connected to a local network at once. There is not expected to be an excessive amount of wireless sensors, so Bluetooth is as adequate as Zigbee.

5) *Topology*: The topology of this level is a star. Communication occurs between the sensors and the central computing and communication node and between the CNC controller and the central computing and communication node. Communication between sensors or communication of external sensors

Fig. 5. Overview of the levels of communication

TABLE V
COMMUNICATION TECHNOLOGY COMPARISON

	Wired	Bluetooth	Wi-Fi	Zigbee
Typical range	5 m	10 m	100 m	50 m
Latency	Lowest	Moderate	Low	Moderate
Throughput	High	Low	Moderate	Low
Scalability	Difficult	Easy	Easy	Easy
Power	-	Moderate	High	low
Topology	Star	Star	Star	Mesh or Star

TABLE VI
COMMUNICATION CONSIDERATIONS AT MACHINE LEVEL

Range	A few meters maximum
Latency	Low latency required for some application
Throughput	Low throughput for most sensors
Scalability	Ability to add additional sensors
Topology	Star topology

with the CNC controller is unnecessary. Bluetooth or Zigbee could be used here.

6) *Optimal Communication Technology*: When possible, a wired connection is preferred. Wired connections have the lowest latency, do not require a battery, have the highest throughput, and have adequate scalability for up to a dozen or so sensors. For sensors that must be wireless, Bluetooth technology is the ideal choice. Bluetooth’s short range is fine for the expected range of communication, has low enough latency, moderate throughput and good scalability up to about seven devices.

B. The Factory Layer

The factory level is the interaction between the individual machine tools, a central computation and data storage server, and several relevant departments. Table VII outlines the key considerations when selecting communication technology. The subsections below cover communication technology recommendations based on each design factor. Most serious computation, data analysis, and data storage occur at this level.

1) *Range*: Communication on this level would be over the entire factory. Typically factories would be about 100 m to 1000 m across. Nodes at this level are all stationary, so wired communication is an adequate solution. If wireless is preferred, 2.4 GHz Wi-Fi would be adequate for these ranges if there are receivers throughout the factory, or Zigbee could be used, and communication could be routed between machines.

2) *Latency*: Most communication on this level does not require low latency. If wireless is preferred, Wi-Fi 2.4 GHz or Zigbee would be more than adequate.

3) *Throughput*: Most communication at this level has high throughput, typically on the scale of KB or MB. For this consideration, a wired or Wi-Fi wireless approach is favourable

4) *Scalability*: It may be necessary to add additional machines to the network. These machines will need power infrastructure so connecting them via a wired connection is not very

TABLE VII
COMMUNICATION CONSIDERATIONS AT FACTORY LEVEL

Range	Up to a few hundred meters
Latency	Low latency not required for most applications
Throughput	High throughput for some applications
Scalability	Ability to add additional machines
Topology	Star topology

cumbersome. Adding machines via Wi-Fi or Zigbee is very easy, and a large number of devices can be easily connected this way.

5) *Topology*: The topology of this level is a star. Communication occurs between the machines and a central data processing server and the server and relevant departments. This communication resembles a star topology. The larger range of communication could mean that a cluster topology (Fig. 6.) may be preferable in some situations.

6) *Optimal Communication Technology*: In many situations, wired connections would be adequate given the static position of each node in this level of communication. If a wireless approach is preferred, Wi-Fi is the preferred technology. The high levels of throughput necessitate communication technology that can transfer large quantities of data; thus, Zigbee is not as viable.

C. Human Interaction in Each Level

There must be a method of interaction between humans and the IoT CM system. At both levels, there will be human interaction, at the individual machine level and at the factory level.

1) *Interaction with the Machine Level*: Operators and maintenance staff need access to information about each machine. The machine interface could provide information to operators, such as if all the sensors are functional, if wireless sensors need to be recharged, and if the machine is still in operating condition. For individuals who are performing maintenance, the machine could tell them the specific issues that are occurring as well as components to inspect or replace. A dashboard similar to the one seen below in Fig. 7 would be available to workers to gather information about the condition of the machine quickly.

2) *Interaction with the Factory level*: Many different users from different departments can interact with the IoT system at the factory level. The maintenance department can access

information about the health of each machine and get alerts when there are issues, faults, or crashes. Production can use information about what machines are available as well as information about the expected availability of each machine to make production decisions. Engineering can examine data from the machines to make decisions about future machine purchasing and program creation. A dashboard should be available for each department which provides them with relevant information for decision making, such as in Fig. 8.

V. ANALYSIS METHODS

Data collected from sensors must be analyzed. This data analysis can be used to determine the condition of the machine tool. Many different types of analysis can be used to determine the condition of the machine. The following methods will be discussed: Vibration analysis, temperature analysis, Kalman filtering, lubrication analysis, machine learning, and statistical process control.

One thing that must be considered when doing analysis is where the analysis will be computed. Some methods require low latency and immediate action. These methods are best done at the machine level. Methods requiring a great deal of data or high levels of complexity should be done on the server level of the factory.

A. Vibration Analysis

Vibration analysis is one of the most common methods of CM available. Vibration measurements are used to detect many faults such as misalignment, imbalance, wear, and looseness [43]. Several factors of vibration can be considered, such as Vibration peak amplitude, velocity, and acceleration. Analyzing the different frequencies of vibration can be useful. Using the Fast-Fourier transform, you can transform a vibration from the time domain to the frequency domain. In the frequency domain, different frequency components of vibration can be analyzed. Different faults manifest at different frequencies. Lower frequency vibration analysis includes imbalance, misalignment and looseness. Higher frequency vibration analysis includes bearing faults and gear faults, among others.

Vibration analysis would primarily be done at the factory level of computing, where trends of vibration could be analyzed. Other vibration analysis methods could be done at the machine level, such as alerting the user if vibrations exceed a certain amplitude.

Fig. 6. Cluster topology [40]

Fig. 7. Machine monitoring dashboard [41]

Fig. 8. Factory level monitoring dashboard [42]

Fig. 9. ISO 2372-1974 Standard for machine vibration [44]

B. Temperature Analysis

The temperature in moving components such as bearings is directly correlated to certain variables such as speed, applied load, and lubrication [45]. Increases in rotational speed applied load, and lubrication velocity will increase temperature. Faults and wear will also increase temperature. The temperature will increase over the course of the run time of machinery. Fig. 10 shows a typical temperature increase of a bearing over its run time. Knowing a system’s speed, applied load, and lubrication, you can build a model for the expected temperatures of a component. Substantial variation from this model can indicate substantial wear or faults. Readings will need to be taken over a long period and compared to models and previous data. Most temperature analysis will occur at the factory level of computation as it involves looking at trends of data.

C. Kalman Filtering

Kalman filtering is an estimation method which uses the systems dynamic model, system inputs, and measurements to estimate the variables of the system. It is often used to improve target tracking and the control of moving objects. Kalman filtering has many derived methods, such as the extended Kalman filter and unscented Kalman filter, which are better estimators for non-linear systems. [46]. Most systems have multiple models to describe their behaviour. Interacting

Fig. 10. Temperature change under running conditions [45]

multiple models (IMM) is a method to use multiple filters to improve estimation. IMM has often been used for fault detection [47]–[50] in actuators. Kalman filtering methods require a steady stream of low latency data. Kalman filtering is best to be performed at the machine level.

D. lubrication Analysis

Lubrication analysis involves analyzing the oil used to lubricate moving parts. This analysis is often only performed on large machines (> 50 horsepower) that use circulating oil systems. Qualities such as oil pH, capacitance, and temperature can be used to determine the condition of lubrication. The presence of chips and debris could also be detected to predict pitting or spalling on a bearing. An overview of lubrication oil CM is covered in a paper by Zhu et al . [30]. Data about the oil condition over time can be analyzed at the factory level. Simple analysis such as alerting the user if oil temperature has gone above a certain level can be computed at the machine level.

E. Machine Learning and Machine Vision

Machine learning is algorithms which can improve automatically through experience and collection of large quantities of Data. Machine learning algorithms are *black box* systems, that is that we only understand the inputs and outputs but not the calculations and variables used to determine outputs. Machine learning is an excellent method for estimating parameters given a large number of inputs making it an ideal choice for CM.

Machine vision is extracting data from images. Visual data collected from cameras could be processed for useful information. Machine vision has been used to detect faults in machine equipment [51] and detect wear in machine cutting tools [52]. Machine vision can be combined with temperature analysis in the form of thermography. Temperatures of each component can be taken without contact using a single infrared camera. Temperatures of the entire system can be analyzed this way.

These methods of analysis require high levels of data storage and computation, so they are best done at the factory level of computation.

F. Statistical process control and trend analysis

Data collected from the IoT CM system can be used for statistical process control (SPC) and trend analysis. Data collected can be used for SPC methods such as control charts Fig. 11 and histograms which can be useful for CM and fault detection applications. These methods would be computed at the factory level as they require data sets over long periods of time. [53]–[55].

VI. CONCLUSION AND FUTURE WORK

After examining available IoT technology and current techniques for CM, it is apparent that IoT technology is advantageous for the application of CM. The primary disadvantage of CM is the requirement to manually collect a great deal of data at a high frequency and the possibility of human error. These

Fig. 11. Control chart [56]

disadvantages are eliminated if data can be collected and analyzed autonomously using an IoT system. An IoT autonomous CM system can help increase production throughput, reduce costs associated with maintenance, and help with decision making. When designing an IoT system for CM, the following design considerations have been examined: Types of available analysis, communication technology, and what sensors are available to collect the needed data. After considering these design criteria, and IoT CM system can be created.

To future augment the literature in the field, additional real-life applications of IoT CM systems should be studied. With more real-life examples, their benefits can be further examined and studied.

Abstract—Digital Terrestrial Multimedia Broadcast (DTMB) has high signal coverage and strong stability, so it can be used in Ambient Backscatter Communication (AmBC). To solve the problem of signal detection performance degradation of traditional algorithm in high backscattering rate scenes, this paper presents a signal detection algorithm based on DTMB frame structure. By introducing preamble, the receiver can not only detect the reflected link signal from the received signal, but also perceive the corresponding relationships between the information symbol and the DTMB signal frame; by introducing training symbol, the receiver can get the decision threshold of the information symbol, and then complete the demodulation of the information symbol. Simulation results show that the proposed algorithm significantly improves the signal detection performance.

Keywords—DTMB, AmBC, signal detection algorithm, signal frame

I. INTRODUCTION

The Internet of Things (IOT) is a network for the interconnection of all things. It has been nearly 30 years since it was proposed. As a product of the rapid development of science and technology, the IOT has formed a very close relationship with various fields of society, and constantly brings convenience to daily life.

Ambient Backscatter Communication (AmBC) uses Radio Frequency (RF) signals present in the environment to communicate, and shares spectrum with communication systems that provide RF signals. Because of less dependence on the dedicated RF sources, AmBC can reduce communication energy consumption and maintenance costs, which means AmBC has broad research space and application prospects.

Digital Terrestrial Multimedia Broadcast (DTMB) has three key advantages as ambient RF signals. First, DTMB has a high signal coverage. As of 2011, the coverage of DTMB in China

has reached 94.52%. Second, the television tower works day and night, so the DTMB signal is stable. Finally, the DTMB system adopts DMB-TH technology so that the DTMB signal has strong anti-interference ability, and the terminal has excellent receiving performance under mobile conditions.

In this paper, DTMB signals are combined with AmBC to study signal detection algorithm under the scene of high backscattering rate.

II. AMBIENT BACKSCATTER COMMUNICATION SYSTEM

The AmBC system is composed of an ambient RF source, a backscattering device and a receiver. The RF signal can be Wi-Fi, FM, LoRa, BLE, base station and other signals present in the environment [2-6]. The information to be transmitted by the backscattering device is superimposed on the radio frequency signal, then the receiver captures the backscattered signal and demodulates it.

A. Backscattering device

Fig. 1 shows the structure of the backscattering device, which is mainly made up of antenna, energy harvesting module, micro-control unit, backscatter modulation module, etc.

- The energy harvesting module provides power to the backscattering device by collecting RF energy in the environment.
- The micro-control unit encodes the information to obtain the binary sequence. According to the binary sequence, the modulation signal of the ambient RF signal is generated, which controls backscattering modulation module to complete the Binary Amplitude Shift Keying.
- The backscattering modulation module realizes the absorption and reflection of ambient RF signal by RF switch. When the impedance of RF switch and antenna match, the RF signal energy is absorbed by the load,

indicating the binary data "0"; when the impedance mismatch, the RF signal is reflected by the antenna, representing the binary data "1" [11-12].

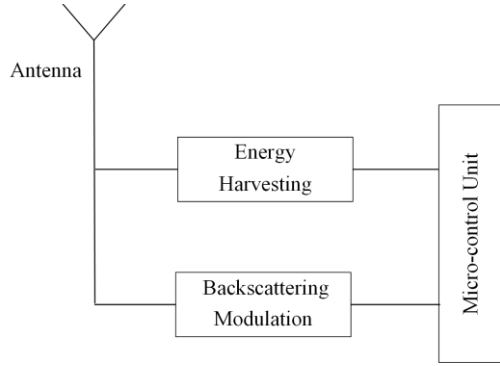

Fig. 1. Structure of backscattering device

B. Receiver

The path of the RF signal from the RF source to the receiver is the direct link, while the path from the RF source to the receiver through the backscattering device is the reflected link.

Fig. 2. Signal captured by the receiver

As shown in Fig. 2, the signal $y(t)$ is the superposition of the direct link signal, the reflected link signal, and the noise.

$$y(t) = s(t) + \alpha B(t)s(t) + u(t) \quad (1)$$

In the above equation, $s(t)$ is the signal sent by RF source, $B(t)$ is the modulation signal, and α is the complex attenuation coefficient of the reflected link signal relative to the direct link signal. The role of backscatter receiver is to demodulate the reflected link signal.

C. Digital Terrestrial Multimedia Broadcast Signal

The AmBC based on DTMB is studied in this paper. DTMB is the Chinese digital video broadcasting standard. The signal frame, as the basic transmission unit, consists of a frame header and a frame body, which is shown in Fig. 3.

Fig. 3. DTMB signal structure

In order to overcome the multipath interference caused by different delays, the standard provides frame headers of three lengths. The parameters are shown in Table 1.

TABLE I. DTMB FRAME HEADER PARAMETERS

Signal Frame	Frame header structure	Frame header length (μs)	Maximum distance (km)
Frame structure 1	PN420	55.5	16.7
Frame structure 2	PN595	78.7	23.6
Frame structure 3	PN945	125	37.5

The baseband symbol rate is 7.56 Mbps. Take the frame structure 1 as an example, the frame header symbol contains 420 symbols, then the length of the frame header is 55.5 μs , and the transmission distance of the RF signal within the frame header is 16.7km, i.e., the maximum distance of the single frequency network.

The average power of frame header 2 is the same as that of frame body, while the average power of frame header 1 and frame header 3 is twice that of frame body [9-10].

III. AMBC SIGNAL DETECTION ALGORITHM BASED ON DTMB

A. Traditional Signal Detection Algorithm

An ambient backscatter communication signal detection algorithm based on the TV Tower signal was proposed in [1] as follows:

Do Nyquist sampling to (1) to get the signal $y[n]$:

$$y[n] = s[n] + \alpha B[n]s[n] + w[n] \quad (2)$$

where $B[n]$ is either "1" or "0", $s[n]$ is uncorrelated with noise, $w[n]$. If the receiver averages the instantaneous power in the N samples corresponding to a single backscattering bit, the following equation is obtained:

$$\frac{1}{N} \sum_{n=1}^N (y[n])^2 = \frac{|1+\alpha B|^2}{N} \sum_{n=1}^N (s[n])^2 + \frac{1}{N} \sum_{n=1}^N (w[n])^2 \quad (3)$$

Say P_{TV} is the average power in the received TV signal:

$$P_{TV} = \frac{1}{N} \sum_{n=1}^N (s[n])^2 \quad (4)$$

Ignoring the noise, when binary "1" is sent, the average power of the received signal is $|1+\alpha|^2 P_{TV}$; when binary "0" is sent, the average power of the received signal is P_{TV} . The

receiver can decode the information from the backscattering device by distinguishing $|1+\alpha|^2 P_{TV}$ and P_{TV} .

In this algorithm, it is assumed that the average power of the TV signal corresponding to different backscattering bits is same. If the average power of the TV signal is different in different backscattering bit duration, the performance of the above algorithm will become worse.

Therefore, if the DTMB signal of frame structure 2 is used in AmBC, the receiver can decode information from the backscattering device through the above algorithm. For the DTMB signal with frame structure 1 or frame structure 3, the receiver can accurately extract information from the received signal only in the scene of low backscattering rate.

B. An Signal Detection Algorithm Based on Frame Structure

In this section, the DTMB signal detection algorithm corresponding to frame structure 1 or frame structure 3 is studied in high backscattering rate scenes.

The DTMB signal average power of a signal frame length can be expressed as:

$$P_f = \frac{T_b}{T_h+T_b} \times P_b + \frac{T_h}{T_h+T_b} \times 2P_b \quad (5)$$

where T_h represents the duration of the frame header in a signal frame, T_b represents the duration of the frame body in a signal frame, and P_b is the average power of the frame body.

The data sent by the backscattering device is composed of preamble, training symbol and information symbol. The preamble is "100", and the training symbol is composed of alternating "10". Each preamble and training symbol lasts for the same time as the length of a signal frame.

The receiver calculates the average power as follows:

$$P_{av} = \frac{1}{b-a} \sum_{n=a}^{n=b} (y_I[n])^2 + (y_Q[n])^2 \quad (6)$$

where $y_I[n]$ and $y_Q[n]$ are the in-phase and quadrature samples of the received signal.

1) The receiver slides to calculate the average power of the output samples of a signal frame length. At the time t_1 , the receiver calculates the average power of the output signal within $(t_1 - T_f, t_1)$; at next moment t_2 , the receiver calculates the average power within $(t_2 - T_f, t_2)$, where T_f is the length of a DTMB signal frame. If data are transmitted, the average power calculated by sliding will exceed the threshold set with reference to $|1+\alpha|^2 P_f$, and the receiver records the time T_1 corresponding to the maximum average power.

2) Starting from time $t_1 + T_f$, the receiver slides to calculate the average power of the output samples of a frame header length. Since the power of the frame header is twice that of the frame body, the average power calculated by sliding will exceed the threshold set with reference to $2P_b$, and the receiver records the time T_2 corresponding to the maximum average power.

3) According to T_1 and T_2 , the receiver can perceive the corresponding relationship between training symbol, information symbol and DTMB signal frame. In DTMB signal, the frame body of the previous signal frame is connected with the frame header of the next signal frame. According to the start of transmission, there are two corresponding relationships between preamble and DTMB signal frame, as shown in Fig. 4.

a) The selection of the second preamble: The second preamble is "0" so that the average power value obtained at the end of the transmission of the first preamble "1" is maximum. Then, the end time of the first preamble is determined, i.e., T_1 .

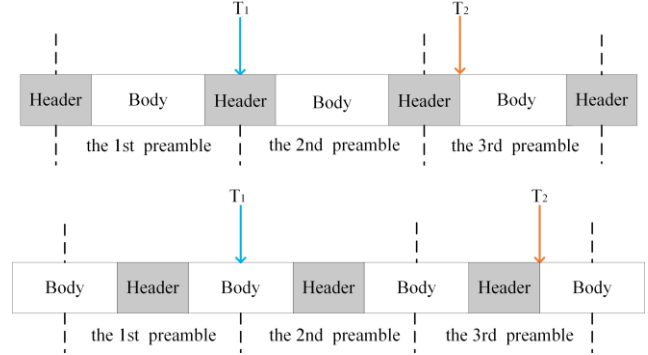

Fig. 4. Two corresponding relationships between preamble and DTMB signal frame

In order to avoid the influence of the frame header corresponding to the second preamble, the receiver start to calculate the average power from time $T_1 + T_f$.

b) The selection of the third preamble: It is the third preamble is "0" that the receiver can determine the moment when the frame header ends, i.e., T_2 . If the third preamble is "1", the receiver may not be able to accurately find when the frame header ends.

Fig. 5. The third preamble "1" may cause the receiver to go wrong.

In Fig. 5, ΔT is the time interval between the frame header and the third preamble. When the following equation is established, the time T_2 found by the receiver will be after the end of the frame header, and the receiver will wrongly perceive the corresponding relationships between the training symbol, the information symbol and the DTMB signal frame.

$$2P_b \times \Delta T < |1+\alpha|^2 P_b \times \Delta T \quad (7)$$

4) According to the corresponding relationship between the training symbol and the DTMB signal frame, the receiver obtains the decision threshold. It is complicated to derive the decision threshold from the channel estimation of the reflected link. For simplicity, the threshold is calculated by using the training symbol[7-8]. The training symbol consists of several groups of "10". The receiver can obtain the power levels of the frame header in the reflection state, the frame body in the reflection state, the frame header in the non-reflection state and the frame body in the non-reflection state, which are recorded as \bar{P}_{hr} , \bar{P}_{br} , \bar{P}_{hn} and \bar{P}_{bn} respectively.

5) The receiver calculates the average power of each information symbol according to the corresponding relationship between the information symbol and the DTMB signal frame. In the high backscattering rate scene, there are three kinds of corresponding relationship between the information symbol and the DTMB signal frame: only corresponding to the frame header; only corresponding to the frame body; and corresponding to the frame header and the frame body. If the information symbol corresponds to the frame header and the frame body, the samples of the corresponding frame header or frame body is selected to calculate the average power. Say B_N is the Nth information symbol and P_N is the average power of the Nth information symbol. The receiver decodes the backscattered information through (8).

$$B_N = \begin{cases} 1, & P_N > \frac{\bar{P}_{hr} + \bar{P}_{br}}{2} \\ 0, & \frac{\bar{P}_{hr} + \bar{P}_{br}}{2} \geq P_N > \frac{\bar{P}_{br} + \bar{P}_{hn}}{2} \\ 1, & \frac{\bar{P}_{br} + \bar{P}_{hn}}{2} \geq P_N > \frac{\bar{P}_{hn} + \bar{P}_{bn}}{2} \\ 0, & P_N \leq \frac{\bar{P}_{hn} + \bar{P}_{bn}}{2} \end{cases} \quad N=0,1,\dots, \quad (8)$$

C. Simulation Results and Analysis

The DTMB signal is generated by the module built in Advanced Design System, the preamble is "100", the training symbol is set to 5 groups of "10", and the backscattering rate of information symbol is 8kbps. At the same time, the noise is added. The performance of the AmBC signal detection algorithm based on DTMB frame structure is shown in Fig. 6 and Fig. 7.

1) Fig. 6 shows the relationship between bit error rate and signal-to-noise ratio when α equals to 0.15. It can be seen that with the increase of the signal-to-noise ratio, the bit error rate of the algorithm proposed in this paper tends to zero. In the high backscattering rate scene, this algorithm takes into account the difference of frame header and frame body power of DTMB signal, and increases the power level to distinguish the reflected and non-reflected states of information symbols from two to four, so that the demodulation performance is obviously better than the traditional algorithm. In addition, there is a certain degree of deviation between the time T_1 and T_2 determined by

receiver and the exact value. The greater the signal-to-noise ratio, the less influence of the offset on demodulation.

Fig. 6. Effect of signal-to-noise ratio on bit error rate

2) Fig. 7 shows the relationship between the bit error rate and the attenuation coefficient when SNR is 4dB. The attenuation coefficient is affected by antenna efficiency and path loss. When the attenuation coefficient is close to 0, the bit error rate approaches 50%, this is because the noise level is greater than the distinction of $|1+\alpha|^2 P$ and P . With the increase of attenuation coefficient, the interference of noise decreases, and the demodulation performance becomes better.

Fig. 7. Effect of attenuation coefficient on bit error rate

IV. SUMMARY

A signal detection algorithm based on DTMB frame structure is proposed in this paper, which solves the problem that the communication rate can't be higher than the frame rate of DTMB signal. Through the introduction of preamble and training symbol, the receiver can perceive the corresponding relationships between the information symbol and the DTMB signal frame, and obtain the decision threshold of demodulation information symbol. The simulation results show that compared with the traditional algorithm, the

proposed algorithm significantly improves the signal detection performance in the scene of high backscattering rate.

Abstract—There is no doubt that big data analysis has a very positive impact on economics, security, and other aspects for countries and enterprises alike. Where we have recently noticed the frantic competition between companies to increase their profits by analyzing the largest amount of data as quickly as possible. Especially analyzing data related to Covid-19 to make the most of information in all areas. Covid-19 has drastically affected many lives in recent years but, even in these hard times, businesses can leverage the current pandemic to make a profit. In this paper, we investigate a variety of tweets using MapReduce, Spark, and Machine Learning methods to determine the sentiment of a given tweet based on the information provided by the dataset. With this information, businesses could learn how to present Covid-19 and pandemic related goods and information in a way that will be well received by its audience. To take this a step further, we will investigate trends in sentiment across demographics tweeting about the virus. This information in sentiment is dynamically useful to understand how specific audiences feel about the pandemic. We explore which Machine Learning methods produce the best results such as Multi-Layer Perceptron neural networks and Logistic Regression.

Index Terms—Big Data, Machine Learning, Dynamic Sentiment Analysis, Spark, MapReduce, COVID-19, Tweets.

I. INTRODUCTION

As time goes on, the amount of data available for analysis increases by quite a large margin. Data mining allows us to find what is important in data, the value. Big-Data programming models such as MapReduce aim to alleviate some of the challenges of working with such large volumes of data. We aim to make use of some of these Big-Data programming models in order to retrieve some value out of a considerably large dataset. The dataset being used contains tweets that are related to the COVID-19 pandemic. The data is extracted from over 2.5 billion tweets and organized into 7 different tables. With this large amount of labelled data, we will explore the relationship between different demographics and how much each has been tweeting about COVID-19.

Our objective is to find the volume of tweets from differing demographics to discover what type of people are primarily

tweeting about COVID-19. To solve this problem, MapReduce methodologies will be used to mine and categorize the data. Although the circumstances are unpleasant, the current pandemic has been leveraged and utilized by businesses to turn a profit, like determining whether to increase or decrease productions for certain products. The findings from this paper can be used, for example, to aid businesses such as e-commerce companies in targeting ads towards these demographics for pandemic-related goods.

A number of methods are proposed, such as the following:

- A MapReduce join to create a full table along with a synthetic text.
- A Spark-based counter to gather instances.
- Machine Learning classification using various methods to determine the most useful approach for this data.

This paper is organized into a number of sections. Section 2 reviews this topic and state-of-the-art literature. Section 3, Materials and Methods, provides a description of the dataset that is being used to conduct the research of this paper, the system architecture with the definition of the problem, and the proposed solution methods. Section 4 is an overview of the simulation results. Section 5 discusses the possible aspects of the improvement, followed by section 6, which concludes this study.

II. RELATED WORK

Es-Sabery et al. [1] provide a paper, “A MapReduce Opinion Mining for COVID-19-Related Tweets Classification Using Enhanced ID3 Decision Tree Classifier,” in which they describe the problem of classifying opinions based on sentiment in the context of big data. The analysis of opinions with sentiment is important due to the fact that its applications can be applied in beneficial ways. Many applications are mentioned such as consumer trends, marketing strategies, and developments in the stock market among other things. The challenges that come with analyzing such data include long execution time due to volume and the variety of content

that comes in Twitter posts. They propose an improved ID3 decision tree classifier to create a model for their COVID-19 related tweets dataset. As for the long runtime execution issue, they propose handling the data in a number of mapping steps that lead to a reducing step that results in the ID3 decision tree classifier. While they propose a unique enhanced ID3 Decision Tree Classifier, our work will instead focus on the comparison of unaltered existing methods like Neural Networks, Linear Models, and Decision Trees. Their COVID-19 dataset is much smaller and focuses on an 11 day time period of tweets exclusively from India (150MB), while our dataset will be magnitudes of size larger. The dataset they use has text included, whereas ours does not and we will need to construct a synthesized text out of select tables.

[2] takes a deep dive into the human element that is in opinion mining and sentiment analysis research. They cover three main ways to implement the research: keyword-based classification, lexicon-based classification, and a wide variety of machine learning-based approaches. The machine learning-based methods are constructed around two core components, feature extraction and a machine learning algorithm. Additionally, they list application areas that can be beneficial to employee use of opinion mining and sentiment analysis, including healthcare, finance, sports, politics, tourism, and consumer behaviour, as well as some other less conventional applications like box office performance predictions based off a movie trailer. In the final sections of the paper they cover some of the open challenges of big data sentiment analysis, both technical and non-technical. The aim of their paper is to provide an overview of the process and procedure behind conducting sentiment analysis, our aim is to implement and take advantage of some of the methods explored in this paper to use in our research.

[3] discusses the power of using sentiment analysis by companies to benefit their market share. The typical use case for sentiment analysis is to analyze a targeted group of people's sentiment towards different entities. These entities could be organizations, products, services, individuals, events, topics, and issues which are gathered online through text, video, and other means of communication. Since they explore the vast number of ways sentiment can be gathered, our scope is focused on a single area, Twitter. There are three categories that the collected sentiment can fall into: positive, neutral, and negative. These can then be used in various applications, which can include stock price prediction, public voice analysis, and crowd surveillance. They also talk about some of the issues that occur with analysis in big data. One of the most prevalent of these issues that occurs is flexible capacity, and having to allocate more time and resources to solve problems. Something that adds to this problem is the fact that the solution to many problems in big data is not black-and-white. The paper talks a lot about frameworks used for sentiment analysis like Hadoop Distributed File System (HDFS), SQL, and Map Reduce for example, as well as outlining general approaches and features of sentiment analysis. We determined that it

would be best to focus on the particular frameworks which fit our use case best, instead of experimenting with a number of different methods. This paper focuses on how sentiment analysis can be used and implemented, whereas our work will focus on the actual implementation of some of these methods to produce results.

In search of the best solutions for sentiment analysis of tweets, a paper which uses Apache spark for sentiment analysis was found. This paper related perfectly to our data set, as the sentiment analysis was also being done on COVID-19 tweets. Spark stores in between data in the memory, making it useful for low-latency jobs [4]. The performance of spark stands out. By using memory in this way, it increases the efficiency of the system. This should not come as a surprise since using memory is a faster option when compared to loading intermediate values on the disk. Where our research differs is in what we are doing with our analysis. While this paper offers solutions for efficiently dealing with the data, we plan to actually create some models to predict sentiment. This paper only provides a solution of how to deal with our large data set, since processes can be slow with so much data.

III. MATERIALS AND METHODS

A. Description of the Dataset

The dataset that is being used in this paper is titled "COVID-19 Tweets Dataset (over 1 billion)"[5] and it is a vast repository of COVID-19 related tweets. The total number of tweets located in the dataset is 2,648,139,275 across the years 2020, 2021, and 2021, which is quite sizable and reaches a total space in memory of over 100GB estimated compressed. When the dataset is uncompressed, the memory it takes up is around 7 times the amount, totalling a probable 700 plus gigabytes. Therefore, within reason, we are limiting our use of the data to a subset of the available 2022 data that takes up around 35 gigabytes uncompressed.

The dataset is split over 7 tables that share a tweet ID as the primary key. The first table is the details of the tweet and this includes, language, if geolocation is in the tweet, if it is a retweet, likes, retweets, country, date, and time created. The next table is hashtags which is a one-to-many relationship where one id maps to many hashtags. Mentions are what the next table is composed of and it functions much like the hashtags table. The fourth table is the sentiment table, here the tweets are labeled and some specific predictions for neutral, positive, and negative are included. The fifth is the NER (Named-Entity-Recognition) table and this includes information relating to entities found within the tweets. The last two tables are the same as the sentiment and NER tables, but with the difference that they are for Spanish (ES) content. The tables are not all stored in a single file, instead, they are spread across files and directories. First off, the years are separated into different GitHub repositories as found in the ReadMe.md of the base repo which contains the latest year data. Each table has its own directory (Example, Summary_Details) and within that, they are further split by

month. Within the month directory, one CSV file is uploaded for every hour of every day of the month.

Nowhere within the data is the raw text of what was actually the tweet, but we still get enough information like hashtags, mentions, and NER values that we should not have to worry about not having the raw tweet text. If the raw text information of a tweet was really required then we can query the Twitter API with the tweet ID provided in one of the tables, this is more limited as the base developer account for Twitter has a limit of 500k calls a month. Therefore, the Twitter API will not be relied on for the majority of this project.

B. System Architecture and Problem Definition

A MapReduce style programming model will be implemented for various parts of the data analysis and preparation, but not through a framework like Hadoop. The data may have to be joined together due to the issue with it being stored across different tables and this is something MapReduce could achieve. Some of the analysis that requires MapReduce can be done through Apache Spark.

For the Machine Learning part of the project we will be using the library Sci-kit Learn. Sci-Kit Learn has a vast library of methods including a number of ML methods. Methods include different kinds of ML algorithms such as classification and regression algorithms, along with some useful scaling methods. Classification methods will be more important for this project, and perhaps we will use many depending on training time, but first we may look into Naive Bayes. Other potentially useful ML methods include Logistic Regression, Support Vector, and Multi-Layer Perceptron.

1) *System Architecture*: Our architecture, as seen in Fig.1, for getting to Machine Learning will work kind of like a pipeline architecture. First the data goes through joins, then feature extraction, and finally training.

2) *Problem Definition*: We hope to gain information from the COVID-19 dataset and see how well a machine learning model can perform, but this is a difficult task with how the data is organized. One such issue is that of the data being segregated into a number of tables. It would be easier if all the feature data we hope to use for Machine Learning is contained within a single table. Another issue is how to deal with the text data, using the text data as it is raw is not doable for the Machine Learning process. Some solution must be proposed for this problem.

C. Solution Method

To attain some information from the dataset that could provide insight, one of the methods we implement will be a MapReduce instance count. The class instance we are going to collect is the sentiment label, which is either positive, negative, or neutral. With the result of this count we should be able to plot the amount of tweets of each instance over time as well as the total class instance imbalance. It will take two MapReduce jobs to accomplish the counts and aggregations for hourly, daily, and total. The first MapReduce job will map out the contents of each file into intermediate values which

correspond to hourly instance counts, and we can keep these. After the map we will aggregate the keys into daily counts. The second MapReduce job will simply have the mapper map out the daily counts as intermediate pairs and then the reducer aggregates them into a total count for the data we are using.

Three of the tables in the dataset include information that could be of value if counted. The NER, mentions, and hashtags tables all include a single column within them dedicated to some kind of text data. If we count all of the values of those columns we can find some of the top values included in a tweet in a specific set of time. This will be accomplished using Apache Spark to count the words and then output them into a list we can sort for top words, as seen in Algorithm 1. There will be a lower limit of how many words must appear in a single hour of data. The lower limit will allow us to filter out low usage terms, and save space on memory and disk. For example, if we set the lower limit to 10, then we are not missing out on much data. Say there are 100,000 tweets per hour, we would only miss out on a maximum of 240 instances of a term over 24 hours of 2,400,000 tweets. Popular terms will have much higher instance counts.

Algorithm 1 Spark MapReduce Count

```

f ← sc.textFile(path)
s ← f.map(Line.split(',').foreachLine)
c ← s.map((lowercase(w), 1)foreachw)
c ← c.reduceByKey(w1 + w2foreachw1, w2)
sort(c)
i ← 0
while i < length(c) do
  if c[i] ≥ somethreshold then
    break
  else
    i ← i + 1
  end if
end while
return c up to i, exclusive

```

One of the sub-problems of this problem is getting the data ready for Machine Learning algorithms. Some of the data has been prepared via MapReduce style programming. Since the data resides across a number of tables, it would be much better for the features that we are going to use to be shared in a singular table. So the proposed solution for this issue is that of a Map-side join. We use this to join the tables into one. The map-only MapReduce job works here because the data we have is split into many small files already which will be able to fit into main memory and produce the many final small tables.

We will also use this Map-side join style for a similar issue before joining every table we are using. Rather than a join, it will be a Map-side concatenate. The issue is that some tables include one-to-many relationships, and because of this we are unable to simply join unless we perhaps want duplicate records. These tables are the NER, hashtags, and mentions

Fig. 1. Pipeline System Architecture.

tables. The proposed solution is that if we combine the many values that are mapped to a single tweet ID into a single string, it shall work as outlined in Algorithm 2. For example, say we have the hashtag value for a tweet as "#hashtag" and there also happens to be a mention for the tweet, "@mention", after the Map-side concatenate algorithm the result will be "#hashtag @mention" as the stored text value. A possible benefit of this is that we will never have to obtain the plain text of a tweet from Twitter, since we will have most of the important values that would be in plain text such as named entities, hashtags, and mentions. Furthermore, possibly less valuable plain text values such as determiners like "the", "a" and other linguistic values that provide less information will not have to be dealt with.

Once we have joined all the text values into a one-to-one relationship table, we can join this with the last remaining table, the details table, as seen in Algorithm 3. Because of the one-to-one relationship of each table, we can join the two tables using the tweet ID as the key. The result shall give us a single table to work upon for our machine learning step. Although, from this point the text and other features may need to be encoded somehow.

Algorithm 2 MapReduce Join Mapper Text

```

f ← fileName
paths ← [ner, hash, mention]
outmap ← emptyhashmap
for P in path do
  lines ← openFile(P + f)
  for l in lines do
    if outmap.in(lid) then
      outmap[lid] ++
    else
      outmap[lid] ← 1
    end if
  end for
end for
emit(f, outmap)
  
```

For the machine learning part, we will test some features and see how they compare to each other. Once the best feature has been found we will use that for further experimentation. A number of different classifiers will be tested to see which

Algorithm 3 MapReduce Join Mapper Full

```

f ← fileName
paths ← [summary, text]
txtmap ← load(paths[text] + f)
for line in open(paths[summary]+f) do
  lines ← openFile(P + fileName)
  for l in lines do
    l.append(',')
    if txtmap.in(lid) then
      l.append(txtmap[lid])
    end if
  end for
end for
  Save Updated paths[summary]+f file
  emit(f, paths[summary] + f)
  
```

provides the best possible score using the accuracy metric. These classifying methods include Ridge, PassiveAggressive, Support Vector, Multinomial Naive Bayes, Stochastic Gradient Descent, Decision Tree, Multi-Layer Perceptron, K-Nearest-Neighbors, and Logistic Regression. All of these methods will be trained from the library sci-kit learn.

Feature extraction of the joined text column of the data set is something that needs to be dealt with. The proposed solution for this is to convert the words into a vector representation that is stored inside of a sparse matrix. The sparse matrix will allow us to save a large amount of memory compared to the usage of a large dense matrix. More useless features will be dropped from the data set as we focus on the features with more potential. Date, country, tweet ID, and language will be dropped. Date and tweet ID do not seem to be much more than arbitrary values that would not provide value to models. Country is a very sparsely populated column within the data set, so the appearance of a country value is an anomaly compared to any other given example. Since we are focusing on English sentiment data, the language feature does not provide value for our usage as all the data will be English language.

IV. SIMULATION RESULTS

We were able to plot the results we received from the MapReduce instance count into a number of figures. The data used is from the start of January 2022 to February 19,

Fig. 2. Instances over time, daily.

Fig. 3. Instances over time, hourly.

Total Sentiment Distribution, 01/01/22-19/02/22

Fig. 4. Class instance distribution.

Fig. 5. Top 10 Hashtags.

2022. When viewing the daily instance counts in Fig. 2, we can see that there is a downward trend in total twitter activity relating to COVID-19. Furthermore, the negative and neutral class seem fairly correlated all throughout this time frame. The positive instances are much lower than the others throughout the entire time. The cause of the lower instance of positive tweets could be from people not being happy and hyped up about COVID-19 on twitter as it is an inherently negative thing. High amounts of neutral came from news sources possibly as news is generally written as a neutral piece of work, or anything that reports general information. Negative instances can come from the many different groups that complain about different COVID-19 related topics.

Within the hourly figure, Fig. 3, many peaks and valleys can be seen. This may just be the difference between Twitter prime and off hours, especially since we just used English data for this part. While many English speakers exist across all time zones, the areas with the highest amount of active English twitter users will influence these peaks and valleys such as North America, a highly populated typically English speaking region.

The total class distribution can be seen in Fig. 4. There

is an unequal distribution of the classes, especially between the positive class and the other classes. The class imbalance could pose a problem to the machine learning methods, since the number of examples for positive is only at 9.3% of the total data set for the time examined. Neutral and negative are pretty close to being balanced between each other with 44.0% and 46.8% respectively.

We were able to gather the results of the top seen values for hashtags, mentions, and NER values. We can derive possibly trending topics for the month of January where these values were from.

Hashtags can be good values to gather data from. Showcased in Fig. 5, the top hashtags are all strictly COVID adjacent values. Perhaps indicating how much of the data from this data set was collected. For example, the majority of the values are #covid19, #covid, and #omicron. Perhaps the usage of less trending hashtags could gain some more value on the sentiment of subtopics within COVID-19 related tweets.

In Fig. 6, the top mentioned accounts can represent highly engaged figures within the community that is active in

Fig. 6. Top 10 Mentions.

Fig. 7. Top 10 NER values.

COVID-19 twitter. As to whether these accounts foster negative or positive communities that engage with them could be of interest for further analysis. All tweets that mention a certain account could be counted for their sentiment value and the accounts can be deemed as positive or negative figures. Government officials can be found high up in the mentioned accounts due to the possibility that many people are likely to try and voice their opinions to them as they hold power in some COVID-19 related policies generally. The second highest mentioned account is suspended, suggesting that they were spreading information of questionable quality that would end up against Twitter’s terms of service. Other mentions include some health officials or experts that may have high interaction due to their knowledge.

The top NER values are presented in Fig.7, and show obvious values that would be trending among COVID-19 related tweets, but beyond that, we can find sub-topics that were of great importance for the month. For example, the values US, India, UK and Canada can indicate significant events within those nations that were related to COVID-19 in January. The CDC and Biden values could indicate important events relating to certain government entities. Now as to whether these values had negative or positive relations with the tweet, that would have to be counted to see the ratios of positive, negative, and neutral with the named entities.

Space was a constraint that made using just one month of the data set very difficult to run machine learning on. With limited resources, only the first seven days of 2022 were used when machine learning was done.

First, correlations between some of the features were investigated. Since lots of the data was categorical, it needed to be converted to numerical values to find correlation. Some of the features were not converted to numerical values, like hashtags, NER values, and mentions, since there were so many unique values in the data. Having so many unique categories would make seeing any relationship unlikely since the categories, at least in this case, are not ranked. For most features, not much correlation was found. There was, however,

Fig. 8. Sentiment against likes.

a considerable amount of correlation between "Sentiment", "Logits Neutral", "Logits Positive", and "Logits Negative", which is to be expected since the feature "Sentiment" is found from the three "Logits" features. These relationships are not useful in developing any sort of model.

Some of the features were plotted against "Sentiment" to visualize their relationship. Sentiment was Label Encoded to numeric values (0 = Negative, 1 = Neutral, 2 = Positive). Each category had many tweets with few retweets or likes and some outliers that greatly exceeded the range of the majority of the tweets. It seemed most tweets with Sentiments of "Positive" had fewer likes and retweets, not exceeding the main clump of points. There was, however, one extreme positive sentiment outlier,

Fig. 8 and Fig. 9, that could have been the result of a COVID restriction being lifted, for instance. Tweets with the most retweets seemed to belong to the "Neutral" category, Fig. 9, while tweets with the most likes seemed to be "Negative", Fig. 8.

Using only likes and retweets, a K-Nearest Neighbors algorithm was used to predict the sentiment of a tweet. Using different values for K, it was found that a minimum of

Fig. 9. Sentiment against retweets.

Fig. 10. K-Nearest Neighbours with different values.

K=5 provided the best accuracy scores, Fig. 10. This model, however, would not be very useful since its accuracy score is not very high.

We can derive from the results of the K-Nearest Neighbors (KNN) classification results, Fig. 10, with just likes and retweets that the features are not that useful on their own. Rather than continuing testing with these, we switched to using the vectored text from the generated text column that we made. Seeing Fig. 11, the results are much better, but still not possibly the best that could possibly have been accomplished.

Out of all the nine classifiers tested, two of them performed the worst with low 50-55% accuracy on the test set. Those classifiers were the Support Vector (SVC) and the Decision Tree. Along with being perhaps a bad model for the task, the SVC took a long time to classify examples and train compared to some of the better performing models.

The rest of the classifiers scored around 70-75% on the test set that was used. The Multi-Layer Perceptron (MLP) performed the best on the test set for accuracy above all else with 76.6% accuracy. The best accuracy did come at a cost, and that was training time. The MLP took around 3 hours to train, compared to other top models which all finished in about a minute at most. Due to the time the MLP took to train, if we were to be doing this training on live data hourly we would probably want to choose one of the faster methods such as Logistic Regression. The time to train the MLP could

Fig. 11. Results of various classifiers.

be alleviated by using a more complex neural network library that allows for GPU acceleration as the library we were using, sci-kit learn, does not support it.

The Ridge, PassiveAggressive, SGD, and Logistic Regression classifiers all performed similarly and this may be due to the fact that they are all linear models.

As to why KNN performed much better on the text data compared to the likes and retweets, the reason can be that there is much more data to compare. Tens of thousands of words compared to only a couple of columns. The difference between a negative tweet and a positive tweet can be more easily distinguished as similarity based on the euclidean distance of any two examples.

V. DISCUSSION

As previously discussed, our best result for predicting the sentiment of a given tweet came from classifying tweets using vectored text. Even with the tested accuracy being acceptable, there are improvements that could be made. Considering the size of the data set being used, surely some trends would present themselves and *some* have. However, limiting the data that was used in machine learning, to a much smaller chunk than what was available, will have some effects on the model produced. Depending on what was happening with respect to the pandemic during the time frame that the data was taken from, it could only be effective at predicting the sentiment of a tweet during that time. The better approach(es) could be to use a larger sample of data, take small samples from different times during the pandemic, or both. Either solution could provide a more diverse set of tweets to design a model based off of, which could possibly mean a more accurate model to predict a tweets sentiment.

VI. CONCLUSION

Our paper is able to figure out many characteristics in the data using big data methods such as MapReduce and a number of machine learning methods for sentiment analysis. The counting algorithms are able to determine instance counts of various features within the data, providing insight

into possible popular trends. The machine learning methods proposed have been fairly successful at determining sentiment when trained on the synthesized text and could be improved by perhaps using more complex neural networks beyond a MLP. Businesses could potentially use the results found to direct their advertisements towards specific audiences based on trending topics and sentiment towards the pandemic found in tweets.

Abstract— Unmanned aerial vehicles (UAVs) began to be used at the beginning of the 20th century, but only for military purposes; however, nowadays their use has become popular in other areas such as mining, construction, security, agriculture, environment, and for research purposes. Therefore, the purpose of this article is to document a systematic review of the use of UAVs related to environmental science issues. The objective of this article is to identify the different uses of unmanned aerial vehicles (UAVs) in an environmental system that will allow the identification, quantification, and data analysis of different variables related to the area of interest such as the concentration of pollutants found within the study area. For the procedure of this article, we used different databases and scientific search engines that allowed us to obtain research conducted from 2019 to 2021. The selection of the reviewed articles was carried out, leaving 25 selected. Finally, it is concluded that more research can still be developed on environmental science topics but focused on flora for its detection, identification, quantification, or monitoring.

Keywords—environmental monitoring, drone, detection, monitoring

I. INTRODUCTION

Unmanned aerial vehicles (UAVs) have different components such as hardware and software necessary for real-time control, controllers such as altitude and heading controllers used to determine altitude and flight respectively, and sensors that are specifically based on what you want to measure, among others [1]. It also allows the collection of data or information related to the detection, supervision, environmental monitoring, and capture of 3D satellite images that favor the quantification and identification of some species [2]. Therefore, in the last decade, there has been a growing popularity for unmanned aerial vehicles (UAVs), increasing interest in the development of new types of drones of different sizes so that they can perform more tasks, which has led to their application in different areas [3].

The main uses that are currently being given to drones, are used for patrols and even surveillance systems in cities, they are also taken as tools in civil engineering to evaluate topographic measurements, in the environmental use are made as surveillance and control systems to identify and counteract the negative impacts caused by pollution, in addition, these UAVs

help to record aerial shots to observe the evolution of vegetation after a fire, in agriculture UAVs control and monitor through images captured by cameras to observe the state of crops, therefore, the use of drones allows or helps systematically, accurately, quickly and economically for monitoring works and research studies [4].

On the other hand, environmental monitoring with drones is an important tool to determine pollutant concentrations in the environment allowing constant data collection using sensors in real-time helping to determine and predict the quality of air, water, and noise. Therefore, drones provide a new opportunity for monitoring potential negative impacts on the environment [5]. In other words, by incorporating an unmanned aerial vehicle (UAV) into a monitoring system, it will be possible to collect data practically at higher altitudes and in areas that are difficult for humans to access.

An example of this is the use of UAVs for monitoring gases such as CO₂ in mining deposits, which are obtained through regression methods and neural networks to generate a mapping of the concentration of this chemical compound in the environment [6]. Such use allows for reducing variables in terms of cost and time of analysis to carry out a study. This would not have been possible at the beginning of the 20th century since its use was exclusively for military matters [7]. Likewise, another study mentions the use of drones in the mining sector for the monitoring of particulate matter (PM), which is generated by the flying that is carried out constantly in the deposits. This measurement was carried out thanks to the incorporation of a dust sensor in the UAV, also allowing the collection of data during the flight, facilitating the characterization of the plumes of each exploitation in real-time [8].

The objective of this article is to review the use of drones or unmanned aerial vehicles (UAVs) integrated into the area of environmental sciences where they perform the function of identification, quantification, analysis, monitoring, supervision, and detection of environmental variables of interest. All the information collected will be captured in a table employing certain characteristics. Finally, conclusions will be presented based on recent trends in the application of drones around interest.

II. METHODOLOGY

For the development of this research a search was conducted in the following databases: Google Scholar, Refseek, and ProQuest where keywords such as drone, environmental monitoring with drones, supervision, and detection were used, obtaining more than eight thousand studies until the year 2021, but we considered only those focused on the branch of environmental sciences and on the other hand that also provide information on the name of the drone, type of drone, sensors, type of pollution, type of action of the drone and type of industry, which considerably reduced the number of articles to be treated. Another selection criterion was access to scientific

articles, of which just over 30 research papers could not be accessed. Finally, the criteria reduced the number of studies to only 25 studies to be published between 2019 and 2021.

III. REVIEW OF PUBLICATIONS

To simplify and structure the research conducted. The information collected related to drones with a focus on environmental sciences was classified according to drone name, type of drone, sensors, type of contamination, type of drone action, and type of industry. Table I shows the collection of information

Note: Abbreviation: P4P: Phantom 4 pro, M600P: Matrice 600 Pro, I2: Inspire 2, DZX3V: DJI Zenmuse X3 visual, ZX3: Zenmuse X3, DZXTR: DJI Zenmuse XTR, YSSC: Yellow Scan Surveyor, C3D: cartography in 3D, PSIM: Parrot @Multispectral imaging sensor, S: Sequoia, SIMLI: Irradiance sensor for incident light measurement, C20: 20-megapixel camera red-green-blue, SF: Fluorescence Sensor, LDOCP: Continuous wave (cw) diode laser for petroleum, SGMP: sensors to PM10, PM2.5, SO₂, NO₂, CO, O₃, VOC, CO₂, XP: Xbee Pro 900HP, SG: Sensors to CO₂, CO, NH₃, SO₂, PM, O₃ y NO₂, SGPM: Sensors to NO₂, SO₂, O₃, CO, PM2.5 y PM10, MHC: Mirage HC, SCH4: Methane Sensor, CT: thermographic camera FLIR C3, CFPV: Camera FPV, SOIA: Optical sensor and artificial intelligence, CMSM: camera MicaSense RedEdge-M with a professional multispectral sensor, SEMOX: Electrochemical and metal oxide sensors, MS: Multi-sensor, CM2: Dual multispectral camera, DLS: Downward light sensor, SMQ: Sensor MQ, SDL: Digital laser sensor for PM1.0, PM10 y PM 2.5, M: Multi-spectral RGB, CTL: Thermal Lidar camera, SPM: sensor of PM 2.5 and PM 10, S03BC: sensor of O3 and BC, Environmental: ENV, Quadcopter: QDC, Hexacopter: HXC, One Propeller: OnP, Multicopter: MTC.

A. Drone

Nowadays, drone technology is very familiar and versatile. The drone can be equipped with different systems allowing it to perform different types of tasks. Nowadays drones are used in warfare, mine inspection, surface reconnaissance, and research, i.e., drones not only help in society, but they are also a threat. So, drones have their predetermined working capability, so it becomes important in today's world [35].

From the information gathered, it has been possible to identify a wide variety of unmanned aerial vehicles that are used for environmental monitoring, identification, quantification, and surveillance systems. Table II describes the characteristics of the drones most used for this purpose.

TABLE II. DESCRIPTION OF THE CHARACTERISTICS OF THE MOST COMMONLY USED DRONES

Drone	Characteristics
M600P	The Matrice 600 Pro has a payload of 6 kg and a flight time of 15 minutes and has a slow flight speed, therefore, these characteristics are essential for good monitoring of emission sources [05].
P4P	This unmanned aerial vehicle has a maximum flight time of 60 minutes and detects obstacles in 5 directions in mid-flight.
E-Drone	The E-Drone are automatic drones that are programmed to perform monitoring and detection at heights that are not above ground level [06].
P3	This drone has a transmission distance of 1 kilometer, therefore, it easily allows the analysis or monitoring in places that may be inaccessible or dangerous for humans [34].

Note: M600P: Matrice 600 Pro, P4P: Phantom 4 Pro, P3: Phantom 3

On the other hand, Table III shows the percentage of use of the drones where the Matrice 600 Pro drone is the one that has had more uses in the list of the mentioned investigations representing 19.20%, followed by the Phantom drone, it is worth mentioning that within this section three different Phantom models were included which were the P4, P4P, P3 and represented 15.40%. While in the other section, drones that were mentioned only once were considered and accounted for 50.00% of the total. Finally, drones that do not specify their names (NE) in the numbered research papers are detailed, accounting for 15.40% of the total.

TABLE III. PERCENTAGE OF DRONE USE

Drone	Amount	
	Frequency	Percentage
M600P	5	19,20%
Phantom	4	15,40%
Others	13	50,00%
NE	4	15,40%

Note: M600P: Matrice 600 Pro, NE: Not specified

B. Type of Drones

One of the most prominent features is the one used to define the difference between fixed-wing systems, multirotor systems, and other systems. There are hybrid systems, which are both multi-rotor and fixed-wing systems, ornithopters, and drones using turbofans. The technology used to maintain the drone's flight defines the type of drone, this characteristic is also the determining factor of the drone's shape and appearance. A second characteristic is the level of autonomy of the drone. The autonomy can vary from fully autonomous operation to one controlled by a remote pilot. Another notable characteristic is the difference in size between drones. The size can vary from drones the size of an insect to drones the size of a commercial aircraft. Weight is also an important characteristic. The weight of drones can vary from several grams to hundreds of kilograms. The last characteristic is the difference in power sources [36]. From one of the characteristics, all kinds of drones can be differentiated by the number of propellers, such as quadcopters (drones with four propellers), hexacopters (drones with six propellers), and fixed-wing drones, single-propeller drones, and multicopters.

Fig. 1. E-DRONE / Quadricopter. Source: Godall Rohi, O'tega Ejofodomi, Godswill Ofualagba, Autonomous monitoring, analysis, and countering of air pollution using environmental drones, Heliyon, [2020]

The drones that have more propellers are more used because they allow a better flight and therefore data collection at higher altitudes. As can be seen in Table IV, the quadcopter and the hexacopter are the most used drones, which represent more than

80.00%, while the rest of the drones (one propeller, multicopter, and flexible fixed wings) are below 5.00%.

TABLE IV. PERCENTAGES OF DRONE TYPES

Type of Drone	Amount	
	Frequency	Percentage
CP	12	54,54%
HC	6	31,81%
UH	1	4,55%
AFF	1	4,55%
MC	1	4,55%

Note: CP: Quadcopter, HC: Hexacopter, UH: One Propeller, AFF: Flexible Fixed Wings, MC: Multicopter

C. Sensors

Designing sensor systems for drone detection is often easier said than done; these systems include weather, visibility, false positives, and bird or aircraft detection. To have better information, alternative approaches have been implemented, such as the use of optical sensors. Optical sensors have been used for various types of object detection and have been successful in UAV detection [37].

Similarly, another alternative has been to use radio frequency (RF) scanners. Several studies have been conducted using RF scanners to detect Micro Doppler signatures to perform drone detection and classification [38].

This section reviews the devices or sensors that accompany the drone to perform the corresponding study. There are different types of sensors and each of them determines a type of pollutant based on concentrations as shown in Figure 2: (a): Gas Sensor, (b): NO₂ Sensor, (c): NH₃ Sensor.

Fig. 2. These types of sensors were programmed to automatically recalibrate themselves every week by collecting statistical data in studies related to environmental sciences. Source: Godall Rohi, O'tega Ejofodomi, Godswill Ofualagba, Autonomous monitoring, analysis, and countering of air pollution using environmental drones, Heliyon, [2020]

Table V also mentions sensors that allow determining the concentrations of PM, CO, CO₂, NO, and other gases that negatively impact the environment.

TABLE V. PERCENTAGES OF SENSORS TYPES

Type of Sensors	Amount	
	Frequency	Percentage
Carbon	1	2.5%
SGMP	1	2.5%
SG	1	2.5%
MHC	1	2.5%

SCH4	1	2.5%
SEMOX	1	2.5%
MS	1	2.5%
SMQ	1	2.5%
SDL	1	2.5%
SPM	1	2.5%
S03BC	1	2.5%
SGPM	1	2.5%

Note SGMP: sensors to PM10, PM2.5, SO₂, NO₂, CO, O₃, VOC, CO₂, SG: Sensors to CO₂, CO, NH₃, SO₂, PM, O₃ y NO₂, SGPM: Sensors to NO₂, SO₂, O₃, CO, PM2.5 y PM10, MHC: Mirage HC, SCH4: Methane Sensor, SEMOX: Electrochemical and metal oxide sensors, MS: Multi-sensor, SMQ: Sensor MQ, SDL: Digital laser sensor for PM1.0, PM10 y PM 2.5, SPM: sensor of PM 2.5 and PM 10, S03BC: sensor of O₃ and BC.

Likewise, the sensors can also be RGB, thermal, lidar, and multispectral cameras as shown in Fig. 3, and are used for detecting, monitoring, and identifying the study areas.

Fig. 3. Unmanned aerial vehicle and sensors. Source: R. Ríos, Hernández, Use of drones or Unmanned Aerial Vehicles in precision agriculture, Cuba: Agricultural Engineering Magazine, [2021]

D. Type of Contamination

Some of the main air pollutants are ozone (O₃), particulate matter (PM), nitrogen dioxide (NO₂), carbon dioxide (CO₂), sulfur dioxide (SO₂), and carbon monoxide (CO). Some of these pollutants occur naturally in the environment and others are generated through human activities [39].

PM pollution is a part of air pollution that is composed of extremely small particles and liquid droplets containing acids, organic chemicals, metals, and soil or dust particles. In addition, a high concentration of NO₂ can irritate the airways of the respiratory system and can aggravate and cause the development of respiratory diseases. Additionally, a high concentration of CO₂ is partly responsible for global warming. Exposure to ammonia (NH₃) can cause immediate burns to the nose, throat, and respiratory tract. Air pollution also has a detrimental effect on climate and crops [39].

In this field, the aim is to show in which medium the contamination (if any) develops. Consequently, Table VI shows three different media: air, water, and soil, which have 15, three, and two studies, respectively. In addition, four other studies were also found that are not based on contamination but the evaluation or monitoring of the state of the crops [9-28], irrigation programs [28], or land topography modeling [8].

TABLE VI. PERCENTAGE OF STUDIES BASED ON THE USE OF DRONES IN DIFFERENT ENVIRONMENTAL MATRICES

Matriz	Amount	
	Frequency	Percentage
Air	15	65,22%
Water	3	13,04%
Soil	2	8,70%
SC	4	17,39%

Note: SC: Without contamination refers to the use of the drone to evaluate the state of the crops or to support irrigation programs, therefore contaminants are not evaluated as in the other cases.

E. Type of action

The exponential increase in the public accessibility of drones has posed a major threat to overall security and confidentiality. Drone sales have been steadily increasing every year and are expected to be much higher in the future [40]. Currently, drones have many uses for different types of activities.

Both monitoring and detection are the types of action present in 48% and 20% respectively of the different research papers. On the other hand, in smaller proportion are two works on monitoring-detection (MD) and one work-related to detection-supervision (DS) which represent 8% and 4% respectively.

TABLE VII. PERCENTAGES OF STUDIES BASED ON THE DRONE ACTION TYPE

Type of Action	Amount	
	Frequency	Percentage
Monitoring	12	48,00%
Detection	5	20,00%
MD	2	8,00%
DS	1	4,00%

Note: MD: monitoring - detection, and DS: detection - supervision.

F. Type of Industry

There is research on the technical capabilities of drone technology, but much less on the practical application of drones in industry. At present, there is a gap between the technological developments of drones and the applications they can offer to the industry. This is due to the novelty of the technology and, in part, because drone development is for purposes other than manufacturing. Current industrial applications of drones are primarily outdoor. Their cost-effective applications in sectors such as agriculture, construction, infrastructure, energy, logistics, and mining take advantage of their ability to fly quickly and safely at high altitudes to locations that are difficult, dangerous, or costly to access. Manufacturing on the other hand, manufacturing operations is almost exclusively performed indoors [41].

Of the studies reviewed, there is evidence of a high representation of environmental issues, which accounts for 76% of the research, while works related to agriculture and ecology each account for 8% and, to a lesser extent, studies related to topography, which only account for 4%. Finally, there is one research work that does not specify (NE) the type of industry to which it is related and represents 4%.

TABLE VIII. PERCENTAGE OF STUDIES BASED ON INDUSTRY TYPE

Type of Industry	Amount	
	Frequency	Percentage
Environmental	19	76,00%
Agriculture	2	8,00%
Ecology	2	8,00%
Topography	1	4,00%
NE	1	4,00%

Nota: NE: Not specified.

IV. CONCLUSIÓN

It is concluded that drones are on the verge of being adopted for use in many industries. The most promising and cost-effective applications are those that aid in the inspection of hard-to-reach or hazardous areas, gas leak detection in large plants, and cycle counting in large warehouses. The findings in the results show that drones could have greater potential in process industries than in discrete manufacturing.

The advancement of technology has also allowed the improvement of drones and their components, especially for unmanned aerial vehicles to travel in areas that are difficult for humans to access. Therefore, their use in recent years has intensified in different areas and the environmental sciences sector has not been the exception. However, there are still scenarios in which studies have not yet been carried out, such as those related to the detection, quantification, or identification of flora as well as the identification of wild species employing the sound they emit. Finally, there is still room for researchers to conduct more studies related to this topic.

Abstract—For the production of white chuño or also called tunta, a suitable environment is needed concerning temperature since they must be produced in very cold temperatures. To create a greenhouse in an HMI interface in the LabVIEW program maintaining the production phases (first freezing, leaching in water, second freezing, and the peeling), where a belt with rollers that classifies the potatoes is used, also a temperature sensor that will help to measure this parameter in real-time, following it enters the tanks with turbines for the leaching phase and then the presses help the removal of the peels and excess water. In conclusion, the system allows to control in real-time the internal temperature of the greenhouse replicating the temperature that occurs in the Andes, the HMI interface helps with the monitoring and control of the processes that are being carried out, on the other hand, the results showed the potential that the system must produce white chuño.

Keywords—White Chuño (Tunta), frozen, greenhouse, leaching, automation

I. INTRODUCTION

Potatoes were domesticated in southern Peru approximately 10 000 years ago and since then have played a major role in human occupation in the highlands of the Andes [5]. The production of white chuño is traditionally done at very high elevations of the central Andes in the altiplano, this process is carried out in places where the temperatures are very cold, where during the nights the potatoes are frozen and the days are warm to have an optimal thawing, and make the bitter potatoes release their poisonous glycoalkaloids and can be consumed without danger to the organism [1-3], the sunlight is a very big enemy for the production because it makes them lose their most precious characteristic which is white color, turning it brown, thus losing its value and quality in the market. [2,4].

For the production of white chuño in an artisanal way, there are three processes to be carried out, once the bitter potatoes have been chosen and classified according to size, first, we freeze them for 3 to 4 nights at temperatures ranging from -4°C to -15°C. Secondly, we leach them in rivers for 21 to 30 days, Second, leaching is carried out in rivers for 21 to 30 days, third, a second freezing process is carried out for 1 to 2 nights at temperatures ranging from -4°C to -15°C, and finally, the peels are removed from the potatoes, which have already been converted into chuño and stored in jute or wool sacks [1,2].

Studies carried out propose, as in [5], the study of the concentrations of proteins, iron, zinc, and calcium, in the

processing of chuño, obtained results of the concentration of proteins and zinc, which has a higher content of calcium, while the concentration of iron does not change, it is also noted that the water used to prepare white chuño increases the concentration of calcium. In [7] liquid chromatography showed the presence of epicatechin, chlorogenic acid, gallic acid, syringaldehyde, and protocatechuic acid in potato samples as in chuño, the results suggest that the antioxidant capacity and phenolic compounds cannot be eliminated during the process, therefore chuño can be used as an antioxidant in diet.

Having a great motivation to develop this project is to have a chuño with a very favorable color which is white. The proposed study aims to create a greenhouse for the production of white chuño taking into account the phases of production in an artisanal way taking it to an automated system, using a Programmable Logic Control (PLC) to control the phases and all this presented in an HMI interface.

II. MATERIALS AND METHODS

For the development of the proposed product, the VDI-2206 methodology developed by "The German Engineers Association" [8], which consists of a standard for the development of mechatronic projects, which generates the connection of several disciplines and their operation, is considered.

The simulation of the automation and control process of white chuño processing will be carried out in LabVIEW software. To carry out the proposed system for the preparation of white chuño, the phases mentioned by the National Institute of Quality (INACAL) in its Peruvian Technical Standard NTP 011.401:2020 PAPA were considered. Tunta. Good artisanal processing practices. 2nd Edition. Where it mentions a series of phases, parameters, and care that should be considered in the processing of white chuño, which are presented in Table I [9].

Table I. White Chuño Production Phases.

Phase	Details	Parameters
Selection and/or classification	The process to clean the potatoes, to later select them according to shape and size.	None
First freezing	The potatoes are subjected to	(-4°C to -

	temperatures below zero, for approximately 3 to 4 nights.	15°C)
Leaching in water	The frozen potatoes are submerged in water for approximately 21 to 30 days, this phase is done in rivers.	None
Frozen second	The potatoes removed from the water are again subjected to sub-zero temperatures for a period of 1 or 2 nights.	(-4°C to -15°C)
Shelling	To carry out this stage, we take advantage of early mornings, since the tunta is wet and the peel is semi-detached.	None

The proposed mechatronic system has all the phases that can be seen in Table I, in the first phase there is a conveyor belt that carries the potatoes to a conveyor belt with rollers, the latter has the function of classifying the potatoes according to their size since the rollers of the belt are separated from each other at strategic distances, to drop the potatoes on a platform based on their proportion. Thus, obtaining the first tubers, which are the largest, second, which are the medium, and third, which are the small ones [2].

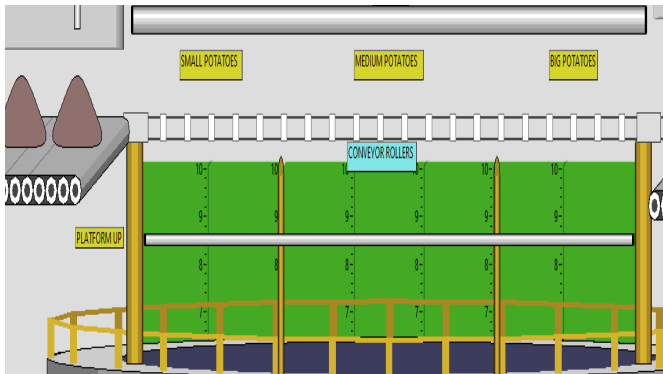

Fig. 1. Potato Size Selection Phases.

In the second phase, the greenhouse replicates natural frosts with an artificial freezing system, where the temperature is graduated according to the requirements shown in Table I, for which the proposed system has temperature sensors to monitor in real-time and constant for a given period, which is automatically and/or manually deactivated.

The third phase, which is leaching in water, merges with phase five, which is peeling because the greenhouse has a series of tanks where the potatoes are soaked. The tanks have a series of turbines that simulate washing machines that allow the water to move and make the potatoes pink and peel slowly throughout the leaching process.

Fig. 2. Leaching and Peeling Stage.

In the fourth phase, which is the last stage, the second freezing is carried out in the same way as in the first freezing, but before proceeding with it, when the submerged platform rises again, the excess water is removed with a press that simulates the handmade footprints. Finally, the final product is removed by conveyor belts for storage and distribution.

On the other hand, the proposed automation system has two main control panels that allow its operation. One of them is directed to control the environmental parameters of the greenhouse and the other one is directed to control the leaching process. Fig. 3 shows that the control panel has an emergency stop system, led indicators that allow visualizing which system is active, as well as switches that allow turning on or off a system manually.

Fig. 3. Environmental Parameters Control Panel.

Fig. 4 shows the control panel to control and monitor the leaching process, it has an emergency stop button which is very important in any industrial process, led indicators to visualize different functions such as the motor, the location of the platform where the potatoes are located and finally the panel has push buttons to raise and lower the platform where the tubers (potatoes) are located manually if necessary, all this to

ensure an optimal process in case the mechatronic systems may fail for any error either mechanical and/or software.

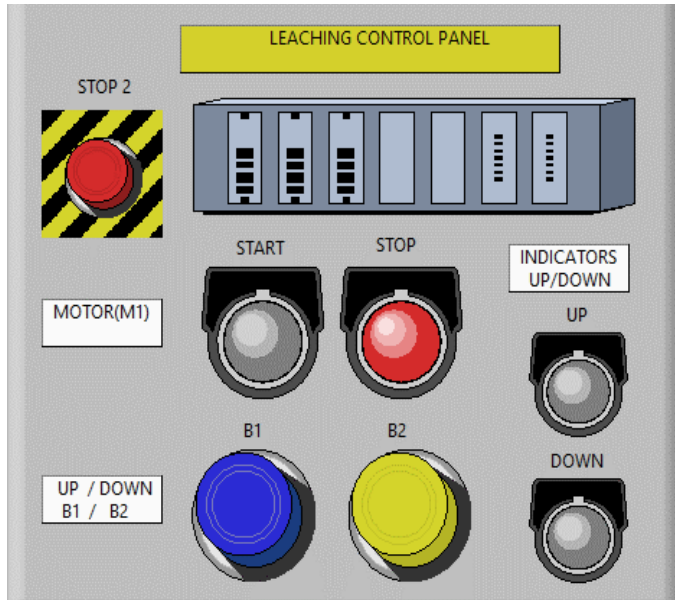

Fig. 4. Leaching Process Control Panel.

III. RESULTS

Fig. 5 shows the behavior of the temperature inside the greenhouse, obtaining as a result that the ambient temperature of the greenhouse is a replica of the real ambient temperature that occurs in the Andes, all this is achieved artificially and thanks to the mechatronic system proposed, ideal temperatures are achieved to produce white chuño since natural temperatures are increasing and climate changes are also negatively affecting the food supply [10]. Under this concept, the use of intelligent greenhouses is necessary to obtain higher quality products [11].

Fig. 5. Temperature Behavior Inside The Greenhouse.

Fig. 6 shows, as a result, the programming done for the simulation, which uses a block diagram consisting of a graphical visual programming language that simplifies the integration of hardware for engineering applications [12]. This

programming can be translated into a ladder language which is a high-level language. Ladder Logic is the most widely used language for programming PLCs throughout the industry [12].

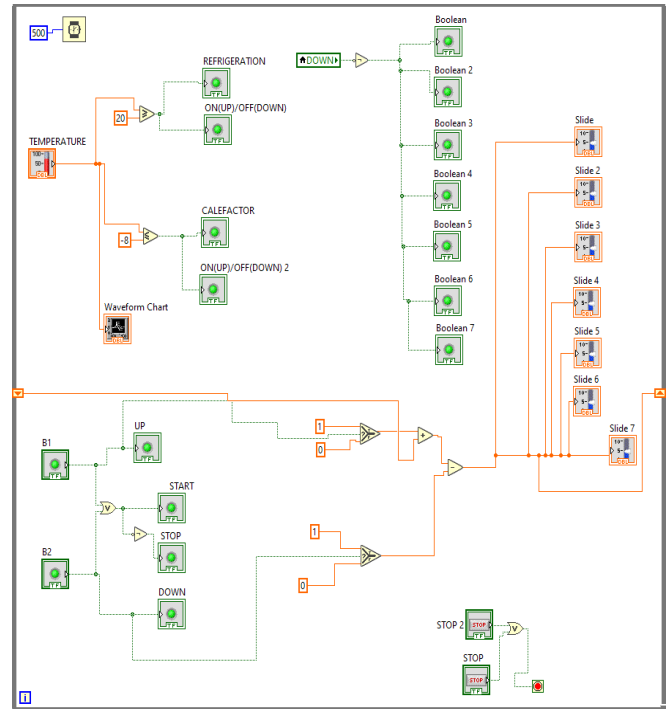

Fig. 6. Programming Block Diagram Developed in LabVIEW.

Fig. 7 shows the mechatronic system in its entirety, including the five phases shown in Table I. In the first phase, the potato enters through a conveyor belt that leads to the second conveyor and sorting belt (roller belt) where the potatoes are separated according to their size. At the end of the selection process, the greenhouse refrigeration system is turned on, bringing the ambient temperature down to -15°C for a period of approximately 12 hours before turning on the heating system and bringing the ambient temperature in the greenhouse to temperatures ranging from 18°C to 30°C, simulating the real ambient temperature that occurs in the Andes during the day and night. At the end of this phase, the potatoes are lowered into the tank to enter the leaching process, because the platform where they fall when selected works as an elevator, having the ability to raise and lower the potatoes automatically or manually when necessary, proceeding to drive the motor that allows the movement of the turbines. Additionally, in the tank, there will be a water cleaning and filtration system to be able to use it in a new process without the need to waste this fluid.

To enter the last phase, which is the second freezing, the pneumatic press will suppress the potatoes by making rapid oscillations that simulate the handmade steps that are made with bare feet to remove excess water [2], the use of the system is to ensure the safety of the food. Once this process is finished, freezing begins and at the end of the period the white chuño is ready, obtaining the characteristic color, the product is removed by employing independent conveyor belts for each size of chuño (small, medium, and large).

Fig. 7. Complete simulation designed in LabVIEW software, HMI environment.

Table II shows because of the approximate times that each phase of the production of white chuño takes in the nursery. As it is an intelligent automation system, it does not depend on external environmental factors, making the production of the white chuño more efficient and higher quality, since the chuño is not directly exposed to the sun, it obtains and preserves its characteristic white color, which is a very important aspect in determining the quality of the tunta.

Table II. Table of Results of Times and Parameters

Phase	Approximate Time	Parameter
Selection and/or classification	30 minutes	potato(small-medium-big)
First freezing	8 hours per day	(-10°C) Average Temperature
Leaching in water	600 continuous hours	(1°C-5°C) Average Temperature of water
Frozen second	8 hours per day	(-10°C) Average Temperature

Respecting the times and phases of production that are carried out in an artisanal manner for the production of white chuño, as well as taking into account the technical standard developed by INACAL for the production of tunta, results in the automation and control system being a sustainable technology since it preserves the artisanal production phases and complies with the standards mentioned in NTP 011.401:2020 [9].

IV. DISCUSSION

In the work done by Hernández-Morales, Carlos A.; Luna-Rivera, J. M. and Pérez-Jimenez Rafael designed a monitoring system for agricultural applications based on IoT applied in a commercial size greenhouse, in which they obtained, as a result, the temperature predictions with an error of 1 °C [10]. This system they developed is very good, but the mechatronic system developed in this paper is specifically focused on the production of white chuño, for which all environmental parameters, automation, and control systems are based on this product, being a greenhouse specialized in the production of white chuño.

In the work of A. Mellit, M. Benghanem, O. Herrak, and A. Messalaoui present the design of a remote monitoring system for intelligent greenhouses, which allows the creation of an optimal artificial environment inside the greenhouse, for which they use as the brain of the prototype an Arduino mega 2560 and a mobile application that allows the control of the different environmental parameters [11]. Unlike the work, a PLC is used as the brain of the prototype which allows automation and monitoring work much more complex compared to an Arduino, and for monitoring an HMI system is used which is much more efficient and practical to control the greenhouse, since you can see all the parameters and control it manually from the same interface if necessary.

V. CONCLUSIONS

The results obtained show that it is feasible to implement an automation and control system for the production of white chuño. For which the system works according to the recommendations and parameters given by INACAL.

The mechatronic system with automation and control concepts allows for regulating the internal temperature of the greenhouse in real-time, which allows replicating the

temperature that occurs in the Andes. The proposed system will also help improve the productivity of community members and companies engaged in the production of white chuño.

The novelty of the proposed mechatronic system involves real-time monitoring and control of the entire white chuño production process, as well as the environmental parameters required to produce it. All these thanks to the Human-Machine Interface (HMI), which facilitates the visualization of all processes and the stage of production. On the other hand, the system also provides very important data that helps to improve productivity, as well as to guarantee the innocuousness of the consumption of the white chuño, as well as the white color, which is a very important aspect that is damaged by too much exposure to the sun, which is avoided by being produced in a closed environment, which leads to a better quality of the product.

Abstract— Biological signals have been extensively studied for disease diagnosis, treatment, and biomedical research to know the patient's health status; however, the potential of these signals goes beyond diagnosis, to the point that they can be used for more precise control of robotic devices in rehabilitation. The purpose of this article is to document a systematic review of the applications of biological signals such as EMG, EEG, and EOG for the development of these devices. The objective is to provide the researcher with a matrix that integrates the types of signals, sensors, and related components for the implementation of robotic devices in rehabilitation. As a method, different databases and specialized search engines were used to collect the information from 2019 to 2021. All the investigations found were selected, 27 being selected. Finally, it is concluded that there are different applications of biological signals for manipulation, of prostheses, orthoses, and robotic devices, which allows continuing the development of these that allow a better rehabilitation to the patient.

Keywords— Sensors, Biological signal, Controller type, TRL, Robotic device

I. INTRODUCTION

Robotics has evolved and today it can not only be seen within the industrial aspect but also in the health area, specifically in the rehabilitation of patients who have temporarily or permanently lost their motor, cognitive or social skills due to a disease. Thus, these guided robotic devices for rehabilitation must be safe and effective, so that the acquisition of biological signals from the patient will allow a more accurate approach when establishing a specific rehabilitation for each disease, since "the bioelectrical signals of the human being contain abundant information, such as perceptual information and physiological states" [1]

Therefore, biological signals are signals produced by the human being, which can be physical, chemical, electrical, optical, or electromagnetic, and whose main function is to provide various types of information and provide the doctor with a possible diagnosis according to the analysis of

waveforms. However, these signals can be used to control robotic prototypes that help in the rehabilitation of patients who, due to a stroke with hemiparesis, spinal cord injuries, neurological disabilities, and, among other diseases, have affected their motor and cognitive or social abilities.

Then, for the control of a robotic rehabilitation prototype, three types of biological signals are essential to carry out an effective rehabilitation in a patient's body, first of all, the EMG signals, are the technique of obtaining electrical signals produced during muscle contractions [2], secondly, the EEG signal is a safe neurophysiological tool that records brain activities at low cost [3] and the EOG signals detect eye movements between the cornea and the patient retina [4].

Therefore, each biological signal has a specific type of control, for example, "Electromyography (EMG)-based control schemes have shown their superiority in human-robot cooperation because movement intention can be well estimated by EMG signals" [5], however, EEG signals, through the development of entity-relationship diagrams, can define specific tasks because "reflecting sensorimotor brain activity through ERD/ERS components are extracted to identify different tasks" [6] and, on the other hand, EOG signals are widely used in human-computer interfaces because they can accurately classify the movements of electrically active nerves at the back of the eyeball [7].

Then, when comparing the devices for the acquisition of the patient's biological signals, clear use of Ag/AgCl electrodes was obtained in each one of them, since these electrodes are beneficial because they are economical and, when properly applied, deviations can be reduced [8]. However, the sensors used by each of the robotic prototypes range from the force, pressure, and torque sensors for the movement of the actuators to the various EMG, EEG, and EOG sensors, most of which are used because they have integrated filtering and amplification circuit for the patient's biological signals that range from + 1.5mV and are easy to use [9].

For these reasons, the main objective of this work is to provide a research matrix in the comparison of biological signals obtained from a patient, within which it will be determined which of them is the most influential today in the control of robotic devices for rehabilitation.

II. METHODOLOGY

To carry out this research, a search query was performed in the Scopus database, IEEE Explore, Springer link, ScienceDirect, journal articles such as Frontiers in Neurorobotics as well as collaboration and dissemination platforms such as ResearchGate. Keywords such as robotic

device, exoskeleton, rehabilitation, biological signals, and control were used. This process resulted in an average of 38 publications spanning 2018 to 2021.

III. REVIEW OF PUBLICATIONS

To simplify and structure the information. The robotic rehabilitation devices were classified according to Type of loss, Robotic Device, sensor, Biological Signal, Biological Signal Acquisition Device, and state of development of the robotic device [prototype or study].

The review describes the different biological signals for the control or manipulation of robotic rehabilitation devices.

A. Type of loss

This section shows the main types of losses that affect the correct mobility of the upper and lower extremities: cerebrovascular accident (CA), spinal cord injury (SCI), loss of movement of upper extremities (LMU), and lower extremities (LML), tetraplegia (T). Table II shows the characteristics of the above-mentioned types of loss.

Diagnosis	Feature
AC (Stroke)	It occurs when blood flow stops in one part of the brain. Its prevalence in the USA increases with advancing age.[40]
SCI (Spinal cord injury)	Spinal cord injury usually causes loss of mobility, strength, and sensation below the affected area.
T (Tetraplegia)	Paralysis is caused by disease or injury.

It is important to consider the type of loss that affects the normal mobility of the patient's limb to develop the robotic device that best contributes to the patient's rehabilitation. Considering the type of loss and the functionality that the robotic device should have, the most appropriate device can be designed. As can be seen in Table III, most of the studies focus on stroke with 36,84%. This is followed by loss of movement of the upper extremities with 15,79% and the lower extremities with 13,16%. To a lesser extent, we find special spinal cord injuries with 7,89%, tetraplegia with 5,26%, and the rest below 5%.

TABLE III. THE AMOUNT BY TYPE OF LOSS

Diagnosis	Amount	
	Frequency	Percentage
AC	14	36,84%
LMU	6	15,79%
LML	5	13,16%
SCI	3	7,89%
T	2	5,26%
MD	1	2,63%
SP	1	2,63%
MA	1	2,63%
ND	1	2,63%
DMO	1	2,63%
OH	1	2,63%
N.E.	2	5,26%

Note: CA: Stroke, LMU: Loss of upper limb movement, MD: Muscle deficiency, BMD: Motor dysfunction, SP: Spasticity, LML: Loss of lower limb movement, MA: Muscle activation, ND: Neurological disabilities, OH: Oral hypofunction, SCI: Spinal cord injury, T: Tetraplegia,

B. Robotic device

This area covers the main robotic devices handled with the control of biological signals: exoskeletons (EXO), robotic systems (ROB), and prosthetics (PROS). Exoskeletons were found to be divided into three groups, exoskeletons, robotic exoskeletons, and soft exoskeletons, each of them with different characteristics, the last one being.

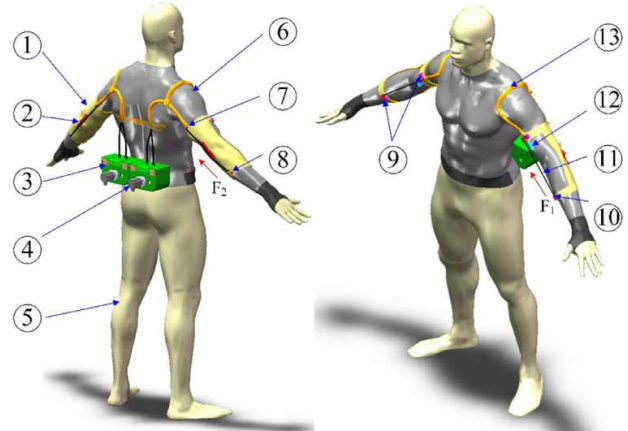

Fig. 1 General mechanical structure of the proposed soft exoskeleton robot for elbow motion assistance. (1-Soft envelope; 2-Guiding mechanism; 3-Actuator unit; 4-Servomotor; 5-Human; 6-Base layer; 7-Sheath support; 8-Anchor point; 9-Inertial measurement unit; 10-Force sensor; 11-Inner tendon; 12-EMG sensor; 13-Outer sheath). Source: Q. Wu, B. Chen, and H. Wu, 201CNeural-network-enhanced torque estimation control of a soft wearable exoskeleton for elbow assistance,” Mechatronics, 2019.

As well as identifying the type of loss that affects the patient's mobility, it is also important to consider the type of robotic device to be used for patient rehabilitation. As shown in Table IV, most of the studies concentrate on developing exoskeletons with 42,11%. In addition, 10,53% are robotic exoskeletons (R-EXO) and 5,26% are soft exoskeletons (S-EXO). Exoskeletons are followed by robotic systems with 18,42% and the rest below 5%.

TABLE IV. TYPES OF ROBOTIC DEVICES DEVELOPED

Robotic Device	Amount	
	Frequency	Percentage
EXO	16	42,11%
R-EXO	4	10,53%
ROB	7	18,42%
S-EXO	2	5,26%
PROS	1	2,63%
S-ROB	1	2,63%
H-ROB	1	2,63%
WC	1	2,63%
ORTH	1	2,63%
VR	1	2,63%

MI-BCI-VR	1	2,63%
SPT-ROB	1	2,63%
N.E.	1	2,63%

Note: PROS: Prosthesis, VR: Virtual Reality, MI-BCI-VR: Brain-Computer Interface with Virtual Reality, S-ROB: Soft Robot, ROB: Robotic System, H-ROB: Hybrid Robot, SPT-ROB: Robot based on Standardized Performance Testing, EXO: Exoskeletons, R-EXO: Robotic Exoskeleton, S-EXO: Soft Exoskeleton, WC: Wheelchair, ORTH: Orthosis, ORTH: Orthosis

OPTS	1	2,63%
MTxS	1	2,63%
e-Health-S	1	2,63%
ATS	1	2,63%
POS	1	2,63%
N.E.	6	15,79%

Note: EMGS: EMG Sensor, MYO: Myo Armband, NUAMPS: Neuroscan NuAmps Express System, FS: Force Sensor, IS: Inertial Sensor, EEGS: EEG Sensor, OPTS: Optoelectrical System, TS: Torque Sensor, PS: Pressure Sensor, MS: Magnetic Sensor, AS: Air Sensor, e-Health-S: e-Health Sensor Shield V2.0

C. Sensors

In this area, a review of the sensors that are most used in the development of robotic devices is made. Each sensor is used to measure a certain variable. According to Table V, the most used sensor for the development of robotic devices in rehabilitation are the EMG sensors (EMGS) with 60,53%. It is important to consider that this percentage represents the studies that use this sensor alone and together with other sensors. Of this total, 17,65% of the studies used the MyoWare sensor. [11], [23], [29], for EMG signal processing, while another 17,86% used the Open BCI sensor for EMG signal processing. Figure 2 shows the electromyography process using the Open BCI device for processing.

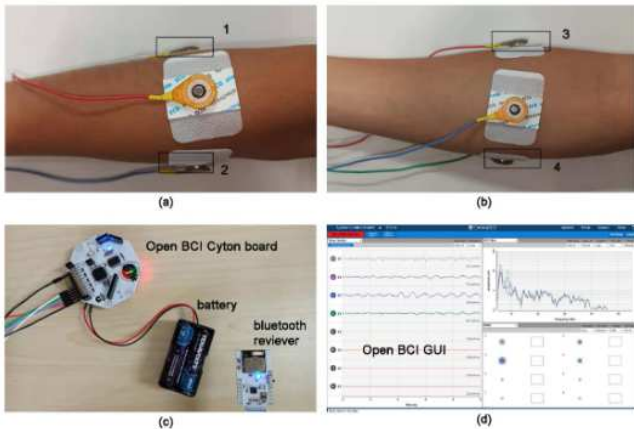

Fig. 2 The process of surface electromyography (sEMG) collection. (a) The electrode positions of 1 and 2. (b) The electrode positions of 3 and 4. (c) The hardware for sEMG collection. (d) The software of sEMG collection. Source: Chen, Y.; Yang, Z.; Wen, Y.A Soft Exoskeleton Glove for Hand Bilateral Training via Surface EMG. 2021

The other most used sensors are the force sensor (FS) and pressure sensor (PS) both with 13,16%, the EEG sensor (EEGS) with 7,89%, and the inertial and torque sensor with 5,26% each. The rest is below 5%.

TABLE V. PERCENTAGE OF SENSORS USED

Sensors	Amount	
	Frequency	Percentage
EMGS	23	60,53%
FS	5	13,16%
PS	5	13,16%
EEGS	3	7,89%
IS	2	5,26%
TS	2	5,26%
MS	1	2,63%
AS	1	2,63%
MYO	1	2,63%
NUAMOS	1	2,63%

D. Biological signal

This section reviews the biological signals used for the control of robotic devices. The human body generates more than 20 biosignals that are used for different medical purposes; according to the research reviewed, it was identified that the signals that were mostly used for this type of application were electromyography (EMG) signals, either superficial (sEMG) or intramuscular (iEMG), electroencephalography (EEG) and electrooculography (EOG) signals. In Table VI the most used signal in the studies is EMG signals with 81,58%. This reflects that the robotic devices developed are mostly employing the EMG signal to be controlled or manipulated by the patient. In addition, 5,26% employed only the EOG signal, and a lower percentage of 2,63% mentioned that they employed only the EEG signal.

The rest of the studies employed two or more signals for manipulation of the robotic devices with a percentage of 11%. However, what is striking is that the EMG signal is almost always present.

TABLE VI. PERCENTAGE OF STUDIES ACCORDING TO A BIOLOGICAL SIGNAL USED

Biological signal	Amount	
	Frequency	Percentage
EMG	31	81,58%
EEG y EMG	2	5,26%
EOG	2	5,26%
EEG	1	2,63%
EMG Y EOG	1	2,63%
EOG, EMG y EMG	1	2,63%

Note: EMG: Electromyography signal, Intramuscular electromyography signal, EEG: Electroencephalography signal, EOG: Electrooculography signal.

E. Signal acquisition device

In this part, a review of biological signal acquisition devices is made. This device is the first contact to capture the signal and pass it for processing. Table VII shows the various devices used in the investigations reviewed for the acquisition of the biological signal. The 86,84% of the investigations reviewed employ electrodes as the biological signal acquisition device, taking advantage of the advantages it offers such as reproducibility, stability, and ease of preparation. Electrodes are devices that convert the bioelectrical signal into electrical potentials to be later treated. Three main types of electrodes were identified, being dry electrodes with a percentage of 90,91% the most used, followed by bipolar electrodes with a percentage of 9,09%, and to a lesser extent wet electrodes with a percentage of 2,63%. Similarly, the electrodes were Ag/AgCl electrodes since these provide greater stability.

TABLE VII. BIOLOGICAL SIGNAL ACQUISITION DEVICE

Device	Amount	
	Frequency	Percentage
Electrodes	33	86,84%
Dry electrodes	30	90,91%
Bipolar electrodes	3	9,09%
Wet electrodes	1	2,63%
Not specified	4	10,53%

Doll	2	5,26%
Mandible	1	2,63%
Foot	1	2,63%
Knee	2	5,26%
N.E.	6	15,79%

F. Development Status

Each research managed to determine different objectives to collaborate in the development of a robotic device that uses biological signals for the control of rehabilitation reaching different states such as functional, prototypes, designs, and studies. The Technology Maturity Levels manual helps to identify the state of technology in the research, in which the reader will know how to associate the 9 levels. In Table VIII, it is observed that TRL 5 (Components validated in relevant environment) out of 38 research obtained 23.68%, followed by TRL 4 (Components validated in the laboratory) with 28.95% and TRL 7 (Prototype validated in a real environment) with 15.79%. This means that most of the studies reviewed are in the prototype and technology development stage.

TABLE VIII. PERCENTAGES OF STUDIES BASED ON TLR

Technology Readiness Levels (TRL)	Amount	
	Frequency	Percentage
2	1	2,63%
3	5	13,16%
4	11	28,95%
5	9	23,68%
6	3	7,89%
7	6	15,79%
8	1	2,63%
9	2	5,26%

G. Rehabilitation body part

In this area, a review is made of the main parts of the body where the robotic device was used for rehabilitation. According to Table IX, the body part where rehabilitation with a robotic device is most applied is the upper extremity with 31.58%. For this purpose, more robotic devices of the exoskeleton type are used, to support the patient to perform daily activities with the least limitations. This is followed by the hand, with 18.42%. On the other hand, the third body part with the highest use of robotic devices to complement its rehabilitation is the lower extremity.

TABLE IX. PERCENTAGES OF STUDIES BASED ON TLR

Body Part	Amount	
	Frequency	Percentage
Upper Limb	12	31,58%
Hand	7	18,42%
Elbow	2	5,26%
Lower Limb	5	13,16%

IV. CONCLUSION

With the growing population and shortage of specialists, many researchers have devised robotic devices to aid in the rehabilitation process. The article reviews various research on designs and prototypes of robotic devices controlled by biological signals for rehabilitation. It is anticipated that these robotic devices will move closer and closer to ideal performance in the future.

This research recognized the details in the development of the different designs and prototypes of robotic devices for rehabilitation intending to be able to develop a scientific article on a prototype of robotic systems controlled by electrooculography signals that do not have the weaknesses found in previous research, in addition to following the latest advances and developments in the subject. Likewise, we found that the EMG signal is the most used for the control of robotic devices and this same signal serves as a support for the use of EEG and EOG signals.

Abstract—There are many techniques focused on capturing the kinematic movement of the human body, all these techniques help in the creation of robotic devices to achieve efficient rehabilitation, many studies provide information that helps the researcher, but these are scattered, each proposing different characteristics, solutions, and methods to obtain body movements. Based on this, the objective is to provide the researcher with a structured matrix that integrates different studies related to the capture of the kinematic movement of the human body, this will allow him to evaluate alternatives where he can choose, analyze the study or characteristics that best contribute to his research topic. As methods, specialized search engines were used that helped structure the matrix. Currently, there is little information on capturing human kinematic movements, through the interaction of different sensors so it was also incorporated into the matrix, also in the proposals is considered captured movements, recognition method, sensor, treatment, and application. In conclusion, the article will provide information to people who want to create robotic devices such as exoskeletons, prostheses, or different suits that help the rehabilitation of the human body. Where it is important to have accuracy in obtaining body movement patterns.

Keywords—Kinect, Kinematic movement, Motion capture, Exoskeletons.

I. INTRODUCTION

The measurement of human kinematics has been a major source of research in areas related to medicine, sports science, and biomedical engineering [1]. An additional use consists of inverse dynamics principles to estimate the forces acting within joints and muscles [2]. Systems for motion capture consist of special hardware and data processing software [3]. Applications include studies to optimize sports performance [5], in medicine for orthopedic analysis or to verify rehabilitation processes, and in 3D animation for applications in film and game production [3]. Among the standardized procedures for detailed body motion capture are stationary and portable optical systems [9], which consist of a network of cameras, usually infrared, video cameras, sensors, and markers (some systems do not require markers) that convert real information into digital data for processing in virtual environments calibrated with each other, in a confined space or laboratory [10]. However, limitations include marker

occlusions when performing certain movements or activities. On the other hand, placement of the markers on the skin requires a significant amount of time and the knowledge of an expert [9]. These are developed from Microsoft Kinect controls and open-source frameworks. Kinect is a motion-sensing input device developed by PrimeSense and Microsoft for the Xbox 360 video game console and later adopted for Windows PCs [3].

IMU (Inertial Measurement Units) inertial measurement systems combine accelerometers, gyroscopes, and magnetometers (compasses) and can solve some of the issues mentioned above. IMUs can be used directly on the body on specific segments to deduce the kinematics of the joints, without suffering from the phenomenon of occlusion, the data can be processed, and the systems are mobile, allowing measurements in the field. Compared to optical systems, the placement of the sensors is less time-consuming and does not require expertise in the process. Despite this, IMUs have certain disadvantages, such as the limitations of direct measurements, a feature that is present in optical systems [9]. In our country, several entities offer interested organizations access to motion capture technologies, useful for the development of film, television, and video game projects, clinical and biomechanical studies, or for pedagogical purposes.

The reason for this review work is to provide detailed information for research who want to develop motion capture methodologies through Kinect. Therefore, this work aims to develop a structured matrix where the inputs of sensor, capture, movement, recognition methods, treatment and application are detailed.

II. METHODOLOGY

For the development of this research, a search was carried out in the database of "Scopus", "IEEE Explore", "Springer link", "Hindawi", "Google Scholar", "Academia Journals", "NCBI", articles from journals such as "BMC", "BMJ", "JMIR" "Indonesian Journal of Electrical Engineering and Computer Science", Learn Tech Lib, MDPI, medRxiv, Taylor and Francis online, as well as collaboration and dissemination platforms such as "Wiley Online Library", and "Semantic Scholar" were also accessed. The publication period of the

selected articles covers from January 2018 to December 2022. The objective of this review is to analyze publications that consider captured movements, sensor types, method of recognition, treatment, and application, the search terms used were: "capture of body movements", and "human kinematic movements through Kinect". A total of 68 articles in English were collected. The result of the review, analysis, interpretation, and integration of the information of each research is presented in the text shown.

III. REVIEW OF PUBLICATIONS

To simplify and structure the information, the capture system and human kinematic movement through Kinect were classified according to the sensors implemented, the approach to the patients' posture, the application of the Kinect recognition method, the treatment applied to patients, and finally, the application of the Kinect in patients. The entire classification is shown in Table I.

A. Types of sensors

In the research, different solutions for human kinematic motion and capture systems through Kinect were developed to capture the original motion of the patient. They are shown in Fig. 1, The Kinect sensor, which is a three-dimensional distance image sensor, was also used for object detection [28]. For this reason, the Kinect sensor is known as a camera capable of layered results in three dimensions of orientation. In this study, we detected a circle as the first step in object detection. Within this group, partial captures and total captures including limbs can be evidenced without the use of external sensors, for which a high precision work is performed were identified. Table II shows that the Kinect stands out with a percentage of 27.94%, the RGB-D camera was also used with a percentage of 25.00%, and finally Kinect® V2 with a percentage of 16.18%. However, the least used sensors have a percentage of 1.47%, as shown in Table II.

KV2	11	16.18%
AGM	6	8.82%
CS	2	2.94%
KCT - EMG	1	1.47%
KCT- SI	1	1.47%
NE	7	10.29%

Note RGB-D camera (RC), Kinect® V2 (KV2), Kinect (KCT), Smartphone camera (CS), Accelerometer Gyroscope Magnetometer (AGM), Goniometer (GO), Inertial Measurement Unit (IMU), Electromyography Sensor (EMG), Inertial Sensors (SI), Depth Sensor (SDP), depth sensor (SDP).

TABLE II. TYPES OF SENSORS

Sensors	Amount	
	Frequency	Percentage
KCT	19	27.94%
RC	17	25.00%

B. Captured Motions

In this area a review is made of the parts where the approaches are applied through the capture system and human kinematic movement through Kinect, according to the reviewed research, applications, side, and front view were identified with a direct approach with the help of Kinect and RGB-D image processing through programs such as MatLab and the same Windows operating system and the application that stands out the most in the studies are movements in MS with 23.53%; it reflects that the prototypes focus on the realization of human kinematic movement and capture system that focuses on the upper limb.

In addition, 16.18% indicates that it is applied in SH this means that it was based on human tracking (full body) and the 3D coordinates of the anatomical landmarks identified from the skeletal model of the Kinect v2 system during functional tasks are simultaneously recorded with the 3DMC system. Finally, 14.71% focused on the development of movement prototypes in PH, which set the coordinates of the local segments, including Thorax λ and Arm η . Each of the segments is based on the global coordinate as illustrated in Fig. 2 [46].

Fig. 2. Full-body human tracking approach: Ye Ma, Dongwei Liu, and Laisi Cai [2020].

The rest of the applications do not exceed 1.47% in Table III. It can also be seen that the most important supported movement is the knee since the mobility of the lower extremities depends on this part of the body.

TABLE III. PERCENTAGES OF STUDIES BASED ON APPROACHES

Approach	Amount	
	Frequency	Percentage
MS	16	23.53%
SH	11	16.18%
PH	10	14.71%
CC	6	8.82%
MI	5	7.35%
H	4	5.88%
M	2	2.94%
DO	2	2.94%
DE	1	1.47%

NE 5 7.35%

Note: Upper limb (MS), human posture (PH), human tracking (full body) (SH), Full Body (CC), lower limb (MI), Shoulder (H), hand (M), knee (R), face (CA), Object Detection (OD), Trunk (T), neurological disabilities (cerebrovascular) (DN), limb discrepancy (DE), hip (C), motor disabilities (DM), upper arm (PSB).

C. Method of recognition

In this area, a review is made of the recognition method of the kinematic capture system and human movement through Kinect. In Table IV, it can be observed that Kinect and Kinect® V2 stand out with a percentage of 14.71%, these devices were used for the better management of recognition in patients, also the RGB-D camera sensor has a percentage of 5.88%. On the other hand, most of the applications of the sensors do not exceed the percentage of 1.47%. The skeleton model is built using the Shotton skeleton detector to locate the different parts of the body and accurately model an articulated structure of connected segments. The obtained 3D skeleton, consisting of 25 joints, represents the human posture as illustrated in Fig. 3 [6].

Fig. 3. The 3D joints defining the skeleton: El-Amine Elforaici Mohamed, Chaaraoui Ismail, Bouachir Wassim, Ouakrim, Youssef, Mezghani Neila [2018]

As it is visualized in the orthosis of 4 DoF, it is given to know the ranges of movements of this orthosis, as it is observed the first joint comes to make of the knee of the movement of extensions from 0° to 0° and the flexion from 0° to 120°, and the other joints come to make of the ankle, as the second joint of the movement is pronation from 0° to 10° and supination from 0° to 3°, the third joint of the movement is dorsiflexion from 0° to 25° and plantarflexion from 0° to 45° and finally, the fourth joint of the movement is adduction from 0° to 40° and adduction from 0° to 30° [69].

TABLE IV. PERCENTAGE OF RECOGNITION METHOD

Method of recognition	Amount	
	Frequency	Percentage
KCT	8	13.33%
KV2	6	10.00%
RC	4	6.67%

D. Treatment

In this area, there is a review of the type of treatment for the human kinematic capture and movement system through Kinect, Table V shows the various treatments used for the capture and movement of patients. 13.24% of the reviewed research is based on motor rehabilitation, on the other hand, we have the human posture, with 7.35%, also the most used pull was the limb discrepancy with 5.88%, and then we get the musculoskeletal disorders pulls, gait analysis and Gait analysis and Parkinson's with 4. 41% and finally the rest of the treatments do not exceed 1.47% since they are not so used in patients and Fig. 4, you can see the positioning and the choice of the appropriate angle for the measurement, for which different measures were chosen and processed with ANOVA which are reported along with the degrees of freedom, the statistic, and the statistical significance. Statistical significance was defined by a value of <0.05 [15].

Fig. 4. Addressing increased accuracy of shoulder measurement: Russell R. Russo, Matthew B. Burn, Sabir K. Ismaily, Brayden J. Gerrie, Shuyang Han, Jerry Alexander, Christopher Lenherr, Philip C. Noble, Joshua D. Harris, Patrick C. McCulloch [2017].

TABLE V. TREATMENT PERCENTAGE

Treatment	Amount	
	Frequency	Percentage
RMA	9	13.24%
PH	5	7.35%
DN	4	5.88%
AC	3	4.41%
PKN	3	4.41%
TME	2	2.94%
CAA	1	1.47%
NE	29	42.65%

Note: Postura humana (PH), Rehabilitación motora (RMA), discapacidades neurológicas (cerebrovascular) (DN), Trastornos musculo-esqueléticos (TME), Análisis del caminar (AC), Parkinson(PKN), Capsulitas adhesiva (CAA), hemiplejia(HA), Osteoartritis (OTS), rehabilitación facial (RFA), Perdida del rango de movimiento en las articulaciones de las manos (PAM), evaluación cinemática de miembros inferiores (ECM), discapacidades motoras (DM),

diagnostic PANU, (DPU), Hemiparesia (HPA), movimiento en la extremidad superior(MES), test de medicina deportiva (TMD), Poli neuropatía amiloidea familiar transtiberina(TTR-FAP) (TTR), rehabilitación de miembros superiores(RMS), motor disabilities (DM), diagnose PANU (DPU), Hemiparesis (HPA), movimiento en la extremidad superior(MES), upper limb Rehabilitation (RMS), sports medicine test (TMD), Poli neuropatía amiloidea familiar transtiberina(TTR-FAP) (TTR).

E. Application

Within these applications, it was possible to identify certain advantages and disadvantages which lead to a deeper development of this system, to achieve quality standards and professional development of moving image tracking. The experimental tests validate the real integration of HCI and HRI in one rehabilitation system through the cooperation between game-based software and the developed wireless robotic exoskeleton. A video is provided with this paper to show the rehabilitation training using the designed interactive game (Supplementary Fig 5) [22]. In Table VI, they were used for the rehabilitation of patients that stand out with a percentage of 17.65%, also shown is the development of games, kinematic analysis of individuals with different biotypes, and data processing follow-up with a percentage of 5.88%, finally, the rest of applications that do not exceed 1.47% are not so frequently used in patients.

Fig. 5. Interactive virtual environment for rehabilitation with interactive games first stage: Yassine Bouteraa, Ismail Ben Abdallah, Ahmed M. Elmogy [2018].

TABLE VI. APPLICATION PERCENTAGES

Application	Amount	
	Frequency	Percentage
RTN	12	17.65%
ACB	4	5.88%
MTD	4	5.88%
PH	3	4.41%
AIP	3	4.41%
DDJ	3	4.41%
AVA	3	4.41%
DN	2	2.94%
MAR	1	1.47%
EAN	1	1.47%
NE	8	11.76%

Note: Rehabilitation (RTN), game development (DDJ), human posture (PH), monitoring and data processing (MTD), rehabilitation technology review with VR, AR (AVA), kinematic analysis of individuals with different biotypes (ACB), analysis of incorrect posture, neurological disabilities (AIP), (cerebrovascular) (DN), evaluation (EAN), rehabilitation (RTN), Rapid and real-time assistance (ARR), LCA risk detection (DRL), lower limb kinematic assessment (ECM), Game based training for people with neurological disabilities (EJN), accurate assessment of operator movements and absolute position (EPA), motion Analysis System (MAS), movement with low error in frequency and amplitude of angles (MBA), compare three techniques to measure motion (CTM), understanding visitor experiences in museums (CVM), rehabilitation of upper limbs (RMS), rehabilitation combined with virtual reality technology (RRV), low cost solution (SBC), segmentation of the human body based on Euler angles (SBE), intelligent human segmentation system (SHM), sitting with one leg (SUP),preventive treatment (TPO), validation of gross movements(VMG).

IV. CONCLUSION

Due to the increase in the number of users who request precision in the capture of body kinematic movements, for the creation of robotic devices such as exoskeletons of lower and upper extremities, prostheses, body rehabilitation suits, etc. Numerous research groups propose the capture of the kinematic movements of the body through the RGB sensor, this electronic device senses the colors where the images are processed, in this way the body movements are obtained. In the same way, the proposal of motion capture is through the Kinect, this sensor has a three-dimensional reading achieving the capture of all body movements.

The techniques used for the quantification of the gait parameters corresponding to the angles of the human body based on the Kinect and the Microsoft SDK consider that it is necessary to make a direct capture for greater precision and from these patterns propose a tool oriented to specialists to help in the diagnostic processes and determine the progress, success or failure of the therapies applied for rehabilitation and thus make decisions regarding them.

The applications of motion capture are oriented in greater quantity for patients in the rehabilitation of their limbs according to the review carried out, it is for that reason that accuracy is fundamental for a rapid improvement of the patient. The article reviewed various investigations on the capture of kinematic movements. However, there is still room for improvement and the development of more technologies or combinations of sensors to obtain accurate body kinematic movements.

Abstract— In recent years, the development of prosthetic limbs has increased due to the various studies that have been carried out around Biomechanics. These technological advances have allowed many amputee patients to return to their daily activities and, in some cases, to recover their social life. However, there are still limitations for some types of prostheses such as passive prostheses, mainly those intended for people with transtibial amputations since they do not perform the physiological function of the joints. Therefore, in-depth research on transtibial prostheses has been carried out. The search period spans from the year 2018 to the year 2021. Information was considered in a simplified and well-structured manner on the design of a transtibial electromechanical prosthesis. Therefore, we will analyze its main features related to its design and application in the patient.

Keywords— *Prosthesis, Foot, Ankle, Transtibial, Parallel (keywords)*

I. INTRODUCTION

In the last decades, the development of prostheses for upper and/or lower limbs has been increasing, since due to several biomechanical studies it is possible to allow people with limb amputations to return to a satisfactory social and working life [1]. However, there are passive prostheses with limited functionality, specifically those designed for people with transtibial amputations since they do not perform the physiological function of the joints [1].

Also, because of these prostheses, these individuals often suffer from asymmetries and reduced locomotor performance [2]-[45]; in addition to presenting greater instability during walking on both regular and irregular terrain. Additionally, passive, and quasi-passive prostheses are not sufficient to facilitate forward propulsion of the push-off phase, which causes amputees with this type of prosthesis to use between 10% and 30% more metabolic energy when walking [3]-[46].

In this context, several studies of electromechanical prostheses for the ankle and foot in which actuators, sensors, and controllers are used [4]-[47], were carried out to mimic the biomechanics of the ankle. On the other hand, to improve energy efficiency, elastic components were included especially in the actuators to regulate the stiffness [5] or tune the position and force tracking performance [6]-[48].

On the other hand, lower limb prostheses do not have a one-size-fits-all design, as it is important to consider the anthropometry of the users because leg shape, muscle stiffness, and gait patterns are diverse [7]-[49]; therefore, a possible solution to this parameter selection dilemma is to use a machine learning approach to choose a control system based on the user's performance [8]-[50].

The objective of this article is to systematically review the development and design trends of electromechanical lower limb prostheses and to analyze the various sensors, input signals, mechanisms, treatment, training modes, rehabilitation movements, degrees of freedom, material, actuators, and stage of development of the prostheses. Finally, conclusions will be drawn based on the recent trends shown by the prostheses.

II. METHODOLOGY

For the preparation of the following review article, a detailed database search was performed, taken from repositories and journals such as the following: IEEEExplore, Scopus, Google Scholar, Sage Journals, Hindawi, Mary Ann Liebert, Inc. publisher, MDPI, Springer Link, BMC, ScienceDirect, Research Square. The search period spans from the year 2018 to the year 2021, and to improve the information search, articles in the English language were prioritized and keywords such as Prosthesis + Foot + Ankle + Transtibial + Parallel were used. In the end, a database of 35 scientific articles was obtained to then classify the important subtopics and improve the understanding of the articles and meet the objectives of writing this work, it should be noted that there were about 15 scientific articles of interest to this work which could not be accessed.

III. REVIEW OF PUBLICATIONS

The information was considered in a simplified and well-structured manner regarding the design of a transtibial electromechanical prosthesis. The reviewed publications of the last 4 years on the topic are shown in detail in Table I, considering the most relevant aspects of the publications.

TABLE I. TRANSTIBIAL ELECTROMECHANICAL PROSTHESIS ON A PARALLEL ROBOT UCU

Note: Abbreviation: EMG: Electromyography, PM: Preset Movements, MCS: Motion Capture System, NE: Not specified; S: Serial, P: Parallel, H: Hybrid, NE: Not specified ; HKA: Hip, Knee and Ankle, A: Ankle; PS: Passive, AW: Assisted Walking, NE: Not specified; RT: Rotational and Translational, PD: Plantarflexion and Dorsiflexion, A: Abduction, PD-A: Plantarflexion, Dorsiflexion and Abduction, PF: Plantarflexion, NE: Not specified ;TRL 1: Basic research, TRL 2: Technology formulation, TRL 3: Applied research, TRL 4: Small scale development, TRL 5: Full scale development, TRL 6: System validated in simulated environment, TRL 7: System validated in real environment, NE: Not specified.

A. Input signals

In this group, the input signals used in the different studies reviewed are mentioned. As shown in Fig. 1 for data collection (input), a motion capture system (MCS) is used to be processed and used in lower limb prosthesis research.

In Table II. Among the most used signals in the study and development of lower limb prostheses are the Preset

Movements (PM) with 51.43% of the developed article, followed by Electromyography (EMG) with 28.57%, and finally, we have the Motion Capture Systems (MCS) with 17.14%. In addition, within this analysis, we have a 2.86% that represents the articles that do not specify data in this field.

Fig. 1. Photograph of a transtibial amputee walking with an experimental prosthesis using a motion capture system (shown in orange) [25].

TABLE II. PERCENTAGES OF STUDIES BASED ON AN INPUT SIGNAL

Input Signal	Amount	
	Frequency	Percentage
PM	18	51,43%
EMG	10	28,57%
MCS	6	17,14%
NE	1	2,86%

Note: EMG: Electromyography, PM: Preset Movements, MCS: Motion Capture System, NE: Not specified.

B. Mechanism

The mechanisms allow establishing classification criteria according to the kinematic structure, which makes it possible to differentiate them in case they are serial or parallel mechanisms, each of them having certain advantages and disadvantages according to the specified task [42].

Among the main virtues of a serial mechanism are the low rigidity and the wide working space in which it performs. However, it has limitations in its precision, for which the parallel mechanism is beneficial for its high performance in these tasks despite its great rigidity. In addition, there are hybrid models, which are in the development phase, which seek to complement both mechanisms concerning better performance and accuracy. In Table III. According to the reviewed studies of the present research, it was observed that 60% of researchers have preferred to use a serial mechanism (S) and 22.85% have chosen the parallel mechanism (P). In addition, a 2.85% preference for the hybrid model (H) was found. Finally, there is a 14.36% which represents the information not specified in the articles reviewed.

TABLE III. PERCENTAGES OF STUDIES BASED ON KINEMATIC MECHANISMS

Mechanism	Amount	
	Frequency	Percentage
S	21	60,00%
P	8	22,85%
H	1	2,85%
NE	5	14,30%

Note: S: Serie, P: Parallel, H: Hybrid, NE: Not specified.

C. Treatment

For each application of a prosthesis, a treatment is performed on the amputee patient. Therefore, from the reviews carried out, we found targeted treatments for both the leg and the foot. Thus, each prosthesis has a different application depending on the amputation of the patient.

In 42.85%, they applied the treatment to the leg in general, that is, considering the hip, knee, and ankle, and in 57.15% they focused on the treatment of the ankle. In this case, there

were no unspecified. This may be due to the need to be able to specify what type of treatment should be applied.

TABLE IV. PERCENTAGES OF TREATMENTS USED BY THE STUDIES

Treatment	Amount	
	Frequency	Percentage
A	20	57,15%
HKA	15	42,85%

Note: HKA: Hip, Knee and Ankle, A: Ankle.

D. Training Mode

In the process of developing a transtibial prosthesis, it is necessary to put the user into practice to better understand the adaptability of the prosthesis to the user. Thus, in the articles reviewed, two main modes of training are presented: passive training and assisted walking.

In a higher percentage, passive training has been applied in the development of 24 transtibial prostheses. Likewise, but to a lesser extent (14.28%), they opted for assisted walking.

TABLE V. PERCENTAGES OF THE VARIOUS TRAINING MODES

Training mode	Amount	
	Frequency	Percentage
P	24	68,57%
AW	5	14,28%
NE	6	17,15%

Note P: Passive, AW: Assisted walking, NE: Not specified.

E. Rehabilitation Movement

In this section, a review of the movements of the lower limbs, where rehabilitation is applied, is developed. Likewise, the lower limbs present different movements shown in Fig. 2, according to the studies, plantar flexion, and dorsiflexion (PD), rotational and translational (RT), flexion, dorsiflexion, and abduction (PD-A), dorsiflexion (D) and plantarflexion (PF) movements were identified. On the other hand, in table VI with a percentage of 71.42% the most used rehabilitation movement was PD, this infers that the studies are focused on knee movements; in addition, with a percentage of 8.57%, movements belonging to the ankle (RT) were analyzed, likewise, there was a tie between the movements of flexion, dorsiflexion, and abduction (PD-A), dorsiflexion (D) and plantarflexion (PF) with a percentage of 2.86%. Finally, 11.43% of the studies did not specify the rehabilitation movements.

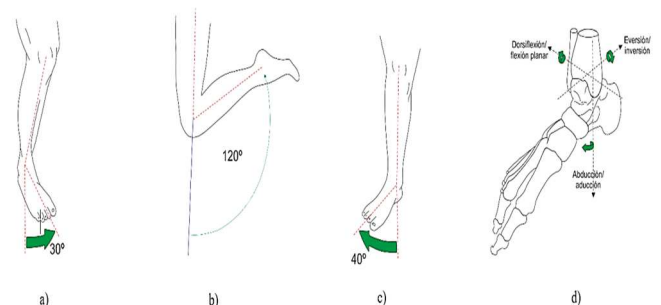

Fig. 2. Identification of exoskeleton joints. a) Internal rotation between 0° to 30°. b) Knee flexion and extension angles from 0° to 120°. c) External rotation between 0° to 40°. d) Foot movement occurs around 3 axes [43].

TABLE VI. PERCENTAGES OF REHABILITATION MOVEMENTS

Rehabilitation Movement	Amount	
	Frequency	Percentage
PD	25	71,42%
RT	3	8,57%
PD-A	1	2,86%
D	1	2,86%
PF	1	2,86%
NE	4	11,43%

Note PD: Plantarflexion and Dorsiflexion, RT: Rotational and translational, PD-A: Plantarflexion, Dorsiflexion, and Abduction, D: Dorsiflexion, PF: Plantarflexion, NE: Not specified.

F. Degrees of Freedom

The DoF can be understood as one of the variables necessary to define all the movements of a body in space. In this section, an analysis and review of the degrees of freedom of the foot, foot-ankle, and transfemoral prosthesis prototypes will be carried out. Fig. 3 shows four configuration systems in transfemoral prosthetic mechanism made up of 1 system of serial mechanism and 3 systems of hybrid mechanisms, in which a comparison is made to opt for a prosthetic mechanism as the reasonable configuration. And Fig. 4 shows the four main movements in a foot-ankle prosthesis.

According to the research carried out, Table I shows that the largest number of lower limb prostheses both foot, foot-ankle and transfemoral, representing 28.57%, have 3-DoF, followed by 17.14% of the prostheses have 1-DoF and 2-DoF, 11.43% of the prostheses have 6-DoF, and 2.86% of the prostheses investigated have 4-DoF, 5-DoF and 9-DoF; finally, 17.14% of the studies do not specify in detail this field.

Fig. 3. Configuration systems in transfemoral prosthetic mechanisms. (a) Series mechanism. (b) The hybrid mechanism I: two 1-DoF mechanisms and one 2-DoF mechanism. (c) Hybrid mechanism II: two 1-DoF mechanisms and one 2-DoF mechanism. (d) Hybrid mechanism III: one 3-DoF mechanism and one 1-DoF mechanism [40].

Fig. 4. Four main movements in the foot-ankle prosthesis: (a) Planar flexion upon contraction of both actuators. (b) Dorsiflexion occurs when both actuators are extended. (c) Eversion occurs with the following configuration: the left actuator contracts and the right actuator extends. (d) In inversion with the following configuration, the left actuator extends, and the right actuator contracts [37].

TABLE VII. PERCENTAGE OF DOF OF PROSTHESIS

Degrees of freedom	Amount	
	Frequency	Percentage
1	6	17,14%
2	6	17,14%
3	10	28,57%
4	1	2,86%
5	1	2,86%
6	4	11,43%
9	1	2,86%

G. Development status of the prosthesis

The Development of Technology Readiness Level (TRL) Metrics and Risk Measures manual [44] was important to identify the state of maturity of the research technology, which is made up of 9 levels. Table VIII shows that TRL 4 out of 35 investigations obtained 28.57%; that is to say that the great majority of studies validated the components in laboratory environments; on the other hand, there was a tie between TRL 3 and 6 with a percentage of 17.14%; therefore, it can be affirmed that the first study worked with the proof of concept and the second one elaborated the system or subsystem of a prototype in a relevant environment. On the other hand, TRL5 has a percentage of 14.29%, this figure infers that the research performed validation of components in relevant environments, as well as TRL 7 in which the researchers demonstrated the prototype in a real environment. Finally, TRL 2 has a percentage of 8.57%, from which we conclude that only 3 studies out of 35 used the formulated concept or technological application.

TABLE VIII. PERCENTAGES OF TRL-BASED STUDIES

Technology Readiness Levels (TRL)	Amount	
	Frequency	Percentage
2	3	8,57%
3	6	17,14%
4	10	28,57%
5	5	14,29%
6	6	17,14%
7	5	14,29%

H. Sensors

The present research mentions the use of various sensors used in electromechanical prostheses for lower limbs, the most used being mechanical sensors with a percentage of 37.14% of the state of the art; on the other hand, 37.14% did not specify the type of sensor used in the studies. Finally, 85% of the studies worked with electrical sensors.

TABLE IX. PERCENTAGES OF THE STUDIES ACCORDING TO THE SENSOR USED

Sensor	Amount	
	Frequency	Percentage
MS	19	54,29%
ES	3	8,57%
NE	13	37,14%

Note: MS: Mechanical sensors, ES: Electrical Sensors, NE: Not specified.

I. Actuators

The researchers established solutions to reproduce physiological movements with various actuators that do not damage the joints with sudden movements. Among the actuators, stepper actuators (APP) were identified with a percentage of 51.42%; in addition, the studies worked with servomotors (S) with a percentage of 22.86%; on the other hand, the studies used hydraulic actuators (AH) and linear actuators (AL) with a percentage of 2.86%. And finally, with 20%, the actuators used were not specified.

TABLE X. PERCENTAGES OF THE STUDIES ACCORDING TO THE ACTUATOR USED

Actuator	Amount	
	Frequency	Percentage
APP	18	51,42 %
S	8	22,86%
AH	1	2,86%
AL	1	2,86%
NE	7	20%

Note: APP: Stepper actuator, S: Servomotor, AH: Hydraulic actuator, AL: Linear actuator, NE: Not specified.

J. Materials

In this section, a review is made of the type of material most used in the prototyping and development of lower limb prostheses. Table # shows the different materials that have been used, in the database collected, for the fabrication of the subject under study. The most used material is carbon fiber with 27.03 %, well above the other materials, its hierarchy in the use of this material is reasonable due to its mechanical properties like steel and at the same time, it is light as wood or plastic. Next are Aluminum and Steel with 8.11 %, Nylon Filament with 5.71 %, Titanium, PLA, and Fiberglass with 2.70 %, and 43.24 % do not specify the type of material used. It should be noted that in several articles more than one material is used in the manufacture.

TABLE XI. PERCENTAGE IN THE TYPE OF MATERIAL

Material	Amount	
	Frequency	Percentage
Carbon fiber	10	27,03
Aluminum	3	8,11
Steel	3	8,11
Nylon Filament	2	5,41
Titanium	1	2,70
PLA	1	2,70
Fiberglass	1	2,70
NE	16	43,24

IV. CONCLUSION

Most of the studies presented in this review worked with preset movements and serial mechanisms for the design and development of transtibial prostheses. However, prostheses with EMG signals and parallel mechanisms progressed in a smaller amount due to the complexity of these, despite this, there is still room for improvement and innovation in the various rehabilitation methodologies. On the other hand, the treatments applied are mostly focused on the knee and ankle. In addition, the most used training mode is assisted walking.

Therefore, these characteristics highlighted in other research can be considered for the development of a transtibial prosthesis with a parallel mechanism considering the use of preset movements or EMG signals as input signals. Finally, different treatments and training modes should be considered to validate the prototype design and reach the maximum scale of the technology maturity state (TRL).

We also consider that one of the future technologies to be considered is neuro-prostheses because they are currently a technology with a lot of potentials, but most of them are invasive, i.e., they require surgery. Non-invasive neuro-prostheses do exist, but the devices on the market are not able to provide good efficiency in the day-to-day use of the wearer. However, a neuro-prosthetic leg can provide sensory feedback such as knee angle and touch, resulting in a significant improvement in amputee gait and thus a better quality of life for the disabled.

Finally, from the literature reviewed, the characteristics that impressed us and are considered important for the research are the Mechanism and the Treatment, i.e., the types of prostheses according to the levels of lower limb amputations. The first characteristic, it gives us very even information regarding the choice of serial and parallel mechanisms. The second characteristic shows that almost half of the prostheses developed are for leg amputees, i.e., considering the hip, knee, and ankle, and the other half focus on ankle treatment. Therefore, both information will be very important for the future design and development of an electromechanical transtibial prosthesis based on a parallel robot.

Abstract— Exoskeletons have been around since 1890 when a passive device was developed to assist movement. Although the exoskeleton initially focused on the whole body, it has become increasingly focused on a more specific area, which makes rehabilitation work more feasible and, consequently, less costly. Therefore, the purpose of the article is to present a systematic review of trends in the technical area of knee and ankle exoskeletons for rehabilitation purposes. The objective is to provide the interested researcher with a structured matrix that integrates essential components and mechanisms in the development of knee and ankle exoskeletons. As a methodology, specialized databases in biomechanics were used that aided in the collection of research conducted between 2019 and 2022. The filtering process resulted in the selection of 37 investigations. Finally, it was concluded that innovations in exoskeletons contribute to patient rehabilitation and that there is still room for further improvement in the implementation of projects on a commercial scale and the development of new exoskeletons based on previous research.

Keywords— ankle exoskeleton, knee exoskeleton, rehabilitation, *TRL*

I. INTRODUCTION

The development of robotics is becoming more and more surprising, to such an extent that an exoskeleton previously considered bulky and heavy for the user, today feels as if it were part of his own body [1]. Exoskeletons are mechanical structures that have different applications such as increasing the user's strength, supporting body weight, and helping to lift heavy loads, among others. [2].

Passive exoskeletons are distinguished by their proven efficacy in preventing injuries caused by performing false movements or maintaining prolonged work postures [3].

In a study of patients with diseases related to lower limb muscle weakness, they indicated that knee-ankle-foot orthoses (KAFOs) offer stability and reduce the cost of standing and walking, but for better performance, they often need to be custom-made. More than 76% of polio survivors reported using

a custom-made KAFO of which 74% obtained greater foot stability and 69% obtained improved walking performance. [4]

Robotic-assisted gait training (HIL) has potential benefits over the process of interactively generating automated exoskeleton assistance patterns to reduce physiological cost function while the user is wearing the device [5]. However, compared to rehabilitation, HIL has not demonstrated better results in combining accelerometer and GPS features to assess community mobility in users [6].

Recently, this problem was addressed through PIGRO, which allows the design of exoskeletons for robotic neurorehabilitation training [7]. In addition to PIGRO, there are other advances in the exoskeleton actuation system such as T-FLEX, which was the first ankle exoskeleton to be experimentally validated in people with stroke. [8].

In this sense, the main objective of the article is to perform a systematic review of the latest advances in the development of knee and ankle exoskeletons for the rehabilitation of healthy users as well as disabled individuals. This analysis of exoskeleton characteristics is composed of sensors, mechanism, material, treatment, rehabilitation movements, and development status. Finally, from the study, conclusions will be developed.

II. METHODOLOGY

For the development of this research, a search query was made in the IEEE Xplore database, Search database, and Science Direct, and access was also gained to collaboration and dissemination platforms such as ResearchGate, National Center for Biotechnology Information (NCBI), Multidisciplinary Digital Publishing Institute (MDPI), SCITEPRESS, as well as access to articles presented in some congresses such as: "Academia Journals International Research Congress, Celaya, 2021". In the search for information, keywords such as an exoskeleton, rehabilitation, knee, and ankle were used. Articles published from 2019 – to 2022 were limited, obtaining 37 articles.

III. REVIEW OF PUBLICATIONS

Articles on Knee and ankle exoskeletons for rehabilitation were classified according to sensors, mechanisms, type of

material used for manufacturing, type of treatment, rehabilitation movements, and exoskeleton development status (TRL).

A. Sensors

Several types of sensors were found in this group: force sensors (FS), kinematic sensors (KS), IMU sensors (IMU), EMG sensors (EMG), measurement sensors (MS), distance sensors (DS), portable sensors (PRS), position sensors (PSS), pressure sensors (PR) and inertial sensors (IS). Table II describes the characteristics of the mentioned types of sensors.

TABLE II. PERCENTAGE OF STUDIES BASED ON THE USE OF SENSORS

Sensors	Amount	
	Frequency	Percentage
FS	13	35,13%
IMU	8	21,62%
EMG	8	21,62%
DS	1	2,70%
PRS	1	2,70%
KS	1	2,70%
MS	1	2,70%
IS	1	2,70%
PSS	1	2,70%
PR	1	2,70%

Note: FS: Fonce sensing, IMU: IMU sensor, EMG: EMG Sensors, DS: Distance sensing, PRS: Portable sensors, KS: Kinematic sensors, MS: Measurement sensor, IS: Inertial sensor, PSS: Position sensors, PR: pressure sensors

It is important to consider the type of sensor we are going to use and be able to develop a suitable exoskeleton for rehabilitation. As can be seen in Table II, most of the studies used the force sensor with 35.13% [8], followed by IMU and EMG sensors with 21.62% [9] and the rest at 2.7%.

B. Mechanism

In this area, we find two general descriptions of the knee and ankle design: Serial (S) as shown in Fig. 1, and Parallel (P).

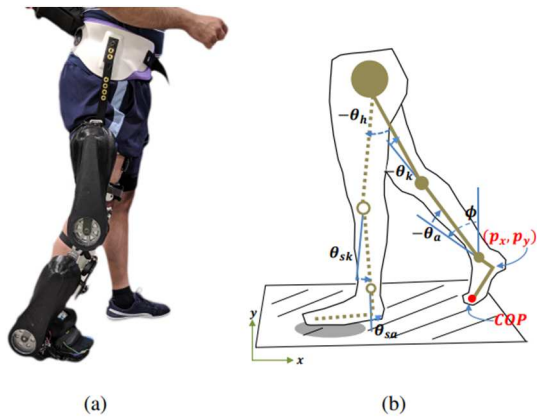

Fig. 1. (a) Comex exoskeleton worn by a healthy user. (b) Kinematic model of the body reproduced from. COP denotes the center of pressure, solid links denote the stance leg, and dashed links denote the swing leg. Source: Nikhil V. Divekar, Jianping Lin, Christopher Nesler, Sara Borboa and Robert D. Gregg, A Potential Energy Shaping Controller with Ground Reaction Force Feedback for a Multi-Activity Knee-Ankle Exoskeleton, USA: 8th IEEE International Conference on Biomedical Robotics and Biomechatronics, [2020]

In the construction of exoskeletons, the mechanism is considered a fundamental characteristic for the simulations and the obtaining of parameters that allow the evaluation of its

effectiveness. These mechanisms were grouped into two large groups, which are described below.

TABLE III. TYPES OF MECHANISM

Mechanism	Description
S (Serial)	Exoskeletons with a kinematic structure take the form of an open-loop chain.
P (Parallel)	Exoskeletons were developed to increase torque and joint work.

Table IV shows that most of the studies used a serial mechanism with 75.67% while the use of a parallel mechanism is 8.11% [9, 10, 11] This trend could be explained by the relative ease of implementation and mathematical modeling of a serial mechanism compared to one of a parallel nature.

TABLE IV. PERCENTAGES OF STUDIES BASED ON THE MECHANISM

Supported movements	Amount	
	Frequency	Percentage
S	28	75,67%
P	3	8,11%

Note: S: Serial, P: Parallel

C. Type of material

This section reviews the type of material typically used to develop exoskeletons. Table V shows in detail the different materials used in the process of developing robotic parts. The most used material is carbon fiber, 18.92% of the reviewed research uses this material which is the lightest and offers higher long-term performance. Another material of greater use in the elaboration of the components of the exoskeletons with 16.22% is aluminum, this material protects from oxidation and is very common in its use in the development of prototypes [12-17]., due to this, it exists as one of the most used materials in the development of exoskeletons. In the research carried out, structures of composite materials were found such as steel with aluminum in a percentage of 5.41%; aluminum with resin in a percentage of 2.7%; nylon with carbon fiber in a percentage of 2.7%; aluminum with titanium in a percentage of 2.7%. The structures composed of only one type of material in low percentage are steel 2.7%, nylon 2.7%, and titanium 2.7%. Finally, 43.24% of the research carried out does not specify the type of material used.

TABLE V. PERCENTAGES OF THE TYPE OF MATERIAL

Material	Amount	
	Frequency	Percentage
Carbon Fiber	7	18.92%
Aluminum	6	16.22%
Steel-Aluminum	2	5.41%
Aluminum-Resin	1	2.70%
Nylon-Carbon Fiber	1	2.70%
Aluminum-Titanium	1	2.70%
Stainless steel 304	1	2.70%
Nylon	1	2.70%
Titanium	1	2.70%
N.E.	16	43.24%

D. Treatment

This section analyzes the purpose of the exoskeleton and/or the type of treatment they offer. From the research conducted and collected in Table VI, it can be seen that 24.32% of the designs are focused on designed to cover the area of knee and ankle rehabilitation (KAR); 18.92% are only focused on knee rehabilitation (KR), 16.22% focus on the assistance or support in knee movements (KS); in the same way 16.22% focus on the assistance and support of the knee and ankle (KAS), when patients exercise heavy activities; 13.51% only focus on ankle rehabilitation (AR) for people with movement difficulties in this joint; 8.11% are focused on neurorehabilitation (NR) for people who have suffered a brain injury that prevents them from moving their lower extremities; finally, 2.7% of the exoskeleton is oriented towards assistance and support for ankle movements (AS).

TABLE VI. PERCENTAGES OF THE TYPE OF TREATMENT

Treatment	Amount	
	Frequency	Percentage
KAR	9	24.32%
KR	7	18.92%
KS	6	16.22%
KAS	6	16.22%
AR	5	13.51%
NR	3	8.11%
AS	1	2.70%

Note AR: Ankle rehabilitation, KR: knee rehabilitation, KAR: Knee and ankle rehabilitation, AS: Ankle support, KS: Knee support, KAS: Knee and ankle support, NR: Neurorehabilitation.

E. Rehabilitation movements

A review was carried out to identify the rehabilitation movements performed; firstly, it was identified which joints were responsible for the movements; thus, knee (R), ankle (T), and knee-ankle (RT) applications were identified. In addition, 24.32% of jobs were found to have additional applications at the hip; however, this was not considered in the study for 2 reasons. First, the actuation of the exoskeleton was dependent on the knee or ankle [18, 19] leaving hip rehabilitation in the background. In other articles, the actuation was not purely focused on the hip but had rehabilitation movements in both the knee and ankle simultaneously [7, 10], so these other two joints were prioritized for the paper.

In most of the studies, it was found that most rehabilitation movements focused on both joints (RT) with 43.24%; in 37.84% they focused exclusively on the knee (R) and, finally, in 16.22%, the work focused only on the ankle (T). These figures suggest that there is a tendency to design exoskeletons for joint rehabilitation of the knee and ankle.

More specifically, the movements performed on these two joints will be detailed. For a better understanding, a figure with the movements found in the review of articles is presented.

Fig. 2. Knee rotation, flexion, and extension. Ankle dorsiflexion, plantarflexion, eversion, and inversion. Sources: Howell, D., Knee Pain Wringing Out – Gait Deviation, United States: Damien Howell Physical Therapy, [2018]. Thompson, N., Muscles That Move the Leg, United States: American Council of Exercise, [2017].

In knee rehabilitation movements, we found that most of the research, 81.08%, focuses on knee flexion-extension (RF), this could be explained by the fact that it is one of the most common rehabilitation movements since it is used in multiple situations such as walking and sit-to-stand movement. On the other hand, only one article was found in which knee rotation (RR) is used.

Regarding ankle rehabilitation, 48.65% focus on plantarflexion (PT), followed by 37.84% on dorsiflexion (TD). These figures are interesting, as both movements are inverse, such as flexion and extension of the knee, but in this type of movement, both are usually worked separately. Finally, inversion and eversion (IT) movements represent 8.11% of items.

TABLE VII. PERCENTAGES OF STUDIES

Rehabilitation movements	Amount	
	Frequency	Percentage
RF	30	81.08%
RR	1	2,70%
TI	3	8,11%
TD	14	37,84%
TP	18	48,65%

Note: RF: Knee flexion-extension, RR: Knee rotation, TI: Ankle inversion-eversion, TD: Ankle dorsiflexion, TP: Ankle plantarflexion.

F. State of exoskeleton development

One of the aspects evaluated was the state of development of the project, so the level of progress of each exoskeleton concerning its stated objectives was seen. In this sense, the TRLs were grouped into 4 stages: Ideation, which corresponds to TRLs 1 and 2; Experimentation, which covers TRLs 3 and 4; Simulation, which corresponds to TRLs 5 and 6; and Validation, with TRLs 7 and 8.

The 10.81% of the articles found to correspond to the earliest stage, where the prototype is developed and detailed. Experimentation has the highest number of articles with 70.27%; at this point, at least one proof of concept or validation in a laboratory has been performed. The next figure corresponds to simulation, where components are tested in a relevant environment usually simulated; this stage could be considered the most developed before commercialization and represents 16.22% of the articles. Finally, there is a validation stage where the product reaches the highest degree of feasibility, so that it can be marketable; this only accounts for 2.70%.

TABLE VIII. PERCENTAGES OF STUDIES BASED ON THE ACTUATOR EMPLOYED

State of development	Amount	
	Frequency	Percentage
Ideation	4	10,81%
Experimentation	26	70,27%
Simulation	6	16,22%
Validation	1	2,70%

G. Type of control

It is crucial to consider the type of control because the coupling between it and the mechanical design represents the efficiency of the mechanism, thus being able to develop an appropriate exoskeleton. As can be seen in Table IX, most of the studies focused on PID with 24.32% and the rest below 3%.

TABLE IX. PERCENTAGES OF STUDIES BASED ON TYPES OF CONTROL

Supported movements	Amount	
	Frequency	Percentage
PID	9	24,32%
PD	1	2,70%
PC	1	2,70%
ROS	1	2,70%
POILC	1	2,70%
MPC	1	2,70%
PID, CC, DC	1	2,70%
RNNs	1	2,70%
PSMC, PID, and FUZZY	1	2,70%
NE	12	32,43%

Note: PID: Proportional Integral Derivative, PD: Proportional-derivative, PC: Position controller, ROS: Robot Operating System, POILC: Parameter Optimal Iterative Learning Control, MPC: Model predictive controller, CC: Centralized Controller, DC: Distributed Controllers, RNNs: Neural Network, PSMC: Proxy-based sliding mode control, N.E.: Not specified.

H. Type of controller

This section considers the type of controller that allows the exoskeletons to perform actions on the actuators based on the data obtained from the sensors. Although most exoskeletons process signals and data in computers with higher capacities, some microcontrollers, and microprocessors act as intermediaries to manipulate the exoskeleton. Based on the articles reviewed and compiled in Table X, 10.81% of the exoskeletons are controlled by FPGAs; 8.11% use STM323F407 type ARM microcontrollers; another 8.11% use dSPACE processors; 5.41% of the exoskeletons are controlled by Raspberry pi 3 microprocessors. Exoskeletons that use controllers in 2.70% are the Arduino MEGA 2560, mbed LCP1864, and PC104; in the same percentage, some exoskeletons use two controllers which are the STM32F407 and Raspberry Pi 4B. Finally, 56.76% of reviewed articles do not mention the type of controller used by their exoskeletons.

TABLE X. PERCENTAGES OF STUDIES BASED ON TYPE CONTROLLER

Controller type	Amount	
	Frequency	Percentage
FPGA	4	10.81%
STM323F407	3	8.11%
dSPACE	3	8.11%
Raspberry Pi 3	2	5.41%
Arduino MEGA 2560	1	2.70%
mbed LCP1864	1	2.70%
PC104	1	2.70%
STM32F407- Raspberry Pi 4B	1	2.70%
NE	21	56.76%

Note: FPGA: Field-programmable gate array, N.E.: Unspecified.

IV. CONCLUSIONS

Since their creation, exoskeletons have served to improve the quality of life through movement assistance. Therefore, they present great potential in the field of rehabilitation. The present article reviewed multitype of research around rehabilitation in the knee and ankle joints. Multiple functions must be improved, as seen in the state of development of the projects, where most of the exoskeletons are still in the early stages of research.

Regarding the structural characteristics of the exoskeleton, it is observed that the most used sensor is the force sensor, the mechanism is primarily serial due to the relative ease for the development of mathematical models and the predominant type of material is aluminum. Regarding rehabilitation, it is observed that the treatment focuses mainly on both joints and that the most used movements are flexion-extension in the knee and plantarflexion in the ankle.

In summary, it is hoped that exoskeletons will continue to be developed in the identified areas of opportunity and that in the future, innovations in the form of rehabilitation with exoskeletons will be presented. It is also expected that the review will serve as a tool to see trends in the way exoskeleton projects have been developed in knee and ankle rehabilitation, and that new projects in this line can be developed.

Abstract—Medical conditions and accidents can cause immobility in certain parts of the body such as the upper extremities. To help people in the rehabilitation process, various robotic devices have been designed, such as exoskeletons; however, they have limited features that did not achieve optimal performance. This article presents a systematic review of the design of hand exoskeletons applied to rehabilitation. The goal is to provide the researcher with a structured matrix of features and components for the development of a much more efficient hand exoskeleton. Different databases and specialized search engines were used because they helped in the collection of information from the different investigations from the year 2019 to 2021. Filtering and selection of the investigations were carried out, so in the end, only 33 investigations were selected. Finally, it is concluded that there is the possibility of improvement in the development of hand exoskeletons that contribute to the rehabilitation process.

Index Terms—hand exoskeleton, degrees of freedom, review, rehabilitation

I. INTRODUCTION

Robotic rehabilitation devices have been perfected and are of great help to people with disabilities. These can replicate the manual work of the therapist, while improving motor recovery and functional independence for patients with physical or neurological disabilities. [38].

Currently, 15% of the world population has some type of motor disability in the lower or upper limbs due to cerebrovascular accidents, rheumatoid arthritis, carpal tunnel syndrome, or due to an injury [39]. When it comes to hand disabilities, exoskeletons help increase the effective range of motion of the joints for repeated activities of daily living. This is done through crucial rehabilitation movements in a planned and controlled way.

Furthermore, considering the complex anatomy and high mobility of the hand, exoskeletons are robotic devices capable of executing almost all the actions of a healthy hand, even being able to be configured according to the task to be performed. Also, they are comfortable and easy to handle by

the patient as they adapt to the size of the hand and the length of the fingers [40].

On the other hand, there are exoskeleton models such as HandMATE [4] and the one designed by Narvaez et. al. [5] that offer better finger mobility thanks to the 15 degrees of freedom they have. A key factor in exoskeleton design is to improve features such as simplicity, low cost, portability, and intuitive control [6]. This is the case of Butzer et. to the. who created a portable 3D prototype based on the Myo bracelet and electromyography (EMG) focused on child rehabilitation; Wang et. al. [37] designed and fabricated a hand exoskeleton controlled by voice commands via a mobile app and Li et. al. [6] created an efficient control system based on brain signals using Brainlink Lite. But, despite the advances that hand exoskeletons show day by day, there are still limited functions that do not achieve the real performance of the hand in its entirety.

Therefore, in this document, our objective is to present a systematic review of these devices and serve as a guide for future projects and research. The materials used in each study, the degrees of freedom, the control mechanisms and finally the state of development are detailed.

II. METHODOLOGY

For the development of this research, the "Emeral Insight", "Frontiers in Neuroscience", "IEEE Xplore", "MDPI", "SAGE Journals" and "Springer Link" databases were consulted. As well as articles from magazines such as "Politeknik Dergisi" and "ScienceDirect", and also university repositories such as the "Digital Repository of the Central University of Ecuador". Keywords such as "exoskeleton", "hand", "rehabilitation" and "robot" were important to identify the publications consulted in this article. From a total of 42 publications, that cover the years from 2019 to 2021, we had access to 33 of them. These articles were read, examined and interpreted within the present investigation.

III. REVIEW OF PUBLICATIONS

The information from the reviewed scientific articles on hand exoskeletons for rehabilitation was systematically arranged in a morphological table. This table was made up of the following fields: Reference, used sensors, number of degrees of

freedom (DoF), type of controller, actuators, type of treatment for which the exoskeleton was used, and the TRL or also called the maturity level of the technology.

The carried out review covers more information apart from that mentioned above, so information on these will be added later. Table I shows what was compiled in the 7 fields.

Table I: HAND EXOSKELETONS FOR REHABILITATION

Note: In training all of them are flexo-extension movements. Abbreviations: EMG: Electromyogram sensor, FPGA: Field-programmable gate array, FSR: Force-sensitive resistor, IMU: Inertial Measurement Units, NE: Non specified, M: Motor, DC M: DC Motor, LS: Linear servo, S: Servomotor, RA: Rotational actuator, LA: Linear Actuator, SGM: Steering gear motor, MT: Torque motor, MS: Micro servo, AC S: AC Servo motor, EA: Elastic Actuator, MMGM: Micro Metal Gearmotor, TRL 2: Formulated concept or technology, TRL 4: Laboratory test results, TRL 6: Results of the tests carried out at the prototype level in a relevant environment, TRL 7: Results of prototype-level tests carried out in an operational environment.

A. Sensors

In this section, a recount of the sensors used in the prototypes of the reviewed hand exoskeletons is made. Table II shows the proportions in percentages of the use of each sensor. It can be seen that the most used sensor is the force sensor, which represents 39.39 % and the least used are the curvature, current, vacuum sensors, etc., which each represent 3.03 % of the total. To calculate these percentages, we considered the 33 investigations as the total; however, the total number of sensors used is not always 33 since in some investigations it is mentioned that more than one sensor was used.

Fig. 1: Hand exoskeleton model from [20]

Table II: TYPES OF SENSORS

Sensors	Amount	
	Frequency	Percentage (%)
Force (includes FSR)	13	39.39
Curvature	1	3.03
EMG	9	27.27
Motion angle	2	6.06
Strain	2	6.06
Flexion	3	9.09
EEG	3	9.09
Encoders	2	6.06
Position	2	6.06
EOG	1	3.03
Current	1	3.03
Flexible	4	12.12
Hall	1	3.03
Touch	1	3.03
Pressure	2	6.06
Vacuum	1	3.03
IMU	1	3.03
NE	5	15.15

Note: Abbreviations: EEG: Electroencephalography electrodes, EMG: Elec-

tromyogram sensor/electrodes, EOG: Electrooculography electrodes, FSR: Force-sensitive resistor, IMU: Inertial Measurement Units, NE: Non specified.

B. Degrees of Freedom (DoF)

In this section, a count of the degrees of freedom (DoF) values of the hand exoskeleton prototypes of the reviewed articles is made. Table III shows the percentages corresponding to the proportion of the DoF. In this field, prototypes with 3 DoF were found more frequently, which represents 21.21 %; while prototypes based on 1, 2, 6, 10, 11, or 14 DoF are less frequent, accounting for 3.03 % individually.

Table III: DEGREES OF FREEDOM (DoF)

DoF	Amount	
	Frequency	Percentage (%)
1	1	3.03
2	1	3.03
3	7	21.21
4	2	6.06
5	4	12.12
6	1	3.03
7	2	6.06
10	1	3.03
11	1	3.03
14	1	3.03
15	2	6.06
NE	10	36.36

Note: Abbreviations: DoF: Degrees of Freedom, NE: Non specified.

C. Controller type

In this section, the proportion of types of controllers used in the prototypes of the hand exoskeletons is observed. Table IV shows the corresponding percentages for each type of controller. In this case, like the sensors, the total sum of percentages is not 100% because more than one controller was used in some projects. Regarding the most used type of controller, it is observed that this is the Arduino Mega 2560, which represents 21.21 % and the least used are the computer chip, the Arduino Nano, and the Atmega 328 controller, which individually represent 3.03 % taking into consideration the 33 items as the total.

Table IV: CONTROLLER TYPES

Controller type	Amount	
	Frequency	Percentage (%)
Arduino UNO	6	18.18
Arduino Mega 2560	7	21.21
Computer chip	1	3.03
FPGA chip	2	6.06
Arduino Nano	1	3.03
Microcontroller	3	9.09
Pneumatic controller	1	3.03
Atmega 328	1	3.03
Servo/motor controller	3	9.09
NE	11	33.33

Note: Abbreviations: FPGA: Field-programmable gate array, NE: Non specified.

D. Actuators

Table V shows the variety of actuators used in the prototypes of the hand exoskeletons. According to what was observed, these can be linear or rotational. In addition, it can be seen that the most used type of actuator is the motor (includes DC), which represents 39.39 % and the least used is, for example, the rotary actuator, which represents only 3.03 %.

Table V: ACTUATORS

Actuator type	Amount	
	Frequency	Percentage (%)
Motor (w/wo E)	7	21.21
DC motor (w/wo E)	6	18.18
Linear servo	1	3.03
Servo motor	6	18.18
Rotational actuator	1	3.03
Linear actuator	6	18.18
Steering gear motor	2	6.06
Soft and rigid actuator	1	3.03
Micro servo	1	3.03
Transmission cable	2	6.06
FA actuator	1	3.03
Elastic actuator	1	3.03
NE	2	6.06

Note: Abbreviations: E: Encoder, FA: Flexion and abduction, NE: Non specified, w/wo: With or without.

E. Training modes and movements

Information about the training modes, which can be passive, active, or assisted, and the types of rehabilitation movement is placed in this section. Regarding the movements, it was found that the most used and which is evidenced in all the articles is the movement of flexion and extension of the joints. Table VI shows the proportion through the percentages of the training modes corresponding to the flexo-extension movement (FE). In the same way, as in Table VI, the total sum of percentages exceeds 100 %, due to the use of more than one training mode in the consulted investigations. According to the table, it can be seen that the training mode based on assisted movements is the most frequent, which represents 57.58 % of the analyzed articles, while active movements are the least frequent, representing only 15.15 % . Likewise, it is important to mention that within Table VI the category "Mixed Movements" refers to training modes that combine the basic ones listed above; i.e. "Active and Passive Movements", "Passive Assisted Movements", etc.

Table VI: TRAINING MODES OF THE FE MOVEMENT

Training mode	Amount	
	Frequency	Percentage (%)
Active Movements	5	15.15
Assisted Movements	19	57.58
Passive Movements	8	24.24
Mixed Movements	4	12.12
NE	3	9.09

Note: Abbreviations: FE: Flexo-extension, NE: Non specified.

F. Technology Readiness Levels (TRL)

This section addresses the maturity levels of the hand exoskeleton prototypes of the reviewed articles. The TRL (Technology Readiness Levels) are numbers that go from 1 to 9, and these are assigned according to the level of development of the technology and its applicability to an environment. Table VII shows the proportion of TRLs using the corresponding percentages. According to the table, it can be seen that the most frequent TRL is 6 (results of the tests carried out at the prototype level in a relevant environment), which represents 42.42 % and the least frequent is 2 (concept or technology formulated), which represents 6.07 %.

Table VII: TECHNOLOGY READINESS LEVELS

TRL	Amount	
	Frequency	Percentage (%)
2	2	6.07
4	11	33.33
6	14	42.42
7	6	18.18

Note: Abbreviations: TRL: Technology Readiness Levels.

G. Control type

This section adds more information on the types of control used in the revised hand exoskeletons. Mostly, the type of control considered is the PID and in a large part of the articles, the type of control used is not specified. Table VIII shows the proportion of the types of control used in the projects. According to the table, it is evident that the most frequent type of control is PID, which represents 33.33 % and the least frequent is, for example, fuzzy control, which represents 3.03 %.

Table VIII: CONTROL TYPE

Control type	Amount	
	Frequency	Percentage (%)
ON - OFF	5	15.15
Fuzzy	1	3.03
PID	11	33.33
With potentiometer	1	3.03
Simple feedback	1	3.03
Proportional control	1	3.03
Closed loop control	1	3.03
Neural networks	1	3.03
NE	11	33.33

Note: Abbreviations: NE: Non specified.

H. Material

Finally, this section deals with more information about the used materials for the construction of the prototypes of the hand exoskeletons for rehabilitation. According to the reviewed articles, the prototypes are made through the use of different materials, highlighting among them the use of PLA through 3D printing. Table IX shows the proportion of the types of used materials. In this case, the total percentage exceeds 100 % due to the fact that some investigations used more than

one material in the construction process. Thus, according to Table IX, PLA represents 36.36 % of the total, while different materials such as VisiJet Glass, RTV Silicone Rubber, among others that were used only once, individually represent 3.03 % of the total.

Table IX: MATERIALS

Material	Amount	
	Frequency	Percentage (%)
ABS	3	9.09
Aluminium	2	6.06
Cristal visiJet	1	3.03
RTV Silicone Rubber	1	3.03
Markforged Onyx	1	3.03
PRR	1	3.03
PLA	12	36.36
Stainless Steel	1	3.03
TPU	2	6.06
NE	12	36.36

Note: Abbreviations: ABS: Acrylonitrile Butadiene Styrene, PLA: Polylactic acid, PRR: Photopolymer Rapid Resin, TPU: Thermoplastic Polyurethane, NE: Non specified.

IV. CONCLUSION

Thanks to technological progress and the improvement of current clinical studies, the development of hand exoskeletons has been evolving; therefore, future designers must adopt increasingly efficient hand exoskeletons designs. Such designs can only be possible after studying the design options of current devices.

In this article, we investigate a wide range of existing hand exoskeletons in the literature based on different design aspects, such as actuator technologies or control strategies.

However, the search for the most efficient device is not over yet. We hope that this review provides useful guidelines and practices for future designers as they create new and efficient hand exoskeletons.

For future works, based on the information obtained from this research about the materials and methods used in the consulted references, the design of a hand exoskeleton will be proposed as a new alternative to contribute to the rehabilitation of arthritis in the elderly.

Abstract— *The use of artificial intelligence (AI) in medicine is already a reality. Everywhere there is talk of the advantages that AI can mean for the future in our daily lives, as well as its possible applications. The future of "standard" medical practice could appear here ahead of schedule, where a patient could go to a computer before seeing a doctor. Through advances in AI, it becomes more possible for the days of misdiagnosis and treatment of the symptoms of the disease, rather than its root cause, to be left behind. Think about how many years of blood pressure measurements you have or how much storage you would need to remove so that you can fit a complete 3D image of an organ on your laptop. The idea of artificial intelligence in medicine may make you think of robots roaming the halls of a hospital in the distant future, but AI is already here.*

Keywords— *Artificial intelligence, prosthesis implantation, prosthetic rehabilitation, nanomaterials, modeling.*

I. INTRODUCTION

Artificial intelligence (AI) is a branch of computer science that includes very transversal concepts related to logic and learning [1]. The process of implanting the human prosthesis is simplified and can be performed in a less complex way aesthetically, being possible to restore a member of the body without so much complexity in its assembly and operation. For this article, he has focused on seeing how artificial intelligence takes a big step by establishing this type of implementation and that it makes it more efficient in the process of it. Health professionals must know this technology, its advantages, and its disadvantages because it will be an integral part of their work [2].

It is key to highlight that there are different types of human prosthesis implantations, which in many cases can be excessively expensive due to the necessary inputs to perform the implantation adding the time it takes the specialist to perform this process that tries to respond to our problem.

Concerning AI, his contribution was in the integration of nanomaterials and biomaterials to be able to reconstruct part of the affected skin. As you already know, this has given a very important takeoff in the development of prostheses, although it has not exploited all the resources it could provide and not only to prostheses but to medicine in general. This leads to a review of articles related to health topics, applications of AI, prostheses, and new technologies in implants. For example, maxillofacial prosthetic rehabilitation replaces missing structures to regain function and aesthetics related to facial defects or injuries [3].

However, it is known that the nerve cuff electrodes have remained stable during the four months since implantation. These results suggest that 16-channel neuroprostheses will provide stronger knee extension moments for longer before fatigue during standing and transfers [4]. That is why AI can be used to address many challenges facing the world's healthcare system, from disease detection to building predictive models for treatment, thereby improving quality, and reducing the cost of patient care. For example, in recent decades, medicine, mechatronics, mathematics, and materials science have progressed together in the search for the ideal active prosthesis for the upper limb [5].

II. METHODOLOGY

To indicate the intensity of the articles reviewed on the artificial intelligence applied in medicine, a systematic review of the simple literature was carried out. It inquired about the topics of artificial intelligence in the implementation of prostheses in different databases such as Science Direct, Scopus Preview, and Springer, each in the "article" segment where the search for articles related to Artificial Intelligence and Medicine was carried out.

The following syntax is used for the search: Prosthesis implantation, bone, direct skeletal union, limb amputation, neurocentral, osseointegration, prosthetic rehabilitation, Nanomaterials for orthopedic implants and applications, Rehabilitation and prosthetics post-amputation, Integration of robotics and neuroscience, Neural Interface Implanted. It is appreciable that "AI" and "prostheses" are the keywords that were entered for search engines on the respective information bank pages.

In addition, it is key to note that these databases were used for the reliability of their studies. The search for information was initially carried out with 130 articles, where due to the Mendeley program, it has been possible to summarize and catalog the respective data and cite them precisely, providing the 83 articles investigated properly to the central study topic. Then, all the information was organized and systematized in tables, in an organized way, indicating the country, material (characteristics), and citation of the different articles collected.

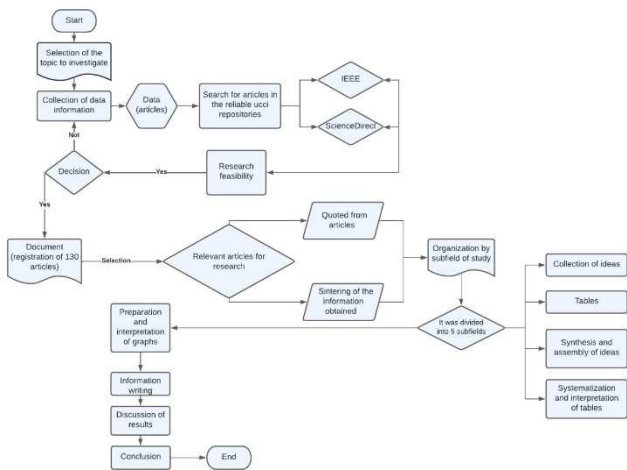

Fig. 1. Flowchart on the elaboration of the article.

III. RESULT AND ANALYSIS

The results that were obtained reflect that the largest number of articles from AI go from the year 2016-2021 collected from repositories such as IEEE and Science Direct having, in the same way, a considerable sum of people involved in recent years to the preparation of these articles and who are in constant exploration on the advancement of AI

Fig. 2. Graph of bars of scientific articles by years of publication.

Fig. 2 shows that the publications about Artificial Intelligence applied in Human Medicine with the Implementation of Prostheses, the years from 2001 to 2013, do not exceed 3 articles. However, as of 2014, it shows an increase to a maximum of 6 articles. This trend continues until 2020 when it manifests an amount greater than 20 articles.

Fig. 3. Histogram of the number of articles collected.

Fig. 3 shows the number of publications we collect for our topic Artificial Intelligence applied in Human Medicine with the Implementation of Prostheses. The compilation is 83 publications in total, according to the year, we divide them into intervals of 5 years starting in 2001. As you can see, most are from recent years, as they range from 2016 to 2021.

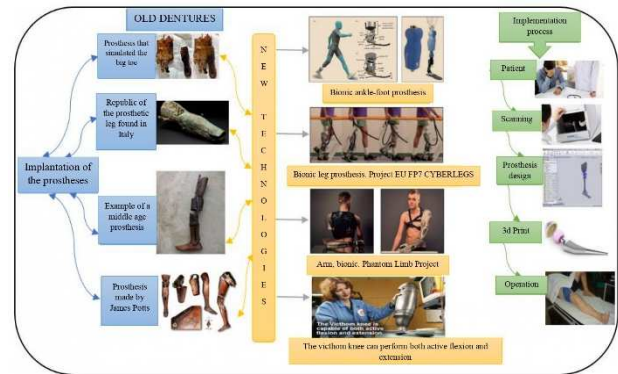

Fig. 4. Process diagram of the evolution of the prosthesis and the implantation process [6][7].

Fig. 4 shows, the evolution of the prosthesis that had over the years which was both the change the evolution of the prosthesis since these date from the twentieth century, until today where modern prostheses are developed and produced thanks to AI and technological evolution within the medicine of computer and robotic advances, it also shows the process involved in the implementation of a prosthesis in humans.

IV. FUNDAMENTAL PRINCIPLES OF AI IN MEDICINE

Table I. Systematization Table Fundamental principles within medicine

Comparative Studies	AI Factors	Medical Factors	Response variable
[8]	Data collection	Prosthesis design	Novel bionic foot when walking.
[5]	Data collection	Prosthesis design	Ideal prosthesis for the upper limb

[1]	Data collection	Medical Decision Making	Personalized medicine
[2]	Data collection	Medical Decision Making	Technology adapted to doctors
[9]	Detection	Treatment prediction	Improving hospital care
[10]	Feedback	Sensory information	Neural prosthesis technologies

According to Table I, 21.4% of the authors focus on the use of AI for the design of prostheses, and the same percentage of authors focus on the use of AI for medical decision making, on the other hand, 14.3% of articles study the application of AI for the prediction of treatments, The same number of articles focus on healthcare, 28.6% of the authors studied the application of AI in four different topics in which sensory information, neurocomputing, systems description and solving previous medical problems are found. It is concluded that in this table studies on the application of AI in favor of prosthesis design and medical decision making predominate.

Therefore, technology and medicine follow a parallel path during the last decades. On the other hand, AI is made up of a series of logical algorithms [11]. That is why, in this sub-theme, we will review the significant advances in sensory neural prosthesis technologies made in recent decades [12]. For example, CIBERESUCICOVID aims to determine through artificial intelligence analysis what are the risk and prognostic factors of patients infected with COVID [13]. In addition, practical intelligent applications (PRINTEPS) are being developed, which is a user-centric platform for developing integrated intelligent applications only by combining four types of modules [14]. For example, the prosthetic knee is one of the key elements in the design of modular prostheses and the appearance of new mechanisms together with the proliferation of knees has complicated its classification and prescription.

Telepresence surgery, on the other hand, is an interactive computerized system, so fast and intuitive that the computer disappears from the surgeon's mind, transforming the environment generated by the system into something real [15]. For example, artificial neural networks (ANNs) are well established in BCI research and have numerous successful applications [16]. On the other hand, thanks to AI, transtibial amputees can better approximate typical movement patterns at slow, normal walking speeds using the new bionic prosthesis [17]. In the past, natural heart valves functioned primarily as live check valves, which are purely fluid dynamics devices in nature [18].

That is why AI can be used to address many challenges facing the world's healthcare system, thereby improving the quality, and reducing the cost of patient care [9]. For example, in recent decades, medicine, mechatronics, mathematics, and materials science have progressed together

in the search for the ideal active prosthesis for the upper limb [19]. However, there is a reflection on the evolution of the field of Neurocomputing that has witnessed the sequence of editions of the International Working Conference on Artificial Neural Networks [20]. Similarly, this review demonstrates that the application of advanced ai methods in healthcare has the potential to improve the quality of care by uncovering non-obvious and clinically relevant relationships and enabling timely care intervention [21].

V. ARTIFICIAL INTELLIGENCE FOR MEDICAL DIAGNOSIS

Table II. Table of Systematization of artificial intelligence for medical diagnosis

Comparative Studies	AI Factors	Medical Factors	Response variable
[22]	Data collection	Prosthesis design	Transfemoral Prosthesis Model
[23]	Data collection	Prosthesis design	A prosthesis system is an artificial arm
[24]	Data collection	Prosthesis design	Implementing AI in Radiology
[25]	Data collection	Prosthesis design	Portable devices for upper limb amputees
[26]	Estimation algorithm	Prosthesis implantation	The precision of implantation of the prosthesis
[27]	Data collection	Implant durability	Neo-intimate incorporation of the Stentrod
[26]	Learning algorithm	Control of electromyogram patterns	Smart prostheses controlled by EMG-PR
[28]	Biomechanics	Postoperative monitoring	Implants with load detection

According to Table II, 23.5% of the authors focus on the use of AI for the design of prostheses, and the same percentage of authors focus on the use of AI for medical decision making, on the other hand, 17.6% of articles study the application of AI for the prediction of treatments, 35.3% of the authors studied the application of AI in six different topics in which medical care, implantation of prostheses, the durability of implants, control of myogram patterns, integration of the nervous system and postoperative monitoring are found.

In such a way in the era of Industry 4.0, sustainable chemistry and processes are undergoing a drastic transformation of the continuous flow system towards the next level of operations [29]. Likewise, technological capabilities are creating an opportunity for machine learning and artificial intelligence (AI) to enable "intelligent" brain-machine interfaces (BMI) designed by nanoengineering [30]. Thus, complementing the study of the active knee joint and the active knee-ankle transfemoral prosthesis [21]. At the same time, the prosthesis system is an artificial arm produced by INAIL en Vigorso [22]. As well as, on the report of electrodes mounted on a stent (Stentrod) capable of

chronically recording neural signals from inside a blood vessel with high fidelity [26]. AI is known to be used to identify new drug therapies and improve a physician's efficiency [31].

However, advances in AI are contributing to a growing reliance on algorithms to make decisions important to humans [32]. Another important fact, breast cancer is the leading cause of cancer death. Survival rates in developing countries range from 50% to 60% due to late detection [33]. However, the use of an intelligent learning algorithm for electromyogram pattern recognition in upper limb prostheses is considered an important clinical option [25]. In contrast, orthopedics has not yet adapted to innovative trends in health control, from an obvious entry point during orthopedic surgeries, physicians remain unable to objectively examine the structural integrity and biomechanics in the region operated through implantable sensors [27].

The use of AI models applied to diagnostics offers multiple benefits such as its large data storage capacity [34]. Thus, we propose an auxiliary decision support system that combines joint learning with case-based reasoning to help clinicians improve the accuracy of predicting breast cancer recurrence [10]. That's why AI has the potential to improve all levels of radiology workflow and practice [23]. Likewise, portable devices (WD) have evolved from purely mechanical devices to intelligent mechatronic systems thanks to the continuous advancement of technology integrating sensors, actuators, novel materials, and above all sensory feedback [24].

VI. ADAPTATION OF THE HUMAN PROSTHESIS

Table III. Table of Systematization of Adaptation of the human prosthesis

Comparative Studies	AI Factors	Medical Factors	Response variable
[35]	Modeling	Prosthesis implantation	Electronic skins
[36]	Information Collection	Prosthesis implantation	Skeletal fixation technology and neuromuscular control technology.
[37]	Modeling	Prosthesis design	Sophisticated portable gripper
[38]	Modeling	Prosthesis design	Spring-shock absorber
[39]	Information Collection	Prosthesis design	Physical activity tracking devices
[40]	Modeling	Prosthesis design	Bioelectric prosthetic hand
[4]	Modeling	Integration of the nervous system	Implanted neuroprosthesis

According to Table III, 28.5% of the authors focus on the use of AI for medical decision making, the same percentage of authors focus on the use of AI for the design of prostheses, on the other hand, 21.4% of authors focus on the use of AI for the implantation of prostheses, the same percentage of authors focus on the use of AI for nervous

system integration. It can be said that in this table the studies on the different approaches are homogeneous.

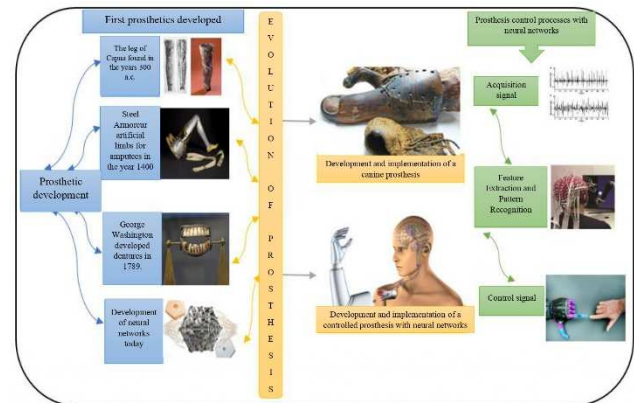

Fig. 5. Evolution of the prosthesis [41][42].

To some extent, advanced AI technology also creates new opportunities to explore the scientific basis of traditional Chinese medicine (TCM) and develop the standardization and digitization of TCM pulse diagnostic methodology. That is why we review and discuss the possible application of AI technology in the diagnosis of TCM pulses [43]. For example, the ability to learn accurate, temporarily abstracted predictions is shown through two case studies: the myoelectric control of a non-disabled robotic arm and the interactions of an amputee with a myoelectric training robot [44]. On the other hand, this system is divided into four separate categories: force detection, temperature sensation, motion detection, and final feedback allows the user to monitor and control the hand through an Android app [39].

After all, robotic technology can help build bipedal robots that allow human gait to be emulated, aimed at building lower prostheses or exoskeletons as can be seen in Fig. 6, which help to walk and perform other muscular activities that would otherwise be impossible [35]. That's why wearable sensors have evolved from fitness trackers that are worn on the body to multifunctional, highly integrated, compact, and versatile sensors [38].

VII. SIMULATION FOR THE DEVELOPMENT OF PROSTHESES

Table IV. Simulation Systematization Table for the development of prostheses.

Comparative Studies	AI Factors	Medical Factors	Response variable
[45]	Modeling	Prosthesis implantation	Control technology
[46]	Information Collection	Prosthesis implantation	Amputee Rehabilitation
[47]	Information Collection	Prosthesis implantation	Joint stiffness
[48]	Modeling	Prosthesis implantation	Application of nanomaterials
[49]	Modeling	Prosthesis design	Osseointegrated prosthesis
[50]	Information Collection	Integration of the nervous system	Artificial neural networks

According to Table IV, 31.5% of the authors focus on the use of AI for medical decision-making, on the other hand, 26.3% of the authors focus on the use of AI for the design of prostheses, as do the authors who focus on the use of AI for the implantation of prostheses. 15.7% of the authors focus on the use of AI for nervous system integration. That's why Gen Z uses their smartphones daily more than any other generation. This aspect of your life should be considered when talking about education, since all your free time is dedicated to these smart devices, educational apps could implement some aspect of learning when using these devices [51]. This leads to a new wave of technologies making their way into clinical practice, including mHealth, which enables constant monitoring of biological parameters, anytime, anywhere, of hundreds of patients at the same time [37]. Thus, AI is viable for patients to rehabilitate, and improve the quality of surgical equipment so that it provides the final prosthesis and meets the objectives set [45].

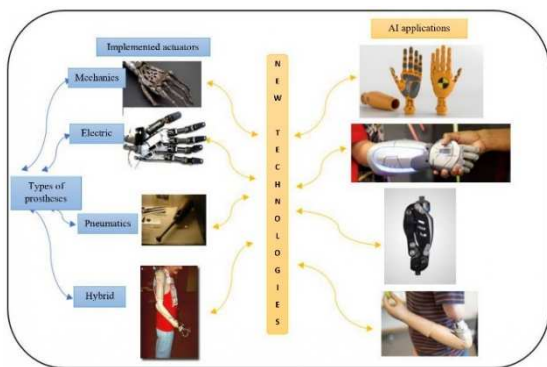

Fig. 6. Types of prosthetic limbs [52].

There have been applications of artificial intelligence (AI) in all aspects of CT imaging (acquisition, reconstruction, analysis, and measurement of new imaging features) that can further enhance value and reduce cost [53]. Likewise, the implementation of hybrid neuroprosthetic systems (HBS) relates artificial intelligence to the human nervous system, so being very important, many researchers investigate the subject more to recover sensorimotor functions in people suffering from different disabilities [54]. In addition, as shown in Fig. 6, an in-line control system for upper limb prostheses based on EEG motor imaging is performed, consisting of the brain-computer interface unit (BCI), motion controller, and target orientation module [44].

Nanomaterials hold promise for orthopedic applications due to their excellent tribological properties, wear resistance, osseointegration, and tissue regeneration capacity. Nanostructured materials play a pivotal role in orthopedic research due to their size range and ability to mimic the characteristics and hierarchical structure of native bones [47]. On the other hand, the WiseTOP real-time communication platform incorporated in an osseointegrated prosthesis is used for the recovery of hand function after amputation and presents the initial results of the performance evaluation [48].

It also features an integrated, real-time framework for finger strength control in upper extremity prostheses [55].

VIII. NEW TECHNOLOGIES FOR THE MEDICAL INDUSTRY IN THE APPLICATION OF PROSTHESES

Table V. Table of Systematization of New Technologies for the Medical Industry in the Application of Prostheses

Comparative Studies	AI Factors	Medical Factors	Response variable
[56]	Detection	Treatment prediction	Diagnosis and therapy and the relationship with AI
[57]	Modeling	Prosthesis design	Smart textiles
[36]	Data collection	Prosthesis design	Upper limb prosthesis
[58]	Modeling	Prosthesis implantation	Restore, retain, or modify damaged tissues
[59]	Information Collection	Integration of the nervous system	The artificial neural feedback network

According to Table 5, 33.3% of the authors focus on the use of AI for healthcare, and the same percentage of the authors focus on the use of AI for the prediction of treatments, in addition, 16.7% of the authors focus on the use of AI for the design of prostheses, 11.1% of the authors analyze the application of AI in the implantation of prostheses, finally, 5.6% of the articles are focused on the study of the application of AI in the integration of the nervous system. Robotics uses information about neuroscience for the implementation of hardware and control in biomedical engineering, implantation of myoelectric hands, hands with portable detection, and haptics [60]. On the other hand, to detect urinary bladder cancer, the multilayer perceptron method was found combined with other common methods, such as convolution neural networks focused on learning [61].

From the basic step of taking a patient's history to processing data and then extracting the information from the data for diagnosis, artificial intelligence has many applications in medical science [62]. AI along with virtual reality help analyze complex anatomy in three dimensions[63]. Likewise, AI improves performance in cancer diagnosis through immunotherapy, also optimizes treatment, predicts outcomes, and reduces personnel costs [34]. On the other hand, it can modify the design of clinical trials which begins with preparation until execution to reduce the R&D burden in terms of pharmacy [64]. For example, the purpose of this latest study was to implement an artificial neural feedback network (FFANN) to predict the KCF of the medial condyle corresponding to two different gait modifications known as medial thrust and trunk swing [58].

The diffusion of AI will depend on the forces that favor the reproduction of robots, systems, codes, and intelligent algorithms, as well as R&D groups and budgets. This is part of a special issue on the future of AI [64]. In conclusion,

artificial intelligence is a very productive factor in medical devices and many technologies today[65].

IX. CONCLUSION

First of all, the combination between medicine and technology was seen to generate various efficient medical methods that benefit medicine, AI helps to progress exponentially and allows the medicine to evolve in favor of humanity, however, it has a great capacity to learn and analyze possible diseases or deficiencies at a very high speed, allowing healthcare professionals to gain time in medical diagnosis to generate medical treatment in the shortest possible time, thus saving many more lives. Traditional prostheses only tried to replace the amputated limb for the displacement or simulation of human movement, however, thanks to the implementation of artificial intelligence, it is now possible to simulate or replicate the different senses that the lost limb possessed, thus giving greater perception, efficiency, and comfort to the user of the prosthesis. It can be observed that to develop a functional and effective prosthesis, an AI-assisted simulation must be carried out to have feedback that allows the prosthesis to be developed much faster and thus verify its correct operation, prevent various accidents or incompatibilities that may affect the user and avoid unnecessary expense in the construction of various prototypes still incomplete.

On the other hand, AI has not yet reached its peak, there is still much to explore and develop in the field of medicine and its advancement will be reflected in the fact of how many resources are used to deepen, develop and replicate the various investigations that promise to implement in a more effective and complex way the use of AI that encompasses the study of medicine and its branches. In short, both technology and medicine have been present for a long period. These technological advances are changing the vision we have about health and how they influence the knowledge of new technologies. Artificial intelligence consists of a series of logical instructions that machines use to be able to decide specific cases based on general principles. This technology is mainly used to make a diagnosis and health analysis of patients since in this way an individual prognosis can be appreciated. However, if we combine this technology and robotics, we can create machines and intelligent devices that can provide diagnostic suggestions or be more efficient in their work. Artificial intelligence will be a technology present in our day-to-day through machines or computer algorithms, in a true way for users, it will help in the daily life of the assistance processes. Professionals must know about this technology, its advantages, and its disadvantages because they will be integrated into the present work.

Abstract—Due to the large number of emergencies and disasters happening around the globe, the technology development to face these difficulties has risen in different areas, one of them being the robotics field: rescue robots. A great amount of incentives have been presented over the years to increase the numbers of studies in the creation of rescue robots, like competitions and funding opportunities. The objective of writing this paper is to document and review different rescue robot works to provide, to interested individuals in the research area, a basis to start in this field. Twenty-six articles on rescue robotics development, ranging from 2017 to 2021, were found and selected using academic search engines.

Index Terms—rescue robots, TRL, sensors, systematic review

I. INTRODUCTION

In recent years, rescue robot development has reached an unprecedented speed due to them being one of the most effective tools in post-disaster search and extraction efforts. Around the world, emergencies pose a frequent and serious threat to the lives of people. These include natural disasters (e.g. earthquakes, landslides, floods), industrial accidents (spills, fires, explosions and structural failures) and terrorist attacks [1]. After a disaster, one of the main interests is to timely rescue and medically attend affected people, and to evacuate affected areas [2].

Due to the highly variable and risk-prone nature of after-accident environments [3], coupled with the low time constraints required for a successful rescue operation, human rescue workers and explorers have been phased out by the

use of modern rescue robots [4]. Recent examples of major disasters from around the world (such as earthquakes in Kobe, Turkey, Iran-Iraq and Fukushima [5] [6] [7]) exemplify the need for robust and dynamically-adaptable robots for S&R operations [8].

Because these robots have a wide range of potential markets and use cases, companies have been involved in stimulating the research and development of rescue robots. Currently, there are some examples of state-of-the-art commercially available robots such as HURCULES [9], a military-employed rescue and casualty extraction robot equipped with high-power actuator and motor systems, a fuzzy logic-based control system, multiple high-definition cameras and dedicated GPUs; and MSRBOTs [10], a coal-mine rescue robot equipped with hyperspectral binocular vision sensors (appropriate for the specialized rescue setting), gas sensors, and an electrohydraulic-powered locomotion system.

Notably, competitions such as the Robocup Rescue branch of the Robot World Cup [11] and the DARPA Robotics Challenge [12] provide a platform for simulation, construction and testing of S&R robots, and further the study of theory in rescue robotics. Five key metrics for rescue robots identified in common within these events include survivability, mobility, sensing, communicability and operability [13]. In order to achieve maximum performance in each of these metrics, the fusion of multiple design, construction and control techniques is considered to be required [14]. Several key insights can be extracted from the multiple published academic works derived from these series of competitions, some of which can be used to improve upon the aforementioned state-of-the-art robots.

Therefore, this article is a paper review summarizing these

findings within rescue robot development, including research on sensors, control methods, actuators, technology readiness levels (TRLs), computing components and control units. The objective is to systematically review the trends in each of these design considerations measuring the frequency. Thereafter, conclusions will be drawn on the observed patterns.

II. METHODOLOGY

In order to conduct this article, we looked for different papers submitted in “Google Scholar”, “SpringerOpen”, RoboCup Rescue Team Description pages and papers, “ResearchGate”, “IEEE Xplore” and other academic search engines. For this search, we use a combination of the words “rescue”, “search”, “ground robots”, “sensors”, “actuators” and “RoboCup Rescue”. From this exploration, we found a total of 53 articles related to the topic of Rescue Robots in the range from the year 2017 until 2021.

However, in the end, we select 26 papers for the present review based on three reasons. The first one is the lack of access to some papers, especially the ones for the years 2020 and 2021. The second one is the absence of paper information

on the characteristics reviewed in this article. The third one is that many papers explain about the same robot, especially the ones from the RoboCup Rescue Team Description for the characteristic that this competition is taken abroad every year.

III. REVIEW OF PUBLICATIONS

The reviewed articles have been gathered and classified to understand the diversity of areas to consider before developing a rescue robot. This robots have been sorted by their control method, actuators, degrees of freedom (DoF), computing and control units, sensors and Technology Readiness Level (TRL). Table I shows a summary of these reviewed areas.

A. Sensors

In this area, a review is carried out about the sensors used to obtain data on the robot’s surroundings. Table II shows 14 different types of sensors found in the 26 revised papers. Which, cameras are the most common device with 96.15% for remote tele operator’s view of the environment, 3D mapping and image processing for victim identification [23] [22].

Furthermore, 80.77% include IMU sensors to obtain orientation, inclination and acceleration data [33] [31]. Besides, 76.92% include laser rangefinder sensors for mapping the surroundings [31] [30] and 30.77% have temperature sensors for two purposes. The first one is to measure the victim’s body temperature [36] [34] [29], while the second one is to acquire data on the ambient conditions of the operating environment [35].

In addition, 73.08% of the robots possess CO2 sensors, 65.38% include thermal cameras and 53.85% include microphones principally for human detection through the identification of respiratory activity, body heat or emitted sounds of the victims respectively [17] [23] [29]. Finally, other types of sensors are included each in less than 12% of the reviewed investigations.

TABLE II
PERCENTAGE OF SENSORS USAGE IN STUDIES

Sensor	Amount	
	Frequency	Percentage
CAM	25	96.15%
IMU	21	80.77%
LRF	20	76.92%
CO2	19	73.08%
TC	17	65.38%
MC	14	53.85%
TS	8	30.77%
US	3	11.54%
GPS	3	11.54%
CS	3	11.54%
AS	2	7.69%
IS	1	3.85%
GNSS	1	3.85%
HS	1	3.85%

Note: CAM: camera (include RGB camera, RGB-D camera, IP camera, stereo camera and other types of cameras except for the thermal ones), IMU: inertial measurement unit, LRF: laser rangefinder sensor, CO2: CO2 sensor, TC: thermal camera, MC: microphone, TS: temperature sensor, US: ultrasonic sensor, GPS: GPS sensor, CS: compass sensor, AS: accelerometer sensor, IS: inclinometer sensor, GNSS: GNSS sensor, HS: humidity sensor.

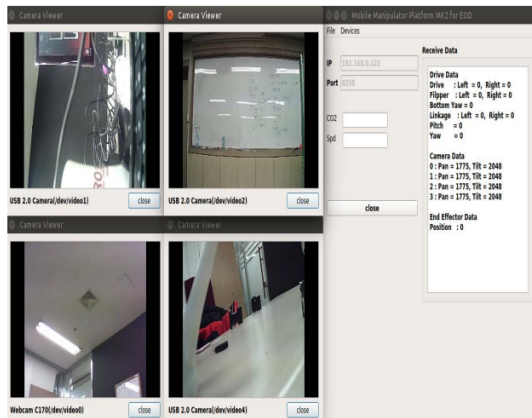

Fig. 1. Cameras for teleoperation by MIT Robotics Team [32].

B. Control Method

In this area, a review of the control method used to drive the rescue robot is performed, according to the research reviewed 3 methods were identified. The autonomous method, the hybrid method, and the manual method. The first one drives the robot using spatial identification algorithms and images to move in a place fulfilling certain functions. The second one uses teleoperation where the robot through artificial vision detects some tags that define its actions and its movement is given with the use of a joystick controller. The last one only navigates and actuates elements using the joystick controller.

As is shown in Fig. 1, all these methods are supported by a command station to analyze the robot’s cameras and sensors.

In Table III, the method that stands out the most is the hybrid method with 76.92% of the research conducted, while the manual method is used by 19.23% and only 3.85% could have an autonomous method for the most part.

TABLE III
PERCENTAGE OF CONTROL METHOD USAGE IN STUDIES

Control Method	Amount	
	Frequency	Percentage
H	20	79.92%
M	5	19.23%
A	1	3.85%

Note: H: Hybrid, M: Manual, A: Autonomous.

Fig. 2. Schematic of the actuators used by the VRU team [29].

C. Actuators

In this area, a review of the actuators used to generate the robot’s movements over the environment is performed. These actions can be classified into two types: locomotion and manipulative movement.

Table IV shows 8 different types of actuators found in the 26 papers reviewed. Which, DC motors are the most used for the locomotion of the robot with 69.23% since their operation is optimal for the rotation of gears, pulleys, or wheels.

In addition, 57.69% include DC Servomotors, which allow having a more specific angular movement for the manipulator movement. Also, 23.08% include BLDC motors for the robot movement since it has a fast response, high efficiency, and speed and 11.54% have DC Servomotors in the locomotion, which are more used for other purposes in robots, as seen above. While for robot arm joints 7.69% of robots have electric cylinders and a DC motor. And only 3.85% of robot arms have an AC servo motor and mini AC servo motor. The actuators are located on the robots as shown in the schematic diagram in Fig. 2

TABLE IV
PERCENTAGE OF ACTUATORS USAGE IN STUDIES

Actuators	Amount	
	Frequency	Percentage
DML	18	69.23%
SDM	15	57.69%
BML	6	26.92%
SDL	3	11.54%
NS	3	11.54%
CEM	2	7.69%
DMM	2	7.69%
SASM	1	3.85%
SAMM	1	3.85%

Note: BML: BLDC Motor for locomotion, SDL: Servo DC for locomotion, DML: DC Motor for locomotion, SASM: AC Servo Actuator Synchronous for manipulator, SAMM: Servo Actuator mini for manipulator, SDM: Servo DC Motor for manipulator, CEM: electric cylinder for manipulator, DMM: DC Motor manipulator.

Fig. 3. 6 DoF robotic arm of the MRL team [28].

D. Degrees of freedom (DoF)

In this area, a review of the degrees of freedom of exoskeleton prototypes is freedom that the robot arms of the rescue robots have. The robot arm is a device used as a manipulator that helps to mobilize elements and also allows holding objects to open doors or move levers. As shown in Table V, the largest number of robots according to the studies reviewed, with a percentage of 55.56%, have 6 DoF, as shown

in Fig. 3. In second place, robots with 5 DoF have a 22.22%, followed by a 16.67% with 7 DoF. Furthermore, robot arms that have 3 DoF have a percentage of 5.56%. While 23.08% have no robot arm. Besides, no robot arms with 4, 2, or 1 DoF were found.

TABLE V
PERCENTAGE OF DOF OF ROBOT ARM IN STUDIES

Degrees of freedom	Amount	
	Frequency	Percentage
9	1	3.85%
8	1	3.85%
7	3	11.54%
6	10	38.46%
5	4	15.38%
3	1	3.85%
0	6	23.08%

Fig. 4. Main Control Unit of ARKA robot, from the MRL Team [28].

E. Computing and Control Units

This area summarizes the main computing and control units of each robot. As shown in Table VI, the General computer units such as PCs, motherboards, mini computers or laptops, represent 65.38% of the computing and control units applied to robots. ARM based microcontrollers and controller boards have been used 38.46% of the time, while AVR based microcontrollers and boards followed closely behind with a percentage of 30.77%. On the other hand, 26.92% of the robots have used tiny computers such as NVIDIA Jetson TX2, Raspberry Pi or Single Board Computers, whereas other units not listed in Table VI represent 23.08% . PIC microcontrollers have been used less frequently, thus having 11.54% of appearances. Finally, Industrial PCs were the least applied units in the selected articles, with one appearance that represents the 3.85% of the times used. As presented in Fig. 4, the main control unit of the MRL Team robot, ARKA, is ARM based [28].

TABLE VI
PERCENTAGE OF COMPUTING AND CONTROL UNITS USAGE IN STUDIES

Computing and Control Units	Amount	
	Frequency	Percentage
GC	17	65.38%
ARM	10	38.46%
AVR	8	30.77%
TC	7	26.92%
OTH	6	23.08%
PIC	3	11.54%
IPC	1	3.85%
NS	2	7.69%

Note: GC: General Computer (include Mini Computers, Laptops, Motherboards, PCs, and other types of computing units like these), TC: Tiny Computer (include NVIDIA Jetson TX2, Raspberry Pi, Single Board Computers and other types of computers like these), ARM: ARM Based microcontrollers and controller boards, AVR: AVR based microcontrollers and boards, PIC: PIC microcontrollers, IPC: Industrial PC, OTH: other computing or control units, NS: Not specified.

F. Technology Readiness Level

In this area, a review is made of the level of development that the studies have reached. For a purpose of standardization, the present paper uses the Technology Readiness Levels to classify the advance of each investigation into 9 categories described in [41]. TRL 1 level corresponds to the observation of the principles in the study. TRL 2 and 3 refer to the formulation and the experimental proof of the technology concept respectively. TRL 4 is related to the validation of the components in a first basic prototype. TRL 5 and 6 correspond to the validation of an advanced prototype in a relevant environment like the RoboCup Rescue arenas. TRL 7 is related to the demonstration of the robot in a live environment like fire departments disaster trials or mines. Finally, TRL 8 and 9 refer to a successful proven system in operational environments

As is shown in Table VII, TRL 6 is the most common level with 42.31 %. This is due to the large amount of RoboCup Rescue teams included in this review. A consideration that in general represents that the prototypes had been validated in environments similar to the Robocup Rescue arenas like the one shown in Fig. 5. These are grounds that have different obstacles like stairs, ramps, gravel terrains or readiness tests. In addition, it can be seen that 73.07% of the review studies have an advanced prototype with a TRL of 5 or more.

TABLE VII
PERCENTAGE OF STUDIES BASED ON TRL

Technology Readiness Level	Amount	
	Frequency	Percentage
TRL 2	1	3.85%
TRL 3	3	11.54%
TRL 4	3	11.54%
TRL 5	4	15.38%
TRL 6	11	42.31%
TRL 7	4	15.38%

IV. CONCLUSION

The development technology is having these days is making possible for a lot of difficulties in the world to be in the way of being solved. In a relatively new field like robotics, competition with funding opportunities as well as support to research departments made a great motivation to a lot of the teams who submitted the studied works in this article to create a path for new people to continue creating new designs for rescue robots for emergencies like natural disasters. This paper was intended to give a basic knowledge for interested individuals on how to begin in the creation of rescue robots, relaying in analysis of the trending components like sensors, computing and control units as well as Technology Readiness Level of each work.

It can be observed that most of the realized robots are still manipulated by humans using teleoperation, however it is getting closer and closer to being able to realize autonomous systems. For the operation, the cameras, the IMU sensors and the LRF sensors are the most common measurement devices. In addition, the locomotion of the robot, DC motors are used in most of the studies analyzed because the access to them and their use is more optimal for this task. While the configuration with 6 degrees of freedom is the most used in the manipulator of the studied robots. Also, the majority of investigations are in the stage of prototype validation in relevant and live environments.

Finally, the next step of our team will be the usage of these founded patterns in the investigation and construction of a land-mobile robot for search and rescue to participate in the 2023 edition of the RoboCup Rescue Robot League.

Abstract—Diesel-engine generators can operate with variable speed to enhance their efficiency over a wide range of loading conditions. Constant-parameter voltage-behind-reactance (CPVBR) models have been developed for efficient simulation of three-phase wound-field synchronous generators (WFSGs). The CPVBR models use fixed branches for interfacing (without any incompatibility, e.g., the need for snubbers, etc.) and are not required to update their interfacing circuit in every time step of the simulation. This paper presents the application of the CPVBR model of a WFSG for efficient simulation of a variable-frequency/speed diesel-engine generator-rectifier system. Simulation studies are carried out in MATLAB using PLECS toolbox to verify the computational performance of the CPVBR model. It is demonstrated that the CPVBR model achieves superior computational performance (without compromising the accuracy) compared to the built-in models of the toolbox, i.e., $qd0$, stator VBR, and full VBR models.

Keywords—Constant-parameter voltage-behind-reactance (CPVBR) model, diesel-engine generator (DEG), numerical efficiency, variable-speed, wound-field synchronous generator (WFSG).

I. INTRODUCTION

Diesel-engine generators (DEGs), aka gensets, are reliable sources for supplying energy for example in microgrids and remote residential areas. They are also considered as emergency back-up power supplies in hospitals [1], data centers [1], etc. DEGs usually operate with constant speed to have fixed nominal frequency at their terminal [2]. It has been demonstrated in the literature that the constant-speed regime hinders the efficiency of DEGs, and instead, adjusting the speed of the machine according to the system load level can increase their efficiency by reducing the fuel consumption [2], [3]. Hence, multiple control methods have been addressed in [1]–[3] to realize the variable-speed operation for DEGs.

In most studies involving DEGs [4], [5], the model for the generator is either in the form of the conventional $qd0$ model [6], or chosen from the available built-in models in simulation programs [7]–[9]. In the $qd0$ model, the generator is implemented as voltage-controlled current sources wherein the stator voltages and currents are considered as the inputs and the

outputs of the model, respectively [10]. This specific input-output relationship requires the usage of fictitious snubbers across the machine terminals to provide the necessary voltages for the model when the machine is connected to an inductive network or a power-electronic converter [10]. These artificial snubbers cause inevitable numerical stiffness and errors and may degrade the computational performance [10].

To address the interface incompatibility of the $qd0$ model, the coupled-circuit phase domain (CCPD) models have been developed which achieve direct interfacing capability (i.e., no need for snubbers, etc.) [11]. However, due to having rotor-position-dependent inductance matrices, the CCPD models are computationally expensive and slow [10], [12]. The voltage-behind-reactance (VBR) models have been proposed [12]–[14] to improve the computational performance by reducing the size of the rotor-position-dependent inductance matrices (compared to the CCPD model) into only one matrix, with the size of $n \times n$ with n being the number of machine phases. Although the CCPD and VBR models lead to a compatible interface with the rest of the network, they result in variable interfacing inductances which cause several simulation challenges. First, modeling of variable inductances is not readily available in all commercial simulation packages (e.g., PLECS [9] allows variable inductance but Simscape Electrical [8] does not). Secondly, the feature of variable-parameter interfacing forces the simulation solver to update the system matrix at each time-step which is computationally costly. To overcome these issues, constant-parameter VBR (CPVBR) models have been proposed in [15], [16] to not only achieve a direct interface similar to the VBR and CCPD models, but also to make the interfacing circuit constant for faster simulations [16].

This paper investigates the numerical performance of the CPVBR model presented in [16] for modeling the DEGs with variable speed/frequency operation, compared to the $qd0$ model and two VBR models [13], [14] available in the PLECS toolbox. It is demonstrated that the CPVBR model benefits from simplicity of implementation and low computational cost with acceptable accuracy compared to the existing counter-part models built in the PLECS library.

II. VBR FORMULATION FOR A THREE-PHASE WOUND-FIELD SYNCHRONOUS MACHINE

For the purpose of this paper, a conventional three-phase wye-connected synchronous machine with sinusoidal distribution of stator windings is assumed here. The machine has N damper windings on the q -axis and M damper windings in addition to one field winding on the d -axis. For having a consistent formulation as [6], [16], the motor convention is used, i.e., the positive direction for the stator currents is into the windings. All the variables are considered to be referred to the stator side. It should be noted that all the formulations are derived from the machine model initially expressed in the $qd0$ rotor reference frame [6], [16] as illustrated in Fig. 1. Also, for the purpose of notational consistency with [16], the vector of three-phase variables is denoted by $\mathbf{f}_{abc} = [f_a \ f_b \ f_c]$, and the vector of $qd0$ variables is denoted by $\mathbf{f}_{qd} = [f_q \ f_d]$. It should be noted that the zero-sequence variables are not considered here.

A. Variable-Parameter VBR

To set the stage for the CPVBR formulation, the derivation of the variable-parameter VBR model is presented first. The VBR formulation was first introduced in [12] by considering the rotor flux linkages as state variables leading to a current-input-voltage-output model. The full-order VBR model has the following stator interface [12], [16]

$$\mathbf{v}_{abc} = r_s \mathbf{i}_{abc} + p[\mathbf{L}'_{abc}(\theta_r) \mathbf{i}_{abc}] + \mathbf{e}''_{abc}, \quad (1)$$

where $\mathbf{L}'_{abc}(\theta_r)$ is the rotor-position-dependent subtransient inductance matrix as defined in [12], and \mathbf{v}_{abc} and \mathbf{i}_{abc} are stator voltages and currents, respectively. The subtransient voltages \mathbf{e}''_{abc} are as [12], [16]

$$\mathbf{e}''_{abc} = \mathbf{K}_s^{-1}(\theta_r) \mathbf{e}''_{qd}, \quad (2)$$

$$e''_q = \omega_r \lambda''_d + \sum_{j=1}^N \left(\frac{L''_{mq} r_{kqj}}{L_{lkqj}^2} (\lambda_{mq} - \lambda_{kqj}) \right), \quad (3)$$

$$e''_d = -\omega_r \lambda''_q + \sum_{j=1}^M \left(\frac{L''_{md} r_{kdj}}{L_{lkdj}^2} (\lambda_{md} - \lambda_{kdj}) \right) + \frac{L''_{md}}{L_{lfd}} v_{fd} + \frac{L''_{md} r_{fd}}{L_{lfd}^2} (\lambda_{md} - \lambda_{fd}), \quad (4)$$

where $\mathbf{K}_s^{-1}(\theta_r)$ is the inverse of Park's transform [6]; The resistances and leakage inductances of damper windings on the q - and d -axis are denoted by (r_{kqj}, L_{lkqj}) and (r_{kdj}, L_{lkdj}) , respectively. Similarly, the resistance and the leakage inductance of the field winding is specified by (r_{fd}, L_{lfd}) and its voltage is shown by v_{fd} . The subtransient magnetizing inductances L''_{mq} and L''_{md} in (3)–(4) are defined as [12], [16]

$$L''_{mq} = \left(\frac{1}{L_{mq}} + \sum_{j=1}^N \frac{1}{L_{lkqj}} \right)^{-1}, \quad (5)$$

Fig. 1. The equivalent $qd0$ model of a three-phase synchronous machine expressed in rotor reference frame shown for: (a) q -axis, and (b) d -axis.

$$L''_{md} = \left(\frac{1}{L_{md}} + \frac{1}{L_{lfd}} + \sum_{j=1}^M \frac{1}{L_{lkdj}} \right)^{-1}, \quad (6)$$

where L_{mq} and L_{md} are the q - and d -axis magnetizing inductances, respectively. The subtransient flux linkages are also defined as

$$\lambda''_q = L''_{mq} \left(\sum_{j=1}^N \frac{\lambda_{kqj}}{L_{lkqj}} \right), \quad (7)$$

$$\lambda''_d = L''_{md} \left(\frac{\lambda_{fd}}{L_{lfd}} + \sum_{j=1}^M \frac{\lambda_{kdj}}{L_{lkdj}} \right), \quad (8)$$

and the magnetizing fluxes are obtained as

$$\lambda_{mq} = L''_{mq} \left(i_{qs} + \sum_{j=1}^N \frac{\lambda_{kqj}}{L_{lkqj}} \right), \quad (9)$$

$$\lambda_{md} = L''_{md} \left(i_{ds} + \frac{\lambda_{fd}}{L_{lfd}} + \sum_{j=1}^M \frac{\lambda_{kdj}}{L_{lkdj}} \right). \quad (10)$$

Subsequently, the state derivatives of the VBR model are represented as

$$p\lambda_{kqj} = -\frac{r_{kqj}}{L_{lkqj}} (\lambda_{kqj} - \lambda_{mq}); \quad j = 1, \dots, N, \quad (11)$$

$$p\lambda_{kdj} = -\frac{r_{kdj}}{L_{lkdj}} (\lambda_{kdj} - \lambda_{md}); \quad j = 1, \dots, M, \quad (12)$$

$$p\lambda_{fd} = -\frac{r_{fd}}{L_{lfd}} (\lambda_{fd} - \lambda_{md}) + v_{fd}, \quad (13)$$

where p is the Heaviside's operator for the derivative with respect to time. The mechanical subsystem is formulated similar to the $qd0$ model and is expressed as

$$p\theta_r = \omega_r, \quad (14)$$

$$p\omega_r = T_e - T_m, \quad (15)$$

where θ_r and ω_r are rotor position and angular electrical speed; T_m is the mechanical torque and the electromagnetic torque T_e is obtained by

$$T_e = \frac{3P}{4} (\lambda_{md} i_{qs} - \lambda_{mq} i_{ds}), \quad (16)$$

where P denotes the number of machine poles. Given the variable nature of the interfacing inductances in (1), the network solver has to re-calculate and re-construct the differential equations of the system at each time-step which significantly increases the model computational burden [15]. Additionally, modeling variable-parameter inductances is not available in many simulation packages [8].

B. Constant-Parameter VBR

To achieve a compatible and constant-parameter interface, multiple versions of CPVBR model were proposed in [16]. The main idea of all such models is to transfer the varying variables in the interfacing circuit to the subtransient voltages (i.e., \mathbf{e}''_{abc}) and represent the interfacing branches with constant RL elements. As discussed in [16], after moving the varying parameters to the subtransient voltages, the decoupled constant-interface circuit (assuming a wye (Y) connection in the stator windings and having access to the neutral) can be written as

$$\mathbf{v}_{abcs} = r_D \mathbf{i}_{abcs} + L_D p \mathbf{i}_{abcs} + L_0 p i_{ng} + \mathbf{e}''_{abc}, \quad (17)$$

where

$$r_D = r_s, \quad (18)$$

$$L_D = L_{ls} + L''_{md}, \quad (19)$$

$$L_0 = -\frac{1}{3} L''_{md}, \quad (20)$$

and i_{ng} is the current of the neutral path of the machine. The subtransient voltages in (17) in the qd frame are defined as

$$e''_q = \omega_r \lambda''_d + p(L''_q - L''_d) i_{qs} + \sum_{j=1}^N \left(\frac{L''_{mq} r_{kqj}}{L''_{lkqj}} (\lambda_{mq} - \lambda_{kqj}) \right), \quad (21)$$

$$e''_d = -\omega_r (L''_q - L''_d) i_{qs} + \sum_{j=1}^M \left(\frac{L''_{md} r_{kdj}}{L''_{lkdj}} (\lambda_{md} - \lambda_{kdj}) \right) - \omega_r \lambda''_q + \frac{L''_{md}}{L''_{lfd}} v_{fd} + \frac{L''_{md} r_{fd}}{L''_{lfd}} (\lambda_{md} - \lambda_{fd}), \quad (22)$$

where

$$L''_{qq} = L_{ls} + L''_{mq}, \quad (23)$$

$$L''_{dd} = L_{ls} + L''_{md}. \quad (24)$$

As noted in (21), this formulation needs the value of the derivative of stator current at the present time which has to be approximated by either a high-pass filter or other numerical methods to prevent the formulation of a nonproper state model [16]. As demonstrated in [16], this approximation leads to a

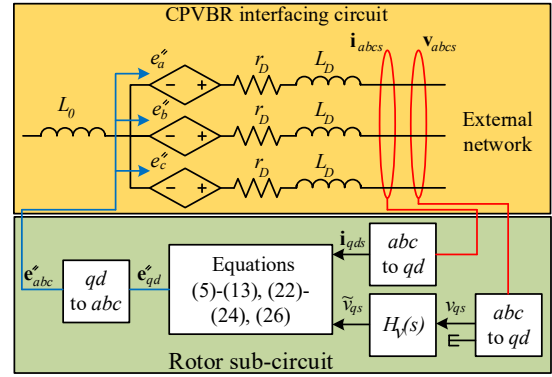

Fig. 2. Implementation of the CPVBR model using a low-pass filter $H_v(s)$ for relaxation of the algebraic loop.

larger error compared to the other following implementation where alternatively, the current derivative term is firstly obtained based on system inputs and states as [16]

$$p i_{qs} = \frac{1}{L''_q} (v_{qs} - r_s i_{qs} - \omega_r L''_d i_{ds} - \omega_r \lambda''_d) - \frac{1}{L''_q} \sum_{j=1}^N \left(\frac{L''_{mq} r_{kqj}}{L''_{lkqj}} (\lambda_{mq} - \lambda_{kqj}) \right). \quad (25)$$

Then, the new q -axis subtransient voltage can be written by substituting (25) in (21) as [16]

$$e''_q = \frac{L''_d}{L''_q} \left\{ \omega_r (\lambda''_d - (L''_q - L''_d) i_{ds}) + \sum_{j=1}^N \left(\frac{L''_{mq} r_{kqj}}{L''_{lkqj}} (\lambda_{mq} - \lambda_{kqj}) \right) \right\} + \frac{L''_q - L''_d}{L''_q} (v_{qs} - r_s i_{qs}). \quad (26)$$

Using (26), the need for approximating the derivative of stator current is eliminated. However, the presence of the stator voltage term v_{qs} in (26) forms an algebraic feedthrough in the model. Solving this algebraic loop requires iterative solutions of nonlinear equations, and hence increases the computational cost of the model. Relaxation of this algebraic loop can be achieved by using a low-pass filter as [16]

$$H_v(s) = \frac{p_0}{s + p_0}, \quad (27)$$

where $-p_0$ is the pole of the filter. The selection of the filter pole is a trade-off between the accuracy and stiffness of the system. As the magnitude of the pole of the low-pass filter increases, the accuracy improves at the cost of making the system stiffer. The systematic approach presented in [17] can be adopted to tune the pole of the filter for the desired accuracy.

It should be noted that the rest of the formulations of the CPVBR model are similar to that of variable-parameter VBR including the mechanical subsystem (14)–(16) and rotor flux linkages dynamics (11)–(13). A block-diagram of the implementation of the CPVBR model is depicted in Fig. 2. As seen, controlled voltage sources in series with decoupled and

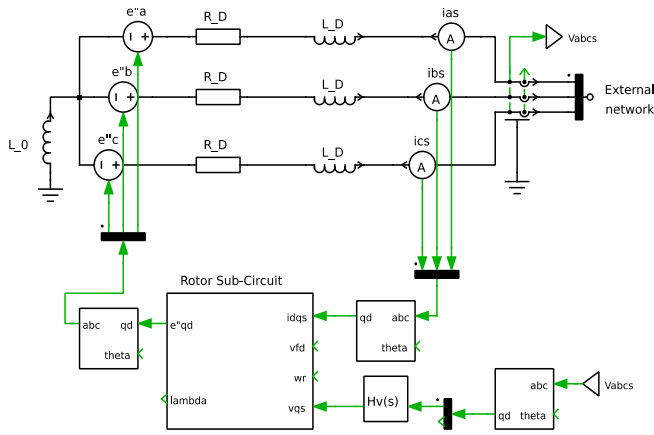

Fig. 3. Implementation of the CPVBR model in PLECS using conventional library components.

constant series resistances and inductances are used for interfacing with the external network. The implementation of the CPVBR model in PLECS environment is also illustrated in Fig. 3 using its conventional library components. It is noted that for a clear presentation, the mechanical subsystem is not shown in Fig. 3.

III. COMPUTER STUDIES

Here, the numerical performance of the CPVBR model is compared with the models available in the PLECS library [9]. Presently, PLECS has three built-in models for synchronous machines, i.e., *qd0*, stator VBR (SVBR) [13], and full VBR (FVBR) models [14]. As stated in [14], the two SVBR and FVBR models are algebraically equivalent and both result in variable-parameter interface which hinders their computational performance. The only difference between these two models is that the field sub-circuit in SVBR needs artificial snubbers to interface with an inductive network, whereas the FVBR model has a direct interface capability both in stator and field windings.

For the purpose of this paper, the DEG-rectifier system shown in Fig. 4 is implemented in MATLAB/Simulink using PLECS toolbox. Here, a three-phase salient wound-field synchronous generator (WFSG) is considered which supplies a resistive load through a six-pulse diode rectifier. All the parameters of the system are summarized in the Appendix. The voltage control loop consists of a PI controller and an actuator (modeled as a transfer function) which regulates the rectifier dc voltage at 1.0 pu by adjusting the voltage applied to the field winding. Also, to limit the voltage ripple introduced by the diode-bridge, a large LC filter is used at the output of the rectifier as shown in Fig. 4. To realize the variable speed operation of the generator and obtain the efficient power-speed trajectory, a considerable amount of data of the engine and the generator including saturation is needed [2]. Here, without loss of generality, it is assumed that the reference speed is changed from two arbitrary values at the moment of load change. In this regard, the regulation of the rotor speed around the set-point is achieved by the speed control loop consisting of another PI controller and an actuator which is modeled as a transfer function. A simplified diesel engine is also used similar to [4], which is modeled as a time-delay unit as shown in Fig. 4. Three fictitious snubbers are also required across the machine terminal in the *qd0* model. As the machine terminal voltages are regulated at the nominal value, the snubbers draw the same amount of

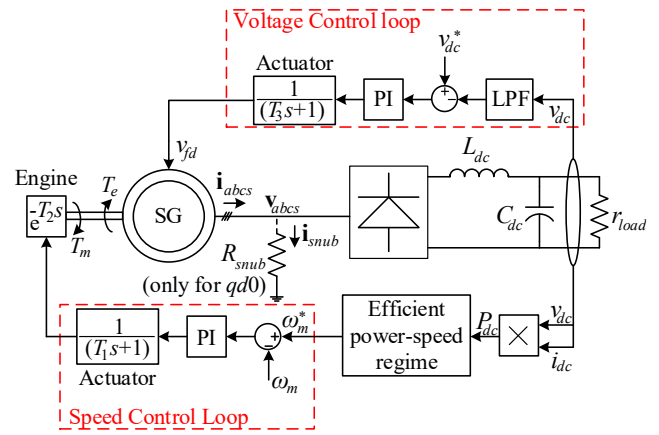

Fig. 4. Variable-speed DEG-rectifier system consisting of voltage and speed control loops supplying a dc load.

current at all operating points. Therefore, as the loading of the machine decreases from the nominal operating point, a larger portion of stator currents i_{abc} will be formed by snubbers currents i_{snub} . Hence, in different operating points, different values of snubbers are required to maintain the stator current error in an acceptable range (i.e., $\approx 1\%$). In this study, the snubbers are chosen to be 350 pu to ensure that the stator current error in the *qd0* model stays in the proximity of 1% for the considered loading conditions. Also, the pole of the low-pass filter required for CPVBR model is chosen to be -4300 , corresponding to the switching frequency of 360 Hz because of the six-pulse rectification [17]. This way, the solutions error of the CPVBR model remains in the acceptable range of 1%.

For consistency, all the subject models are run using MATLAB's stiff solver *ode23tb* with maximum and minimum time steps of 1ms and $0.01\mu s$, respectively. The absolute and relative errors are chosen to be 10^{-4} . The simulations studies are performed on a personal computer with Intel® Core™ i7-10750H CPU @ 2.60 GHz processor. Since the FVBR formulation includes no approximations/snubbers in its implementation, it is chosen as the reference model. The reference solution is obtained with the maximum time-step of $1\mu s$ using the same *ode23tb* solver.

In similar studies for comparing different models of ac machines [18], [19] in the presence of power-electronic converters, two different approaches are commonly adopted. In one approach, the speed of the machine is considered as an input to the system, e.g., in wind turbine studies. This way, the same speed is considered for all models which eliminates the need for solving the mechanical subsystem and excludes the impact of its error on simulation results [18]. The other alternative is the consideration of a grid-connected application where the grid provides a point of reference for the system [19]. These considerations cause all the results from different models to be synchronized, and a fair comparison can be drawn between all implementations by calculating the 2-norm error [16]. A similar approach is adopted here by inserting the speed profile obtained by the reference model into all subject models, and consequently, eliminating the impact of the error introduced by the mechanical subsystem in the simulation results. This approach is justifiable since the major differences between all the subject models originate from the properties of the electrical subsystem; and neglecting the impact of the error of the

Fig. 5. Transient response of several variables when a load rejection of 0.25 pu and step down in reference speed occur at $t = 0.5$ s: (a) rectifier dc voltage, (b) dc load power, (c) electromagnetic torque, (d) rotor speed, and (e) stator phase- a current.

Fig. 6. Magnified view during the moment of transient: (a) electromagnetic torque in Fig. 5(c), and (b) stator phase- a current in Fig. 5(e).

mechanical subsystem does not affect the final conclusions about the numerical performance of the subject models.

For the considered transient study, the system in Fig. 4 is simulated for 2.5 seconds. The simulation results for the selected variables are provided in Fig. 5. As shown in Fig. 5(a)–(d), the system initially operates in the steady-state where the generator is supplying a load of 0.5 pu at the speed of 0.78 pu while the dc voltage is maintained constant at 1.0 pu. Then at $t = 0.5$ s, a 0.25 pu load rejection occurs (as shown in Fig. 5(b)) which leads to an immediate 0.08 pu over-voltage across the load, and it is regulated back to 1.0 pu by the control loop as shown in Fig. 5(a). At the moment of load change, the reference speed is also stepped down to 0.68 pu which is assumed to be the fuel-efficient speed according to the new loading condition. The governor adjusts the rotor speed to the new set point according to Fig. 5(d). As can be seen in Fig. 5(c), the electromagnetic torque profile follows the same transient as the dc power profile and decreases suddenly at the moment of load rejection. The stator phase- a current is also affected by the decrease in the load

Fig. 7. Magnified view of variables in Fig. 6: (a) electromagnetic torque, and (b) stator phase- a current.

TABLE I. COMPARISON BETWEEN THE COMPUTATIONAL PERFORMANCE OF SUBJECT MODELS

Model	2-norm error		No. of steps (<i>ode23tb</i>) (<i>ode45</i>)	CPU time (<i>ode23tb</i>) (<i>ode45</i>)
	Torque (T_e)	Stator current (i_{as})		
<i>qd0</i>	1.05%	1.04%	53,918	5.71 s
			1,484,733	103.78 s
FVBR	0.03%	0.03%	41,928	10.92 s
			31,947	8.09 s
SVBR	0.02%	0.03%	42,808	6.48 s
			28,717	6.22 s
CPVBR	0.13%	0.15%	43,102	3.56 s
			35,162	3.25 s

as depicted in Fig. 5(e). To provide a more detailed snapshot of the considered transient about the moment of load rejection, the magnified view of electromagnetic torque and stator phase- a current are demonstrated in Fig. 6.

To qualitatively compare the results of the subject models with respect to the reference model, a further magnified view of the electromagnetic torque and the stator current are shown in Fig. 7. It is observed in Fig. 7 that the VBR models and the CPVBR model predicted the current and torque with great accuracy contrary to the *qd0* model which has a visibly large error due to the interfacing snubbers. For a quantitative comparison between the accuracy of the subject models, the cumulative 2-norm errors of the stator phase- a current and the electromagnetic torque for the considered transient study are calculated and provided in Table I. As observed in Table I, both FVBR and SVBR obtained the torque and current with very small error ($\sim 0.03\%$) which is the result of having a direct interface with the network. The *qd0* model has around 1% error both in torque and current due to having fictitious snubbers. Meanwhile, the CPVBR model obtained an acceptable (i.e., less than 1%) error in torque (0.13%) and in stator current (0.15%).

The comparison of the computational performance between the subject models using *ode23tb* (stiff) and *ode45* (non-stiff) solvers are also included in Table I. As seen in Table I, the CPVBR model achieves the fastest simulations compared to

other models. Specifically, when using the stiff solver *ode23tb*, the CPVBR model allows 38%, 67%, and 45% faster simulation compared to the *qd0* (3.56s vs. 5.71s), FVBR (3.56s vs. 10.92s), and SVBR (3.56s vs. 6.48s) models, respectively. It is worth mentioning that, as a result of having constant inductances, the *qd0* model was faster than the FVBR and SVBR models which have variable-inductances in their interface, although the *qd0* model needs more time steps (i.e., 53,918 vs. 41,928 and 42,808, respectively). It is noted that the number of steps used by the CPVBR model is on the same order as the VBR models (i.e., 43,102). Using the non-stiff solver *ode45*, the *qd0* model takes significantly more time (103.78s) and computational resources (1,484,733 time steps) due to having large snubbers across the machine terminals to maintain the acceptable accuracy. Meanwhile, the CPVBR outperforms all other models by achieving 97%, 60%, and 48% efficiency in CPU time compared to the *qd0* (3.25s vs. 103.78s), FVBR (3.25s vs. 8.09s), and SVBR models (3.25s vs. 6.22s), respectively. It should be noted that the number of time steps of the two VBR models (31,947 for FVBR and 28,717 for SVBR) and the CPVBR model (35,162) models are significantly fewer than the time steps used by the *qd0* model.

IV. CONCLUSION

In this paper, the application of the previously-introduced CPVBR model has been investigated for simulation of variable-speed diesel-engine generators (DEGs) consisting of wound-field synchronous generators (WFSGs). Due to having a current-input-voltage-output model, CPVBR model can be connected to power-electronics-based networks without any snubbers contrary to the conventional *qd0* model. Also, as a result of having a constant-parameter interfacing circuit, it is computationally more efficient than other variable-parameter VBR models. The computational advantages of the CPVBR model were validated through offline simulation studies. It was verified that the CPVBR model could achieve the fastest CPU time compared to the available built-in models of synchronous machines in PLECS for simulation of DEGs while having acceptable error of about 0.1~0.2%.

APPENDIX

Three-phase WFSG parameters [8]:

Rated ac voltage: 2.4 kV, rated dc voltage: 3.24 kV, rated power 3.125 MVA, poles: 4, rated speed: 1800 rpm, inertia time-constant: 1.07s.

$r_s = 0.0036$ pu, $X_{ls} = 0.052$ pu, $X_{md} = 1.508$ pu, $X_{mq} = 1.008$ pu, $r_{kd} = 0.0616$ pu, $X_{lkq} = 0.1532$ pu, $r_{fd} = 0.00245$ pu, $X_{lfd} = 0.2911$ pu, $r_{kd} = 0.0159$ pu, $X_{lkd} = 0.2563$ pu.

DC filter parameters:

$L_f = 1$ mH, $C_f = 10$ mF.

Voltage controller parameters [20]:

$K_p = 500$, $K_I = 10$, $T_3 = 0.02$ s.

Speed controller parameters [4]:

$K_p = 6.09$, $K_I = 5.9$, $T_1 = 0.1$ s, $T_2 = 0.1$ s.

Abstract—The problem of detecting types of DDOS attacks in large-scale networks is considered. The complexity of detection is explained by the presence of a large number of connected and diverse devices, the high volume of incoming traffic, the need to introduce special restrictions when searching for anomalies. The technology of developing information security models using data mining (DM) methods is proposed. The features of machine learning of DM algorithms are related to the choice of methods for preprocessing big data (Big Data). A technique for analyzing the structure of relations between types of DDOS attacks has been developed. Within the framework of this technique, a procedure for pairwise comparison of data by types of attacks with normal traffic is implemented. The result of the comparison is the stability of features, the values of which are invariant to the measurement scales. The analysis of the structure of relations by grouping algorithms was carried out according to the stability values on the determined sets of features. When forming the sets, the stability ranking was used. For classification, various existing methods of machine learning are analyzed.

Index Terms—types of DDOS attacks, Machine Learning, classification, informative features

I. INTRODUCTION

A DDoS attack is the actions of intruders aimed at disrupting the performance of a company's infrastructure and client services. To carry out a DDoS attack, hackers use the so-called botnet networks, which create an avalanche-like increase in requests to an online resource in order to increase the load on it and disable it. Protecting a system from DDOS attacks is about detecting and preventing an attack before it affects the end user. At the same time, detection should be performed with a high attack detection rate and a low false positive rate [1]. Recently, data mining has become an important component to prevent DDOS attacks.

DDoS attack detection methods play a very important role in protecting the security of computer networks. However, the existing methods of detecting DDoS attacks based on the flow face a significant time delay and are not common for different types of DDOS attacks with different speeds [2], [30]–[32]. To fill this gap in research, a quick approach to detecting DDOS attacks based on informative signs is proposed.

Machine learning can be defined as the ability of a program (system) to learn in order to improve its performance

relative to a given task for a certain time [13], [14]. Machine learning methods focus on building a system that improves its performance based on previous results, that is, machine learning methods have the ability to change their execution strategy based on newly acquired knowledge [3]. This feature is the main advantage of this approach, the main disadvantage is resource intensity. In many cases, machine learning methods coincide with statistical methods and data mining methods.

The main prerequisite for creating machine learning classifiers is the effective and efficient detection of DDOS attacks. However, their achievement of machine learning models to distinguish between DDOS attacks depends on how to choose appropriate and minimum attributes in network flows [4], [33]. A method for the formation of a new feature space from heterogeneous (quantitative and nominal) features is proposed [8], [34]–[37]. The formation process is based on a nonlinear transformation of features using the functions of belonging objects to classes [6]–[8].

The purpose of the work is to review existing algorithms for classifying data based on machine learning, evaluate their effectiveness and develop a method for detecting network DDOS attacks using machine learning algorithms [5]. Its achievement involves solving the following main tasks: selection of a training data set, data preprocessing, formation of a feature space, justification of the choice of a machine learning model, quality assessment and testing of the model in real conditions.

DDOS attack detection can be viewed as a classification problem [6], [7]. It is required to classify objects as representing a certain type of attacks and normal traffic. Classification is one of the 5 standard types of patterns used in data mining [11], [12]. Its main purpose is to predict whether new objects belong to classes [9], [10].

In order to achieve maximum effect in forecasting both accuracy and resource costs, the tasks of detecting hidden patterns through an informative feature are considered. In this paper, an experimental comparison of various machine learning models used to detect computer attacks is carried out. The training and testing of models was performed on one of the most relevant data sets, CICDDOS2019, was selected among the available public datasets. Previously, an analysis of the significance of the features was carried out and a reduction in the dimension of the feature space was performed.

II. CICDDOS2019 DATASET. PROBLEM STATEMENT

The data set contains 12 different types of DDoS attacks, which were described using the TCP/UDP protocols. Classification of attacks in the data set is made in terms of attacks based on exploitation and reflection. The main purpose of forming the set was to use it for training and testing. Attacks identified as UDP, SNMP, NetBIOS, LDAP, TFTP, NTP, SYN, WebDDoS, MSSQL, UDP-Lag, DNS, and SSDP are included as attack types in the training. As a separate set, testing data was generated, which contains 7 types of DDoS attacks: SYN, MSSQL, UDP-Lag, LDAP, UDP, PortScan and NetBIOS. PortScan attack data is not included in the test and training set for internal evaluation of the detection system. The data description contains 88 quantitative and qualitative characteristics of the flow, which were obtained using CICFlowMeter tools. The CICDDoS2019 data is available on the website of the Canadian Cyber Security Institute. Brief information about the CICDDoS2019 data [15] is contained in Table 1 [39]–[43].

TABLE I. Values of compactness measure by types of DDOS attacks.

	Type of DDOS attacks	Number of objects
1	Benign	56 863
2	DNS	5071011
3	LDAP	2179930
4	MSSQL	4522492
5	NetBIOS	4093279

11	SSDP	2610611
12	UDP	3134645
13	TFTP	20082580
	Total	50006249

A set of $E_0 = \{S_1, \dots, S_m\}$ objects is considered, divided into l disjoint subsets (classes) $K_1, K_2, \dots, K_l, E_0 = \bigcup_{i=1}^l K_i$. The sample objects are described by a set of n different types of features $X(n) = \{x_1, \dots, x_n\}$, ξ of which are measured in interval scales, $(n - \xi)$ – in nominal.

Required:

- according to the description of objects E_0 in $X(n)$, form a set of features $Y(n)$ in the interval scale of measurements;
- the description of the class $K_i, i = 1, \dots, l$ by $Y(n)$ is represented as a row in the table “object-property” $T(l, n)$;
- to investigate the structure of the connections of objects from $T(l, n)$ by dividing them into a given number of disjoint groups according to the specified sets of features from $Y(n)$.

A. Data preprocessing

When developing a model based on machine learning algorithms, it is important to decide which features should be used

as input data [38]–[45].

Data preprocessing consists of the following steps:

- removing socket features such as source and destination IP address, source and destination port, timestamp and stream ID;
- saving one representative from repeating objects;
- removing objects with omissions (unmeasured values) in the data.

According to the results of data preprocessing, more than 10 million objects described by a set of 80 features were obtained. The number of objects for each type of DDOS attacks is shown in Table 2.

TABLE II. Values of compactness measure by types of DDOS attacks.

	Type of DDOS attacks	Number of objects
1	Benign	50635
2	DNS	108211
3	LDAP	28871
4	MSSQL	193656
5	NetBIOS	18017

11	SSDP	958766
12	UDP	1156894
13	TFTP	6109716
	Total	10070590

Due to large amounts of data, attempts to solve the problem of selecting informative features [1,2,9] by classical methods for 12 classes of DDOS attacks are unpromising. Based on the specifics of the selection task, its solution is proposed to be sought as follows. Consider data samples $\Omega_i(K_1, K_2), i=1,2,\dots,12$ in which class K_1 is represented by normal traffic, K_2 is one of the types of DDOS attacks. For each sample $\Omega_i(K_1, K_2)$ arrange the features from $X(n), n=80$ by their stability values (stability calculation is given below). To form 12 sequences of features based on the results of their ordering on $\Omega_i(K_1, K_2)$.

The goals that are pursued in the selection of informative features.

- Ordering the types of DDOS attacks according to the complexity of their detection;
- Selection and justification of rules for classification of types of DDOS attacks.

In the presence of large volumes of initial data, it is relevant to solve the problem of choosing and justifying algorithms for calculating the values of the stability of features.

B. Formation of a feature space

When developing a machine learning model, it is important to decide which features should be used as input for the learning algorithm [11]. In some problems, the dimension of the feature space can be very large [12].

A method of forming a new feature space from different types (quantitative and nominal) features is proposed [11]. The formation process is based on the nonlinear transformation of features using the class membership functions of objects.

The inclusion of features in the informative set is based on their ranking with respect to stability. The implementation of the proposals is associated with the modification of the algorithms of the interval method described in [19]. The essence of the modification is to reduce the combinatorial complexity of the algorithms of the method due to the large volume of source data.

The formation of a feature space is an important stage in solving classification problems [18]. The specificity of the considered problem of space formation is that the raw features are presented in different scales and scales of measurements [19]. To achieve invariance to the measurement scales, it is proposed to use the transformation of quantitative features using interval methods.

The choice of both the number and the boundaries of the division of quantitative features into intervals is widely practiced in solving problems of discriminant data analysis [16], [17]. Within the scope of this study, it is not possible to make a complete review and qualitative analysis of existing methods for such a choice.

There is a need to apply interval methods to calculate generalized estimates of objects. Generalized estimates are considered as latent features, the analysis of which is aimed at finding hidden patterns in the data. For decision making, the composition of the set of raw features used in calculating the values of generalized estimates is of interest [17], [18].

A hypothesis test is required: For each sample of $\Omega_i(K_1, K_2)$, there is a unique set of raw features for making a decision on a specific type of DDOS attacks. When proving the truth of the hypothesis, it is proposed to use the method of calculating generalized estimates of objects.

In the classical version, the calculation of generalized estimates by a set of different types of features is performed by a stochastic algorithm. The results of the stochastic algorithm analysis depend on the choice of initial approximations. The question remained open which of the sets should be considered informative for decision-making. To answer this question it is suggested:

- To convert the values of quantitative characteristics into nominal gradations;
- Implement the calculation of generalized estimates by a deterministic algorithm;
- Use a hierarchical agglomerative feature grouping algorithm to calculate generalized object ratings.

The implementation of the proposals is associated with the modification of the algorithms of the interval method described in [19]–[21]. The essence of the modification is to reduce the combinatorial complexity of the algorithms of the method due to the large amount of initial data.

In this paper, we consider the division into intervals for each quantitative feature according to the $\Omega_i(K_1, K_2)$, $i = 1, \dots, 12$ sample, within the boundaries of which the values

of objects of class K_1 or K_2 dominate. To do this, the values of the $x_c \in X(n)$ attribute are ordered in ascending order

$$r_{c_1}, r_{c_2}, \dots, r_{c_m}. \tag{1}$$

According to the criterion defined below, the sequence (1) is divided into τ_c , ($\tau_c \geq 2$) disjoint intervals $[r_{c_u}, r_{c_v}]^i$, $1 \leq u, u \leq v \leq m$, $i = \overline{1, \tau_c}$. The values of the features lying in the interval $[r_{c_u}, r_{c_v}]^i$ can then be considered as a gradation of the nominal feature.

Let $d_1^i(u, v)$, $d_2^i(u, v)$ be the number of representatives of classes K_1, K_2 respectively, in the interval $[r_{c_u}, r_{c_v}]^i$. For the recursive procedure for selecting r_{c_u}, r_{c_v} values, the

$$\left| \frac{d_1^i(u, v)}{|K_t|} - \frac{d_2^i(u, v)}{|K_{3-t}|} \right| \rightarrow \max. \tag{2}$$

criterion is used. The boundaries of the first interval $[r_{c_u}, r_{c_v}]^1$ on sequence (1) are calculated according to the maximum of criterion (2). Similarly, the boundaries for $[r_{c_u}, r_{c_v}]^p$, $p > 1$ are determined on values (1) that are not included in $[r_{c_u}, r_{c_v}]^1, \dots, [r_{c_u}, r_{c_v}]^{p-1}$. The condition for stopping the procedure is to cover all values (1) with disjoint intervals.

One of the options for using the division of feature values into intervals according to (2) is the grouping of objects. The transformation of features into nominal gradations makes it easier to search for similar objects in the training set $\Omega_i(K_1, K_2)$. Otherwise, in the raw feature space, it was necessary to look for a method of normalization, a measure of proximity between objects, set grouping criteria and prove the stability of the solution for them.

Let $\eta_{1i} = \frac{d_1^i(u, v)}{|K_1|}$, $\eta_{2i} = \frac{d_2^i(u, v)}{|K_2|}$ denote the results of optimal partitioning by (2) for each interval $[r_{c_u}, r_{c_v}]^i$, $i = \overline{1, \tau_c}$. The value of the membership function of feature $x_c \in X(n)$ to K_1 over the interval $[r_{c_u}, r_{c_v}]^i$ is defined as

$$f_{ci} = \frac{\eta_{1i}}{\eta_{1i} + \eta_{2i}}. \tag{3}$$

If the feature is $c \in J$, then η_{1i}, η_{2i} in (3) can be considered as the number of values of the i -th gradation, respectively, in classes K_1, K_2 . The generalized estimate is calculated using stochastic algorithms

$$g_c = \frac{1}{m} \sum_{\{[r_{c_u}, r_{c_v}]^i\}} \begin{cases} f_{ci}(v - u + 1), & f_{ci} > 0.5, \\ (1 - f_{ci})(v - u + 1), & f_{ci} < 0.5 \end{cases} \tag{4}$$

Stability values (4) are necessary for the conversion of the original raw features into binary values. Experts can use the division into intervals according to (2) when forming linguistic rules for knowledge bases. The number of class dominance intervals indirectly indicates the status of patterns [22], [23]. The smaller the intervals of dominance, the stronger the manifestation of regularity on a specific feature in the class. This property can be used when ranking quantitative indicators in applied tasks. The highest ranks are obtained by those indicators, the number of intervals of dominance

of classes K_1, K_2 of which is minimal [24]. An additional alternative for ranking by K_2 with an equal number of intervals is an indicator that expresses the degree of uniformity (non-displacement) of the values of the c -th feature of objects within the boundaries of the dominance intervals determined by (2).

C. Machine learning algorithms for classification

SVM is widely used to transfer different types of data by including a nuclear function for mapping into the data space [25]. Such functions are most often used as a linear kernel, a polynomial kernel, a Gaussian kernel with a radial base function, and a sigmoid kernel.

The purpose of SVM is to classify data points of an X_n -dimensional space using an $(n - 1)$ - dimensional hyperplane [26]. Any hyperplane can be written as a set of points X satisfying $w^T x + b = 0$, where the vector w is a normal vector perpendicular to the hyperplane and b is the displacement of the hyperplane $w^T x + b = 0$ from the original point along the direction w .

The distance from the data point to the separating hyperplane $w^T x + b = 0$ can be calculated as $r = (w^T x + b)/|w|$, and the data points closest to the hyperplane are called reference vectors.

Linear SVM is solved by formulating the quadratic optimization problem as follows:

$$\begin{aligned} \arg \min_{w,b} (\frac{1}{2}|w|^2), \\ y(w^T x + b) \geq 1 \end{aligned} \tag{5}$$

Random Forest (RF) is a machine learning algorithm that combines two ideas: a decision tree and ensemble learning [25], [26]. The forest contains many decision trees that use randomly selected data attributes as input. The forest has a collection of controlled dispersion trees. Finally, the result of the classification can be determined by a majority vote or a weighted vote. One of the advantages of random forest is that the variance of the model decreases as the number of trees in the forest increases, while the bias remains the same. In addition, random forests have many other advantages, such as a small number of parameters and resilience to overfitting.

The decision tree (DT) is a tree-like structural model that has leaves that represent classes or solutions, and branches that represent conjunctions of features that lead to these classifications [26]. Tree classification of the input vector is performed by traversing the tree, starting from the root node and ending with a leaf [25]. Each tree node computes an inequality based on one of the input variables. Each sheet is assigned to a specific class. Each inequality that is used to partition the input space is based on only one of the input variables. Linear DT is similar to binary DT, except that the inequality calculated at each node has an arbitrary linear form, which may depend on several variables. The DT depends on the "if-then" rule, but does not require any parameters and metrics. This simple and interpretable structure allows decision trees to consider attribute problems of various types [25], [27].

The Decision Tree can also manage missing values or noisy data. However, they cannot guarantee optimal accuracy unlike other machine learning methods. Although Decision Trees are easy to learn and implement, they don't seem to be popular intrusion detection methods. A possible reason for the lack of popularity is that finding the smallest Decision Tree is an NP-hard task.

Algorithm of k-nearest neighbors. The construction of a classification model based on the k-nearest neighbor algorithm consists in memorizing a training sample of data [25], [28]. To make a prediction for a new data instance, the algorithm searches for the nearest point of the training sample to it, thereby finding the nearest neighbors. The new instance is assigned a label belonging to the nearest point of the training set. The algorithm allows you to take into account not only one nearest neighbor, but also an arbitrary number of them (k). Let's give a training sample with pairs of the form "object-response":

$$x^m - \{(x_1, y_1), \dots, (x_m, y_m)\} \tag{6}$$

Let the distance function $\rho(x, x')$ be given on the set of objects, which should be a fairly adequate model of similarity of objects, that is, the greater the value of this function, the less similar are the objects x, x' . For an arbitrary u , arrange the training sample objects x_i in order of increasing distance to u :

$$p(u, x_{1,u}) \leq p(u, x_{2,u}) \leq \dots \leq p(u, x_{m,u}) \tag{7}$$

where $x_{i,m}$ is the training sample object that is the i th neighbor of object u . Similarly, we introduce the notation for $y_{i,u}$ to answer the i th neighbor. The nearest neighbor algorithm in its most general form looks like this:

$$a(u) = \arg \max_{i=1}^m [x_{i,m} = y]w(i, u) \tag{8}$$

where $w(i, u)$ is a given weight function that estimates the degree of importance of the i -th neighbor in classifying the object u [122]. This function must be non-negative and must not increase in i -th.

The k-nearest neighbor algorithm has several advantages, including ease of interpretation of the model, satisfactory prediction quality that can be obtained without using a large number of settings [28]. Moreover, usually this algorithm allows you to build a classification model very quickly. However, if there is a large training set, the model needs additional time to learn. It is also worth noting that the k -nearest neighbors algorithm is inefficient for working with sparse datasets that have zero values, as well as with datasets where there are many features for model estimation. The k -nearest neighbors algorithm is not so often used in practice due to the fact that it has a relatively low computational speed and cannot process a large number of features.

Naive Bayes is a simple Bayesian network model that assumes that all variables are independent [27], [28]. Using

the Bayes rule for NB classification, it is necessary to find the maximum likelihood hypothesis that determines the class label for the test data x . Given observed data x and a group of labels of class $C = c_j$, the naive Bayes classifier can be solved by the maximum a posteriori probability (MAP) hypothesis as follows:

$$\arg \max_{c_j \in C} P(x|c_j)P(c_j) \tag{9}$$

NB is effective for inference problems and is based on the assumption of independent variables.

D. Metrics for evaluating classification methods

To evaluate the performance of classifiers, the following metrics are used: accuracy of classification, completeness, accuracy and F-measure. Four classification cases are possible for any classification algorithm, and this helps to understand the difference between the metrics under consideration: true-positive results (True Positives, TP), false-positive results (False Positives, FP), true-negative results and false-negative results (False Negatives, FN).

Accuracy of classification can be defined as the proportion of correct results that is achieved by the classifier.

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \tag{10}$$

The accuracy shows what proportion of objects identified by the classifier as positive is really positive.

$$\text{precision} = \frac{TP}{TP + FP} \tag{11}$$

Completeness shows which part of the positive objects was allocated by the

$$\text{recall} = \frac{TP}{TP + FN} \tag{12}$$

classifier.

The F-score is a metric that combines measures of precision and recall:

$$F1 = \frac{2 \times \text{recall} \times \text{precision}}{\text{recall} + \text{precision}} \tag{13}$$

III. COMPUTATIONAL EXPERIMENT

For the computational experiment, the CICDDoS 2019 data set was used [29], the presentation form of which is given in Table.2. For each type of DDOS, a selection is made of features whose stability value by (4) is greater than 0.90. The results of such selection are given in Table 3.

TABLE III. Values of compactness measure by types of DDOS attacks.

	Type of DDOS attacks	Number of objects
1	DNS	11
2	LDAP	26
3	MSSQL	23
4	NetBIOS	20
5	SNMP	22
<i>continued on next page</i>		

<i>continued from previous page</i>		
	Type of DDOS attacks	Number of
6	UDP-Lag	4
7	WebDDoS	9
8	SYN	13
9	NTP	19
10	SSDP	26
11	UDP	26
12	TFTP	26

Based on the results of feature selection (see Table 3), the following conclusions can be drawn. The worst in terms of stability (4) are the 3 types of DDOS attacks UDP-Lag, WebDDoS and DNS. The first 20 signs from the descending ordered (average by types of attacks) stability values of the sequence are given in Table 4.

TABLE IV. Values of compactness measure by types of DDOS attacks.

	Feature name	Average value
1	Fwd Packet Length Mean	0,946463889
2	Max Packet Length	0,946463889
3	Avg Fwd Segment Size	0,9427
4	Average Packet Size	0,941544389
5	Packet Length Mean	0,941252833
6	Packet Length Mean	0,931808306
7	Fwd Packet Length Min	0,927713917
8	Fwd Packet Length Max	0,925263917
9	Bwd Packets/s	0,924822222
10	Flow IAT Std	0,922172167
11	Flow IAT Max	0,921088861
12	Flow Packets/s	0,920752833
13	Flow Duration	0,920708333
14	Flow IAT Mean	0,917563861
15	Total Length of Fwd Packets	0,915383361
16	Fwd Packets/s	0,910708278
17	Subflow Fwd Bytes	0,910708278
18	Inbound	0,899558333
19	Flow Bytes/s	0,897586167
20	Total Backward Packets	0,895905583

The stability values (4) are proposed to be used for ordering (ranking) features and forming a new data sample. The purpose of the formation is to study the structure of links of 12 types of DDOS attacks. An important role in the experiment is played by the number of options from combinations of features. Table 5 shows a comparative analysis of the considered approaches to detecting DDOS attacks.

TABLE V. Values of compactness measure by types of DDOS attacks.

	Type of DDOS attacks	Number of objects
1	DNS	11
2	LDAP	26
3	MSSQL	23
<i>continued on next page</i>		

<i>continued from previous page</i>		
	Type of DDOS attacks	Number of
4	NetBIOS	20
5	SNMP	22
6	UDP-Lag	4
7	WebDDoS	9
8	SYN	13
9	NTP	19
10	SSDP	26
11	UDP	26
12	TFTP	26

Random Forest and KNN proved to be the best machine learning model for detecting DDOS attacks. When using feature selection methods, the Random Forest classifier showed the greatest efficiency. We managed to reduce the attribute from 87 to 20 without compromising the accuracy of the classifier. Feature selection improves the performance and accuracy of the classifier.

IV. CONCLUSION

A methodology for analyzing the structure of the relationship of DDOS attacks types using the values of the stability of the signs for pairs of classes normal traffic and type of DDOS attacks” has been developed. Sets of features for calculation were formed based on the results of their ranking by stability. The analysis technique is used to justify and construct classifiers of DDOS attacks types, taking into account their connectivity.

In the course of the work, the existing algorithms for classifying data based on machine learning were considered, and the possibility of their application for detecting network distributed DDOS attacks was evaluated. A comparative analysis of the considered approaches to the detection of DDOS attacks is given.

Abstract—According to the 2021 Report from the World Health Organization (WHO), more than 700,000 people have taken their life. Suicide can be prevented but so far most of the efforts to do so have fallen short. However, the use of machine learning and artificial intelligence offers new opportunities to increase the accuracy level of prediction and aid the goal of suicide prevention. This paper reviews literature concerning the machine learning methods used to help identify various risk factors and help prevent suicide. This paper also presents our research and analysis findings which were used to identify various suicide risk factors and additional analysis of whether there are any correlations or variations in the risk factors from pre- and post-pandemic datasets regarding suicide rates. This is especially important during times of high stress, such as a worldwide pandemic and quarantine. The dataset(s) obtained from WHO suggest that high levels of risk factor identification are possible and This paper and the analysis serve as supporting research and guide to aid in the continued ambitious goal of suicide prevention worldwide

I. INTRODUCTION

Suicide is a complex global public health problem. According to the World Health Organization (WHO), every year, more than 700,000 people take their own life and there are many more who attempt to do so. Only 38 countries report having a national strategy for suicide prevention. Suicide and suicide attempts have a devastating ripple effect that impacts the community, families, friends, coworkers, and societies. The COVID pandemic has created a new sense of urgency to analyze and engage all countries and communities in aiding the prevention and finding an achievable and sustainable solution

to the growing problem. The quarantine lockdowns and restrictions over the past couple of years, may have led to a heightened sense of loneliness, anxiety, fear, and depression in many people across the globe. Suicides are preventable and a lot can be done to improve the international strategy efforts for suicide prevention. Our mission is to identify the key drivers of suicide, without underscoring that suicide is determined by multiple factors.

Early identification of individuals who are at higher risk of suicide is vital in preventing suicide. According to multiple studies, machine learning and the advantage of Big Data are becoming the new promising approach in this “early identification” objective. But unlike weather forecasting, traffic, or medical predictions, suicide prediction is uniquely different. Especially when surveying and analyzing data on a global scale and considering additional life stressor factors such as the COVID-19 crisis, prolonged quarantine periods, or the resulting strains on the economy and the job market. The topic of predictive analytics being used to possibly identify suicide risk factors has been controversial. Some experts believe the risks should be identified by in-depth clinical evaluations and not risk assessment tools or data models. Making the argument that the risk of misidentification of suicide risk can be associated with inadvertent negative consequences. Still, the power of big data and technology should not be overlooked and, instead, be optimized to work in conjunction with clinical evaluation methods in addressing the suicide problem.

When understanding the motive behind suicide there are many factors that must be noted:

- Geographic Location
- Mental Health Conditions

- Life Stressors
- Relationship Problems
- Financial Problems
- Cultural/Societal Expectations
- Current Events

II. BACKGROUND

Death by suicide is a very complex issue that causes torment and distress for hundreds of thousands of people globally. But with timely intervention and prediction, suicides can be prevented. This is especially important for times of high stress, economic uncertainty, pandemic or natural disasters, and other stress factors that can have a serious effect on mental health and morale.

The WHO compiles and disseminates data on death and morbidity annually. This data is reported by all participating “Member States”, according to the WHO mandates. These Member States are foreign countries, which at first started out as only 11 back in 1950, right after the inception of WHO, then growing to 74 in the year 1985, and reaching 183 in 2019. Thus, this is one of the most complete and thorough mortality data banks that are publicly available, and reported suicide deaths are an integral part of this data bank. However, although this global data bank is from a reputable organization and with specific data classification requirements, it still offers some challenges. It’s very difficult to get a high quality and high accuracy reading of suicide rates around the world. Only about 80 Member States provide good-quality, reliable data that can be used to estimate the risk factors associated with suicide deaths. “This problem of poor-quality mortality data is not unique to suicide but given the sensitivity of suicide – and the illegality of suicidal behavior in some countries – it is likely that under-reporting and misclassification are greater problems for suicide than for most other causes of death.” [1]. In addition, the official statistics relating to attempted suicide are even more skewed, which makes it difficult to analyze and correlate national global suicide trends to suicide attempt trends. “...suicide may be hidden and underreported for several reasons, e.g. as a result of prevailing social or religious attitudes. In some places, it is believed that suicide is underreported by a percentage between 20% and 100%.” [1].

In spite of these dataset collection and classification challenges, the WHO mortality dataset is one of the most comprehensive and reliable data banks in the world. An important role of big data gained from sources such as the World Health Organization (WHO), Electronic Health Records (EHR) [2], or social media regarding suicide, is supporting the objective of prevention. “The potential in this area is tremendous. The suicidal phenotype is characterized by extreme heterogeneity, and potentially suicidal individuals are very often excluded from any clinical trials. Big data could help by combining very complex and large data samples to detect patterns, signaling suicidal inclinations [3] With such a powerful tool as big data available, research teams and analysts should be able to predict high risk factors with a high degree of certainty. So far there have been cases where scientists were successful in implementing tools to survey and predict risk, with 91% accuracy [4], but unfortunately this level of accuracy is only due to the smaller and more controlled groups, such as adolescents in the state of Utah. The challenge still exists, not only for a nationwide population for all age groups, but also a worldwide population and especially during high stress time periods caused by economic downturns.

Big data is already being used in the fields of psychology and psychiatry for a variety of reasons and goals. But the velocity of data acquisition is one of the main challenges because the majority of the data is updated on a periodic basis, and there aren’t many options available for real-time data. “It should also be recognized that as big data gains a more prominent role in psychiatry, issues of governance and security will need to be clearly considered, and that there must be a thorough and open public dialogue on ethical issues.” [3] Even still, big data in the world of psychiatry can offer significant benefits to help with not only treatment of the patients but also comprehension of their disorders and early diagnosis and prevention of suicide or self-harm. Although, it’s important to keep in mind that machine learning, predictive algorithms, and big data needs to also run hand in hand with additional efforts and factors to be fully effective in identifying risk factors and preventing suicide. Medical and psychiatric professionals need

to recognize the potential of big data technological advancements, while at the same time also being careful to maintain a high standard of professionalism, as well as the traditional doctor-patient relationship which is based on trust and confidentiality.

III. RELATED WORK

As mentioned in the introduction as well as in the background, there are various reasons, risk factors, and warning signs that lead to suicide and suicidal thoughts. Many studies have been conducted over the years that focus on the various factors in an attempt to better understand and hopefully lower suicidal rates.

In this paper, we reviewed six literatures that were published between 2012 and 2020. Of the two that were published pre COVID-19, each focused on suicide rates in the USA during economic recession during a different period. The third pre COVID-19 paper discussed the national cost of suicides and suicide attempts in the United States in 2013. The remaining three literatures observed trends and discussed whether the COVID-19 pandemic resulted in suicide rate increases.

In the report titled, "Increase in state suicide rates in the USA during economic recession" by Reeves et al., it mentions evidence from European countries that show a rise in suicides during economic recessions. Among the worst being Greece, where suicides have risen more than 60% since 2007. Using data on suicide mortality rates from 1999 to 2010 from the Centers for Disease Control and Prevention, along with 'unemployment' data from the Bureau of Labor Statistics, the authors extended their previous analyses of recessions and suicides in Europe to assess trends in all 50 US states. Their findings showed that in the years before the recession (from 1999 to 2007), the suicide mortality rate in the USA were rising on average at a rate of 0.12 per 100K per year. During the recession period (2008-2010), the suicide rate increased at a rate of 0.51 deaths per 100K per year. This difference in rate corresponds to an additional 1580 suicides per year [5].

Another study by Harper et al. explores suicide mortality rate in the USA over a 30 year period. Prior to this study, there were several studies that suggested strong associations between eco-

nomie downturns and suicide mortality. This study aimed to provide more robust evidence by using a quasi-experimental design. The researchers analyzed 955K suicides that occurred in the USA from 1980 to 2010 and used a broad index of economic activity in each US state to measure economic conditions. Based on the quasi-experimental and fixed-effects design, and after accounting for secular trends, seasonality, and unmeasured fixed characteristics of states, they found that an economic downturn in magnitude to the 2007 Great Recession increased suicide mortality by 0.14 deaths per 100K population or around 350 deaths. The effects were also stronger for men than women and for those with less than 12 years of education [6].

The third paper reviewed addresses economic costs of suicides in the United States in 2013. Understanding that suicide would not be eliminated from our society anytime, we felt it was important to review some literature on its economic cost to better put things in perspective. According to the authors, there were three previous studies using different approaches to address the matter. For their study, to seek to improve on the previous by addressing the increase in the number of suicides since those publications by incorporating adjustments for underreporting and using additional data. Shepard et al. paper concluded that the national cost of suicides and suicide attempts in the United States in 2013 was \$58.4 billion based on reported numbers. Lost productivity represented most (97.1%) of the cost. When adjusted for under-reporting, it increased the total cost to \$93.5 billion [7].

Similar to understanding how economic downturns effected suicide mortality rates in the first two reviewed literature, we reviewed a few more literatures that were published during the COVID-19 pandemic to observe how and whether the pandemic affected the rate.

In the paper titled "Suicide risk and prevention during the COVID-19 pandemic", Gunnell et al. seek to understand how suicide is likely to become a more pressing concern as the pandemic spreads and its effects on the general population, the economy, and vulnerable groups. Suicide risk might increase among people with mental illness due to self-isolation, exacerbated fear, and physical distancing. Those with psychiatric disorders might

experience worsening symptoms, while others in stressful work environments (such as health care) might develop new mental health problems. During these extraordinary moments, people in suicidal crises need special attention. Not all will seek help in fear that services are overwhelmed or not willing to attend face-to-face appointments [8].

Deterioration in population mental was one of several factors that underpinned the concern that suicide rates may increase during the COVID-19 pandemic. Based on some widely reported studies modelling the effects of the pandemic on suicide rates predicted increases ranging from 1% to 145% [9]. In the study titled “Trends in suicide during covid-19 pandemic”, the authors tracked and reviewed relevant studies for a living systematic review. In the early months of the pandemic, reports suggest either no rise in suicide rates (Massachusetts, USA; Victoria, Australia; England) or a fall (Japan, Norway) in high income countries. Not much is known for low income countries.

IV. PROBLEM DESCRIPTION

The main purpose of this analysis is to identify risk factors in the hopes of mitigating suicide rates and help combat the worldwide phenomena. Identifying these drivers could help communities implement proactive protective practices and decrease the rate of suicide.

We are approaching this problem by identifying which factors effects the trigger of suicide in each individual like their country GDP or their Income or which place they are from and so on. We will be cleaning the data using R/Python and use scatter plot and ggplot packages to form comparison between the data from 1986 to 2016, and data from 2019 to current.

Questions we aim to answer:

- Is a prior suicide attempt a clear risk factor and indicator of another attempt?
- Is there a correlation between a county’s GDP and suicide rate?
- Is there a correlation between gender and suicide rates?
- Is there a correlation between the year and suicide events? If so, is this due to any global events at the time?

- Do the countries that invest more in mental health see a lower suicide rate?
- Do countries that are more impacted by the opioid epidemic see a higher rate of suicide?
- On average how many combined factors does a suicide victim have?
- Do the countries that have easier access to suicide methods (substances, firearms, etc.) have a higher suicide rate?

V. DATA, TOOLS, TECHNIQUES AND APPROACHES

Methodology:

The team began by cleaning and formatting the suicide datasets using Excel. Once the data is in the proper format, utilizing programming languages like R and Python, the data will be analyzed through a series of analytical techniques that will assess how suicide rates have changed from before and during the pandemic. This will include visualizations, charts, and maps showing the patterns seen within the dataset.

How we collected the data:

The team used secondary data gathered from the “1986 - 2016 Suicide Rates” [10] dataset which we obtained from Kaggle. This dataset is a combination of four datasets, linked by time and place to help identify risk factors worldwide. The four datasets were:

- 1) United Nations Development Program. (2018). Human development index (HDI). Retrieved from <http://hdr.undp.org/en/indicators/137506>
- 2) World Bank. (2018). World development indicators: GDP (current US\$) by country:1985 to 2016. Retrieved from <http://databank.worldbank.org/data/source/world-development-indicators>
- 3) Szamil . (2017). Suicide in the Twenty-First Century [dataset]. Retrieved from <https://www.kaggle.com/szamil/suicide-in-the-twenty-first-century/notebook>
- 3) World Health Organization. (2018). Suicide prevention. Retrieved from http://www.who.int/mental_health/suicide-prevention/en/

Preliminary Results:

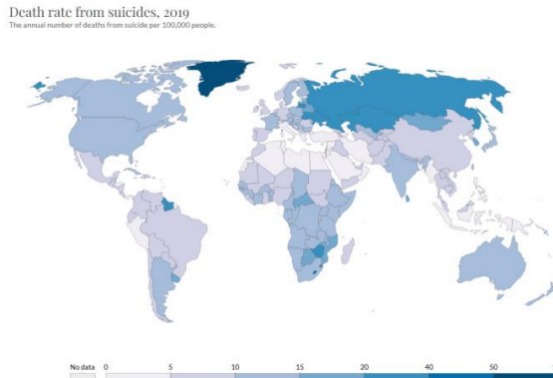

Fig. 1: Death Rate From Suicides

Fig. 7

have a higher suicide rate?

VI. CHALLENGES

Due to limitation of recent and extended periods of worldwide suicidal data from credible sources like WHO or CDC (who only publish suicide figures up to 2019), it is difficult to make clear comparisons of pre and post-pandemic suicidal rates and factors. From our review of recent articles and publication, most do not draw a conclusion that suicidal rates increased during the pandemic, but state that previous pandemics have been associated with increases in suicide rate. The U.S. reported an increase in suicides during the Spanish Flu (1918-19) [11]. Africa did experience an increase in suicides during the Ebola epidemic spanning

2013 to 2016 [12]. Hong Kong did observe an increase in elderly suicides during 2003 SARS outbreak [13]. One common denominator among these publications is that they were all completed years after the epidemic/outbreak or after multiple years of data was available for analysis. There are multiple factors that lead researchers to believe that the current COVID-19 pandemic will share similarities with past events. By the end of 2020, over 76 million people worldwide were infected by the COVID virus, SARS-CoV-2 [14]. Shutdown of businesses and business activities because of lockdown measures affected those living in poverty, relied on hourly wage positions, and many that relied on government programs. As mentioned in the literature review that examined US suicide rates during 2008 as well as a publication by Oyesanya et al. [15], both conclude that economic stress has been associated with higher suicide rates. Another effect of the COVID lockdown is social isolation. Studies such as the one by Christensen et al. have documented that social isolation is associated with increased suicidal thoughts. A 2016 study by VanderWeele et al. show that participating in religious communities is associated with lower suicide rates, however, with churches and community centers closed during lockdowns, social isolation possibly increased suicidal thoughts. One factor that differs greatly from the current pandemic to previous epidemic/outbreaks is the amount of media coverage. With 24-7 news coverage, social media outlets, unlimited SMS service, etc., it's possible that anyone with preexisting mental health conditions will experience intensified anxiety and fear. To make matters worse, during lockdowns, increased restrictions at healthcare facilities were another barrier to those that required mental health treatment.

VII. CONCLUSION

Similar to the report by John et al. that examined suicide rates during the earlier stage of COVID (lockdown, stay-at home period), other reports by Faust et al., Applyby et al., and Qin et al., all [16], [17], concluded that suicide rate for the same period compared to a year ago were similar or did not show significant difference from previous years. Despite these similar conclusions, we find that it

is too early for a study to compare pre and post pandemic suicidal rates due to the lack of data and that the pandemic is still ongoing.

VIII. FUTURE WORK

For a follow on study to be more conclusive, it is best to be done after WHO declares the end of the pandemic and when most countries' citizens have returned to a lifestyle similar to pre pandemic. In the follow on study, instead of focusing on worldwide figures, we suggest to examine certain groups that may be more vulnerable to the effects of the pandemic and experienced increased suicide rates.

- Unemployed: In early 2020, the International Labour Organization (ILO) predicted the pandemic cost 25 million jobs worldwide. Studies of the Great Recession in the early 2000s found an increase of suicide risk by 20-30% between 2000 and 2011 with a peak during 2008 [18].
- Mentally ill: individuals with preexisting mental health conditions were likely affected by interruption in treatment, and experienced increased isolation and intensified anxiety and fear due to the pandemic [19].
- Healthcare workers: In the early stage of the pandemic, medical staff have reported increased hopelessness, guilt, and insomnia. All which can increase the risk for suicide [20].
- Racial minorities: Racial minorities who owned small businesses or worked at hourly waged positions were affected more by lockdowns and shutdown of business activities.
- Youth: Preliminary data from England suggest that child suicide deaths may have increased during the early stages of lockdown, possibly due to disruptions to education, outside activities, and support services [21].
- Elderly: Similar to youth, elderly suffered greatly from social disconnectedness during the pandemic. Social and self-isolation affects elderly who do not have close family and friends, or who have decreased literacy in or access to digital resources [22].

Abstract—Garments and textile industry is one of the vital organizations in the modern world. In the world market, Bangladesh is the second largest manufacturer and supplier of clothing industry. Bangladesh has been facing many problems in the clothing industry. Employee turnover means to leave manpower from existing organization to another in the sake of better opportunity, better salary and so on. For this reason, organization faces many problems because of employee turnover. So there need a system or model that can predict the employee turnover rate and help the organization to take necessary step to stop employee turnover by providing necessary demands of employees. In this research, several machine learning algorithms are used to predict the turnover of employee. Among them 98% accuracy has been achieved with the Random Forest and an accuracy of 92% has been achieved with the Gradient Boosting classifier.

Keywords—Employee turnover ; Machine Learning; SVM; Logistic Regression; Random forest; Decision tree classifier; Gradient Boosting classifier.

I. INTRODUCTION

Employee turnover is high especially for Garments organizations in Bangladesh. The client could unserved appropriately thinking about their normal pay with their spending conduct [2] causes employee turnover. Employee turnover is high especially for Garments organizations in Bangladesh.

The issue of Bangladeshi organization's employee turnover rate has become an important part of a company's strategy. In the event of replacing an employee, the human resources team needs around two to eight weeks to find a good candidate for the given role and also a number of interviews must be conducted in order to find the optimal candidate that we rapidly

come to the conclusion that replacing an employee is a costly process. Garments and textile are leading to Bangladesh economy and in future its area is growing largely. Actually, this is manpower based low labor wages organization where employee turnover rate is high. Therefore, organization faces great loss due to this turnover. Since Bangladesh is over populated country, second generation industrialization is going on. Around four million people directly or indirectly depends on garments industry and about 40% of total GDP contributed by garments organization. As the second business hub of garments industry in the world faces many challenges due to employee turnover. Our proposed system identified the employee turnover prediction through machine learning algorithm so that turnover can be resist.

In this paper, we have implemented some of the well-known ML techniques namely Decision Tree, Logistic Regression, Support Vector Machine (SVM), Gradient Boosting classifier and Random Forest on the Human Resources (HR) Employee turn-over by collecting data from Bangladeshi Garments Organizations.

The rest of the paper organized as follows: section II describes the related work. Section III illustrated the methodology where section IV describes the data analysis and results are shown in section V. Finally section VI gives the conclusion with future work.

II. RELATED WORK

Employee turnover to any organization is commonly a bad practice to employee. Here creates a big financial loss to organization. Also, it reduces the working efficiency, productivity remarkably. Some Research has been done to find out the reason that is responsible for employee turnover [1]. In [1] an expert system has been implemented to predict employee churn. Employee turnover firmly related however not

indistinguishable from client beat is comparatively agonizing for an association, prompting disturbances, client disappointment, and time and endeavors lost in finding and preparing substitution. In [2] customer and employee segmentation were developed based on clustering method. In [3], the author explored several machine learning algorithms to predict employee turnover using a data set comprising 1450 records and 35 attributes. They used the following machine learning algorithms: K-Nearest Neighbor, Support Vector Machine, Decision Tree and Random Forest. And found result KNN 86.39%, SVM 86.84%, DT 81.63% and RF 88.43%.

In [4] the author gives an overview of churn and types on churn. In [6], the author described several machine learning algorithms to predict employee turnover using a data set comprising 1470 records and 34 attributes. They used the following machine learning algorithms: NB, Linear Regression, KNN, SVM, RF and found result DT 76.5%, NB 79.1%, Logistic Regression 87.1%, SVM 85.7%, KNN 84.4% and RF 85.0%. In [5], the author used Logistic Regression, LDA, DT, RF to predict employee turnover. And found result Logistic Regression 57.8%, LDA 57.7%, DT 56.3% and RF 59.7% In paper [6] author represented the similitudes between the issues of client turnover and employee turnover. An illustration of an employee turnover model created to utilize traditional AI methods. Representative turnover is the general churn, which alludes to individuals finding employment elsewhere in an association [7]. Representative turnover likewise can be called attrition. Attrition is basically the turnover rate of employees inside an organization. In [9] the author explored several machine learning algorithms to predict employee turnover using data set comprising 10616 records and 39 attributes and got accuracy 98%. by using Logistic Regression.

In [10] author worked on Swedbank employee turnover prediction by using RF, MLP, SVM machine learning methods where RF achieved highest 98.62% accuracy. In [11] they collected data from XYZ company duration of 2015 to 2017, 16,649 instances personal data and applied C4.5 classifier gained 95% accuracy. In [13] HR data of the employee collected from three IT in India and applied SVM algorithms achieved accuracy 85%. In [14] author worked on the effect of employee occasion functions on classifier where overall performance calculated on worker chance to turnover in the meantime preserving the interpretability of classifiers for advantages of retention interventions development.

However, we have implemented some of the well-known ML techniques using new and unique feature to predict employee turn-over by collecting data from Bangladeshi Garments Organizations.

III. METHODOLOGY

Figure 1 demonstrate the major components of the methodology which have been used in this paper to predict the employee turnover.

A. Data collection

The data set have been prepared by collecting data from organization. In data set, there are two types of data, numerical and categorical. There are no null values and for implementation categorical data is converted into numerical data. Finally Random Forest, Support Vector Machine, Decision Tree, Gradient Boosting classifier and Logistic Regression algorithm are implemented. Here precision and recall have been used to evaluate the performance. Moreover, we use 7-fold cross validation for algorithm, which removes to over-fitting.

Then dataset are categorized into two values numerical and categorical values. Then important feature are selected from database. After that feature scaling have been done to preprocess the dataset. Here we use 20 features to implement our model. Different machine learning algorithm is used to predict employee turnover where 70% data are used for training and 30% is used for testing. Here we have used confusion matrices to find the accuracy of the model. In addition, 7 fold cross validation is used to test the model. The flow chart is given below.

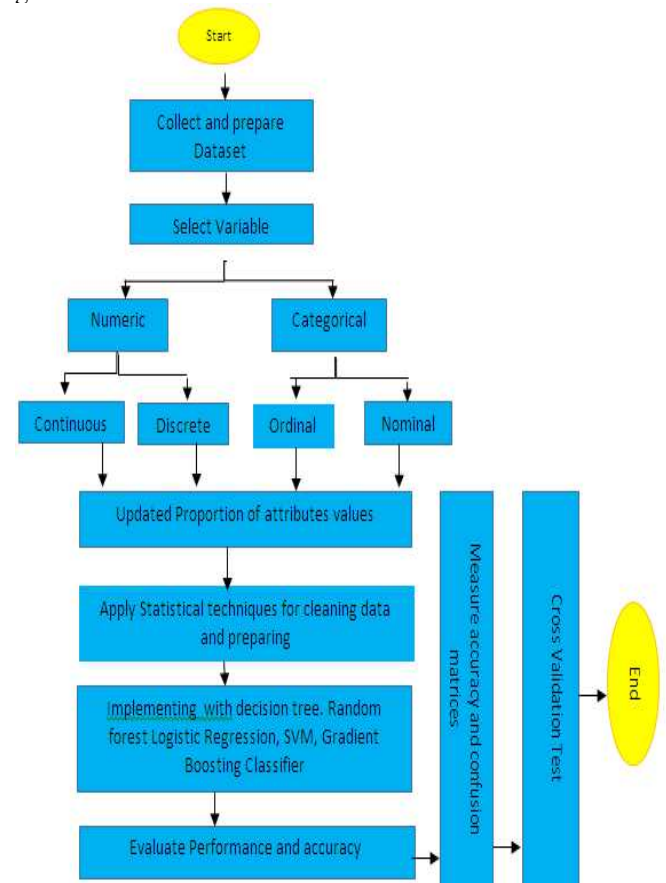

Fig.1. Flowchart of proposed work

B. Classification

In this paper several machine learning algorithm have been used to predict employee turnover. The description is given below.

Logistic Regression

The Logistic Regression is a linear classification algorithm. The models learn the weights of input dimension that separate output into two regions. Logistic regression is easy to implement and work well on linearly separable classes. This algorithm creates a logistic curve, which values lies between 0 and 1.

Random forest

Random forest (RF) is one of the most powerful supervised machine learning algorithms for generating classifications and regressions. Each tree votes for a classification label for a certain data set, then the RF model chooses which class had the most votes from the decision trees. Its output prediction accuracy is very high. If any missing value finds in data set, don't create any impact on accuracy.

Gradient Boosting Classifier

Gradient boosting classifier is also ensemble of decision tree method. The difference between RF and GBT is the gradient boosted tree models learn sequentially in attempts to correct the mistakes of the previous tree in the series. It provides predictive accuracy. There also lots of flexibility which optimize different less of functions and provides different hyper parameter tuning options and no need to preprocessing of data for this. It handles missing data and imputation is not required.

Support vector machine

It is not only used for classification but also use for Regression. SVM will train algorithms with assigned classes by separating each class through a decision boundary, also known as a hyperplane. Some problems are considered nonlinear in so far as it is difficult to draw the decision boundary. However, this can be solved by using a kernel function. This function returns the dot product of the two vectors, where it then maps data points to a new, transformed, high-dimensional space. Moreover, there are several types of kernel function can be used such as linear, Gaussian, and polynomial kernel.

Decision Tree

It is the most used for classification problem. Decision tree is only one single tree. It can be explained into two entities such as decision node and leaves.

C. Evaluation Measurement

To evaluate the accuracy precision, Recall, F-measure is used. We also find out confusion matrices shown in Figure 2 and the correlation matrices is shown in figure 3

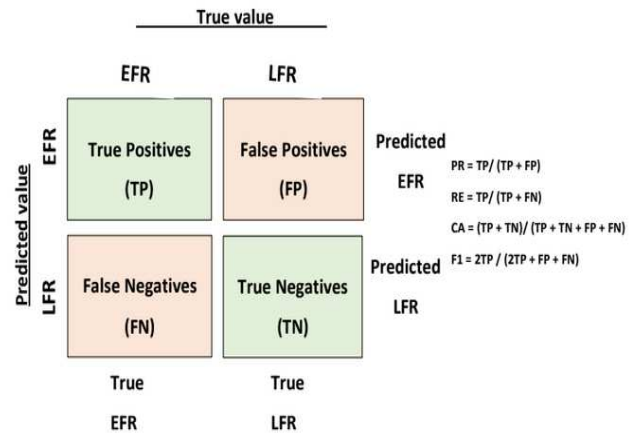

Fig.2. Confusion matrix

IV. DATA SET ANALYSIS

We have collected data from two organization named TRU Febrics and Z&Z organization. We also collected few data by google Form. Table 1. Shown the 19 generated feature which are completely helpful to predict turnover of employee. Some features have been included from Kaggle where analyzed Employee Attrition and Performance [12].

Table 1: Generated Feature

1	Gender	11	On time salary
2	Age	12	Yearly Salary Increment
3	Marital Status (Married / Unmarried)	13	Overtime Bill Allowance
4	Education Field	14	Salary Satisfaction
5	Departments	15	Employee Promotion Status
6	Education Qualification	16	Transport Facility
7	Human Resource Policy	17	Distance From Home(km)
8	Safety Satisfaction	18	Annual Refreshment Facility
9	Job environment Satisfaction	19	Stress Level
10	Job Satisfaction	20	Turnover

This dataset comprises twenty attributes and seven hundred tuples.

Fig.3 Correlation matrix

V. EXPERIMENTAL RESULTS

Table 2 shows that Random Forest achieved highest precision, recall and f1-score then other different machine learning algorithms.

Table 2: Comparison of different approach

Method	Precision	Recall	F1-score
Random Forest	0.99	0.99	0.99
Gradient Boosting	0.92	0.91	0.92
Decision Tree	0.97	0.96	0.96
SVM	0.91	0.91	0.91
Logistic Regression	0.72	0.71	0.72

Figure 4 has shown that comparison of accuracy of different approaches where Random Forest has higher accuracy over other compared machine learning approaches.

Fig.4. Comparison between different approaches.

Roc curve is a curve where we can see the accuracy of several model and ROC curve defines the comparison of the accuracy among different model. In this curve, we can easily understand that Random forest outperform better that other algorithm.

Fig.5. ROC Curve of accuracy model

In addition, a comparative study have been done on survival analysis where feature based analysis have been implemented. It will help the employer to take decision in recruitment. In figure 6 and 7 it is shown that the turnover rate is high for 27-28 years old employee and also if the distance of the organization from home is 7 to 9 km. In figure 8 we have seen that after higher

secondary education the employee turnover rate is low but in secondary education level it is high.

Out[46]: <AxesSubplot:xlabel='Age', ylabel='count'>

Fig.6: Employee Turnover based on age

Out[47]: <AxesSubplot:xlabel='Distance from Home(km)', ylabel='count'>

Fig.7: Employee Turnover based on distance.

Fig.8: Employee Turnover based on education

VI. CONCLUSION AND FUTURE WORK

In the perspective of Bangladesh, this research has been worked newly though many proposals study and method already been established considering other countries. Collecting data from different organization is very hard. In our proposed work, we do some machine learning approaches to predict employee turnover.

With the machine learning approach, a good accuracy of 98% has been achieved with Random Forest algorithms. In future we will expand our dataset and deep learning approach will apply for more improving more accuracy.

Abstract—Coronavirus can be transmitted through the air by close proximity to infected persons. Commercial aircraft are a likely way to both transmit the virus among passengers and move the virus between locations. The importance of learning about where and how coronavirus has entered the United States will help further our understanding of the disease. Air travelers can come from countries or areas with a high rate of infection and may very well be at risk of being exposed to the virus. Therefore, as they reach the United States, the virus could easily spread. On our analysis, we utilized machine learning to determine if the number of flights into the Washington DC Metro Area had an effect on the number of cases and deaths reported in the city and surrounding area.

Index Terms—coronavirus, Washington DC, virus prediction, machine learning

I. INTRODUCTION

The COVID-19 pandemic has caused a serious impact on the world economy, with many deaths and long-term injuries across the world, an increase in businesses bankruptcy with an associated increase in lost jobs, and an increase in food scarcity as well. Moreover, health care systems, as well as the airline industry, faced enormous financial challenges as 30% of the United States airlines' stock prices decreased during this crisis [1]. During this crisis, many airlines canceled their flights and applied travel restrictions to control the spread of coronavirus, leading to a significant impact on the airline sector. According to [2], [3], the ongoing COVID-19 pandemic is the gravest crisis that happened to the aviation sector, and it may take around five years to recover from it. As thousands of employees were released, international tourism was frequently stopped, and global quarantine restrictions limited the flights that continued.

Given the serious effect COVID-19 has had on the world, there is a significant necessity to understanding how the novel coronavirus is transmitted and the various factors that allow it to rapidly disperse through a community, city, or nation. Among the risk factors to a given location, air travel may well be a factor, or have historically played a factor in allowing additional spread of the coronavirus from more infected regions to those with limited or no prior infections.

Numerous airplanes are supported with High Efficiency Particulate Air (HEPA) filters; however, the filter's effectiveness only applies to the air that goes through it, and it does not necessarily filter every onboard virus; therefore, airlines require people to wear masks during the flight [4]. Additionally, close contact between people is the prime cause of spreading the COVID-19 easily [5] which led many airlines to leave the middle seat empty in their aircraft [6]. However, with all travel restrictions and procedures, COVID-19 can still

be transmitted between people on airplanes, as stated by [7]–[9]. Therefore, our aim is to discover the correlation, if present, between the number of flights and resulting coronavirus cases in the DC area.

The importance of learning about where and how coronavirus has entered the United States will help further our understanding of the disease. According to CDC [10], the first coronavirus case in the US has been identified in Washington state, and that was due to air travel from Wuhan, China. The most common way COVID-19 can spread is by human interaction, through respiratory droplets such as talking, coughing, sneezing, and more. Air travelers can come from countries or areas with a high rate of infection and may very well be at risk of being exposed to the virus. Therefore, as they reach the United States, the virus could easily spread. In our analysis, we intend to use the OpenSky dataset records and combine it with CDC data to determine if the number of flights into or out of the Washington DC metro area may have impacted the number of coronavirus deaths reported in those counties and the region surrounding the respective airports in question.

Other analyses have concluded that coronavirus can travel via flight and there is an inverse relationship between distance to an airport and how many coronavirus cases result from travel into the region. We suspect that the District of Columbia will show different results as a significant portion of business and political activity in the region is focused on the US federal government.

In the next sections of this paper, we make the following contributions. First, we summarize the datasets that have been utilized in this study. Second, we provide an overview of the related work in relation to this study. Third, we discuss the methodology for the analysis of this project. Finally, we present our primary findings followed by the future work.

II. DATASETS

In this paper, we have utilized two dataset sources. The flight dataset was obtained from OpenSky, showing the air traffic during the coronavirus pandemic. Table I summarizes the OpenSky attributes [11]. The coronavirus dataset was obtained from the New York Times and shows the number of cases and death in the United States. Table II summarizes the New York Times [12].

As for the cleaning process. From the OpenSky dataset: the destination variable (filtering for Baltimore International Airport, Dulles International Airport, and Reagan National Airport), and Last seen variable as that gave us an indication of the date the flight was occurring. From the New York times dataset, we used the date, state, and county to filter down to the specific counties surrounding each of the airports mentioned

earlier, and the area surrounding Washington DC itself. We further intend to use the cases and deaths to calculate the number of new cases and deaths occurring each day.

Data cleaning is performed using Python and Tableau Prep. Pandas library in python is used to drop the missing values and the redundant entries and remove the irrelevant columns from the datasets to decrease the processing time and enhance performance and efficiency. Moreover, we resolved the data inconsistencies, filtered the destination variable, and converted the UTC timestamp to date format using the Tableau Prep tool.

TABLE I
OPENSKEY ATTRIBUTES

Variable Name	Description	Type
Callsign	the identifier of the flight	String
Registration	the aircraft tail number	String
Origin	the origin flight airport represented with four letters.	String
Destination	the destination flight airport, represented with four letters.	String
Firstseen	UTC timestamp of the first message received by the OpenSky Network.	String
Lastseen	UTC timestamp of the last message received by the OpenSky Network.	String

TABLE II
NEW YORK TIMES ATTRIBUTES

Variable Name	Description	Type
Date	the date of the reported Covid-19 cases and deaths.	Date
State	the name of the state.	String
County	the name of the county.	String
Fips	standard geographic identifier.	Number
Cases	the total number of cases of Covid-19.	Number
Deaths	the total number of deaths from Covid-19.	Number

III. RELATED WORK

The rapid spread of coronavirus cases across the world motivates us to discover the number of flights effect on coronavirus deaths rate. As in almost every country, the first infection cases of coronavirus were brought by travelers. While travel restrictions have been applied in many countries, they had a modest effect on limiting the spread of coronavirus cases [13], [14]. These restrictions were effective in only delaying the transmission of coronavirus [15].

In order to minimize the transmission of coronavirus during flights, several airports implemented a temperature screening to check for fever. This however was determined to be ineffective, as estimations suggest only 45% of infected people would be detected by temperature screening with an even lower result in young people [10]. Khanh et al. [7] study shows that thermal imaging scans have their limitations at determining if someone certainly has coronavirus. An additional lack of self-disclosure of coronavirus symptoms before and after boarding leads to an increase in the spread of the COVID-19 [7]. Previous studies have also reported that coronavirus can be transmitted before

symptoms appear [8], [9], as people can be infected with coronavirus disease and show no symptoms, or have symptoms develop over a period of several days. Overall, Khanh et al. [7], Bae et al. [8], and Choi et al. [9] concluded that coronavirus could be transmitted on aircraft and consequently increase the infection risk.

A case study was applied in China to calculate the risk index of COVID-19 imported cases from inbound international flights [10]. Through this study, Zhang et al. [16] used global COVID-19 data and international flight data from UMETRIP, and they found that the risk index increases significantly when there are active flights associated with highly infected countries. A research on the effect of the United States local flights on COVID-19 cases indicates a high correlation, i.e., 0.8 between travelers and population and COVID-19 cases at the onset of the pandemic [17].

However, a study conducted and published in 2020 by Desmet and Wacziarg [18] used a cross-sectional regression model to analyze the relationship between COVID-19 cases and deaths and the distance to the closest airport with direct flights from the top five affected countries and found a negative correlation. Throughout this study, Desmet and Wacziarg [18] used the collected COVID-19 cases data from the New York Times and the international flights from the Bureau of Transportation Statistics. A retrospective case series was conducted by Yang et al. [19]. It was clinical data collected from ten patients with no symptom history before the flight. Yang et al. [19] found that coronavirus disease can be transmitted through airplanes and the way how transmitted was unknown. Similarly, a medical evaluation was conducted by Hoehl et al. [20] on twenty-four passengers from an international flight from Israel to Germany. Seven passengers were tested positive for coronavirus (SARS-CoV-2). Hoehl et al. [20] concluded that coronavirus transmission in an airplane depends on other elements such as passenger’s movement, contact, etc. at the same time, wearing a mask during the flight could reduce the transition rate. On the other hand, a study by Schwartz et al. [21] stated that Coronavirus disease 2019 transmission was absent base on patients who traveled an internationalflight with one stop from China (Wuhan) to Canada (Toronto). Although several passengers developed some symptoms after the flight but tested negative from COVID-19.

Another study was conducted to investigate the association between air traffic volume and the spread of COVID-19. This study was conducted using the publicly available of domestic air traffic and passenger data from 2013 to 2018 through CAAC (Civil Aviation Administration of China). This data was used to predict the data for 2019. For the international air traffic and routes, data were derived from Chinese international air traffic from the Official Aviation Guide (OAG) and COVID-19 data from WHO [22]. They had found the continuous measurements using mean ± standard error, statistical significance using t-test, and correlation analysis using linear regression. The analysis indicated a strong direct correlation between domestic covid cases and the number within China itself. The international air traffic analysis also

showed a strong correlation with the cases as it depends on air traffic network [22]. Moreover, a study based on a cross-country regression analysis approach was contacted to find the correlation between coronavirus deaths and cases and global tourism [23]. The COVID-19 cases and deaths data for this study were collected from the European Centre for Disease Prevention and Control while the international tourism data were obtained from the World Bank. [23] found a positive association between coronavirus cases and deaths and international tourism.

Furthermore, a mathematical modelling study was conducted to see whether the spread of COVID-19 was related to international cases imported. The study compared the ratio between the international imported cases and the internal cases in May 2020 and September 2020 in different countries [24]. Since each country has its own regulation implemented on the restriction, the results found at international cases imported made larger impact on May 2020 than September 2020. In fact, imported cases effect the internal spread in May 2020 was reduced compared to September 2020. However, the data collected for this study were from OpenSky data found the impact of international imported cases to internal spread is still little with 10% or less. [24]

IV. METHODOLOGY

The first step in this project was cleaning the datasets. Specifically, the Open Sky data, being crowd sourced, included errors such as duplicate entries or null origin and destination values among other things. We further cut out the irrelevant data from the OpenSky dataset (that being the time period from 2019 until the start of the pandemic) as that information is irrelevant to our analysis. At this stage in the process, the coronavirus data were also filtered to only include the relevant region. Specifically, all cities and municipalities between the airports being studied and Washington, DC itself (including the counties containing each airport).

Our proposed method will involve marking the major airports in the Washington DC Metro Area and their immediately adjacent counties. We will then run a count on all flights arriving at each airport across the United States aggregated by week. Current CDC data suggest that the time from infection to onset of symptoms is 4 – 5 days [25] and research published in the Journal of Medical Virology indicates death from coronavirus has a median of 14.5 days after initial exposure [26]. As a result, based on this information, we intend to pair our flight data with new coronavirus cases averaged over the next 14 days after the flight. This should allow us to run several initial tests, including (assuming linear correlation) a Pearson Correlation Coefficient to determine if a correlation exists between number of flights and number of coronavirus deaths.

We can further take this data and produce scatterplots to visualize any correlation and determine other factors like spread and variance. Depending on the results of this analysis and visualization, we will then use machine learning in MATLAB to experiment with appropriate regression methods and attempt

Fig. 1. Flights activity per day in DC Metro Area

to produce a model that can determine (within a degree of confidence) the likely number of additional coronavirus deaths that may result from the ongoing flights into a given airport. Control counties with 0 flights will be added to the model as well, chosen at random, which do not contain airports and are not adjacent to counties with airports.

To allow for public review and availability of our data and ongoing progress, we will be posting the progress of our project online [27].

V. INITIAL ANALYSIS AND VISUALIZATION

When the initial data preparation and cleaning were completed, we began using MATLAB to visualize the data available. To begin, we took a look at the number of flights per day to determine if there are any clear trends, we should look at in the corresponding coronavirus data. As can be seen in Fig. 1 below, we were able to spot several regions of particularly low and high activity relative to the average of 447 flights per day.

Additionally, at this stage we began looking at the increases in cases and deaths per day for each region. Fig. 2 illustrates the cases and deaths reported in Washington DC itself for the time period of March 2020 through March of 2021. Noting that our flight data ends on January 1st of 2021, there are still several clear peaks that can be looked at (at least in this data set) to determine if the number of flights into the DC region have an effect on the resulting cases/deaths.

To accomplish this initial look at how closely correlated flights are with deaths and cases per day, we ran some preliminary analysis and attempted to create scatterplots around our initial concept for the Washington DC area. That is to say that we compared flights with the number of cases reported a week later when we anticipated those would be detected or otherwise reported to the appropriate health agencies. When looking at this data we found unexpectedly that there was very limited negative correlation. Running Pearson's correlation coefficient against the two values yielded a result of -0.29 where the more

Fig. 2. Washington DC cases and death per day

Fig. 4. Washington DC flights and deaths reported three weeks later

Fig. 3. Washington DC flights and cases reported a week later

flights reported the fewer cases were reported 7 days later. This can be roughly seen in Fig. 3 the scatterplot of these two values with a slight negative trend. Note however that the large accumulation of points near the right end of the graph at 1000 flights per day reflects early flight data towards the beginning of the pandemic and may need to be considered differently as lockdowns and containment procedures by airlines had not yet been implemented at the time.

A similar attempt was made at analyzing the relationship between flights and deaths reported 21 days later. Fig. 4 shows a slightly more pronounced negative correlation of -0.31 and a similarly more pronounced trend in the visible scatterplot of these values. Note that the same limitation of the cases applies, where the cluster of dots at the right side of the graph reflects data from early on in the pandemic before the coronavirus was as widespread.

As our team had initially hypothesized that there would

be a clear positive correlation between these values, it's clear that these unanticipated results may require further review to ensure that our existing methodology is correct, particularly in light of the literature review that we previously conducted. It is however possible that our methodology is correct and that the negative correlation is due to other factors, such as local lockdowns, restrictions and policy which we also have yet to conclusively determine. Additionally, as noted before there is still data in our current analysis and visualizations reflecting the period early in the pandemic where the results of flight into the region may reflect differently on resulting cases than it would later when the virus is more common.

VI. ANALYSIS

After reviewing the results of our initial analysis, we determined that starting our analysis on April 1st (after any government restrictions were put in place) would better reflect the impact of flights on case numbers. Additionally, as our initial method of looking at cases and deaths a number of days past the flight misses the large number of cases reported before and after the chosen day, we determined that a better method would be using an average of the number of new cases reported up to 14 days after the initial flight. Based on these updated methods, here were our analysis results:

A. Loudoun County and Dulles International Airport

When looking at Dulles Airport and the surrounding Loudoun County, we determined that there was a fairly minimal but still present positive trend between the number of flights and new cases over 14 days, with a correlation coefficient of 0.16. In attempting to model this with linear regression however, the following result in Fig. 5 was produced.

The blue dots are a scatterplot of the actual data points, while yellow is the prediction based on the model. With 25% holdout validation, the root mean square error was 35.866.

Fig. 5. Linear Regression Model- Flights into Dulles Airport and New Cases in Loudoun County over next 14 days.

Fig. 6. Linear Regression Model- Flights into Reagan National Airport and New Cases in Arlington County over next 14 days

Based on this, and the visible chart above, it seems apparent that while a positive correlation may exist, there is significant variance in the 14-days average of new cases that limits the predictive power of linear regression.

B. Arlington and Reagan National Airport

A similar result was achieved when looking at Reagan National Airport and the surrounding Arlington County. Based on our data, we unexpectedly observed a negative trend between the number of flights and the number of new cases in Arlington, with a correlation coefficient of -0.376 . Our linear correlation model is illustrated in Fig. 6. Based on the same 25% holdout validation, the root mean square error of this model was 15.084. While a much clearer negative trend exists in this chart, it should however be noted that there may be unaccounted confounding variables, such as the closure of Gate 35X at Reagan National Airport and subsequent opening of a new concourse over the next few months.

C. Anne Arundel County and Baltimore Airport

Anne-Arundel County holds the last of the three major airports in the Washington DC Metro Area. Unlike Reagan National, this airport showed a slight positive correlation between the number of flights and the 14-day average of new cases, with a correlation coefficient of 0.2 . Our resulting model can be seen in Fig. 7 below.

With 25% holdout validation, the root mean square error for this model was 41.43. As can be seen above, while there is a slight positive trend, most 14-day averages are clustered around 50 cases per day, regardless of the number of flights reported.

D. Washington, DC itself

Among the considerations we had when looking at this data, we suspected that a large number of travelers into these airports may be flying into the region to work in Washington, DC as the largest city in the region. As a result, the final

Fig. 7. Linear Regression Model- Flights into Baltimore International Airport and New Cases in Anne-Arundel County over next 14 days

model we produced took all flights into all three airports and, like prior models, paired them to the 14-day average of new cases reported in Washington, DC. Our correlation coefficient showed a slight negative trend of -0.767 , the specific model produced is illustrated below in Fig. 8.

As can be seen above, this was unfortunately the least predictive of our models. Based on 25% holdout validation, the RMSE of this model was a comparatively high 69.238.

VII. CONCLUSIONS

What we determined based on our work in modeling the number of flights and resulting cases into the DC Metro Area is that the number of flights by itself seems to have a very minimal impact on the number of new cases reported over the next 14 days. We suspect this may be due to several reasons. It is possible that the number of flights (which notably non-passenger flights carrying cargo) isn't a good metric for

Fig. 8. Linear Regression Model- Flights into IAD, BWI, and DCA, and New Cases in the District of Columbia over the next 14 days

measuring how flights impact the number of reported cases in a region. It is also possible that airline policies have played a significant role in reducing in-flight transmission of coronavirus. We also surmise that a lack of testing requirements either before or after flights coupled with varying testing infrastructure in Maryland, Virginia, and Washington, DC may cause cases resulting from flight to be missed by our sources. Regardless, our conclusion at this time is that the number of flights by itself does not strongly correlate to the resulting number of new cases reported in the surrounding county over the next 14 days and should not be used as the sole predictor in future machine learning systems.

VIII. FUTURE WORK

Although the results showed little correlation because of travel by flight and COVID-19 cases in the DMV region, there are still significant improvements that can be made to our work. As COVID-19 is relatively still new, there are a lot of different experiments and tests that can be done. As a possible example, future algorithms may consider taking the origin airport into consideration. Another plausible research idea would be to see what kind of safety precautions were taken and using hypothesis testing to determine which specific measures reduce coronavirus transmission and to what degree. As a direct improvement to our method, rather than looking at the number of flights another approach for this project would have been to look at the total number of passengers each day, thus excluding the commercial cargo flights. This may allow for a clearer understanding of the correlation between air travel and COVID-19 cases. While it was deemed inappropriate for our usage (as we were anticipating and trying to determine linear correlation), yet another improvement would be attempting to model these data with an array of other unsupervised machine learning algorithms, selecting for the lowest RMSE to find a better model for the data (likely combined with other improvements mentioned above).

Abstract—During two decades, there have been a revolution in the field of digital communication and internet access. Today, it became possible for users to access the internet while on the move through an infrastructure of high-speed mobile broadband networks. Technologies such as LTE and 5G became essential. Mobile broadband networks allow mobility; connection reliability drops during movement. Thus, some failure intolerant processes, such as system updates, necessitates the utilization of a reliable connection. This paper introduces a model that predicts whether the user is mobile or stationary. This is done based on the traffic patterns at the server-side. Distinct network technologies entails distinct nature of traffic patterns. In this paper, machine learning is utilized at the server-side to allow differentiating between data transmitted by a stationary user and data transmitted by a mobile user at the server-side. Supervised training is utilized to train the model. Then, the model was tested and prediction accuracy of this model was 92.6 percent. Finally, the proposed system is a novel work and the first of its kind since it is the first to attempt to predict mobile network user's mobility at the server-side by utilizing packets' arrival patterns. The proposed system can be applied at mobile apps and allow them to collect data about the apps users mobility while using this service without needing to access the GPS. Also, it can be used network management and public safety.

Index Terms—machine learning, traffic, mobile, stationery, broadband

I. INTRODUCTION

In recent years, there have been prompt improvements in communication and information technology fields. Since the beginning of this century, these fields have caught a huge revolution that has had profound and powerful influences on humans' lives. At the start of the new millennium, users had to be stationary to be able to access the internet. Landline telephone systems with dial up internet were the main means of communication between individuals. Today, billions of individuals utilize their mobile phones and cellular network infrastructure to access the internet while on the move.

Today, mobile network subscribers have reached 5.31 billion worldwide [1]. Not only has the number of subscribers increased but also the number of devices.

According to Juniper Research, by the end of 2022, the number of devices connected to the internet will reach an astounding 46 billion [2]. Moreover, this communication revolution is linked to a revolution in data-processing, particularly with technologies, such as artificial intelligence, cloud computing, internet of things, robotics, and others.

Mobile broadband networks utilize cellular wireless technologies that allow users to connect their mobile devices (e.g., smartphones, tablets) wirelessly to a broadband internet connection through the mobile cellular network. Such networks offer high-speed internet access provided by the infrastructure of the mobile cellular networks network (e.g., CDMA, GSM, 3G, LTE, and 5G). However, traffic coming from mobile networks is still behind fixed networks' counterparts. As of 2018, the traffic arriving through the fixed broadband infrastructure was four times its mobile counterpart in the US [3]. This is because those mobile networks are less available. Further, the data transmission speed fluctuates due to resource sharing. Mobile networks are more costly compared to fixed networks. Therefore, data usage caps are in place with mobile data plans.

While mobile networks offer users internet access while on the move, this access is subject to several variables and, therefore, might be less reliable. Such variables include the coverage level and the presence of gaps in coverage. Also, in mobile networks, users compete for resources with other users, and when the network is busy, the mobile network assigns more bandwidth to users with better channel conditions, and sometimes the network would disconnect users with bad channel characteristics to serve other users with better channel conditions [4]. Therefore, when mobile devices conduct critical function (e.g., system update) that necessitates the use of a reliable internet connection. Some systems require users to be connected to a fixed broadband network to be updated. On the other hand, access to a mobile network while driving is dangerous

and illegal. This paper proposes an approach that distinguishes whether a user is mobile or stationary. This is done by examining the patterns of packets arriving at the server. Then, a machine-learning algorithm is utilized to differentiate whether the user connected is mobile or stationary. The proposed system has several use cases such as data collection and data mining, surveillance, public safety, network management, and load balancing.

II. MOTIVATION

Access to data networks from anywhere has become necessary in our lives today. The server-side of the application is usually clueless to whether the user of the application is mobile or stationary. Further, if a virtual private network is used it makes it very difficult for the server to determine the type of network used by examining the source IP address. This paper employs machine learning to determine the user's mobility status by utilizing the incoming traffic at the server-side. Knowledge of mobility status can be utilized for security and management applications. For example, limiting certain types of services to stationary users or ensuring that the appropriate kind of connection is employed for important processes such as system updates. Moreover, this can be used for data collection about users whether they use a service while mobile or stationary. Another application would be public safety. For example, if you suspect the user is driving, access to the service can be put on hold.

III. BACKGROUND

A typical objective of analysis of packet patterns is to gauge the quality of service of systems and networks [5][6]. Several research projects examine traffic patterns to extract new knowledge. For instance, a research project examined packets payload to determine the application sending and receiving these packets [7]. Another research project examined HTTP packets for the purpose of detecting attacks such as denial of service attacks [8]. Correspondingly, packet patterns analysis is employed to study user behavior [9]. Generally, there are three categories for packet analysis. The first is port-based analysis, where the port number of the TCP or UDP service is employed to specify the type of traffic [10]. The second category is payload analysis, where the packet's payload is inspected if not encrypted [11], or patterns are inspected if encrypted [12]. The last category is statistical [13], where the statistical patterns of traffic are examined.

Some of the traffic data analysis methods discussed above employ machine learning algorithms such as Bayesian [14] and Ripper [15]. Machine learning has been a paramount instrument to determining traffic types especially for the quality-of-service purposes, as

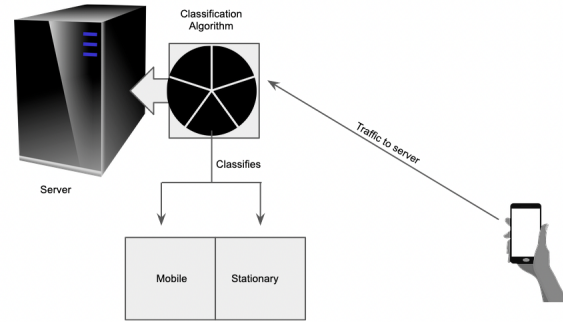

Fig. 1. Overview

detecting dropping nodes [16], or for security purposes as intruders' detection [17]. Several works [18][19][20] used machine learning to predict mobility at the network side. However, it was done using physical layer measurements, which are only accessible by the service provider. As seen from the discussed related work, most of the research projects discussed investigate traffic patterns to specify applications, measure the quality of service, or detect anomalies. Other works use machine learning on the mobile network side to determine the mobility of users. Our study is novel and the first of its kind. It is the first attempt to detect of user's mobility status at the server-side by employing the pattern of the arriving packets.

IV. METHODS

This research project goal is to allow servers to determine whether the user is mobile or stationary. To achieve that, the application server incorporates a machine learning model. This model classifies the incoming traffic and determines whether it is coming from a mobile or a stationary user. This is done by analyzing the arrival patterns of the received packets. The proposed system architecture is illustrated in Fig. 1. As the figure shows, the user sends data through the network medium in-use to the server. At server side, a classification algorithm analyzes the pattern of the incoming packets then classifies this traffic as traffic coming from a connection with a mobile user or from a connection with a stationary user. This work can be combined with our previous work [21], which differentiates between users using fixed(e.g., fiber or cable) networks from users using mobile networks. If the traffic appears to be coming from a mobile network, using the same data set, the classifier above would be able to determine whether the user is mobile or stationary.

As discussed above, the server incorporates a classification model that is used to determine the user's

mobility status using a number of received packets. Supervised machine learning is used to train this model. A label is attached to the training data. The labeled training data includes the following attributes:

- 1) The number of packets received in a window of five seconds.
- 2) The differential time of arrival of the packets received during this time window. The differential time of arrival is the time of arrival of a packet subtracted from the time of arrival of the previous packet. The differential time of the arrival measured in seconds.
- 3) The packet length in bytes. Packet length is usually adjusted based on the bandwidth and channel condition.

Diverse sets of data ought to be utilized in training to improve the classification model accuracy. Thus, improving the overall robustness of the system. A diverse data sets include data from various locations and various mobile carriers. The following section unveils more information about the data used in the training of the classification model. Further, it discusses the classification algorithm used, the test data, and the test results of the trained classification model.

V. EXPERIMENT AND RESULTS

To deploy a testing environment for the proposed system, a cloud Linux server was used. On this server, an HTTP server was installed and configured using Apache. On the HTTP server a large file of the size of 1 Gigabytes was hosted. This file was downloaded by a user using three different mobile network service providers following the scenario below:

- 1) Three hours of data collected while downloading the file discussed above while the data collector is driving at various speeds.
- 2) Three hours of data collected while the data collector is stationary at 9 different locations.

During the time the file is being downloaded generated traffic packets were recorded and monitored at the server. A total of six hours of data collection was done. Packets were collected at the server using Tshark[18].

The collected data is then preprocessed. In the pre-processing, incomplete entries and inconsistent rows are removed. Each five seconds of data was combined in a single record. The number of packets arrived during the five seconds was added to the record. One file combined the recorded data. The file was formatted to include the reflect three types of attributes discussed in the previous section. Then, the records in the file were labeled to define the data class. The collected data was divided into two sets. The first set contains 80 percent of the original data (3,456 records), was used to train the

classification model. The classification model employed the random forest algorithm. After training the model was tested using the second set of data, which consists of 20 percent of the data (864 records), to determine the accuracy of the trained model. The test results. are as shown in Table I.

TABLE I
SUCCESS RATE

N = 864	Actual	
	stationary	Mobile
True	TF = 47.2%	TM = 45.4%
False	FF = 4.1%	FM = 3.3%

In the table above, the confusion matrix displays the accuracy-test results. True stationary(TF) means when the model predicted that the user is stationary and the user was actually stationary. False stationary (FF) means when the model predicted falsely that user is stationary. True Mobile (TM) reflects the times the model predicted the user to be moving and the user was actually mobile. False Mobile(FM) reflects the times the model predicted the user to moving but the user was stationary. Equation 1 below is used to calculate the validation success rate.

$$\frac{True\ Positive + True\ Negative}{N, Total\ number\ of\ a\ dataset} \times 100 \quad (1)$$

As a result, A validation success rate of 92.6% is provided by the proposed scheme.

VI. CONCLUSION

The availability of network access when mobile is becoming essential today. User can access these network while is stationary, moving, or moving at higher speed when driving . Different user mobility status entails different forms of traffic pattern.

A machine learning model at the server-side is employed by this paper to enable the server to distinguish between data generated from a connection with a mobile user and data generated from a connection with a stationary user. This model was trained through supervised training. The test result of the model showed an accuracy of 92.6 percent.

The work in this paper is novel and the first of its kind. It is the first attempt to detect the user’s mobility status at the server side by utilizing the arrival patterns of traffic packets. Machine learning was employed at the server-side to obtain new knowledge. Such knowledge can be utilized to data mine the users’ behavior. Further, it can be employed in applications such as safety and security management. From this point, s next step would be attempting to differentiate between traffic transmitted using different internet service providers. Likewise,

differentiating between traffic transmitted by different mobile networks protocols (e.g., 3G, LTE, 5G).

Abstract—Nowadays, data has become more and more important. Most governments have passed laws to control how they are owned and used, such as the GDPR in Europe. However, any law is never perfect. We can see it when a company scattered around the world is hampered by the fact of not being able to exploit customer data outside the borders of a territory. Also, we can add that a data owner is not anymore once he sells them to a third party to be exploited. In this work, we propose a solution based on a permissioned blockchain, namely the Hyperledger Fabric, to allow any stakeholder with data to take part, with value providers, in creating Decentralized Autonomous organizations (DAOs). Once created, a DAO can attract other investors to expand it. The Hyperledger Fabric handles this whole process through channels. The infrastructure needed to run the business of the DAO is generated automatically through special transactions taking place at the blockchain level. In the opposite direction, the cloud infrastructure sends notifications to the Hyperledger for traceability and monitoring purposes. Finally, through simulations of wealth distribution models, we show that to keep control of a DAO based on the proposed architecture, the shares must be negotiated according to a Pareto law.

Index Terms—Data-Marketplace, Cloud, Blockchain, Hyperledger Fabric, IoT, DAO, Secure multi-party computation, Data.

I. INTRODUCTION

We will remember 21st century technology for its data-driven gold rush. In fact, the amounts of data do not decrease but increase exponentially. It all started when Sir Tim Berners Lee invented hyperlinks (WWW), which gave life to data sharing around the world. Today, more and more people are using the Internet and new services are appearing, thus generating even more many and diversified data. Nowadays, companies can provide personalized content to each individual user.

Currently, IoT infrastructures generate a large part of the data in the world [1]. Large enterprises are competing to provide the next generation of smart devices to provide their customers with a new lifestyle, as well as to provide enterprises with real-time monitoring of their business operations [2]. Huge futuristic projects are being carried out thanks to the huge amount of connected smart sensors. Smart cities are the perfect example of this, as we are not just

envisioning but seeing it solving many problems in urban areas [3]. Sectors such as transport, energy, networks of networks up to public administration all benefit from these solutions. Regardless of the IoT-based system, the underlying infrastructure will always generate a dataset to be mined.

But if you get six good things about the data, you have half a dozen challenges around them. Let us cite the enormous storage capacity necessary to keep the data with a view to their exploitation and/or archiving (Big Data paradigm) and the legal aspect of their exploitation which has sounded the alarm of many organizations in order to protect those of privacy which led them to publish laws that dictate their collection, storage and use [4]. However, these laws do not sufficiently respect the economic aspect of the exploitation of data given the absence of mechanisms allowing their use on a large scale while preserving their private nature. Whichever party may regulate the use of data, whatever the nature of the data, it must not impede technological advances by the measures it imposes.

It is in this context that we introduce in this work a solution that gives more rights to the owner of the data. Indeed, deciding how to exploit the data by giving more control to its owner and guaranteeing him the most interesting return on investment possible are the essential objectives of this work. To prevent the use of data without the knowledge of their owner, we offer a solution based on the encryption of the latter using a secure multi-party calculation. The blockchain makes it possible to keep traces, which are very useful in the event of disputes, thanks to the concept of immutable registers. [5]. To preserve the rights of data users, the architecture proposed in this work stipulates an organizational structure according to the paradigm of Decentralized and Autonomous Organizations (DAO). In fact, a DAO is created as soon as a data owner and a value provider agree. New value provider can join an already created DAO by redistributing the benefits and updating its version. The process repeats itself until the DAO stabilizes on a state of equilibrium which may be due, for example, to an unattractive return on investment for new entrants.

We structure this paper as follows: The section II summarizes the technologies used in our system. The section III outlines some of the related work and explains how our approach is unique. We present the proposed architecture and

its components in the section IV. Next, we show how the stakeholder in our system interact with each other in the section V. In the section VII, we cover some aspects of our architecture, along with an explanation of the benefit sharing process. Finally, we end the article with some benefits, general uses of our system, and future work that we can and will implement in our system.

II. BACKGROUND

In this section, we are presenting an overview about various technologies that are the building blocks for our system.

A. Hyperledger Fabric

1) *Overview:* Hyperledger Fabric V1.0 was released by the Linux Foundation in 2017. It is an open-source permissioned blockchain framework. It came to life to provide a secure, scalable and flexible groundwork for industrial blockchain solutions. Fabric got rid of the mining process and made sure that access to the data in the ledger is only to authorized members by creating subnets in the network called Channels. Peers can join a channel (or multiple channels at the same time) by enrolling through MSP (Membership Service Provider) and therefore it will have its ledger and chaincodes (smart contracts) installed. Consensus is achieved in Hyperledger Fabric after three phases: Endorsement, Ordering and Validation.

- **Endorsement phase:** Endorsing peers will simulate and execute transactions in an isolated environment and then either sign it as endorsed or not. The result is sent back to the transaction initiator.
- **Ordering phase:** Ordering service (also called ordering service nodes) will receive the transaction and the endorsement signatures and determine the order of transactions.
- **Validation phase:** Validating the authenticity and correctness of blocks of transactions

2) *Events in Hyperledger Fabric:* There are three sorts of events that can be subscribed to in Hyperledger Fabric:

- **Block events:** Events that are set automatically after committing a block.
- **Transaction events:** Also set automatically after committing transaction.
- **Contract events:** Events explicitly added to the chaincode and is set with the contract invocation.

By listening for these events, the application can respond without having to initiate a transaction. In our system, we will use the contract events by setting up an event listener and handler that will allow us to utilize data included in these notifications to automatically command and control an infrastructure.

B. Secure Multi-party computation

The idea of outsourcing data processing and computing without handing over the keys to it is the basis of our system. We know that fully homomorphic encryption [7], [8], allows such privacy, but we also know that it is fully unpractical. It basically goes like this:

Alice encrypts her data $AliceData$ and sends it $E_{Alice}(AliceData)$ to Bob, does his computation $f(E_{Alice}(AliceData)) = R$ and returns the encrypted result. Alice then decrypts $D_{Alice}(R)$ to find out the results. Multi-party computation [9] on the other hand is a scheme first developed in 1980's that aims to provide techniques allowing entities to collaboratively calculate a function while keeping their inputs private.

Many protocols are being developed to optimise further the performance of such systems. SPDZ [10], a universal multiparty computing protocol that is safe against up to $n-1$ of the n players being corrupted by an active attacker, is an interesting one that can be implemented to ensure data privacy.

C. Decentralized Autonomous Organization

A decentralized autonomous organization (DAO) is a collection of entities that work together using smart contracts [11]. This implies that all corporate processes, definitions, and restrictions are encoded in the blockchain and cannot be changed. This type of organization was inspired by the decentralized cryptocurrencies by not having any central authority controlling all the flow and risking both single points of failure and privacy issues. As a result, investors may now purchase DAO shares and get tokens that reflect their ownership in the organization and let them to vote on future initiatives. DAOs are established in our system when two parties agree to collaborate. It's worth noting that one or both of them might already be a DAO.

III. LITERATURE REVIEW

Numerous blockchain based data marketplaces have been introduced in the last few years, each with its own vision and architecture. In [12]–[15] they proposed a decentralized buy/sell architecture based on blockchain as the new solution to traditional data markets. It enforces the fair play between the parties by a punishment system for dishonest behaviours. Elimination of central trusted authorities so that owners of data can have control over it. The implementations of immutable ledgers and smart contracts enabled the users to browse and pick with who they want to work. And to ensure data privacy during the transaction so that no one but the authorized parties can see it, various approaches are presented; Selling the decryption key to an encrypted database [12], or by using swarms in Ethereum network as a decentralized storage for example [13].

In [16]–[18] systems are designed for IoT devices by providing a decentralized platform to sell data streams. These infrastructures are characterized by their low-resources, computational power and lack of security and privacy which requires some sort of middle-system that helps compensate for these weaknesses so they can serve multiple buyers at once. [19] took a step forward with what was already done. A mix of different technologies as hyperledger fabric as an immutable ledger, Cosmos [20] for token interoperability and Mainflux as an IoT gateway. The trade is done by exchanging tokens

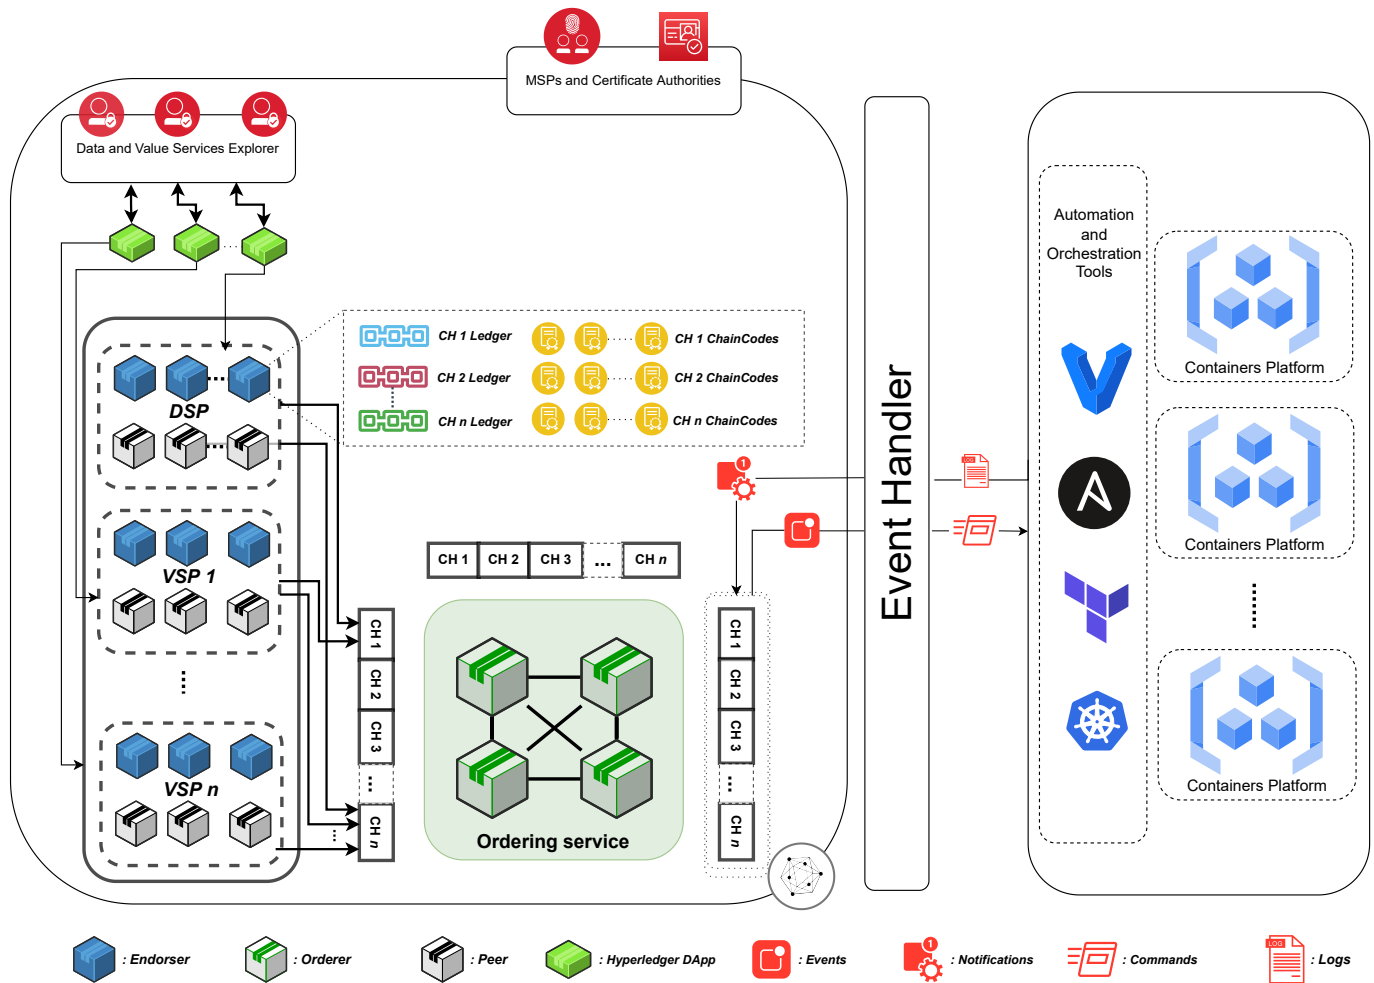

Fig. 1. Data ownership centric architecture

for a Proxied URL with an expiration date determined in the transaction.

We can see in these examples how they all provided a sales marketplace, and at some point the data will be at the other side in plain text with no proof of where it is and how it is being used. Our approach is different. Firstly, we are not interested in selling data as it has already been done before many times. We took the famous sentence ‘Data is the new Oil’ to the letter. Any person having an oil field can either sell it and be satisfied with the one time payment, which is not what people do, or can be part of the business and invest with his land. As for data, it is important to ensure privacy and anonymity in the exploitation phase. Secondly, we want a decentralized control and monitoring over the infrastructure where all the business is running through blockchain.

IV. DATA OWNERSHIP CENTRIC ARCHITECTURE

A. An overview of the proposed architecture

Here, we present an overview of the architecture and its components (Fig. 1). Several parts make up the proposed architecture. Namely, a Hyperledger Fabric module and a

Cloud Infrastructure, as well as an event handler facilitating communication between the two by converting Hyperledger events into commands executed by the Cloud and conveying notifications from the latter to the Hyperledger fabric to be registered IV-C. Our goal is to provide a framework for building data-centric DAOs in a non-trust environment. In this way, a data owner would own shares of the DAO concerned as tokens, allowing him to be a member shaping its evolution.

B. The hyperledger part

The Data and Value Services Explorer is where each service is exposed to the various interested parties, with a description containing all the details needed to conclude a business contract. At this level, the stakeholders sign up to benefit subsequently from a space for negotiation in order to launch new DAOs or to join one or more existing ones.

A business contract can be concluded either between one or more data service providers and one or more value providers, or between one or more value providers and an existing DAO. In case of consensus, the stakeholders create a

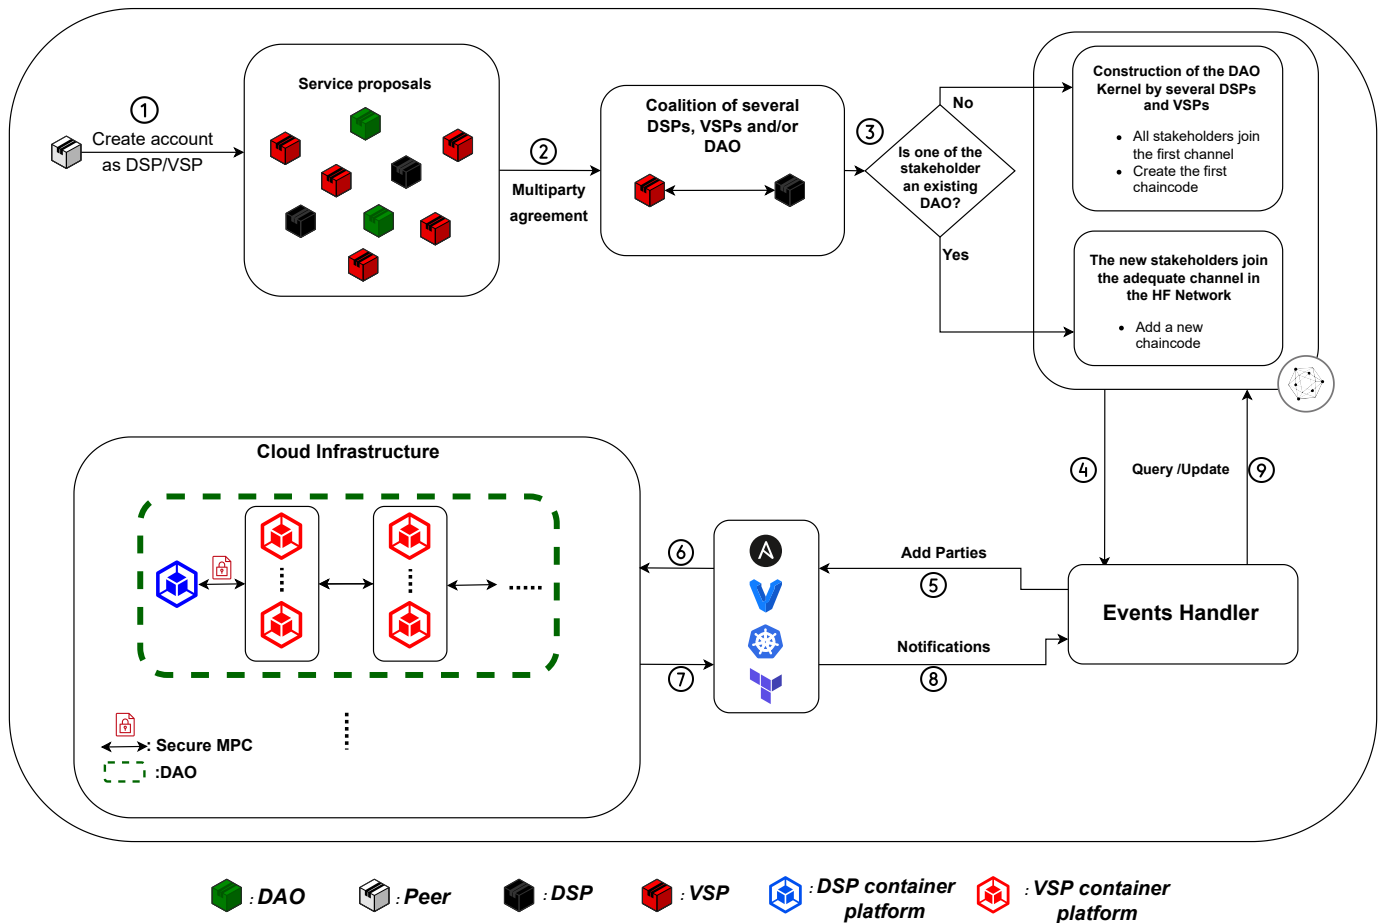

Fig. 2. Interactions between system actors

new DAO or they update the existing DAO.

A concluded contract is materialized by the creation and/or the addition of a new chain in the Hyperledger Fabric where the various transactions will be recorded immutably. Special transactions can auto-generate a cloud infrastructure reflecting the commitment in terms of resources of the stakeholders vis-à-vis the DAO of which they are members. Other types of transactions may concern either the monitoring of the evolution of the DAO or a transfer of rights between an active member and another internal to the DAO or with a new member.

Within each channel, there is a set of blockchain codes that specify the rules of the transactions within it. Then they will send several event notifications to the event handler to command the cloud infrastructure.

A data service provider is the owner of the data, the value provider is any party that can increase the value of the data by subjecting it to a set of operations, such as those relating to machine learning algorithms to derive models for decision making. So the more services above the data layer, the more

valuable the DAO.

Channels play a crucial role in maintaining confidentiality within DAOs. In fact, a data service provider DSP and a value provider VSP_1 which form a DAO will be assigned to a channel $CH_1 = \{DSP, VSP_1\}$. This will regulate the workflow using chaincode: profit sharing, approval policies, contract duration and other parameters regarding the business model and the infrastructure ordered. Any other VSP_2 party wishing to join the current DAO will join a new channel CH_2 with the CH_1 still running. Thus, after this last step, the active channels are: $CH_1 = \{DSP, VSP_1\}$, $CH_2 = \{DSP, VSP_1, VSP_2\}$. Each time a new value provider joins an existing DAO, this process will be repeated. In general, the channel CH_i will always have the form of the equation (1):

$$CH_i = \{DSP\} \cup \{VSP_j \mid 1 \leq j \leq i\}. \quad (1)$$

Any party in a given channel will have its ledger and channel codes installed, as well as subsequent channels. For example, the VSP_2 will have the registry and chaincodes from CH_2 up to CH_n . But not CH_1 since he is not a member. That said, we see how the data service provider will be at the heart of the DAO since it takes part in all channels.

C. The infrastructure part

Part of the transactions that take place at the Hyperledger Fabric level concern orders sent to the Cloud infrastructure. In fact, blockchain-level transactions should be able to automatically establish, update, and maintain cloud infrastructure dedicated to running the underlying DAO business processes.

It is by using automation tools [21] such as Vagrant [22], Ansible [23], Terraform [24], Kubernetes [25] that we can launch the instances working in a cloud environment. If a user wishes to work on his own machines, this will be defined in his contract. If no notification comes from his machine, the system assumes he abandoned the job and the contract will be terminated. In sec. VI we will define a future strategy for how to manage and create confidence in the market.

V. ARCHITECTURE COMPONENTS INTERACTIONS

A. A chart flow for the proposed architecture

We present in this section, see Fig. 2, the set of interactions between the system components, as well as the flow of actions inside the application.

① A user creates an account so he can be identified, then he selects his user type; Data service provider or a value service provider. Offers are posted on the distributed application with a specific description along with terms and conditions imposed by the original poster. These terms though can be changed as negotiations take place. Users browse and pick their desired partner for a specific job.

② Negotiations are a normal phase before any business agreement. Parties interested in each talk about their terms in order to find a mutual ground, each determines a stake which determines their portion of the DAO.

③ Once everything is set and done, the parties are now considered as one DAO. Now if one of the parties is an existing DAO, the new member joins them in the adequate channel. If not, a new DAO is created combining the two users.

④ Hyperledger fabric will be communicating with the cloud infrastructure using an event handler. It basically reads chaincode events and acts accordingly. This allow us to keep track of all the instances created.

⑤ The event handler should have converted events to script files for our automation tools by this step like Ansible, vagrant, kubernetes and terraform. It will give us the ability to systematise the infrastructure orchestration. ⑥ In this step, the script files are executed and everything is in place. The business will be running inside the cloud infrastructure. ⑦ Frequently, notifications about the big picture of the infrastructure will be sent back into the blockchain so that all members can monitor the flow of work.

⑧ The event handler will be the one converting these notification into queries.

⑨ Queries received are executed and new blocks are created reflecting the current state of the cloud infrastructure.

B. Data privacy

As in [26], a combination of Homomorphic encryption and multiparty computation will allow us to achieve a privacy-preserving framework to make our system even more data centric. It will enable our system to keep the data encrypted all the way through the computations and still have valuable results out of it.

VI. SOME ASPECTS OF THE PROPOSED ARCHITECTURE

As previously stated, our main goal is to make data driven projects preserve the right of privacy with no middle trusted authority. Data will never be decrypted during the whole process. Data owners will be able to make a profit from the final project as our vision is not to sell but to invest with data. One example of the possible business model will be a pay per use or subscription based, it all depends on the contract between the providers.

IoT infrastructures will rely significantly on our technology to offer a wide range of data to other parties for analysis and use while maintaining data privacy.

In terms of profit splitting, our system distributes profit π group wise and according to each party's stake as defined in the chaincodes of each channel. See Fig. 3 for a detailed tree graph describing the ownership percentage in a given DAO. The (i) in $DAO^{(i)}$ describes the version of the DAO created in channel CH_i . In order to compute the profit of a specific $DAO^{(i)}$ or VSP_i , we use the equations 2 and 3.

$$\pi[DAO^{(i)}] = \pi[DAO^{(n)}] \times \prod_{k=i+1}^n \beta_k \quad (2)$$

$$\pi[VSP_i] = (1 - \beta_i) \times \pi[DAO^{(i)}] \quad (3)$$

For stakeholders to build or integrating a DAO, the various stakeholders must agree on ratios β_i for the distribution of wealth. This value is used to calculate a member's share of total profit.

To visualize the evolution of the shares of the data owner as well as those of the value providers integrating the DAO step by step, we present in Fig. 4 and Fig. 5 graphs for two different scenarios: (i) In the first scenario we let's simulate the β_i from a uniform law, (ii) In the second scenario the β_i are taken from the equation 3 on which we have imposed a distribution of wealth according to the law of Pareto. We inject the deducted β_i into the equation 2 to generate the profits, as shown in the Fig. 5.

1) *Randomly selected values:* Creating β_i with this method is straightforward. Generate uniformly distributed and sorted values in an interval. We started with 25 – 99% then we increased it gradually and noticed that the value of all β_i should be at least 70% (in our example of 7 VSPs) in order to keep the Data Owner at the top of the pile(see Fig. 4). We also notice how the VSPs will have more leverage if they join a job at the end of it. This will make VSPs refuse to join works

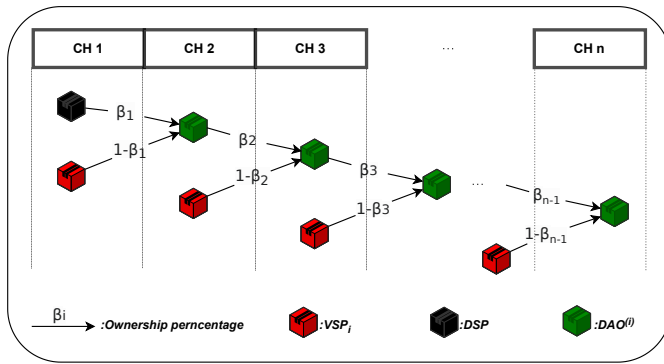

Fig. 3. Ownership percentages of each member in corresponding DAO

in its beginning. It can be solved by changing the range of β_i 80 – 99% but it will bring more problems than it solves as the DSP would monopolise the whole business. In this approach, we created β_i then analyzed the total ownership percentage.

2) *Selecting values according to Pareto Principle:* The Pareto principle [27], named after Vilfredo Pareto, an Italian economist and sociologist. It was developed to describe the distribution of majority of wealth in the hands of a top percentage of the population. It has many uses in multiple areas besides economy as insurance, manufacturing, management and many more. We will be using it to generate numbers following the distribution in question representing the total ownership percentage.

Algorithm Generate β_i fitting the total ownership to a Pareto distribution

Require: $n \geq 2$ ▷ Number of β_i

- 1: Generating n random numbers following Pareto’s distribution.
- 2: Scale (between 0 and 1 to describe percentage) then sort descending these numbers.
- 3: Assign each value with corresponding member starting with DSP and the highest value. ▷
Now we have for each member his total percentage. We can calculate β_i by reversing formulas 3

As we can see in Fig. 5, the percentage of total ownership drops down as we add more VSPs. This is a better result than what we got before. It is logical that as long as we add more VSPs, the value of the DAO will increase which leads to higher share prices. Contrary to what we did on the first one, in this approach we defined the total ownership percentage then deduced the β_i .

VII. CONCLUSION

Our system presents a functioning framework that allows anyone, and especially IoT infrastructure owners to invest their data in a DAO amongst other service providers to further increase the value extracted from that data. This will benefit IoT device manufacturers since our future consists of more gadgets and sensors all over the cities and infrastructures,

analytics services by having broader data point thus reducing the effects of ‘small dataset curse’ also known as overfitting, having real-time data to stay up to date. And the end users of course that will use the final service. Our motivation is to have always our data protected but still making it work in the real world to improve services, applications and overall user experience. As a future development, a user reputation system may be implemented. Parties can offer feedback on their interactions with a specific user by including a quality of experience mechanism, which will help us sanction poor conduct. This will boost user confidence, which is an important component of the online experience.

Abstract—Systems are ideally and rapidly evolving with the development of the Internet and modern web technologies. Example, Ecological monitoring information system has become very important in determining its superiority as a system, so it should be tested. This article describes how to benchmark a system by creating a state change graph to simulate different intuitions on the part of each subsystem, and then comparing the graph to Petri net modeling based on Functioning table (PNMFT). Test cases can be prepared based on the accessibility of trees based on comparable PNMFTs. The existing fact-testing strategy for comprehensive testing of the system will be further generalized to improve the consistent quality of the remaining tests. After that, talk about algorithmic analysis of the system is an important for information security issue. The initial stage of ongoing research to improve the reliability of algorithmic analysis of algorithmic formalization of web systems is described. It may also be advisable to include a set of dynamic coverage criteria for web systems defined for the statistical testing approach used through algorithmic analysis to improve testing quality and algorithmic formalization of the web system through algorithmic analysis.

Index Terms—algorithmic analysis, functioning table, information security, ecological monitoring, algorithmic formalization.

I. INTRODUCTION

The rapidly evolving information and communication technologies are making significant changes in all aspects of our daily life [1], [39]–[42], [44]. Nowadays, the concept of “information” is often used as a special trademark that can be bought, sold, exchanged for another product. Moreover, the cost of information [5]–[9], [43] often exceeds the cost of the computer system in which it is located, several hundred and thousand times. Consequently, there is an urgent need to protect information from unauthorized access, deliberate alteration, theft, loss and other criminal activity. However, the desire of society for a high level of automation makes it dependent on the level of security of the information technologies used [10]–[16].

The importance of information has been known since ancient times. Therefore, in ancient times, various methods were used to protect information [17]–[22], [45]. One of them is a mysterious inscription. No one but the addressee could

read the message. For centuries, this art - the mysterious writing - has not gone beyond the upper strata of society, the residences of state embassies and intelligence missions. Just a few decades ago, everything changed dramatically, that is, information acquired value and became a mass product. Now it is produced, stored, transferred, sold and bought. In addition, it has been stolen, distorted and falsified. Thus, there is a need to protect information.

Not only computers, global and corporate networks (Internet), but also modern, highly efficient means of information technology [23]–[26], [46] and processing of large amounts of information, such as statistical and financial institutions, were selected as the area of computer crimes.

Therefore, it is impossible to imagine the activities of any organization without the use of manual or computer tools for obtaining a variety of information, obtaining certain decisions as a result of the analysis of information and its transmission through communication channels. The computer can be viewed as an object of aggression and as an instrument of aggression.

The complex of measures for information security [27]–[30], [47] should be based on an information protection strategy. It defines the objectives, criteria, principles and procedures needed to build a robust security system.

An important feature of the general information protection strategy is the prohibition of the security system. There are two main areas:

- Analysis of guarantees;
- Detect an attack.

The second problem in the information security hierarchy is policy definition. Its content consists of the most rational means and resources, the goal of the problem and its approach.

This document consists of several pages of text that form the physical architecture of the network, and the information in it determines the choice of security product.

When developing an information security policy, first of all, the protected object [31]–[36], [48] and its functions are determined. Then the level of the enemy’s interest in the object, the possible types of attacks and the damage inflicted are assessed. Finally, the weak points of the object

are identified that do not provide adequate protection against the available countermeasures.

II. LITERATURE REVIEW

Algorithmic analysis methods for rational linear hybrid automata have been used in such tools as HYTECH and POLKA. In addition, when used on a secure system, the inspection procedures of these tools are used to detect security property violations [2]. Provide a way to bridge models at the computational and algorithmic levels and define levels of analysis between computation and algorithm. Often, computational level models involve a deeper introduction of the applied concept of rationality to the algorithmic level [3]. Rational analysis is taken to the algorithmic level [4]. Algorithmic stability was used to analyze the adaptive data [5]. Kuhn-Munkres parallel genetic algorithm and its application to algorithmic analysis of large-scale wireless sensor networks [6].

III. MATERIALS AND METHODS

Individual elements of a Petri net (positions and transitions) can have different properties, on the basis of which the properties of the nets themselves are first determined, and then their classification is built.

The simplest property of a position is the number of labels that can be placed in it. If in any reachable markup the number of labels in a given position is at most one (0 or 1), then such a position is called safe. A Petri net is said to be safe if all its position are safe. In secure networks, the state of each location is described by just one bit, so such networks can be easily implemented in hardware using certain types of switches (triggers). By the way, the original version of the definition of a Petri net, given by Adam Petri himself, just implied that the net is secure. However, for most applications, the requirement for network security is overly stringent. It can be weakened by allowing each location to store some limited number of tags. More strictly, a position is called k-bounded if in any reachable markup at a given position there are at most k labels. Obviously, 1-limited space is safe. A position is called restricted if there is such k such that this positions is k-restricted. Finally, a Petri net is k-bounded if any of its positions are k-bounded, and simply bounded if all of its positions are bounded. Bounded networks also allow for an efficient hardware implementation, in which each location is represented by a counter (for example, a register) of some given capacity. Unlimited networks are, as a rule, of only theoretical interest.

Another property of Petri nets, based on counting the number of labels, is the property of conservatism. A network is called conservative if the number of labels in any reachable markup is kept the same (equal to the number of labels in the initial markup). Such a model is used, for example, in cases where labels represent some system resources that are not destroyed or created. These resources can move from one part of the system to another, but their total amount does not change during the operation of the system. It is easy to show

that any transition that occurs in at least one reachable markup must have the same number of input and output arcs - as many marks he chose, he must put them as many.

A. Formalization of the Functioning table through the Petri net

Petri nets for the Functioning table are classical models for modeling systems that demonstrate parallelism, synchronization and randomness. A Petri net based on a Functioning table is an oriented bipartite graph with two types of nodes called position and transitions. Nodes are connected by directional arcs. Connections between two nodes of the same type are not allowed, such as a simple Petri net. In the graphical representation, positions are represented by circles, and transitions are represented by stripes or rectangles [37], [38].

The position P is called the input transition position t if there is a directional arc from P to t , P is called the output position t if there is a directional arc from t to P . A transition is termed enabled if every of its input positions includes "enough" tokens. The enabled transition may work. Starting the transition t means consuming tokens from input positions and creating tokens for output positions.

Arcs are marked by their weight (positive integers), where a k-weighted arc can be interpreted as a set of k parallel arcs. A marked-up Petri net is shown as an algorithmic formalization.

The markup of the Petri net is a vector of natural numbers $M = (m_1, \dots, m_n)$, where n is the total number of positions. M_i represents the number of tokens in position P_i .

The markup M_n is said to be achievable from the initial markup M_0 if there is a sequence of launches that converts M_0 to M_n in the Functioning table. Then, based on it, it is possible to determine the sequence of markings $\{M_0, M_1, M_2, \dots\}$ and the sequence of transitions $\{t_1, t_2, \dots\}$. The reachability set $R(M_0)$ of the Petri net is the set of all labels achievable from $M(M_0)$ with an algorithmic description. The set of reachability of a Petri net can be algorithmically formalized by a tree. The tree ceases to expand if algorithmic formalization of the system with previously defined markup is achieved. Such a reachability tree can be used to search for dead-end marks in algorithmic analysis, that is, marks in which the transition is not allowed.

IV. RESULT AND DISCUSSION

A. Statistical testing through algorithmic analysis of the web system

This article describes how to use a Petri net model based on a Functioning table generated from a web system to obtain test cases that meet the criterion of all facets. This section summarizes the current statistical testing method for all-k-path and all-edge testing of web systems to improve the reliability of structural testing through algorithmic analysis.

An algorithmic analysis method based on a function table is used to define the specification of a sequence of methods, while this approach is to define the structural aspect of a system as a web system in terms of pathways. The algorithmic analysis method includes the following steps:

TABLE I

NUMBER OF TESTS N NEEDED TO ASSURE TEST QUALITY Q

N	q
66	0.91
129	0.991
193	0.9991
256	0.99991

- 1) The system is divided into several controlled subsystems based on the Functioning table.
- 2) The state transition graph is created for the algorithmic model of the behavior of each given subsystem based on the Functioning table.
- 3) Each state transition graph is transformed into an imitation of a Petri net based on the Functioning table, in which each transition has exactly one input and one output arc.
- 4) For each Petri net, based on the Functioning Table, reachability with reachability tree is created.
- 5) The criteria for covering all edges are applied to the reachability tree.

The position P is called the entry point to the transition t if there is a directed arc from P to t, the point P is called the exit point t if there is a directed arc from t to P.

Test cases play an important role in ensuring high quality system testing through algorithmic analysis. Incorrect test cases lead to unreliable web systems. It is also necessary to measure the quality of testing against some coverage criteria. In Denise and Gouraud [1], it is slightly reformalized to carry out statistical testing in congruence with any given graphical formalization of the character of the system under test. The

Fig. 1. Subsystem state transition graph based on the Functioning table

formalization of this method is as follows.

Let D be some algorithmic description of the system under test. D can be a specification or an algorithm, depending on the type of test of interest (functional or structural). Based on D , one can determine coverage criteria such as all k-paths, all edges, etc. D . A coverage criterion C is covered with probability $q_{C,N}(D)$ if each element of the corresponding set of elements $E_C(D)$ has probability at least $q_{C,N}(D)$ for N executions with random inputs. Quality $q_{C,N}(D)$ is a measure of test coverage relative to C . The following denotes the algorithmic relationship between test quality and test size N :

$$q_{C,N}(D) = 1 - (1 - q_{C,1}(D))^N \quad (1)$$

It is clear that the probability of reaching an element is equal to one minus the probability of not reaching it N times when N tests are performed.

This method can be used for structural testing of web systems. The completion of this work is shown below. When testing all k-paths on a reachability tree generated from a Petri net model based on a Functioning table of an example of an ecological monitoring subsystem shown with algorithmic formalization, $P \leq n$ and $AP \leq n$ denote a set of such paths, and all-k-criteria for covering paths respectively. In this case, the test quality can be obtained as follows:

$$q_{A,P \leq n,N}(D) = 1 - (1 - q_{C,1}(D))^N \quad (2)$$

In this example, choosing $n = 7$ results in 28 paths of length less than or equal to 7 (see Table 1). Equation (2) takes the form

$$q_{A,P \leq 7,N}(D) = 1 - (1 - \frac{1}{28})^N \quad (3)$$

and can be used to obtain test quality. The result is shown in Table 2. If the criterion for covering all edges is chosen instead of all k-paths, the result will be exactly the same as shown in Denise and Gouraud [1].

V. CONCLUSION

This article proposes a method of end-to-end algorithmic analysis of testing based on a Functioning table for algorithmic formalization of web systems. The web system can be divided into several subsystems depending on their characteristics using a Functioning table. State transition graphs and the corresponding Petri net model based on the Functioning table

can be created on the basis of various subsystems. The criterion for covering all edges is subsequently applied to the reachability tree derived from the Petri model based on the Functioning table for each subsystem to facilitate algorithmic analysis of the algorithm. Scientific novelty: The problem of algorithmic analysis of the system is performed on the basis of Functioning table.

All facets of the algorithmic formalization of the web system can be subjected to algorithmic analysis. The existing method of statistical testing of traditional systems is used to measure the quality of testing and algorithmic formalization of a web system with algorithmic analysis in relation to the criteria for covering all k-paths and all edges.

VI. ACKNOWLEDGEMENT

The scientific results obtained in the article are based on the project BV-M-F4-004 Development of Principles Of Algorithms for Control Of Complex Systems On The Basis Of Algebra Over Functioning Tables.

Abstract—Today, the development of modern digital technologies requires them to solve existing cyber security problems. Thus, in this study, by building an algorithmic model for user access control based on a functional table, information security of existing systems can be used to create imitation of processes occurring in the system, which allows you to apply and analyze specific problems. This study attempted to focus on algorithmic issues.

In this algorithmic model based on Functioning table, the user's access control process is active at all transitions in the Petri net, and cases can be reached and detected with an initial marking, a sequence of transitions leading to a particular state.

The algorithmic model based on the Functioning table of user access control has a strictly formal description that allows you to analyze the process of interaction of three subjects of information relations. This model allows switching the algorithmic model of user access control to the system to software implementation.

Index Terms—algorithmic modeling, functioning table, security, objective attribute, datalogical model, Petri net.

I. INTRODUCTION

Under this century, no one can doubt that smart robots, technologies and other technical devices that humans could not have imagined will be created. The development of information technology will ensure increased productivity, quality and, most importantly, high efficiency for each organization [1]–[5]. Newfangled digital technologies, along with the construction of conveniences, also pose new challenges. Over the last few years, the rapid expansion of information and telecommunications technologies in the world has had a significant impact on the worthy place of states in the global information society [6]–[12].

Today, the threat to the security of information stored in databases and circulating in telecommunications systems is growing rapidly. As a result, the problem of information security [13]–[16] has become a topical issue for the world.

To date, one of the most reliable tools in ensuring information security is cryptographic protection of information. In the world, this direction is developing rapidly. New cryptographic systems, algorithms [17]–[19], standards are being developed and applied in various fields. As noted, the information resources of any organization are one of the factors determining its economic and military potential. The effective [20]–[23] use of this resource will ensure the security of the country and the successful formation of a democratically informed society. In such a society, the speed of information exchange will increase, the application of advanced information and communication technologies [24], [25] for the collection, storage, processing and use of information will be widespread.

An informed society is rapidly evolving. In the world of information, the concept of state borders is disappearing. The global computer network is radically changing public administration.

Regardless of the regional location, in everyday life, a variety of information entered the Internet through an international computer network [26]–[30]. That is why it is important to protect existing information from problems such as illegal access, use and alteration, loss.

The organization's policy in the field of informatization is aimed at creating an information system that takes into account the modern world principles of development and improvement of information resources, information technologies [8] and information systems. The policy of the organization in the data protection sphere will be aimed at regulating social relations in the information sphere and determines the basic duty and

works of state powers and management in the information security sphere of person [31], [32], [44], community and the country.

Data safeguard in workstation systems [33], [42], [45] and grids means the use of various tools and methods, taking measures and implementing measures in order to systematically [34], [43] ensure the reliability of transmitted, stored and processed information.

The basic concept of information security is a comprehensive approach based on the integration into a single system with different communication and security subsystems, common hardware, communication channels, software and databases [35], [41].

Regardless of the form in which the integrated approach is applied, it solves complex and multidisciplinary specific issues with their interrelated solutions. The most pressing of these issues are the restriction of access to information [36], [40], [46], [47], technical and cryptographic protection of information, reducing the level of adjacent radiation of technical means, technical strengthening of objects, their protection and equipped with alarm devices.

The effectiveness of the facilities information security system is critical. For computer systems, this efficiency can be assessed by the choice of hardware and software used in the computer system. Such an efficiency assessment can be made through a growing curve showing that the level of security depends on the strengthening of control [37]–[39], [48] over access rights(Fig 1).

Fig. 1. Scheme for the developed algorithmic model of user access control system

II. MATERIALS AND METHODS

The algorithmic model was intended for use in a system that uses algorithmic modeling to determine the user access control workflow and takes into account some changes in the model based on the Functional Table. The user provides personal information, identifiers and / or is provided before logging in. As a result of algorithmic modeling for the administrator, a corresponding working window appears, which can display a list of active and passive users. When entering information into the database, the fettle of the motionless

/ moving executor swaps and the work that is being done separately begins. It is possible to change the user based on the subjective attribute and / or the objective attribute, it is advocated to apply this parameter only in the event of minor failures in information input(Fig 2).

It may be implemented in in practical analytical work founded on the correct of the note by monitoring the timely completion of the users work. The correct of the outcomes, in order to result in fresh approaches in survey. In this case,naturally, the notes are likened to the antecedent outcomes attained. It is therefore advocated to reserve the notes in concatenated relational databases. Increasing data size causes inconvenience and issues in performing a series of operations on information. It is therefore recommended to apply normalization in information pastures.

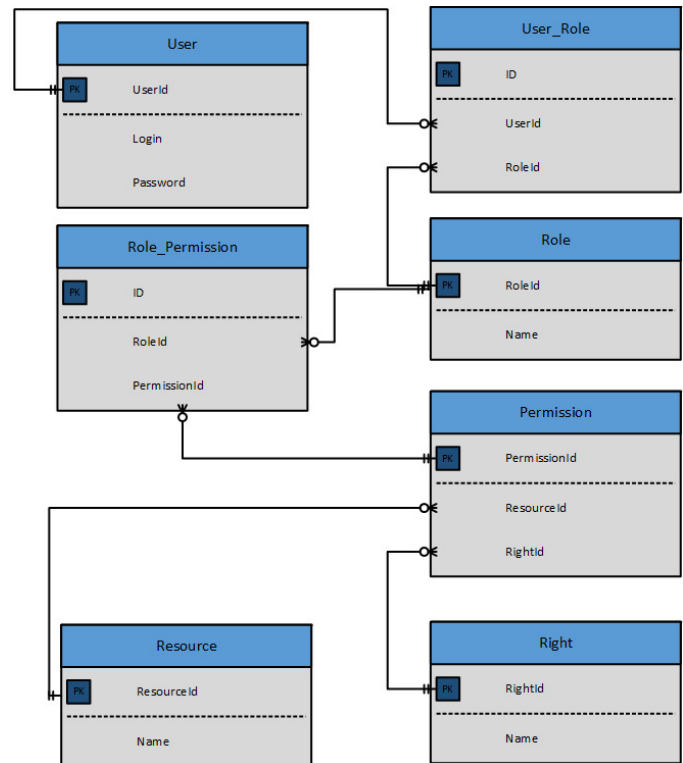

Fig. 2. Datalogical model for the developed algorithmic model of user access control system

III. RESULT AND DISCUSSION

The input label is made appropriate to the JSON Web Token standard. The norm defines JSON-based input labels. The label is made up of three components: header, payload and signature. The label is produced by the structure that provides a service, signed with a private key and conveyed to the users device, which then utilizes this label to prove his personality.

A relational database is used as a data store about the user on the server. It can be described using the datalogical model is shown in Figure 2.

It has ability to made corrections to user, create and destroy users applying the administration interface produced into the

TABLE I

DESCRIPTION OF THE PETRI NETWORK'S POSITIONS THAT IMITATES THE USER ACCESS CONTROL EVENT IN THE ALGORITHMIC MODEL BASED ON THE FUNCTIONING TABLE

p_0	User without access token
p_1	Authentication Manager received the user's login and password
p_2	The structure that provides a service adopted the executor's username and password
p_3	The structure that provides a service did not perceive a ratio in the executor's database
p_4	Authentication Manager adopted a failure information
p_5	The structure that provides a service perceived the executor in the structured set of data held in a computer
p_6	The structure that provides a service produced the executor input label
p_7	Authentication Manager adopted an input label from the structure that provides a service
p_8	User with access token
p_9	Authentication Manager adopted an input label from the executor
p_{10}	Label has been successfully made sure to the Authentication Manager
p_{11}	The label consists of the necessary consents
p_{12}	Permission to access the system
p_{13}	The label does not consist of the necessary consents
p_{14}	Expired label
p_{15}	The token with invalid signature

structure that provides a service. In order to subsequently move on to the program execution of the replica of the constructed algorithmic model based on Functioning table, it will build an algorithmic model for controlling its operation based on the Petri net inside Functioning table(Tab 1,2).

The algorithmic model implemented on the Petri network within the Functioning table is depicted as a six $\langle P, T, I, O, \mu, F_t \rangle$, where P and T are finite position sets and transition sets, I and O are sets of incoming and outgoing functions, μ is a set of state markings. The incoming function I maps the transition t_j to the set of positions $I(t_j)$, F_t to the set of components for operation and the output function O maps the transition t_j to the set of positions $O(t_j)$.

- finite position sets : $P = \{p_0, p_1, p_2, \dots, p_{15}\}$
- finite set of transition: $T = \{t_0, t_1, t_2, \dots, t_{15}\}$
- set of transition incoming positions:
 $I = \{I(t_0), I(t_1), I(t_2), \dots, I(t_{15})\}$.
 $I(t_0) = \{p_0\}, I(t_1) = \{p_1\}, I(t_2) = \{p_3\},$
 $I(t_3) = \{p_4\}, I(t_4) = \{p_5\}, I(t_5) = \{p_6\},$
 $I(t_6) = \{p_7\}, I(t_7) = \{p_8\}, I(t_8) = \{p_1\},$
 $I(t_9) = \{p_9\}, I(t_{10}) = \{p_{10}\}, I(t_{11}) = \{p_{11}\},$
 $I(t_{12}) = \{p_{12}\}, I(t_{13}) = \{p_{13}\}, I(t_{14}) = \{p_{14}\},$
 $I(t_{15}) = \{p_{15}\}.$
- set of transition outgoing positions:
 $O = \{O(t_0), O(t_1), O(t_2), \dots, O(t_{15})\}$.
 $O(t_0) = \{p_2\}, O(t_1) = \{p_3\},$
 $O(t_2) = \{p_4, p_6\}, O(t_3) = \{p_5\},$
 $O(t_4) = \{p_0\}, O(t_5) = \{p_7\},$
 $O(t_6) = \{p_8\}, O(t_7) = \{p_1\},$
 $O(t_8) = \{p_9\}, O(t_9) = \{p_{10}, p_{14}, p_{15}\},$

TABLE II

THE DESCRIPTION OF THE PETRI NETWORK'S TRANSITIONS THAT IMITATES THE USER ACCESS CONTROL EVENT IN THE ALGORITHMIC MODEL BASED ON THE FUNCTIONING TABLE

t_0	Lapsing the login and password to the authentication manager
t_1	Lapsing the login and password to the server
t_2	Searching for a user in the database
t_3	Lapsing the error message to the authentication manager
t_4	Lapsing the failure note to the executor
t_5	Producing an executor input label
t_6	Lapsing an input label from the structure that provides a service to the authentication manager
t_7	Passing the access token to the user
t_8	Passing an access token from a user to an authentication manager
t_9	Verification of access token
t_{10}	Checking access token permissions
t_{11}	Access to the system
t_{12}	Sending a message about successful object access
t_{13}	Lapsing the failure note to the executor
t_{14}	Lapsing the failure note to the executor
t_{15}	Lapsing the failure note to the executor

$$O(t_{10}) = \{p_{11}, p_{13}\}, O(t_{11}) = \{p_{12}\},$$

$$O(t_{12}) = \{p_1\}, O(t_{13}) = \{p_1\}, O(t_{14}) = \{p_1\},$$

$$O(t_{15}) = \{p_1\}.$$

- Inceptive labeling:

$$\mu = \{1, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0\}$$

The execution of the Petri network inside Functioning table is carried out by starting transitions(Fig 4). A transition is induced by detaching labels from its input positions and producing recently developed labels placed at its output positions. A transition is able to only be launched if it is permitted, if every one of its input positions contains amount of labels at least equaling the number of arcs from position to transition.

Evenness in modeling on Petri nets inside Functioning table is determined by the motions deriving position in the mechanism, as well as by the conditions foregoing the supervene of the transitions, after that the cases after the realization of the events. Analysis of the outcomes of the algorithmic model execution is able to talk about the cases in which the algorithmic model was or was not, which cases are not attainable(Fig 3).

Fig. 4. The incident matrix for this algorithmic model based on Functioning table

It is simulate the process of user access control in the algorithmic model based on Functioning table. The designations of the elements of this model are as follows:

The obtained algorithmic model is analyzed based on the basic properties of Petri nets: security, constraints, stability, reachability and activity. A description of every one of these features is presented and on their basis the characterization of the built algorithmic model is given(Fig 3).

A position p_i is called secure in a stated inceptive labeling μ if, during the procedure of this algorithmic model, more than k one label (marker or token) never shows up in a given position p_i , that is, $\mu(p_i) \leq 1$. A Petri network inside the Functioning table is called safe if all of its position.

From this definition, it follows that the model represented by the Petri network, which implements the process of user access control in the algorithmic model being suggested, is secure, since there is no elements' gradual gathering in the positions of this algorithmic model.

A position $p_i \in P$ is called limited in a stated inceptive labeling μ if, during the procedure of this algorithmic model, more than k markers never appear at a given position p_i , that is, $\mu(p_i) \leq k$. A Petri network inside the Functioning table is called limited if all of its positions are limited.

The model simulating the process of user access control in the suggested algorithmic model is limited with the value $k = 1$, since the number of labels in each position is considered for the case of $k = 1$.

A Petri net inside the Functioning table is called stable if, for any of its transitions $t_i \in T$, the following condition is satisfied: the case of agitation of this transition is not able to be detached by inducing any other transition. If the algorithmic model has deputy transitions, then it is unsteady.

In the algorithmic model, the process of user access control in the FT, there are alternative transitions, for example, transitions t_2, t_9, t_{10} , therefore, this algorithmic model is erratic.

Labeling μ' is called attainable from some labeling μ if for a stated algorithmic model of the Petri network inside the Functioning table it is achievable to indicate such a pattern of transitions that modifies labeling μ into labeling μ' .

The absence of dead-ends in the algorithmic model shown in Figure 3 allows us to assert that its markings are achievable. A transition $t_i \in T$ is called active in a stated inceptive labeling μ if, for any labeling μ' attainable from μ , it is achievable to indicate a sequence of transitions flashing, which attends to the transition's t_i agitation. The algorithmic model is called active in a stated inceptive labeling μ if whole of its transitions are active.

IV. CONCLUSION

Petri network, which imitates the user access control event in the algorithmic model based on Functioning table being suggested, is active, since all its transitions are active, and the cases are attainable with the inceptive labeling, and it is permissible to designate the pattern of flashing of the transitions such will attend to one or another case.

The constructed algorithmic model based on Functioning table of the user access control has a strict formal description that allows analyzing the process of interaction between three subjects of information relations, namely, a user, an authentication manager and a server. This model makes it possible to go to the program execution of the replica of the user access control algorithmic model for a system.

Abstract—In-situ control to predict and mitigate defects in Additive Manufacturing (AM) could significantly increase these technologies' quality and reliability. Thorough knowledge of the AM processes is needed to develop such a controller. Recent studies utilized various methods to acquire data from the process, build insight into the process, and detect anomalies within the process. However, each sensory method has its unique limitations and capabilities. Sensor fusion techniques based on Machine Learning (ML) methods can combine all the data acquisition sources to form a holistic monitoring system for better data aggregation and enhanced detection. This holistic approach could also be used to train a controller on top of the fusion system to master the AM production and increase its reliance. This article summarizes recent studies on sensor utilization, followed by ML-based sensor fusion and control strategies.

Index Terms—Sensor Fusion, Data Fusion, Machine Learning, Additive Manufacturing (AM), In-situ Defect Detection, In-situ Process Control, Defect Classification

I. INTRODUCTION

Additive Manufacturing (AM) technologies are known for providing cheap and fast prototyping methods. However, these technologies suffer from unreliable part's quality. Extensive research utilizing different sensors and algorithms has been conducted to study the AM processes and sources of part's defects. Each sensory information would

enable the possibility of detecting a limited variety of defects. Therefore, as a tool for combining information from various sources, sensor fusion gained the attention of many researchers.

Holistic defect detection can be achieved by applying ML-based sensory data fusion methods. These methods play a significant role in enhancing the data processing section of the recent studies and lead to a higher generalization by considering various aspects and correlations of data sources within the networks' training. Capabilities of ML methods have been pointed out in many recent scholarly work in various domains such as bio-printing [1], high dimensional system identification [2], and Structural Health Monitoring (SHM) [3], [4]. Implemented sensor fusion can also be combined with control and prediction algorithms leading to a more accurate and reliable control over the process.

This review summarizes different sensing methods and their capabilities and limitations in section II, followed by various machine learning-based sensory data fusion methods in peer's works and their findings in section III. Then control systems by application of the sensory data fusion are reviewed in section IV. Section V provides a short overview of the gaps found in the literature, and the future work is illustrated. Finally, the review's conclusion

is presented, in section VI.

II. SENSING METHODS

A. Offline Sensing Methods

Peer studies used offline sensing methods to determine parts' mechanical properties and structural integrity. These studies are based on destructive measurement methods that make them unsuitable for in-situ sensor fusion aspects. Among recent studies, Sabyrov et al. [5] correlated Ultimate Tensile Stress (UTS) of the parts with process parameters, and literature [5], [6] used the SEM method to study the bounding and strength of the parts. Their work showed the correlation between process quality and part property. Although the method is unsuitable for sensor fusion, their findings can significantly contribute to process control and error mitigation when combined with online sensory methods.

B. Online Sensing Methods

For online control and error manipulation, online sensing methods are crucial. Some of the most common and popular online data acquisition methods are vision-based sensors, thermal profiler sensors, laser surface profilometers (LSP), and Acoustics Emission (AE) receivers. Literature [7]–[9] used visual information about the process, literature [6], [9]–[11] used infrared and pyrometer sensors to record the thermal history of the ongoing process, literature [7], [10]–[14] used AE of the printer as a primary study tool, literature [8]–[11] used LSP technology to study the process. Here we will discuss selected peers' works on these sensory techniques.

1) *Vision-Based Sensors*: Vision-based information about the ongoing process proved to be beneficial to many researchers. Vandone et al. [8] suggested using a camera system to detect the laser's working state in a Direct Energy Deposition (DED) machine; Baumann and Roller [15] suggested utilizing a cheap webcam camera for in-situ major fault detection of the FDM printing process. And Pearce et al. [16] Stepped even further and came up with a better strategy to cover up a few of the previous works' shortcomings. The author suggested using three pairs of cameras situated 120-degrees apart around the printing bed to reconstruct

the part three-dimensionally to detect any horizontal or vertical geometrical deviation.

To make in-situ data acquisition and processing feasible, peers' studies each demonstrated a new idea for processing vision-based sensory data. Vandone et al. [8] suggested applying two levels of thresholds over the intensity of the pixels in each captured image to detect the area of the heat-affected and melted zone. By summing the number of pixels and locating the center of those regions, the author retrieved critical information such as pool diameter, the center of the heat-affected and melt pool zones, and the existence of any sparks. Baumann and Roller [15] Suggested using image processing algorithms such as CV-HoughCircles and CV-CannyEdge to detect Region of Interest (ROI). Then, by following the center and boundary of ROI, major abnormalities such as part detachment, part deformation, and clogged extruder were detected. Pearce et al. [16] proposed a fusion of camera pairs to combine their field of view. By this method, the author reconstructed the part's 360-degree representation. Then, for 3D reconstruction based on the 360-degree imagery input, the author suggested using the images' non-rescale and rectification method. This pre-processing algorithm helped the author compare the printed part's dimension to the CAD data.

Each method suggested above proved that the vision-based study of the process is useful. However, some of the assumptions are not accurate and generalizable to other applications. Vandone et al. [8] suggested a thresholding approach. Although they considered light intensity changes due to the generated fumes, they didn't consider the effect of the printing area's ambient light changes or the reflection properties of the printing material. They should repeat the thresholding in any new environment or different material. The method presented in Baumann and Roller [15] showed an acceptable detection rate, although it relies on the user's manual input and instability toward ambient changes. However, this method is only valid for major faults. For detailed defects such as surface quality and over/underprint, this approach wouldn't work. Pearce et al. [16] proposed a time-efficient and accurate algorithm. But, their method wouldn't work for shallow or overhung shadowed parts.

2) *Thermal Sensor Utilization:* Heating the raw material to form a material bonding is the basis of many AM techniques; FDM machines use a heater to melt down the filament, and DED and PBF machines utilize a high-power laser module to melt down the metal powder. Due to the nature of the process, the material's thermal history proved to help detect abnormalities in the process or the part's quality. Kuznetsov et al. [6] utilized a FLIR thermal camera to study the FDM process and correlate the temperature history of deposited layers with the part's quality. Wang et al. [17] suggested the usage of a FLIR thermal camera to monitor a Large Scale Additive Manufacturing (LSAM). The author used the printing bed's online thermal map and numerical modeling to lower the layer's printing time. Li et al. [18] utilized a FLIR thermal camera to monitor a metal printer. Based on the thermal images gathered, the author predicted any abnormalities in the process parameters, such as high/low printing speed or power.

The thermal history of the material undergoing 3D printing is used in different ways to determine any abnormalities in the goal part. Kuznetsov et al. [6] varied the extruder's temperature and the cooling rate. Each manufactured piece was analyzed by mechanical testing and SEM to gather UTS and inner filaments' bonding conditions. It was shown that the part's UTS linearly increases by the extruder's temperature. They justified this result by referring to the better interlayer bonding of filaments and part's weight increase due to higher fluidity of melted filament in higher temperatures. Wang et al. [17] pointed out that LSAM processes must be within a specific range of temperatures before deposition of the next layer. This limitation is posed to let previous layers be rigid enough to hold and be warm enough to bond with new material. For that reason, by theoretical and experimental data, they lowered the print time of each layer and increased the part's quality by meeting the acceptable bonding temperatures. Li et al. [18] proposed a Deep Convolutional Neural Network (DCNN) for studying abnormal process parameters such as high/low speed and power. To train this network, they gathered a big data set consisting of the thermal images of multiple classes of process abnormalities.

The works mentioned above all showed the benefits of thermal monitoring of the process for defect detection. However, there are some points worth mentioning. The author in [6] didn't consider the effect of flow rate by changing the temperature. They could have stabilized the mass flow rate by fixing the filament flow rate, leading to a better Design Of the Experiment (DOE). Wang et al. [17] lowered the layer time successfully. However, the author changed all other process parameters to adapt to the goal printing time. These changes lead to the appearance of different realms of defects. In Li et al. [18], the author used a fixed value for normal process parameters; however, normal printing processes would be different in other parts and geometries, which means they have to train their network once again for a new part.

3) *Laser Surface Profilometer Utilization:* One of the AM parts' downsides is their rough surfaces, which are caused by the process's layer-by-layer production. Previous works showed that it's possible to advance the final surface roughness qualities by adjusting the parameters. For that reason, Lin et al. [19] utilized an LSP to monitor the printer's top surface quality in-situ. The author aimed to detect under/overprinted regions based on the point cloud processing generated from the top surface. The author obtained the depth map by performing point cloud processing and dimensionality reduction of data. In parallel, by processing the goal object's STL representation, the goal depth map was generated as ground truth for comparison. The region was then labeled by comparing the depth maps and applying upper and lower tolerances. A feedback signal is generated based on the abnormal areas' volume and dimensions to stop the process and prevent further time and material loss. This idea can be further advanced to cover the sides of the part as well. The author could also have considered changing process parameters to overcome the defects detected throughout the algorithm to obtain real-time quality control. Their work is illustrated in "Fig. 1".

Borish et al. [20], [21] suggested mounting an LSP on a Large-Scale Metal AM (LSMAM) and a Large-Scale Polymer AM (LSPAM) machine, respectively. The author performed the top surface scanning layer by layer to acquire the height

map's point cloud. Like Lin et al. [19], they sliced the CAD representation to obtain the goal part's height map ground truth. By comparing the height maps, determining whether the print's state was under/overprint was deemed feasible. The algorithm dynamically increases the underprint state's feed rate and decreases the overprint state's feed rate. Their method, combined with the control over the printer's process parameters, showed the possibility of in-situ defect mitigation. However, their study was limited to feed rate adjustment, which raises future research to involve other parameters combined with feed rate to mitigate the total height error.

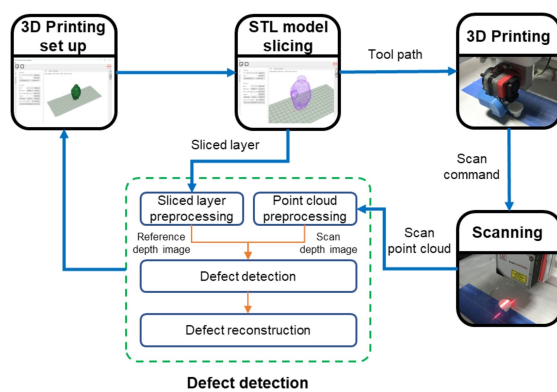

Fig. 1: Defect reconstruction process presented in [19]

4) *Acoustic Emissions And Vibrational Sensors Utilization:* On top of the previous measurement aspects, the Acoustics emissions and Vibrational signals of the printer proved to help determine a new realm of defects. These methods can capture the state of the mechanical systems and pinpoint any abnormalities in the structure. However, processing their signal is expensive and requires complex computations. Zhang et al. [12] proposed utilizing an attitude sensor consisting of 3-axial angular velocity, vibratory and magnetic receivers for dynamic condition monitoring. Li et al. [13] proposed a gearbox fault diagnosis system based on Acoustic Emissions and vibrational sensors. Wu et al. [22] suggested using AE sensors for in-situ state detection of an FDM machine. The author aimed to study normal machine state, idle, material loading, out-of-material, semi-blocked, and blocked extruder head conditions. For data processing, each paper presented a different path. Zhang et al. [12]

utilized sparse autoencoder networks depicted in “Fig. 3” to combine the sensory inputs and study the system. The author implemented nine predefined defect states during each print and aimed to classify the AE readings into nine categories. Li et al. [13] mounted the sensors on the gearbox's body to record the signals of healthy and ten different abnormalities in various system members. The proposed method relies on the Wavelet Packet Transform (WPT) to pre-process the data before feeding them to two Deep Boltzmann Machines (DBM) networks to construct a feature map. In the end, a Deep Random Forest (DRF) fusion method was applied to combine the features to achieve a better generalization. Their network structure is summarized in “Fig. 2” Wu et al. [22] mounted an AE sensor on the extruder head and recorded the FDM machine's performance in all states. After signal processing, they achieved each state's frequency and time domain features, such as ABS energy and RMS values. Then by applying the SVM method, they compared each state with another to distinguish boundaries and classification.

The recent studies mentioned above all proved usefulness of these sensors. Zhang et al. [12] showed that it is possible to detect the deficiencies with reasonable accuracy. However, their work scope is limited to the printer's mechanical faults, and they didn't propose any idea to mitigate the defect when it is detected. Li et al. [13] implied that combining these sensors fulfilled a better prediction of 96.8% accuracy over 11 different classes. Although their work showed a significant improvement in error detection, they still didn't propose an alternative for the system when a fault is detected to overcome the defect. Wu et al. [22] proposed a process resulting in a 95% accuracy in predicting machine states. However, their SVM method is not the best approach due to its linearity. Changing the algorithm with a nonlinear multi-class one could have achieved a better classification. As seen so far, online monitoring is capable of detecting many abnormalities in the process. To conclude the online monitoring section, the peer studies are summarized in Table I.

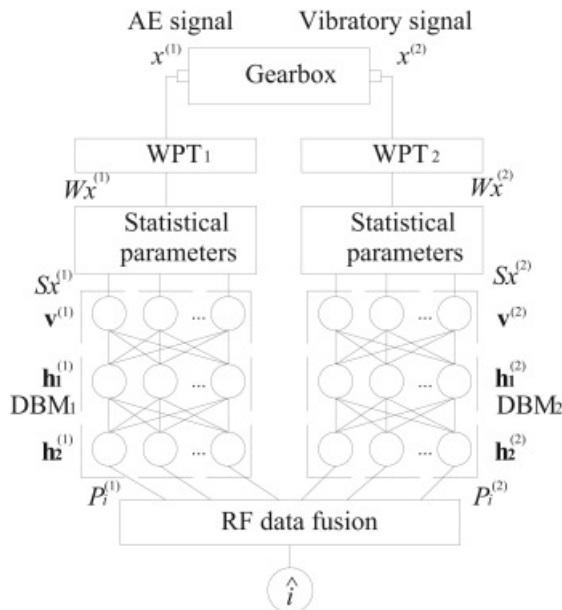

Fig. 2: Summary of data fusion used in [13] for AE signal and Vibrational data using DRF

III. SENSORY DATA FUSION

Each paper discussed so far by utilizing one or a few sensors can cast some light over a limited variety of defects. However, for a general multi-aspect study of the process, a combination of sensory data is needed. But, each sensory data requires a different approach for processing and classification based on its nature. Also, the fusion of information from various sources requires a method to decide on each aggregated data best weight or importance level, which ML methods would come in handy in this part. Previous studies approached sensor fusion from different aspects. Here a summary of them will be discussed.

Data fusion based on Hall and Llinas [23] is divided into three different categories: 1) decision-level, 2) data-level, and 3) feature-level. Some studies fused multiple sensors independently to combine their decisions; Borish et al. [21], among the peer works, utilized an LSP to detect surface quality and control the system's feed rate along with a thermal camera, used to monitor the printed part's temperature. The data from each sensor was processed separately to actuate independent alteration of the process. In some studies, such as

Vandone et al. [8], the author took advantage of the data-level fusion strategy by using multiple sensors to register the data in the time/space domain. They used vision-based sensors and system parameters to register the data in the time domain, the surface profilometer, and the G-code to register data in the space domain. The author then designed a closed-loop data-driven controller to enhance the process and meet the part's geometrical requirements. Their work is represented in "Fig. 4."

Studies like Rao et al. [24] used feature-level sensor fusion by utilizing thermocouples, cameras, and accelerometers all in parallel to achieve informative results. Their setup is shown in "Fig. 5". Zhang et al. [12] used SAE networks to obtain the feature maps; Zhang et al. [7] operated a camera, AE sensor, and Arc Voltage of the machine to predict the welding's quality.

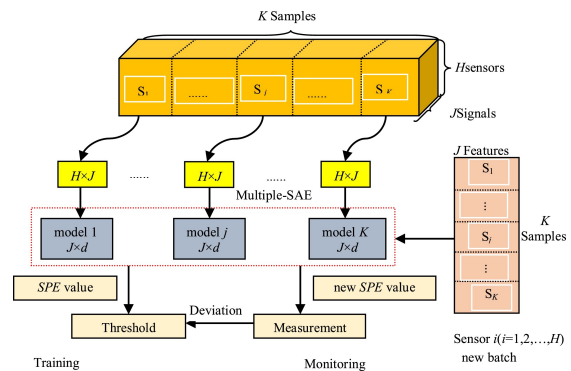

Fig. 3: Data Fusion using sparse autoencoder networks presented in [12]

The author used Support Vector Machine-Cross Validation (SVM-CV) technique to fuse the feature maps. The author compared a single sensor with multisensory data classification. They reported that spectrum-based models achieved 100%-87% accuracy, while for multisensory models, they got 94.5%-93.4%. They concluded that the multisensory model had better repeatability while the spectrum-driven model performed more accurately. But their conclusion is based on utilizing a linear binary classification algorithm (SVM). It might be possible that the author missed some nonlinear behavior of the system. This caused the drop in the accuracy to 94.5%, which could have been increased by implementing a more advanced method

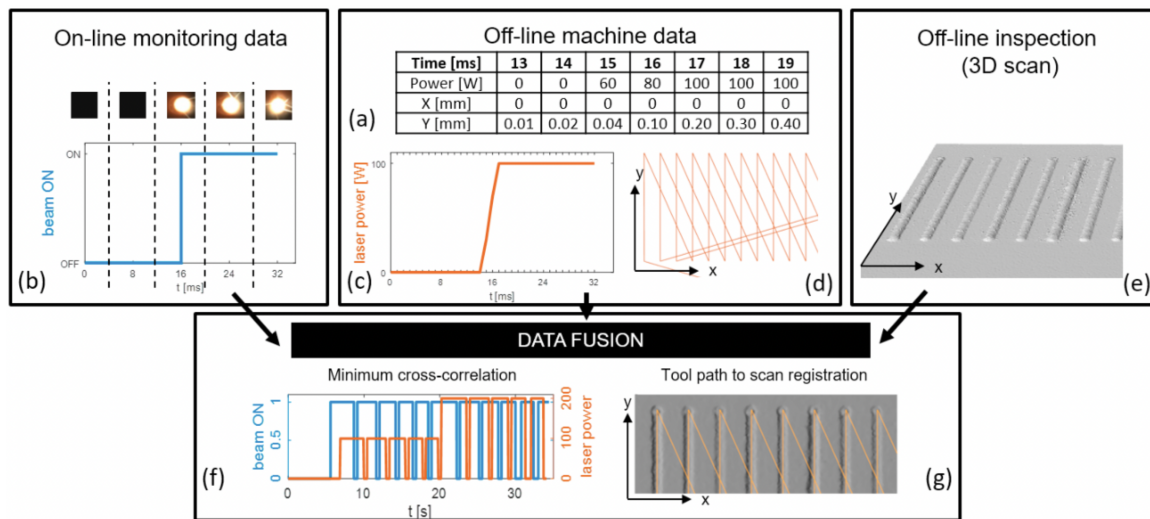

Fig. 4: Data fusion structure presented in [8]. a) The process parameters such as laser power and coordinated of the print are aggregated b) Process observation data c) Laser power schedule and d) Tool path generated from G-code e) Offline inspection results from 3D scanner f) Time alignment of the aggregated data and g) Spatial alignment of the data after fusion.

such as a deep network.

Although sensor fusion enables the ability to extract meaningful feature maps, processing and decision-making require advanced algorithms such as ML methods. Many options are currently available for researchers, from shallow to deep networks, each with many structures. In most prediction cases, the algorithm used requires significant training data, making the study expensive. According to the most recent sensor fusion works, hybrid algorithms can be used to extract information faster with less training data. Among the literature, Lyu et al. [36] suggested a hybrid convolutional autoencoder decoder network structure to automate data feature extraction, which significantly reduced the need for a thoroughly labeled dataset. Li et al. [37] recommended utilizing a one-shot learning algorithm. The author claimed that this approach would change the typical training approaches that rely on extensive training samples to only one instance of each defect. Convolutional Generative Adversarial Encoders for data fusion were suggested by Wang et al. [17] to create a predictive model with only normal condition signals. These studies show that fault detection is possible even when lacking training data or very sparse data is available. However, these studies wouldn't be

practical unless combined with a control system to mitigate the detected anomalies.

IV. QUALITY CONTROL USING SENSORY DATA FUSION

Quality assurance has been a concern of many researchers in all manufacturing domains, especially in AM. A minor flaw in the initial layers builds up to a significant deviation in the top layers. So, early detection and correction of defects would significantly advance the reliability of AM technologies. The fusion of sensory data and process parameters has shown significant value in awareness development and strategizing control signals. The approach in which a flaw can be addressed in AM strategies in this paper, depending on how they aim to fix the deviations, is categorized into the Addressing Future Defects method and the Addressing Existing Defects method.

A. Addressing Future Defects

In addressing the future defects reduction, once the defect is detected, and enough knowledge regarding the coordinates and severity of the anomaly is gathered, then the control module aims to either follow negative defect implementation to minimize older defects' effect on the total part's quality or

TABLE I: Summary of sensor utilization in peer works

implement an active control to prevent new occurrences although there has been a defective feature recognized. In fact, this approach wouldn't fix the previously made errors but aims to keep the part's integrity and quality intact.

In line with this method, Borish et al. [20], [21] presented a decision-level fusion for process control of LSMAM and LSPAM methods, respectively. They utilized a surface profilometer and a thermal camera to study the ongoing process. The machine's feed rate passively would be adjusted based on analyzing sensory input from the surface quality once a layer print is done. Based on the temperature maps gathered by the thermal camera, the process would pause until the desired temperature is achieved. Their proposed method would eliminate under/overprint defects and layers' instability due to the high temperatures of previous layers.

Vandone et al. [8] also proposed a data-driven control approach based on multiple online sensory data and offline mechanical test results fusion to decrease the print's deviation from the goal tolerances. Their proposed model, by actively monitoring and controlling the laser profile and melt pool dimensions, aims to eliminate variations from manufacturing standards and minimize the machine's parameters' total changes, also guaranteeing

mechanical properties within expectation.

Garmendia et al. [26] presented a layer height controller based on structured light to ensure the part's overall quality. The author used the point-cloud data gathered with structured light coupled with process plan data extracted from the CAD model and G-codes to determine the deviation from the anticipated partially manufactured artifact. Once the deviation is calculated, a negative defect implementer would engage in adjusting the future layer deposition parameters.

B. Addressing Existing Defects

Despite the addressing future defects method, which aims to create appropriate changes to compensate for the previous deficiencies, the addressing existing defects approach focuses on innovative engineering solutions to eliminate the errors. This approach eliminates the defect before the next deposition, which not only implies that the part's quality is within tolerances and acceptable, but also all the layers are manufactured within tolerance and evenly. Addressing existing defects approach lowers uncertainties in parts quality and properties fluctuation and also increases productivity and resiliency of the AM processes. Here a few instances

of the addressing existing defects approach in the peers work are summarized.

Inasaki [14] suggested using fuzzy reasoning and genetic algorithms to control grinding processes. Their sensor fusion and control strategy approach eliminated the need for parts' post-processing due to off-tolerance surface roughness by implementing an intelligent grinding cycle adjuster. Based on the part's surface quality and fuzzy logic, the process is adopted to achieve the desired quality.

Also, Sardinha et al. [38] proposed a method called ironing for ABS material in Fused Filament Fabrication (FFF) printers for quality and property advancement. This method utilizes the available printer's head to perform a thermal treatment for the top layer of the manufactured part. This method not only showed significant capabilities in lowering the surface roughness of the artifact but also aided the process of preventing defects such as warping to happen and residual stress reduction. Integrating this method whenever the surface quality of the manufactured layer deviates would allow a smooth fabrication and predictable results.

Chen et al. [39] integrated a laser module in-situ with an FFF printer. This laser module would act as an interactive agent to mitigate surface roughness anomalies in this case study. The proposed method not only showed effective improvement of surface quality and elimination of surface anomalies but also showed that the laser-based thermal treatment can increase the mechanical properties of the part, such as storage modulus (E') and loss modulus (E''). Laser polishing showed to be helpful in keeping the material above or around the glass transition temperature, which is a crucial factor in AM fabricated parts' quality. This example can also expand to the CNC machines as [40] illustrated the capacities for integration of the CNC machines with 3D printers.

V. FUTURE WORK

One of the common bottlenecks in the peer's work was reliance on extensive training for defect detection. Building the training set, in many cases, is expensive and time-consuming due to the nature of the AM processes. A deep hybrid network could be useful for automating the data training in order to reduce the amount of data needed to

Fig. 5: a) Schematics of FDM machine, b) Schematics of multiple sensors implemented for in-situ data acquisition [24]

train the classifiers and regression required models for anomaly detection. On the other hand, most of the proposed works are designed to minimize the final part's error and deviation by reducing the new defect's occurrence. In other words, most controllers are designed to affect the printed layers while the faulty sections are already deposited and won't change. Nevertheless, if an active, interactive controller were developed, a defect could be mitigated, and a path for future layer deposition could be determined if an anomaly were to be detected. In summary, by benefiting from deep learning capabilities for sensor fusion and online process and part monitoring, a robust control within process time that would focus on future defect prevention and provide alternatives for mitigation or elimination of the detected defects can be achieved.

VI. CONCLUSION

Based on this literature review and the discussions presented, the significance of each sensory module and a summary of a few breakthroughs in AM technologies for abnormality detection have been illustrated. Reviewed literature proposed various ideas to capture process faults in-situ, and prevent additional material and time loss, for example, early stopping the process for parts with unacceptable deviations from the CAD model before fabrication completion. Many steps have also been taken to create a generalized multisensory technique to capture as many defects as possible with higher repeatability and accuracy. However, there is still more room to advance the algorithms' capabilities further to achieve a smarter detection for other varieties of defects and generate a more in-depth correlation between data features. Then,

sensory data fusion approaches and their capabilities and limitations have been discussed. State-of-the-art studies based on sensory data fusion, primarily using Deep Neural Networks, can now predict the system's faults or deviations while having the minimum effort as in training time or training data. Having all the above achievements in the detection field, the author found there are still gaps for error mitigation and compensation field. Sensory data fusion, combined with the control system, can be used for defect mitigation. However, this combination requires much further studies, and there are plenty of opportunities for researchers to take on and expand as in expanding current fusion strategies for control applications. Control algorithms so far mainly focus on future error mitigation and aim to compensate for past deviations with alternations in future depositions. However, a very efficient approach would be utilizing interactive modules to address the anomalies, clear out the part's anomalies to continue the process. As such, ideas of utilizing a CNC robotic arm or a laser module in-situ with the print to remove or mitigate the anomalies would be a great exemplary area to explore.

Abstract—Neural Networks are a series of data manipulations inspired by how neurons perceive information in the brain. This technology is useful for accomplishing tasks that conventional computers do poorly, but people do accurately. Neural Networks are utilized in this project to control an Unmanned Aerial Vehicle (UAV) with hand gestures. For this case the model produced by TensorFlow will take twenty-one different hand points on a user's hand using MediaPipe and distinguish which of eight gestures the user is signaling. This data is received through a camera on the UAV and once ran through the model the flight path will be controlled. The hand points are logged as two-dimensional coordinates in relation to the pixel they are in the frame. This creates a model with forty-two inputs and nine outputs. The model can run at around twenty frames per second due to the low number of inputs. The UAV can handle efficiently due to an acceptable processing time of its commands.

Keywords—Neural Networks, machine learning, artificial intelligence, neurons, Unmanned Aerial Vehicle (UAV).

I. INTRODUCTION

Neural Networks were originally modeled by neurophysiologist Warren McCulloch and mathematician Walter Pitts in 1943 [1]. The idea was to solve computer problems in a similar way that a brain would. The neurons in the brain have one job and that is whether to fire off a signal or not, much like a digital computer. What makes neurons different is how they are connected. One neuron can be attached to many other neurons that control the conditions in which it signals a response. Each of these input neurons have a different “weight” or bias. These weights can be very small or very large depending on the purpose of the neuron. Unlike computer logic which has two conditions, high or low, the brain works much like an analog computer rather than a digital one. The idea that this system of weights and biases can be applied to a computer is what created the idea of a

neural network. Originally neural networks were not very accurate. Two things improved this, loss functions and multiple layered networks. Loss functions take the accuracy of the network from a training set and adjusts the weights of the network based on the error [2]. Originally, networks were just an input layer, the neurons, and the output layer. The neuron layer could be expanded to multiple layers with different numbers of neurons and different weights to improve accuracy. With these two improvements and lots of research neural networks are used in many different computer applications today where a conventional program would not suffice.

To track the hands in this project the software developed by MediaPipe was utilized. MediaPipe is a software that is compatible with JavaScript, Python, C++, IOS, and Android [3]. It has applications that can track body poses, hands, objects, faces, and so much more making it an incredibly useful software. For the purpose of this project the hand tracking was utilized with Python. The software uses twenty-one hand key points starting at the bottom of the palm, to every joint, ending on each fingertip.

To model the network TensorFlow is used. TensorFlow is an end-to-end open-source platform for machine learning [4]. It makes modeling complex data easy, and it used by many well-known companies such as Google, Coca-Cola, Twitter, Airbnb, and intel. TensorFlow has applications for all levels of machine learning. Both TensorFlow and MediaPipe have python libraries increasing the usability.

The UAV used for this experiment is the Tello drone developed by Ryze Robotics. Tello drones are small and simple making them great for indoor work. They use an Intel 14-Core processor and contain features such as automatic takeoff/landing, low battery protection, collision detection, failsafe protection, and a vision positioning system. The Tello drone has a camera on the front that is used for gathering the visual data needed for this project. The drone connects to the use via Wi-fi and can be programmed using the Tello Python library.

The IDE used for this project is PyCharm developed by Jet Brains. The version of Python used

is Python 3.8. PyCharm is a very easy use IDE that has predictive text and quick error fixing. This IDE also allows for easy download of libraries. It will open the library documentation within the IDE which allows for ease of use when reading library codes.

The gestures used for this project are shown in Fig. 1. There are eight different gestures that control eight different commands. Gesture one and two commands the drone to move forward or backward. Gesture three commands the drone stops. Gesture four and five commands the drone to move up or down. Gesture six and seven commands the drone to move left or right. Gesture eight commands the drone to land. To always keep the hand in the center of the frame the drone will rotate left or right depending on where the hand is located. This concludes the motion of the drone.

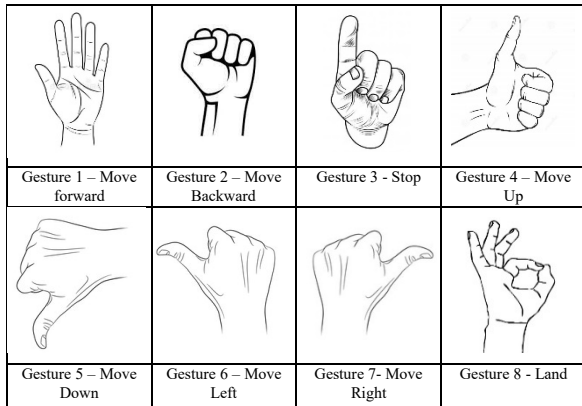

Fig. 1. Eight gestures and their respective commands.

II. METHOD

The MediaPipe software uses twenty-one hand key points as seen in Fig. 2. These are set on the knuckles and tips of the hand. To obtain images of the hand, an external webcam was used for quality purposes. The images were processed using OpenCV which is an image processing software. When the hands are found in the image the MediaPipe software draws points on each landmark, and the lines between them. Then it takes the data on each point's x-coordinate and y-coordinate. The value of which are the pixel they are on in the camera feed. The top left point of the camera feed is the origin. As you move to the right or down the number representing each pixel is increased. To gather the data a 640x480 pixel width times height frame was used. The data in this twenty-one by two list will be used as the data for the neural network. The software can track both hands at once, however, for the purpose of this experiment only one hand was tracked at one time. The data set does contain both hands however as to not discriminate against which hand is being utilized.

To build the training set a code was made that transfers a list of all the hand key point coordinates to an excel file. Whenever the space bar is pressed down the program will append all the hand key points seen in an image to a new list. This allowed many sets of coordinates to be logged without using individual photos. This list contains forty-two coordinates, or an x-coordinate and y-coordinate for each of the twenty-one hand key point. Data is taken from both left and right hands at distances from ten centimeters up to five meters; and orientations to ensure a large variety of data in the training set. Once one gesture is fully logged from all distances and orientations, the data is added to a large excel file that contains all twenty-one coordinates and the gesture that corresponds. A small sample of which can be found in Fig. 3 and Fig. 4. Data was taken from three different people to add to variety in the data. The more variety the data has the more accurate the model will be.

Fig. 3. A sample of the training data set. This contains the last few lines of the set.

0x	0y	20x	20y	Gestures
300	426	350	313	1
300	433	349	321	1

Fig. 4. Example of training set data for x and y coordinates of hand key point 0 and 20. The gesture that corresponds to these points is on the right.

The training set, once completed, is converted into a CSV file. A CSV file is like an excel file but without formatting [5]. Instead, each column is separated by comma instead of a formatted cell. Due to the simple formatting the computer can process the data much quicker.

The TensorFlow model used for this experiment was the Sequential Model which is the most common model used for a plain input. There are forty-two inputs or each of hand key point's x and y coordinate.

The three hidden layers consists of sixty-four neurons, thirty-two neurons, and sixteen neurons. The output has nine neurons which are the eight gestures plus no gesture when a wrong signal is given. The training set is normalized, meaning that TensorFlow converts all the coordinates to values between zero and one. Without this the model would not be able to handle the data given to it. The optimizer used is named ‘Adam’. The Adam optimizer is a stochastic gradient decent method [5]. The loss function used is sparse categorical cross entropy [6]. This loss function is best used when there are two or more label classes. For this experiment there is eight. The model is then fit using sixty-four epochs each with a batch size around twelve thousand. TensorFlow calculates accuracy and loss while training which is displayed to the user for each epoch.

With a trained model real time data can be given to it. Every time the code loops a frame is taken from the drone, twenty-one key points are added to a hand in frame, if there is no hand the code will keep looping, the pixel coordinates of each hand key point is then normalized and sent to the neural network, the network chooses the highest probability or the most likely gesture, then a command is sent to the drone respective of that gesture. This process repeats up to twenty times per second with a usual framerate between fifteen and twenty. Every part of the methodology is done using a python code with many imported libraries and modules such as MediaPipe, OpenCV, TensorFlow, etc.

III. RESULTS AND DISCUSSION

The training set contains three different people’s hands independent of left or right, and up to 37,000 lines of coordinate sets. 8,000 set of coordinates are for gesture one, 3,000 for gesture two, 5,000 for gesture three, 5,500 for gesture four, 5,600 for gesture five, 3,200 for gesture six, 3,500 for gesture seven, and 4,000 for gesture eight. It produces an accuracy of 94% as seen in fig. 5. A testing set was made that contains 200 sets of coordinates for each gesture. The accuracy and loss of the testing set can be seen in fig. 6. The confusion matrix for this testing set can be seen in fig. 7.

loss: 0.2441 - accuracy: 0.9439

Fig. 5. Training result of neural network.

loss: 0.0711 - accuracy: 0.9744

Fig. 6. Testing result of neural network.

1	0	0	0	0	0	0	0
0	0.985	0	0	0	0.005	0.01	0
0	0	1	0	0	0	0	0
0	0	0.005	0.995	0	0	0	0
0	0	0	0	1	0	0	0
0.02	0	0	0	0	0.845	0.135	0
0.02	0	0	0	0	0	0.98	0
0.005	0.005	0	0	0	0	0	0.99

Fig. 7. Confusion Matrix of testing set.

The model has a more difficult time differentiating the hand gestures that are a thumb pointed in a certain direction. Most likely this is because of errors in the data set mainly for gesture six. As seen in Fig. 7. Gesture six is the most inaccurate and conflicts with both gesture two and seven.

The model is increasingly accurate when the hand is at a close distance such as within two meters. It becomes much less accurate at farther distances greater than five meters. The biggest reason for this is because the MediaPipe software struggles to classify the hand at far distances. This leads to errors in data and sometimes no data at all. This is not practical for large UAV operations that require large distances; however, it is useful for indoor operations. Ways to improve upon this in the future is to be able to adjust the image frame to only include the hand no matter the distance or orientation. Also, to improve drone camera quality.

The reason the input to the model is forty-two hand key points instead of a whole frame is due to the speed of the program and processing power of the computer. To process twenty frames per second a GPU or Graphics Processing Unit is a necessity [8]. The frame used in the training set was 640x480 pixels with an area of 307,200 pixels vs 42 coordinates as the network’s input. To run a neural network with this many inputs would be intensive on any computer without a GPU. Most of this project however was done using a laptop with only 16GB of RAM and it could handle processing the images up to twenty frames per second because of the low number of inputs needed for the network. With a GPU it would be much faster. Neural networks are a great way to solve problems that computers typically cannot. However, if your average household computer cannot run it then it is impractical.

Abstract— Data dimensionality is increasing at a rapid rate, posing difficulties for traditional mining and learning algorithms. Commercial NIDS models make use of statistical measures to analyze feature sets including packet length, inter-arrival time, and flow size, in addition to other internet traffic parameters. Emerging algorithms must deal with diverse data. While multiple deep learning-based solutions exist in the literature, their commercialization is still in its infancy. Currently available machine learning techniques create a large number of false positives. As the quantity of data to be processed has increased in recent years, feature selection (FS) appears to have become a basic requirement for any type of model. The recent advent of promising techniques and different kinds of features advances existing computational research and continuously improves feature selection, seeking to make it applicable to a broader range of applications. This paper intends to provide a fundamental investigation to feature selection throughout NIDS, which will take into account basic concepts, categorization of existing systems, a framework and taxonomy for NIDS, the feature selection methods used by researchers to develop NIDS methods, and a comparison of FS Algorithm classification and Python FS library contents. By examining existing contributions, this study provides an overview of the majority of techniques proposed in the feature selection research. Additionally, we discuss the most recent FS algorithms for NIDS that were established to select the optimal feature subsets. By classification and comparative study, the paper provides a road map for comprehending and constructing the current state of NIDS FS. As a result, a study is presented to help the reader comprehend the research progress, the FS Algorithm's characterization, and the establishment of a new taxonomy for emerging developments and existing challenges.

Keywords— NIDS, Feature selection, Machine learning, Python, Deep Learning

I. INTRODUCTION

In recent years, attention has been focused on FS (Feature Selection) techniques and optimization techniques for selecting the most important features. Feature selection has been demonstrated to be an efficient and effective method for prepping large-dimensional data for machine learning and data mining[1]. All current NIDS (Network Intrusion Detection System) use characteristics of user and system behavior as input to their analysis algorithms, which determine the likelihood of an attack. While numerous network protection methods exist, such as access control, encryption, authentication, and advanced firewalls, there is an urgent need for intelligent NIDS that can automatically detect known and novel attacks[2]. A NIDS is composed of several stages, including data collection, pre-processing, FS, and classification. The FS phase is difficult, as the NIDS must deal with a massive amount of data.

The mathematical equation of FS is as follows: 6-Tuplet FS = D, F, C, S, fs, E, where D denotes a dataset and F denotes a feature set. $D = \{i_1, i_2, \dots, i_m\}$, where m is the number of instances. F is a collection of characteristics. $F = \{f_1, f_2, \dots, f_n\}$ with n features. C is a class that is intended to be used. $C = \{c_1, c_2, \dots, c_k\}$ where k denotes the target classes. S is a search space of the set F that includes all subsets that can be constructed using F. $S = \{s_1, s_2, \dots, s_l\}$ ($l = 2^n - 1$: NP-Hard) with $s_i = \{f_{j_1}, f_{j_2}, \dots, f_{j_n}\}$ ($1 \leq j_1 \neq j_2 \neq \dots \neq j_n \leq n$), where E is evaluation measure and fs represents the feature selection process: $fs: F \rightarrow S$ [3]. Selecting the best feature selection method hinge on on the input and output. This paper intends to provide a basic study of feature selection throughout NIDS, including a framework and taxonomy for NIDS, categorization of existing systems, FS methods used by researchers in developing NIDS methods, and a summary of FS Algorithm categorization and Python FS library contents[4].

The remaining sections of the paper are organized as follows. In section 2, we represent a literature review for feature selection methods used in NIDS. Feature selection framework and taxonomy for intelligent NIDS in section 3. In section 4, a comparison of FS Algorithm characterization and Python FS libraries contents is done. In section 5, we present a conclusion.

II. LITERATURE SURVEY

Feature selection provides an insight into the current methods for dealing with a variety of problem classes[5]. K. Vamsi Krishna et al. presented a Least Variance Feature Elimination approach for feature selection in a Network Intrusion Detection System in a cloud environment to reduce computational time without sacrificing detection rate[6]. Rawaa Ismael Farhan et al. proposed Enhanced BPSO and CFS correlation-based feature selection on DNN classifiers and the CSE-CICIDS2018 dataset [7]. Amrita et al. used a machine learning technique to perform a feature selection and technical evaluation survey on anomaly-based NIDS. Their paper offered an empirical example of how to choose a more appropriate solution [8]. Zhao Yongli et al. describe an enhanced feature selection algorithm based on Distance feature ranking and an enhanced exhaustive search to select a more advantageous combination of features. On the KDD CUP datasets with reduced feature subsets, they used SVM and KNN classifiers [9]. K. Vamsi Krishna et al. proposed a Hybrid Feature Selection algorithm that uses a mutual information-based feature selection algorithm to analytically select the optimal feature for classification. In comparison to state-of-the-art methods, feature selection using Least square Support Vector Machine-based IDS (LSSVM-IDS) achieves higher accuracy at a lower computational cost [10]. Pankaj Kumar Keserwani et al. proposed an anomaly-based NIDS combined with a bald eagle search algorithm for VCN. The classification was performed using a deep sparse auto-encoder (DSAE). Python was used to simulate the proposed system. [11]. Jabali et al. provided an overview of the Intrusion Detection taxonomy and current feature selection techniques, as well as details on IDS design and development issues. It is investigated for dimensionality reduction to determine which methods achieve a higher level of accuracy and workload reduction, followed by existing techniques for comparing classifiers and classifier designs[12]. Gholamreza Farahani et al. proposed a new cross-correlation-based feature selection method and compared it to the cuttlefish algorithm and mutual information-based feature selection methods [13]. Badii Atta et al. described an integrative knowledge representation framework for virtualization, focusing on a topic map-enabled representation of features for pattern recognition within the NIDS domain[14]. Kok-Chin Khor et al. proposed a method for identifying critical features by combining two feature selection algorithms with a filter approach. Domain experts validated the selected features and added additional features to the final proposed feature set [15]. Hebatallah Mostafa Anwer et al. presented a framework for selecting

features for efficient network anomaly detection using a variety of machine learning classifiers based on filter and wrapper methodologies[16]. Mubarak Albarka Umar et al. proposed a method for developing IDS models using the UNSW-NB15 dataset that combines FS and machine learning algorithms. Their method achieved the highest degree of reproducibility (DR) of 97.95 percent[17]. Chaouki Khammassi et al. selected the best subset of features for network intrusion detection systems using a wrapper approach and logistic regression learning algorithm [18].

III. FEATURE SELECTION FRAMEWORK AND TAXONOMY FOR NIDS

FS is the method of selecting unique features based on specific criteria in machine learning[19]. It is a significant and widely used dimension reduction technique in many fields. When selecting features, there are two parts to a selection method: Feature set selection strategy and an evaluation technique for evaluating feature subsets. Listed below are the activities for selecting a subset of features[4]. Because the dependent variables lack sufficient additional information about the classes, they act as noise for the predictor.

TABLE 1: FEATURES TYPES

Feature Type	Description	Accuracy	Training Time
Strongly Relevant	It is necessary for an optimal feature subset	High	Low
Irrelevant or Noisy	It cannot help discriminate between supervised or unsupervised data.	Low	High
Redundant or Weakly Relevant	It can be completely replaced with a set of other features	Low	High
Weakly relevant or non-redundant	It may not always be necessary for an optimal subset and depend on certain conditions.	Low	High
Noisy	It is not relevant to the learning or mining task.	Low	High

We can obtain an overview of the process and enhance the computation necessities and model accuracy by using feature selection techniques. f1 is a pertinent feature that distinguishes between classes 1 and 2. f 2 is an irrelevant feature. f4 is therefore a noisy feature. f6 is a redundant attribute [20]. If f1 is chosen, removing f6 doesn't affect learning performance. The dataset includes insignificant, redundant, and noisy features. Features types are discussed in Table 1. and depicted as a graph in Figure 1.

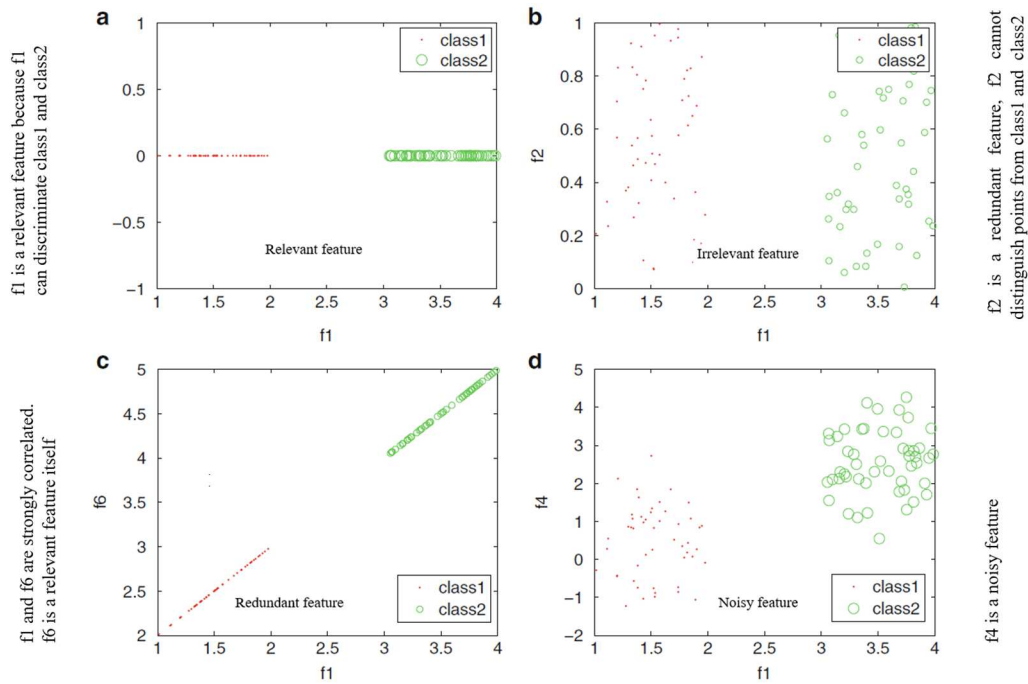

Fig. 1 Relevant, Irrelevant, Redundant, and Noisy features [20]

Feature elimination doesn't always generate new features because it reduces the number of input features. Once the feature selection condition has been chosen, a procedure for locating the subset of important features must be developed. As

the number of features increases, assessing all the feature subsets (2^N) for a data set becomes an NP-hard problem [20]. Classification of NIDS FS methods as shown in Figure 2., described as follows:

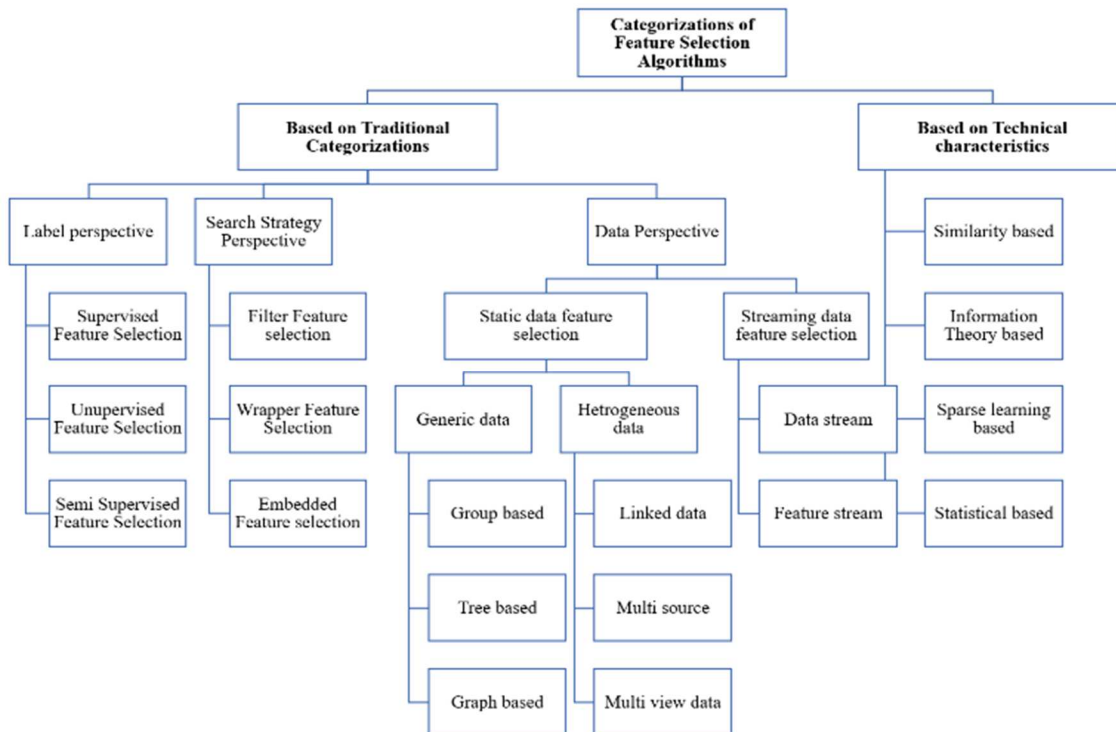

Fig 2 Taxonomy of Feature selection for NIDS

A. Based on Traditional Categorizations

Based on traditional classification feature selection methods can be broadly classified as follows:

1) Label Perspective of Feature Selection Algorithms

The final output is referred to as labels. Based on label perspective feature selection algorithms can be classified as follows:

a) *Supervised Feature Selection*: The goal of the supervised feature selection process is to select a set of features that can distinguish samples collected from different classes and are intended for regression and classification problems. After dividing the train and test sets, classifiers employ supervised feature selection on a subset of features. Based on the selected features, the trained algorithm assumes the class labels of datasets in the test set [21].

b) *Unsupervised Feature Selection*: The Unsupervised feature selection approach is intended for use with clustering problems. Due to the absence of label information to assess feature weights, unsupervised techniques look for alternative criteria to define feature relevance, such as local discriminative information. Unsupervised feature selection makes use of all instances available during the feature selection phase [21].

c) *Semi-Supervised Feature Selection*: For supervised classification, the small amount of labeled data may be inadequate in delivering correlation information about features and for unsupervised methods, class labels may contain useful information for class discrimination. As a result, developing semi-supervised methods that utilize both labeled and unlabeled samples is desirable [22].

2) Search Strategy Perspective Feature Selection Methods

In terms of selection strategies, there are three types of feature selection methods:

a) *Filter methods*: The filter methods are preprocessing procedures that employ variable ranking techniques as the primary criterion for selecting features by ordering the features and applying only the highest-ranked features to a predictor. If a feature is linearly separable from the class labels, it can be considered irrelevant. The process of determining the significance of a feature can be univariate or multivariate. Mutual Information, Correlation, Chi-Square Test, ANOVA Information Gain, Variance Threshold, and Fisher Score are all examples of common filtering techniques [23].

b) *Wrapper methods*: The wrapper method improves the performance of selected features by relying on the predictive accuracy of a predetermined learning algorithm. A typical wrapper method for a given learning algorithm performs two steps: first, the feature set search attribute generates a subset of features; and then the learning algorithm evaluates the quality of these attributes. Wrapper feature selection has several examples, including backward feature elimination, forward feature selection, and recursive feature elimination. Recursive Feature Elimination for Logistic Regression, Boruta, Permutation Importance, and SHAP are all common wrapping techniques [24].

c) *Embedded Methods*: Embedded methods offer mediation between filter and wrapper techniques by combining algorithms with built-in feature selection with model learning that incorporates variable selection during the training process without dividing the test and train sets. Embedded methods are classified into three types: pruning techniques, models with built-in feature selection mechanisms, and regularisation models. LASSO, Elastic Net, and Ridge Regression are all examples of embedded methods. Embedded Random Forest, Embedded LightGBM, and others are frequently used examples [25].

3) Feature selection based on Data Perspective

Based on Data perspective feature selection methods are of the following types:

a) *Static feature selection*: In static data, all data features and instances are known in advance, whereas in streaming data, the number of data instances, features, or both is unknown. Statistical-based techniques entail evaluating the correlation between each input parameter and the target value using statistics and then selecting the input variables with the strongest relationship to the target variable[26]. It can also be classified as generic data or heterogeneous data. Static features could be classified as follows:

i) *Feature Selection on Generic Data*: The focus of previous feature selection techniques for generic data is premised on the false presumption that features are completely independent of one another, oblivious to the intrinsic structure of features. Feature selection methods for generic data can be classified into similarity, information theory, sparse learning, and statistical methods [27].

- *Feature Selection with Group Feature*: Features observe group structures in a wide variety of real-world applications. Each factor is linked to various groups and it can be expressed through the use of a group of dummy features. It is more appealing to consider the group structure of features explicitly when performing feature selection [28].
- *Feature Selection with Tree Feature*: Tree structures can be demonstrated using features that represent a tree, in which the root node, child nodes, and leaf nodes are all represented as features in the spatial locality structure[29].
- *Feature Selection with Graph Feature*: Features exhibit some degree of dependency and can be structured as an undirected graph, with nodes and edges representing pairwise dependencies among features. When there are dependencies between features, we can encode them using an undirected graph $G(N, E)$. Examples include Graph Lasso, GFLasso, and GOSCAR[30].

ii) *Feature Selection with Heterogeneous Data*: Given that the data from each source may be noisy, incomplete, or redundant, determining which sources to use and how to combine them for efficient feature selection becomes a difficult problem. Three

aspects of feature selection techniques for heterogeneous data are as follows:

- *Feature selection for linked data:* In real-world applications, linked data is becoming more ubiquitous. Linked data is distinguished from traditional flat data by the use of various types of links. Eg. Feature Space Selection for Linked Data, Feature Extraction on Network systems [31].
- *Feature selection for multi-source data:* Multi-faceted characterizations of data can enable the outline of several intrinsic patterns hidden insights, the availability of various data sources that allow for the solution of some problems that would otherwise be unsolvable with a single source [31].
- *Feature selection for multi-view data:* Multi-view sources use different features which are innately dependent and high-dimensional, feature selection is asked to undertake these sources for efficient data mining tasks like multi-view clustering [32].

b) Streaming feature selection: By removing redundant and irrelevant, streaming feature selection enables the most insightful features to be selected. In comparison to older methods of feature selection, online feature selection results in models that are easier to interpret for researchers and users, require less training time, avoid issues and challenges associated with dimensionality, and exhibit greater generalization due to reduced overfitting. The selection of streaming features is critical in real-time applications where the action must be taken immediately [31].

i) Feature Selection algorithms for Data Streams: It is critical to develop solutions for dealing with high-dimensional sequential data. One of the most critical characteristics of any effective feature selection approach is its ability to deal with massive amounts of data [31].

ii) Feature Selection Algorithms with Feature Streams: The number of instances is assumed to be constant in the feature selection task with streaming features, while candidate features show up one at a time. Rather than searching the entire feature

space, which is expensive, streaming feature selection (SFS) processes a new feature as it arrives. The process is repeated until no additional features appear [33].

B. Feature Selection based on Categorizations

a) Similarity-based Methods: To define feature relevance a group of methods for determining the significance of features based on their maintaining data similarity is used. These methods are referred to as similarity-based feature selection methods [34].

b) Information Theory-based Methods: Information-theory FS methods comprise a large group of previous feature selection algorithms. Techniques in this family primarily use various heuristic specifications to determine the significance of features. Furthermore, most information-theoretic concepts are only applicable to discrete variables. For example, entropy, conditional entropy, information gain, and conditional information gain [35].

c) Sparse Learning-based Methods: Sparse learning-based FS methods are applied for minimizing fitting errors and sparse regularisation terms. The sparse regularizer makes some feature coefficients small or exactly zero, allowing the corresponding features to be easily eliminated [36].

d) Statistical based Methods: Statistically based FS algorithms examine each feature individually. As a result, feature redundancy is invariably overlooked during the selection stage. T-score, Low Variance-score, Chi-Square Score, T-score, and Gini Index are some examples [36].

IV. EXISTING PYTHON FEATURE SELECTION LIBRARIES

The Python language has grown in popularity in most applications of machine learning [37]. The ML Feature Selection library includes heuristic techniques and algorithms based on machine learning methods and evaluation techniques [35]. Existing open-source repositories in Python with feature selection algorithms are mentioned in Table 2 and a comparison of FS algorithm characterization and Python FS libraries contents in Table 3.

TABLE 2: PYTHON-COMPATIBLE FEATURE SELECTION LIBRARIES FOR NIDS [35]

Machine Learning Library	Full form	Description
Weka	Waikato Environment for Knowledge Analysis	Weka includes different filtering methods and wrappers for feature selection.
MLR	Machine learning libraries for R	It includes a filter, a wrapper, a filter ensemble, and clustering.
ITMO	Information Technologies Mechanics and Optics	This FS library architecture includes wrappers, filters, hybrid, and embedded components.
ASU	Arizona State University library	It is created by Arizona State University's machine learning and data mining Lab.
SKL	scikit-learn library	It is an accessible FS repository based on scikit-learn.
FES	FES book support code	It focuses on evolutionary algorithm
Caret	Classification and Regression Training	Automate the process of developing predictive models in R.

TABLE 3: COMPARISON OF FS ALGORITHM CHARACTERIZATION AND PYTHON FS LIBRARIES CONTENTS[34]

FS Algorithm	Label	Learnin g	Output	Feature Type	ITM O	ASU	SK L	FES	Weka	Caret	MLR
Chi-square	S	ST	FW	DM	✓	✓	✓				
CIFE	S	IT	FW	DM		✓			✓		
CMIM	S	IT	FW	DM		✓					
DISR	S	IT	FW	DM		✓					
FCBF	S	IT	FS	DM		✓					
Fisher Score	S	SI	FW	DM		✓					
F-score	S	ST	FW	DM		✓					
Gini Index	S	ST	FW	DM	✓	✓					
ICAP	S	IT	FW	DM		✓					
JMI	S	IT	FW	DM		✓					
Laplacian Score	S	SI	FW	CD		✓					
Least square loss	S	SL	FW	DM		✓		✓			
Logistic loss	S	SL	FW	DM		✓					
Low variance	U	ST	FS	DB	✓	✓					
MCFS	S	SL	FW	CD		✓					
MIFS	S	IT	FW	DM		✓					✓
MIM	S	IT	FW	DM		✓					✓
MRMR	S	IT	FW	DM	✓	✓					
NDFS	U	SL	FW	CD		✓					
ReliefF	S	SI	FW	DM	✓	✓					
RFS	S	SL	FW	DM							
SPEC	U	SI	FW	CD		✓				✓	
Trace Ratio	S	SI	FW	DM		✓					
T-score	S	ST	FW	DB		✓					✓
UDFS	U	SL	FW	CD		✓			✓		✓

FS Algorithm characterization:
a) Label-S: Supervised; U: Unsupervised
b) Learning-ST: Statistical; IT: Information theory, SI: Similarity, SL: Sparse learning
c) Output-FW: Feature weight; FS: Feature subset
d) Feature Type-DM: Discrete(multi-class); DB: Discrete(binary-class); CD: Continuous and discrete
Box with ✓ means that the algorithm is implemented in that library.

V. CONCLUSION

All current NIDS use characteristics of user and system behavior as input to their analysis algorithms, which determine the likelihood of an attack. There is an urgent need for intelligent NIDS that can automatically detect novel attacks. A NIDS FS phase is difficult, as the NIDS must deal with a massive amount of data. In this paper, we have provided a review of feature selection methods used in NIDS. Feature selection framework and taxonomy for intelligent NIDS along with a comparison of FS Algorithm characterization and Python FS libraries contents are presented.

ACKNOWLEDGMENT

The authors would like to thank other researchers who have contributed to the field of NIDS.

Abstract— The main idea is to develop an intelligent computing system for disabled people, especially handicapped people who are willing to use a computer for their us-age purpose. Still, due to their disability, they can't use it. Nowadays, engineers try to make some equipment to solve this problem because this century is the computer century. The usage of the computer nowadays is very important. A person needs to use computers for their office purpose, education, and communication. A normal person can do this easily, but a disabled person, especially handicapped people, can't do this. This is a hard situation for a handy cap person because He also needs to communicate with the world. The proposed design can help handicapped peoples use computers for their usage purpose. Intelligent Computing System (ICS) is based on two units one is a head unit which contains a LASER which is used as a remote control, the other unit is ground unit which contains LDR sensor-based keyboard, controlling circuits may assets in performing the whole functionality of the ICS system by providing the instructions through the coding directed by PIC Controller which sending the data to the computer through MAX233 IC. The proposed LDR-based-matrix keyboard system sensor was sensitive enough to detect laser light which was tested on ten different users and shown promising accuracy; for future enhancement in order to use this device as a commercial device, instead of LDR matrix, we can, or the fabrication industry can fabricate LDR matrix during the fabrication process, to minimize the size of the system in order to save the power consumption of the system and may also allow a handicap people to use a computer and communicate with the world and gain knowledge and information just like a normal people.

Keywords—Intelligent computing systems, handy capped assistive device, LDR sensor , matrix keyboard and matrix mouse.

I. INTRODUCTION

This project was motivated by the novella/film "The Diving Bell and the Butterfly" based on the life of Jean-Dominique Bauby. At the age of 42 Bauby, the then French editor of the magazine ELLE, suffered a massive and spontaneous stroke while driving down a road in rural France. After several weeks in a coma, He awoke with what's known as "locked-in syndrome", with full muscular paralysis and with only the control of his left eye remaining. Despite the loss of all His physical ability, His sight, hearing, and especially mental function remained unchanged. He (the butter-fly) was trapped inside His body (the diving bell). With the aid of an

extra-ordinarily patient speech therapist, He gained the ability to communicate again by blinking as she orally read a frequency sorted alphabet to him. In this way, he would slowly form words and then sentences, and over the period of months, with extreme difficulty, he was able to write the account of his experience. This primitive form of communication was excruciatingly tedious to both Bauby and His "interpreter", requiring extreme patience from both individuals as letter entry was quite slow and any mistakes were not easily corrected. Besides this, a lot of work has been carried out to develop keyboard/mouse layouts for non-disable people.

In contrast, a little for physically disabled users, one of the systems designed by the researcher they named BAHDON based on text entry system provided access to the specific user who was unable to use keyboard easily in that system they can interact with the computer using their thumb toe and ankle movement [1], another studied the researcher proposed to design virtual or on-screen keyboards that supported multiple modes of access and had optimum layout based on the frequency of occurrence of the alphabet in English text, the proposed virtual keyboard in this studies designed in visual basic environment which consisted of eight sub circles in a large circle and arrow which were rotated in a clockwise direction each of circles consisted of different keyboard keys [2]. As in previous studies, only researcher focused on keyboard designing layout while this study may also focus on keyboard layout as well as mouse layout to give more access to specific users to use both . The proposed designed is an innovative idea helping the disabled person especially handicap who likes to use pc but due to their disability, they can't use it. In a designed project arrays of LDR are worked on the keyboard principle. The LDR (Light Detecting Resistor) is working on the principle of keyboard containing 26 Alphabets, 0 to 9 Digits, some special keys, scroll keys, enter key, space key, and backspace key. One LDR for mouse mode and one for keyboard mode. Proposed design may use the same principle for mouse usage. The U key for upper movement of mouse, M key for lower movement of the mouse, H key for the mouse's left movement of the mouse, K key for the mouse, P for a single click, O for double click, R for double click, R for right-click. ICS may exceed handy cap person expectations with accurate laser communication and precise sensing. [3-15].

II. DESIGN AND METHODOLOGY

A. Hardware Description

The working principle of the ICS is based on the keypad principle micro-controller, which is PIC16F877A. Another main circuit is the op-amp which uses as a comparator for LDR. The MAX233 is connected to the microcontroller. It amplifies the voltages. The MAX233 IC is connected with an RS232 cable which interfaces the whole project with the computer. We use the same principle for mouse usage, as

shown in Figures 1-2. The U key for upper movement of the mouse, M key for lower movement of the mouse, H key for the mouse's left movement of the mouse, K key for the mouse, P for a single click, O for double click, R for double click, R for right-click. Detection of light using LD. Elimination of daylight which falls on LDR using op-amp comparator. PIC microcontroller receives the data and sends it to the computer through MAX233 IC and RS232 cable. Visual studio.net software receives the serial port data and activates the mouse and keyboard function. A comparator circuit may be designed to respond to continuously varying (analog) or discrete (digital) signals, and its output may be in the form of signaling pulses that occur at the comparison point or in the form of discrete direct-current (dc) levels. [4].

B. Handicap Keyboard and Mouse Pad designed matrix

LDR-based keypad designed, the LDR activated by the LASER, which is mounted on the user's head. 48 arrays of LDR were made on the basic pattern of keyboard keys. These arrays are then connected in 3x16 matrixes consisting of 3 Rows and 16 Columns, as shown in Figure 3. The LDR has 2 pins; one is connected in rows, and the other is connected in columns, as shown in Figure 4. The first pin of LDR has connected in rows; each row relates to the LM741 Operation Amplifier windows comparator as shown in Figure 4, while the LDR signal conditioning circuit is shown in Figure 5. The output of the OpAmp comparator is connected with the PIC microcontroller input port; through programming, we designed non-triggerable one short signal was picked at every 1 second to give LDR matrix sufficient time to respond upon user response to type another letter by moving their head towards the LDR matrix keyboard layout, because some part of LDR matrix is assigned for mouse pad cursor moving the same timing delayed was given for this purpose too. Letter. While the second pin of LDR is connected in columns, and then each column is connected to PIC microcontroller input port pins, as shown in Figures 4 and 5. Now the arrays of LDR are connected to PIC16F877A. The proposed design has three (3) I/O ports used as an input port of the PIC controller. The ports are B, D and E. The columns of LDR are connected at PORTB and D as shown Figure 4-6, PORTB and D both have eight (8 bits); therefore, each pin relates to three (3) LDR's, as shown in Figure 4-5, then the output of the op-amp comparator is connected at PORTE of PIC microcontroller., for this purpose, PORTE bit E0, E1, E2 were used as an input port pins. Now the second pin of LDR is connected in rows, and there are three rows; each row contains 16 LDR arrays, each row relates to LM741 op-amp, which use as a comparator. The

handicapped person may also use and control the mouse with these Keypad LDR matrix pads to give mouse access control to the user; some of the proposed LDR keypad keys were assigned for mouse controlling functions, respectively, as mentioned in Table 1.

TABLE I. LDR BASED MOUSE PAD.

Mouse Keys	Mouse Key Functions
U	For Upward Mouse Movement
M	For Downward Mouse Movement
H	For Left Mouse Movement
K	For Right Mouse Movement
P	For selecting Single Mouse Click
O	For selecting Double Mouse Click
R	For selecting Right Mouse Click

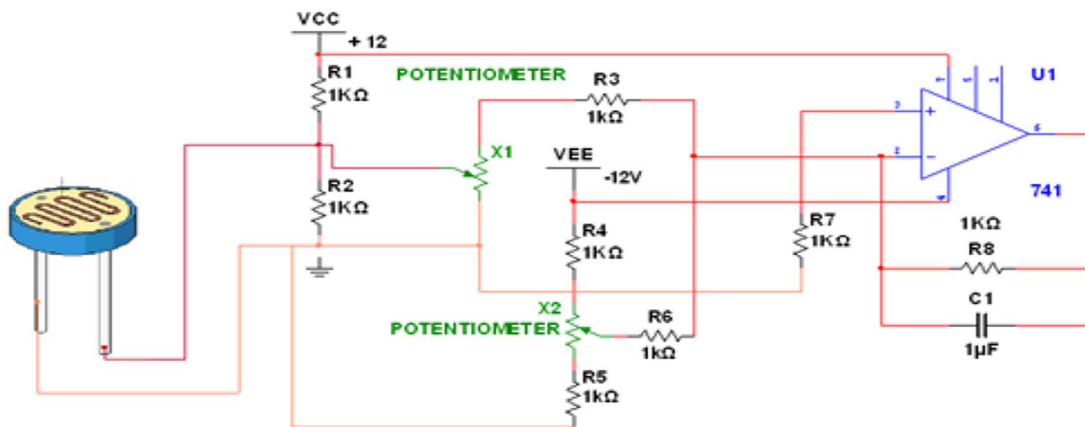

Fig 5. LDR signal conditioning circuit

Fig 6. LDR Row/Column wiring diagram

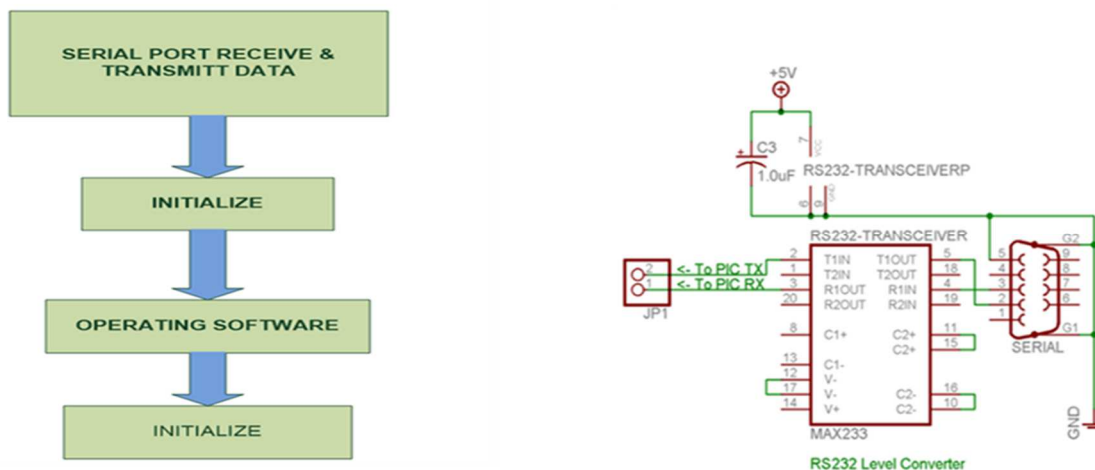

Fig 7. At Right shows the data transmission/receiving flow . At Left shows the connection b/w Pic microcontroller with RS232 connector

C. Data Acquisition

Step by step sending data procedures were needed for sending and receiving LDR data for this purpose Serial port of PIC Microcontroller was also used the designed circuits were operating at 5 V while for interfacing the hardware circuit with user computer MAX233 IC was used, A MAX233 is used to convert the logic level signals of the PIC microcontroller to RS-232 compatible voltage levels. Technically the MAX233 is an RS-232-line driver/receiver, but an easier way to explain its operation is that it allows a PIC microcontroller to

communicate at RS-232 voltage levels with a computer as shown in Figure 7, the MAX233 should nominally be run at 5 Volts.[3] for serial communication to communicate the LDR Matrix circuits with user Pc. To achieve this serial communication within the designed circuitry and pc USART interfacing protocol was adopted. The PIC Microcontroller sends the LDR matrix data through an RS232 cable to the computer. Then the RS232 cable transmits the information to the controller that waits for a while, and the sending data perform the expected task. This basic RS-232 transmit/receive

circuit is necessary for PIC microcontrollers to communicate reliably with a PC serial port.

D. Software programming description

In the coding part IF ELSE condition statement were used to recognized LDR-based keypad detection. When the user moves him/her head bend consisting of Laser LED embedded on these head bend, this laser light will fall towards the character, user willing to type on a computer screen. The LASER activated that particular LDR character where the light falls. The controller checks the whole LDR arrays "if" the LASER activate the "A" letter, LDR then the controller send the "A" letter ASCII code to the computer. If the LASER is not activated the "A" letter LDR, check the other ones. Therefore, IF ELSE condition statements were used in whole programming codes, the same technique was used to recognize all characters.

III. RESULT AND CONCLUSION

The proposed design exceeded our expectations with accurate laser communication and precise sensing. The prototype device was given to 20 users to use it as a keyboard and mouse with their computers, to type the sentence "An Approach to design Keyboard and Mouse assisting device for handicap users" it's showing the promising result with 85 to 90 percent accuracy and the average time taken to type the stated sentences for all these users were between 90 seconds to 2 minutes. It was noticed that the proposed LDR-based-matrix keyboard system sensor was sensitive enough to detect laser light. The distinctive signal provided by the op-amp (window comparator) helped filter out daylight from the laser light used, for future enhancement in order to use this device as a commercial device, instead of LDR matrix, we can, or the fabrication industry can fabricate LDR matrix during the fabrication process, because in this proposed design lot of LDR used and connected in a matrix format may increase the power consumption and may reduce the sensitivity of the system detection. In short, the proposed design will allow disabled person, especially handicapped people, to use computers and communicate with the world and gain knowledge and information just like a normal person. Hope this system may "HELP THE HUMANITY."

Abstract—Respiration is an important vital sign which can help in the indication of human's health status. Sleep apnea, which is defined as a cessation of breathing while sleeping, is recognized as a common and critical popular health problem. By monitoring the patient's respiration rate, sleep apnea can be diagnosed. The received signal from the patient, which is a variation in temperature, is converted into a variation in voltage and then the respiration rate can be calculated. A portable device is proposed that can continuously monitor the breathing rhythm in a manner which is fast, safe and costly effective. The system consists of a nasal-oral thermistor that is mounted inside a nebulizer mask for detecting the irregular respiratory interruption and providing audible and visual alarms when this interrupt indicates an apnea event. Otherwise, if an out-of-range value occurred the alarm also will be initiated. Thus, the device will contribute to reducing the death associated with sleep apnea.

Keywords—Respiratory monitoring system, Sleep apnea, Respiratory rate, Nebulizer mask, Nasal oral thermistor.

I. INTRODUCTION

Respiration is considered as an essential vital sign which gives a clue of the health condition of human. Several health conditions and diseases may affect the respiration rate. Sleep apnea is known as an interruption of breathing during sleep. Sleep apnea is considered as a serious and common disease. Undiagnosed sleep apnea can significantly affect the quality of a person's life. Prolonged apnea reduces oxygen levels in blood and tissue, leading to permanent brain damage and, if not remediated, death. A highly sensitive, accurate, reliable and portable monitoring system is needed for apnea detection. The monitoring system is based on calculating the respiration rate which is the number of breathing cycles per one minute. A portable device is proposed that can continuously monitor the breathing rhythm in a manner which is fast, safe and effective [1][2]. Since this respiratory monitoring device is used by sleep apnea patients at home, it is highly secure and easy to use. Hence, the system is noninvasive [3]

The primary aim of this project was to design a portable respiratory monitoring system that provides a reliable, inexpensive, noninvasive, and faster approach to continuously monitor the respiration rate of the sleep apnea patients for this an airflow-based method was designed in monitoring respiration rate by using a nasal-oral thermistor for detecting and analyzing the respiration signal and

extracting the respiration rate an algorithm has also been developed [3-15].

II. DESIGN AND METHODOLOGY

A. Hardware Description

The nasal-oral thermistor which is mounted in a nebulizer mask is used to detect apneic events by measuring respiration rate. The proposed device presents a noninvasive respiration monitoring system that is appropriate and secure for home utilizing on adults. It proposes an approach to monitor sleep apnea patients prior to, through and after treatment. The system is composed of a nasal-oral thermistor. It detects the breathing rhythm of the patient. A thermistor is placed snugly below the nose and ahead of the mouth. The cool inhaled and warm exhaled air temperatures are sensed by the thermistor. The variance in temperature provides an indication of the continuity of breathing [2]. A certain circuit is designed to receive the sensor's data, then the circuit output is transmitted to the processing unit (Arduino) placed in the same area as the patient. The signal is processed through computational series, keeping track of the occurrence of an interruption in breathing. In healthy adults, the normal range of respiratory rate is between 12 and 18 bpm at rest conditions [4]. That means a breath each 3 to 5 seconds [2]. The normal breathing frequency is falling in the range of 0.2-0.3 Hz [5]. This method is able to detect all types of apnea [6]. The thermistor is considered the most ordinary method for detecting respiratory events [7]. The nasal-oral thermistor should have a low thermal mass and an adequate sensitivity [8]. If the processor detects a signal below the normal range, this will be considered as an apneic event. After that, the action is taken by the processing unit depending on whether the patient's breath is normal, or apnea is detected. In the case of apnea, the alarm will be activated. If the patient starts again 30 breathing unaided, the alarm ends. In case that the patient still does not carry on breathing, the alarm signal remains to warn the caretaker that instant awareness is mandatory. The main components of the system are shown in Figure 1. The respiratory monitoring device requires a highly sensitive thermistor in order to detect a small variation in the temperature. The thermistor is a type of sensors with a variable resistance that changes when the temperature changes, then this change in resistance is translated into voltage. The negative temperature coefficient

(NTC) thermistor was used in this proposed device, since most of the medical applications are used it. The main characteristic of NTC is that the temperature and the resistance of the thermistor are inversely proportional. As the temperature increases, the thermistor's resistance decreases. Equation (1) illustrates the relationship between the thermistor's resistance and temperature.

$$R_{th}(T) = ae^{-bT} + C \quad (1)$$

Where a,b, and c = constants T = the air temperature, °C. It is noticeable that the temperature and resistance have a non-linear relationship [9]. Biomedical applications use a thermistor with a sensitivity in the range of 0.1 to 100 Ω.m [10]. By increasing the thermistor's core temperature, the resistance will exhibit a large decrease but not in a linear relation. To predict this relation accurately, the thermistor calibration stage must be considered. The thermistor circuit is shown in Figure 2. As the patient is breathing, the warm exhaled air changes the R_{th} of the thermistor, therefore, resulting in a proportional change in the output voltage V_{out} . The main idea behind the design circuit in Figure 3 is to detect the variation in the temperature by the 100k NTC thermistor through the designing of the three stages. These stages are: thermistor circuit stage, amplification stage, and low pass filter stage. Furthermore, the output of the circuit, which is taken from the op-amp's pin number 7, is connected to the pin number 8 in the Arduino UNO. Here in Figure 4, the sensor symbol represents the circuit output. After the processing for the input of the Arduino UNO, the output is the respiration rate. Depending on the value of the respiration rate the action will be taken. If it is normal it will be displayed on the LCD. In contrast, if the respiration rate is below the normal, which means below 12, the respiration rate and "Sleep Apnea" text will be displayed on the LCD. At the same time, the audible and visual alarms will be initiated to warn the patient. Moreover, the patient can stop the alarms by pressing the stop button. In case of the respiration rate was not logical, which means above 25, the text "System Error" will be displayed and also the alarm will be initiated.

The thermistor circuit captures the variation in temperature from the subject's air flow and transmits it as a voltage to the second circuit stage. As the temperature increases the thermistor's voltage decreases.

The operational amplifier circuit: It amplifies the thermistor's voltage by a gain value of 3.167. This value is found by dividing the output voltage measured by the amplifier (3.686 V) by the output of the thermistor circuit stage (1.164 V). This stage is shown in Figure 3. The output of the amplifier is transmitted to the third stage which is a low pass filter. In Low-pass filter stage, an active low-pass filter with unity feedback was designed as shown in Figure 3. The cutoff frequency of the filter is calculated based on the values of the capacitors and resistors. The calculations for the cutoff frequency are done by using: $R_1 = R_2$, $C_1 = 2 C_2$.

$$f = \frac{\sqrt{2}}{4\pi RC_2} \quad (2)$$

The cutoff frequency of the active low pass filter is equal to $f=0.938$ Hz. The purpose of this stage is to suppress any frequencies above the cutoff frequency. The suppressed values considered as noise and interruption for the respiration signal.

B. Algorithm Flowchart.

The designed circuit output digital signal is acting as an input for the processing unit. The breathing timer will be initiated with the first inhalation and then it will measure the time for every respiration cycle. This time will be used to calculate the respiration rate in breaths per minute unit. The respiration rate value will be displayed on LCD. As an action, if the respiration rate is less than the minimum of the normal range which is 12 breaths per minute, an audible and visual alarm are initiated indicating an apnea event to warn the patient and wake him/her up [11]. A 'System Error' text will be displayed on LCD in the case of respiration rate value that is not logical (above 25), and also here the alarm will be initiated. Finally, the alarm will continue until someone press the button to stop it.

C. Hardware / Experimental Setup

The hardware of the proposed device is composed of the circuit design, Arduino UNO, visual alarm, audible alarm and LCD which are shown in Figure 6. The Arduino UNO was powered using a 9 V adapter in order to operate the uploaded program in the Arduino UNO electrically erasable programmable read-only memory (EEPROM). The respiration rate was displayed on the LCD as shown in Figure 7 and Figure 8. Both figures are examples of normal and abnormal (apnea) respiration rates. Also the “system Error” text is displayed as shown in Figure 9: LCD display of “System Error” when the not logical value appears.

III. RESULT AND DISCUSSION

The proposed design shows satisfying results compared with the previous sleep lab database results. As shown in Figure 10, by counting the numbers of peaks in the circuit’s output signal, the breathing pattern consists of 12 peaks (breaths) per minute which falls in the normal respiration range (12-18 Bpm). One peak represents a one respiration cycle (respiration cycle = inhalation + exhalation). Refer to characteristic of NTC it shows that the thermistor’s voltage decreases as the temperature increases. All of the respiration signals that was taken in this stage were from the pin number 7 of the op-amp which represents the output of the whole designed circuit.

However, Figure 11 shows an apneic event. It shows that the regular respiration is described by the existence of a specific pattern and the existence of an amount of energy in the signal. Apnea is simply detected by the lack of rhythm in addition to a lack of energy [8]. As seen, the subject’s breath stopped for around 10 seconds which represents the sleep apnea breathing pattern.

When doing the trial using Arduino UNO serial monitor, Figure 12 demonstrates the subject’s results. For the first respiration rate = 2.02 Bpm, "Sleep Apnea" warning message was displayed. For the second respiration rate = 17.44 Bpm, no message was displayed because the result falls in the

normal respiration range. The Third respiration rate = 10.32 Bpm, the warning message was displayed. We take Respiration Rate Trials of 3 subjects and plot Time vs. Voltage by using MATLAB.

The three previous graphs show a different breathing rate patterns from a different three subjects. The first, second and third breathing rate = 13.50 Bpm, 13 Bpm and 15.4 Bpm respectively. So, the proposed respiratory monitoring system is capable to measure and display a reliable respiration rate values for different subjects.

A prototype device for respiratory monitoring system for sleep apnea patients has been developed, implemented, and tested. This device is suitable for monitoring of respiration and detection of sleep apnea. The proposed device may be used with patients sleep apnea in their homes, as an alternative to medical supervision in healthcare institutions, with a detection degree of accuracy similar to the commercially available devices.

IV. CONCLUSION

The main advantage of proposed device is this is portable, inexpensive, noninvasive, and faster approach to continuously monitor the respiration rate of the sleep apnea patients. A nasal-oral thermistor is used to monitoring respiration rate. It also has audible and visual alarms to alert the patient or its care giver. Normally for diagnosis of sleep apnea Polysomnography (PSG) device is used. A Polysomnography device converts body electrical signals to graphical representation . While doing this assessment, the patient has to stay all night at a specifically prepared sleep laboratory supervised by a sleep technician. A full set of sensors is used in PSG to monitor physical functions in sleep. They are attached to the patient’s body by wires that join into a central box. A computer system is associated with the central box to record, store and display data. Despite that PSG is considered the gold standard for sleep diagnosis, there are several disadvantages associated with this test It does not provide the exact home sleep environment, and it causes discomfort to the patient by all the wires attached to it. The results acquired from the PSG may be distorted and not accurate. PSG needs considerable complex equipment to record data and extensive expert clinicians to determine the severity of sleep disorders. In general, most of the devices and procedures are extremely time-consuming and costly process since it costs several thousand dollars. This is a big problem to the patients and makes them carry on having undiagnosed sleep apnea. 82% of men and 93% of women with sleep apnea are not diagnosed As a result of these disadvantages, the patient may desire to have a home diagnosis as an alternative Portable monitoring is a satisfactory option in patients supposed to have sleep apnea. Portability-based approaches are the primary component for the new health technology to make it comprehensive, cost-effective and a beneficial solution to the sleep apnea patients. Our proposed device is portable and wireless. Adoption of new and innovative sleep health monitoring ideas or

applications can increase the level of promoting better health for the society. In addition, it increases the availability of wide and fast techniques of how the physiological signal can be picked up from the patient, analyzed and displayed. All these in a carry-out small box beside the patient's bed can offer a comfortable, easy to use and possibility of home sleep monitoring to sleep disorder patients [16-23].

Abstract—The simplicity and ease of implementing the Distance Vector Hop (DV-Hop) localization method is mostly used as a range-free localization technique in location-based services. But it has poor positioning accuracy, particularly in a complicated, unequally distributed structure. To overcome this problem, an upgraded DV-Hop localization method based on BN (Beacon Node), hop thresholds, and balanced matrices are suggested, known as the enhanced-DVHLA method. The enhanced-DVHLA approach proposes the improved contribution in the DV-Hop localization by using ALO optimization algorithm. The proposed method is more efficient and reliable as compared to other approaches in WSNs as it has optimized the error rate (LE) to more than 77 percent, and improved the localization accuracy compared with other techniques. The LER dropped by 40.1 percent, and 27.8 percent, respectively, when compared with the TWDV-Hop and TWDV-Hop-AODV methods.

Index Terms—Node Localization, Wireless Sensor Network, enhanced-DVHLA method, Traditional Distance Vector Hop Algorithm, Node Distribution

I. INTRODUCTION

Wireless Sensor System is an essential innovation for the 21st generation of scientists and academicians. Recent advancements in Sensing Applications (Micro Electro Mechanical Systems) and Communication Technologies have enabled the development of low-cost, low-energy, small, and sophisticated sensing devices that can be deployed across a wide area and connected via wireless channels and the Internet for a variety of commercial and domestic uses. To enable sensors, data processing, integrated computation, and communication in a WSN, sensors and actuators are installed in dense populations and often in huge quantities. Recent technological and computer advancements have resulted in many sensor improvements, computing infrastructure, and wireless transmission. These sophisticated sensors have the potential to bridge the gap between the digital and physical worlds. Sensing devices are used in various instruments, businesses,

equipment, and the environment to aid in the prevention of infrastructure failures, disasters, natural resource preservation, increased output, and protection, among several other aspects.

These intelligent sensors can serve as a link between both the digital and physical world. Sensing devices are employed in various instruments, enterprises, equipment, and the surroundings to assist infrastructure breakdowns, disasters, and preservation of natural resources, animal conservation, increased production, and protection, among other things. In MEMS, VLSI, and wireless networking, advancements have facilitated the use of a wireless sensing system or network. With the development of technologically integrated circuit chips, more efficient integrated circuits are significantly smaller and thinner than previous-generation devices. The evolution of computer processing and sensor systems has led to compact, low-power detectors, regulators, and controllers. Fig. 1 depicts WSN's basic architecture.

Fig. 1: General Architecture: WSN [2]

The various applications of WSN are explained below: (i) Area Monitoring: Sensor nodes are installed in areas where certain activities must be observed; for example, sensor nodes detect the opponent's location and provide the information to a central for more evaluation. Sensor networks are often used to

track the location of vehicles [3]. (ii) Environment monitoring: WSNs offer a wide range of uses in oceans, forests, and other environments. These systems are used to fire alarms in the woods. WSNs can identify the beginnings of a wildfire and how much it spreads. Animals' movements are also detected by sensor nodes, allowing researchers to study their routines. WSNs are also deployed to monitor the position of plants growing. (iii) Industrial automation: A wireless sensor network is used in various smart applications. For efficient results, it is employed in industrial automation. The wireless sensor network can be used for various applications in industrial automation, including product flow monitoring, protection, and safety, quality control, and factory digitalization. (iv) Smart agriculture system: Traditional irrigation methods increase crop yields by controlling biological impacts. On the other hand, manual farm handling diminishes productivity, consumes a lot of energy, and raises labor costs, making the process less efficient. A smart wireless sensor-based greenhouse with smart sensors is easy to handle, but it also allows us to alter its temperature [4].

WSN network has several advantages; since the WSN (Wireless sensor network) is expandable, new nodes or sensors can be added at any moment. WSN networks are dynamic. Due to battery exhaustion and other issues, adding or transferring some new sensor nodes into the network can meet the task requirements. Because the topology may change, dynamic, reconfiguration and self-adjustment functions are required for the WSN topology [5]

- The sensor node in a WSN can only communicate with its immediate neighbours. However, only a multi-hop path will suffice if a node needs to communicate outside RF (radio frequency) range. The intermediary nodes in this multi-hop path can transfer data.

- Architectural boundaries aren't a problem for WSN because it's flexible by nature.

- All wireless sensor nodes can be accessed through a central monitoring system.

- Because WSN is wireless, it does not require cables or wires.

- WSNs, which refer to the difference between a wired and a wireless connection, can be employed on a large scale in various situations, including industrial, medical, monitoring, and agriculture [6].

Positioning is commonly used to analyze the sensor node location in wireless sensor networks. Installing a Global Positioning System across each sensor is expensive in a WSN with hundreds of sensors. GPS (Global Positioning System) may not provide accurate location results in an inside area. Individually generating location references across each sensor network in a complicated system is not practicable [7]. To solve the shortcomings of prior location tracking, the GPS (Global Positioning System), which is among the most extensively used techniques for location, was established in 1973. Defence, industrial, and, more recently, customer uses have all

employed GPS. GPS delivers three-dimensional geolocation data and needs a direct connection with at least four spacecraft, with only a precision of 0.3 m.

Furthermore, GPS is restricted in its usability in dense forests, hillsides, and even indoor spaces. It does not function over obstructions that hinder LOS (line of sight) transmission between the spacecraft and the Global positioning system. Several of these issues are solved by employing wireless signals for positioning [8], especially with the construction of cellular towers, which offer enough data to locate mobiles. The wireless sensor network can overcome GPS's location limitations. Scientists have developed non-GPS methods for identifying nodes throughout the wireless sensor network. Anchoring detectors are sensors placed in predefined locations and used to locate all other devices in random locations using arrival time and acquired signal intensity approaches. Analyzing location-related factors can infer a component in an unknown area. Techniques like sequential identification, which uses sensors with low interaction bandwidth to achieve location, can be scaled. The main drawback of these methods is that they necessitate exact range and orientation measurements. The embedded methods and methodologies used to obtain location data in indoor spaces include web-access microwaves, structural modelling, multiple antennae, and ZigBee [9].

An improved technique is provided by [13] to minimize localization error in the wireless network. In [13], the DV-Hop algorithm for the localization of normal nodes in WSN was studied. The technique was known as TWDV-hop, where T is the hop threshold and W is the weighted matrix. The algorithm was corrected during the first step in the proposed technique. It resolved the problem of average hop size because with increase in the number of hops between the two beacon nodes, their distance also increases and The average hop size showed much more error. That means the traditional DV-Hop algorithm performs efficiently with the nodes that are much closer to each other and offer a lot of errors if they are farther apart. In [16], a routing protocol based on DV-Hop algorithm is explained known as AODV Algorithm. This protocol integrates the target serial no. and includes routing discovery and routing maintenance. When the source node communicating with other nodes fails to reach the routing of destination node, it requires the grouping of RREQ and it is received by all nodes, It checks whether such information exists or not and then the information should be abandoned accordingly or RREQ is recorded the routing table and broadcasted continuously until some central node or the routing request grouping reaches the routing of destination node.

The existing techniques suffer from high hop value and low accuracy—more accuracy error when the distance between the Beacon nodes is greater. Computational cost is high and requires more energy and, in some cases, incorrect results of position localization. Therefore, there is a need for a methodology where computational cost is low, accuracy is

high, and Beacon nodes are less. Also, there is a need for a methodology where the average hop distance is cut off if the number of hops is more than 3, as it reduces the overall error when finding the location of the unknown nodes. The proposed technique (enhanced-DVHLA) has improved localization accuracy in WSNs. The proposed method created three enhancements depending on the TWDV-Hop, and TWDV-Hop with AODV. (i) It evaluates their estimated distance with the MHN (minimum-hop-number) and signals broadcasting from one node to another for data transmission. (ii) It modifies the average hop-size between UN and BN. After this modification process, the route replies from source to destination node when the signal has been activated. (iii) It calculates the optimized nearest neighbour route based on the minimum distance for data transmission and reduces LE and LER.

The sections of this paper are: The brief Introduction of node localization is explained in section 1. In section 2, various existing methods for node localization are surveyed. The proposed methodology is explained in section 3. The simulation results and discussions are elaborated in section 4. Section 5 defines the conclusion and future scope of the research work.

II. RELATED WORKS

This section provides a survey of several existing methods of node localization in WSNs. Messous S., et al., (2021) [10] presented an enhanced DV-Hop technique to reduce the significant path loss throughout the existing DV-Hop technique. The obtained wireless signal confirmations and the quadratic correction factor were used to measure the location of neural sources and news stations. Furthermore, the suggested technique enhances the effectiveness of position estimation by recursively computing the positioning procedure. The suggested localized approach minimizes path loss and enhances positioning accuracy, according to experimental observations. Kanwar, V., et al., (2021) [11] included a conversion factor in the proposed methodology to change the hop dimensions of the cluster centres. The suggested methodology reduces communication with unidentified and attached endpoints by determining the hop dimensions, including all anchor points at neural sources. The broadcasting abnormality framework demonstrated the usefulness of the proposed automated system in a transversely isotropic system. Simulations were performed in MATLAB, as well as our suggested approach was compared to classic DV-Hop, evolutionary automated process DV-Hop, and metaheuristic optimization-based PSO optimization-based DV-Hop. Compared to existing detection techniques, modelling results indicate that the proposed autoencoder lowers localized failure, error variance, and computation time. Wang, G., et al., (2021) [12] implemented the lowest hop count, as well as a spectrum were set using the RSSI technique so that when the minimal Hop count was similar to the real quantity as well as the location reliability of the DV-Hop method was increased. In a subsequent study, the balanced

refinement for every white node's minimum hop ranging might be done using the balanced parameter to effectively consider the global structure and eliminate the problem generated by the minimum hop distance. Han, F., et al., (2020) [13] studied WND-DV-Hop, an upgraded DV-Hop technique with dynamic load balancing factors and a novel scaled minor-square placement technique. First, the unidentified node's single-hop was adjusted using RSSI (Received Signal Strength Indication) technique. A modified coefficient dependent on the beacon node count was developed to minimize minimum hop range uncertainty. To tackle polynomial equations problems, a novel balanced least-squares technique was incorporated.

Furthermore, extensive experiments were carried out to determine WND-DV-performance, Hop's, and the results compared to effective direction vector-hop, improved DV (direction vector)-Hop, checkout- direction vector hop, and new direction hop shown in the literature. WND-DV-Hop considerably surpassed other localization techniques, according to the results. Xue, D., et al., (2019) [14] presented an improved distance vector hop methodology based on hopping narrowing and range adjustment. The minimum hop distance was reduced by using RSSI (Received Signal Strength Indication) extending technologies. The average path range was reduced using the balanced overall average of hopping range inaccuracy and predicted range inaccuracy. As a result, the Hop-DV localization method's available localization quality had increased, and the positioning error had decreased. The modelling investigation of the revised approach was performed in the MATLAB simulation model. According to the experimental outcomes, the suggested method decreased localization loss and improved localization accuracy.

A N Jadhav et al. 2018 [17] discussed how node location played a vital role in WSNs. It comprised WS (wireless sensor) localization method using EHP (expected-hop-progress) to analyze the area of sensors in the network. The introduced method is based on a careful study of hop-progress in a WSN with random deployed SN and AND (arbitrary node density). The distance between any pair of SNs can be precisely calculated by deriving the EHP from a WSN model in network metrics. The DE (distance estimation) was the central issue in LSs (localization systems) for networks. The research method range-free EHP attains better performance and minimum COH (communication overhead) as compared to some existing techniques such as DV-Hop and AODV protocol. AODV is the RP (routing protocol) based on the distance-vector method that defines the target SNO. (Serial number). This method generally includes RD (routing discovery) and RM (route maintenance). If the start node transmitting with other SNs fails to spread the routing of the sink node, it needs the grouping route request. After the other SNs get this route req, whether such data exists/not. AODV routing protocol, the SN requests for the routing of the sink node through distributed route re message. Like a flooding protocol will unluckily create

an important route req message, outcoming a significant signal error and the COH.

The above discussed methods have various Problems and research gaps which has been discussed below:

- Low accuracy for node localization and low stability of the network.
- More complex to implement in a real-time environment.
- Implementation issues, sparse network issues.
- Computational complexity is high.
- Distance estimation is a main problem in localization systems.
- Node localization error

To eliminate the above research gaps, an enhanced method is proposed in this paper.

III. PROPOSED WORK

The main aim of proposed work is to reduce the LE and improved the LA rate. It will assess the LER in terms of the following metrics: (i) Effect of Total Number of Nodes (ii) Effect of Beacon node ratio, and (iii) Effect of Communication Range. Figure 2 depicts the flow chart of proposed work.

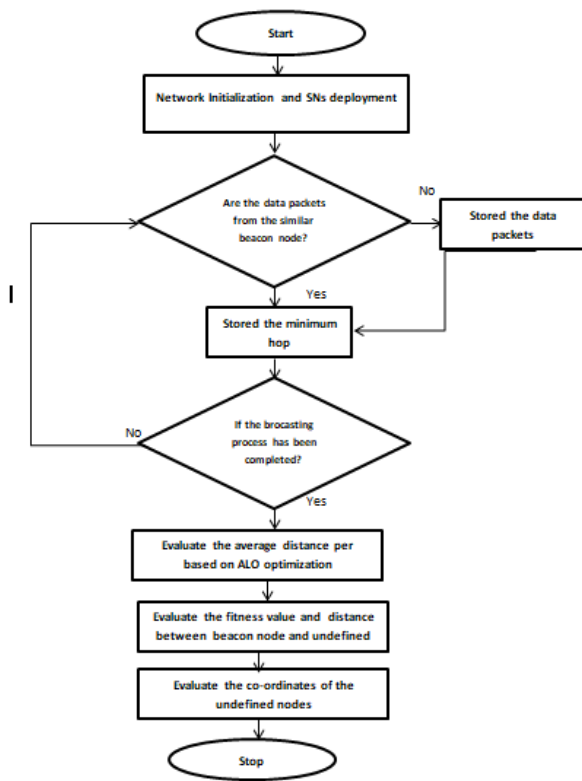

Fig. 2: General Architecture: WSN [2]

The main principle of enhanced DVHLA is to estimate unknown node locations through known node locations and the HC (hop count) between SNs (sensor nodes). WSN networks have two categories of nodes, one is BN whose locations

are known, and the other nodes are UNs (unknown nodes). The main procedure for the enhanced DVHLA method can be described as three steps. (i) Initially, each BN transfers its location throughout the complete network (WSN). By taking the benefit of relay nodes, each node would know the MV (minimum value) of HC to BNs and the corresponding position, if they are associated. (ii) Secondly, the average distance of each hop for BNs is evaluated by the MV of HC and the total distance between BNs. The average distance for a UNs is similar to the BN optimized nearest it. The distances to BNs can be estimated for the UN by multiplying the middle distance by HC's MV to ANs. (iii) Lastly, if there are at least three optimized distances for a UN that have been evaluated in the existing procedure, the location of the UN can be assessed. DV-hop is more straightforward to design than the other LA (localization algorithms). So, it has the demerits of a minimum positioning accuracy rate. This research work has enhanced the DVHLA method by the ALO optimization method HC to optimize distanced EE in this research paper. This proposed method has evaluated the minimum distance and nearest route for data transmission in the network. ALO method helps to optimize the route and distance for high range for data transmission and less error rate as compared with existing methods. This proposed model has reduced the LE and improved the LA rate.

IV. SIMULATION RESULTS AND DISCUSSIONS

A. Arithmetic Formula

LE and LER are used to calculate the achievement of our research based on enhanced-DVHLA algorithm.

- LE (localization error): The difference between real and evaluated coordinates of UNs, its expression is defined in (1)

$$LE = \sqrt{((x1_u - x2_a)^2 + (y1_u - y2_a)^2)} \quad (1)$$

- LER (localization error radius): It is the ratio of average LE to the CR (communication range).

$$LER = \sum_{U,n=1}^N (\sqrt{((x1_u - x2_a)^2 + (y1_u - y2_a)^2)}) / N * r \quad (2)$$

B. Simulation Environment

An illustration of sensor node deployment in two-dimensional space is shown below in fig. 3. The total number of 100 sensor nodes is randomly deployed in the 100*100 meters sq. area, adding twenty BNs (beacon nodes) denoted by the '*' pink star. In training to test the network performance of the Enhanced-DVHLA method, simulations were designed in MATLAB 2018a. The simulation results were compared with TWDV-Hop [13] and TWDV-Hop with AODV [16]. Table 1 defines the experiment metrics.

To better study the research method, all simulations for methods were performed as many as a hundred times for

Fig. 3: Node Deployment

TABLE 1. SIMULATION METRICS

Metrics	Values
Size of network	100*100 m
Total number of nodes	100
Beacon Nodes	20
Communication range	25

each outcome since SNs are randomly deployed in the screen field. The proposed model used the average value to calculate the enhanced method. This experiment was defined under the scenario that a hundred SNs were unevenly plotted in the network area of 100*100 meters sq. with 20 per cent BN. The CR (communication range) is 25 meters.

Fig. 4: LR for each UN (unknown node)

Fig. 4 shows the localization error for each unknown SN under three methods in a similar environment. It is observed that the proposed method (enhanced-DVHLA) gave better results. The LE of TWDV-Hop is around 6m and almost

three times larger than the enhanced DVHLA method. All LE of enhanced-DVHLA is between 2m and 3m, with a flat modify trend and almost near direct line, which means the network performance of enhanced-DVHLA is more reliable and efficient. The reduction of LE in the enhanced-DVHLA method is 77 percent. Compared with TWDV-Hop [13] and TWDV-Hop - AODV [16], the error is reduced to around 55 per cent, and 35 percent, respectively.

TABLE 2. COMPARISON ANALYSIS OF LE AND STANDARD DEVIATION

Localization Algorithms	Max-LE (m)	Min-LE (m)	Avg-LE (m)	Std-LE
TWDV-Hop	3.97	2.965	3.425	0.22
TWDV-Hop AODV	3.935	1.881	3.391	0.93
Enhanced DVHLA	2.446	1.47	0.056	0.21

Table 2 shows the comparative analysis of LE and its SD (standard deviation) under three-node localization methods. Compared with the other two ways, the enhanced-DVHLA process has achieved minimum LE in the form of MIN, MAX, and AVG. The proposed method has minimum SD, which indicates the enhanced-DVHLA way had better efficiency and accuracy.

Fig. 5: LER under several total no. of SNs

Fig. 5 defines the localization error radius w.r.t total number of SNs. It defines a downward trend an increase in SNs under three methods. The proposed method always showed the minimum error radius under all conditions, normally when the SNs exceeds 120. The LER of the research method decreased by 70 per cent, and 55 per cent when compared with TWDV-Hop [13] and TWDV-Hop-AODV [16] methods, respectively.

The total no. of SNs was regularly increased from 50 to 350. Though, the CR (communication radius) and the proportion of BNs ratio are fixed at 25 meters and 20 percent, respectively.

TABLE 3. COMPARATIVE ANALYSIS WITH LER VS. TOTAL NO. OF NODES

Localization Algorithms	Max-LER	Min-LER	Avg.-LER
TWDV-Hop	0.1848	0.0426	0.0804
TWDV-Hop AODV	0.148	0.050	0.0791
Enhanced-DVHLA	0.138	0.040	0.068

Table 3 compares LER of proposed method with TWDV-Hop [13] and TWDV-Hop with AODV [16] method.

Fig. 6: LER under BNs (beacon nodes)

Fig. 6 defines the LER with variation in BN ratio. The research method consistently scored the minimum LER under all conditions using optimized route selection, commonly when the BN exceeded 30. LER of the research method decreased by 40 per cent, and 30 per cent when compared with different node localization methods such as TWDV-Hop [13] and TWDV-Hop-AODV [16], respectively.

TABLE 4. COMPARATIVE ANALYSIS WITH LER VS. BNS

Localization Algorithms	Max-LER	Min-LER	Avg.-LER
TWDV-Hop	0.2309	0.1594	0.1819
TWDV-Hop-AODV	0.221	0.1551	0.1781
Enhanced-DVHLA	0.20	0.1390	0.1652

Table 4 shows that the research method enhanced-DVHLA outperformed the rest under LER, with the avg. Accuracy rate reaching up to 90 per cent. The localization accuracy is under avg. form of the research (enhanced-DVHLA) method decreased by 42.23 per cent, and 31.4 per cent, compared with TWDV-Hop [13] and TWDV-Hop-AODV [16] methods, respectively.

Fig. 7 defines the LER with variation in CR (communication range); the enhanced-DVHLA always showed the lowest value

Fig. 7: LER under Communication Range (CR)

under all conditions. The localization error radius of the research method enhanced-DVHLA decreased to 35 per cent, and 37 per cent, compared with TWDV-Hop [13], and TWDV-Hop-AODV [16], resp.

TABLE 5. COMPARATIVE ANALYSIS WITH LER W.R.T. CR

Localization Algorithms	Max-LER	Min-LER	Avg.-LER
TWDV-Hop	0.2154	0.1184	0.1563
TWDV-AODV	0.214	0.1150	0.1521
Enhanced-DVHLA	0.20	0.1023	0.1495

Table 5 shows that the research method has better network performance with reduced LER. Compared with the research model, the LER, under avg form, decreased to 40.1 per cent, and 27.8 per cent compared with TWDV-Hop [13] and TWDV-Hop-AODV method [16].

V. CONCLUSION AND FUTURE SCOPE

This research paper introduces an enhanced DVHLA method based on DV-Hop with the ALO Optimization technique. It optimizes the Localization accuracy of the proposed algorithm for random topology WSNs. The research method enhances DV-hop with an ALO algorithm by localization estimation based on position evaluation and optimized evaluation of the average hop distance of SNs. The evaluation of the research model is well-defined through experiment outcomes compared with TWDV-Hop [13] and TWDV-Hop-AODV [16] methods. The localization accuracy of the research method is better than that of the other two localization methods at several random topologies of WSN. An enhanced-DVHLA (enhanced-distance-vector hop localization) method to overcome the existing problems such as high error rate and less accuracy. Under the localization radius, the research approach provided superior network performance. This proposed model has enhanced the localization accuracy rate while reducing

the localization error. The Localization Error Radius (LER) will be evaluated using the following performance measures: (a) Total Number of Nodes; (b) Beacon Node Ratio; and (c) Communication Range Effect. These recommended parameters are compared to currently used approaches. Compared to the other study models, the LE is optimized by more than 77 per cent. The LER dropped by 40.1 per cent, and 27.8 per cent, respectively, when using the TWDV-Hop and TWDV-Hop-AODV methods.

Further improvements such as (i) the proposed technique will be expanded with 3D WSNs in the future. (ii) Noting that NL (network lifetime) is a significant problem in the wireless sensor network. It plans to explore a trade-off between LA (localization accuracy) and EC (energy consumption) for the research method.

ACKNOWLEDGMENT

Author would like to thank the Director, National Institute of Technical Teachers Training and Research, Chandigarh and also extend my sincere gratitude to Dr. Kanika Sharma, Asst. Professor, NITTTTR Chandigarh and Dr. Amod Kumar, Professor, NITTTTR Chandigarh for their sincere advice that helped me to complete my project.

An Exploration of Mis/Disinformation in Audio Format Disseminated in Podcasts: Case Study of Spotify

Kevin Matthe Caramancion

College of Emergency Preparedness, Homeland Security, and Cybersecurity
University at Albany, The State University of New York
Albany, New York, United States
kcaramancion@albany.edu / www.kevincaramancion.com

Abstract—This paper examines audio-based social networking platforms and how their environments can affect the persistence of *fake news* and mis/disinformation in the whole information ecosystem. This is performed through an exploration of their features and how they compare to that of general-purpose multimodal platforms. A case study on Spotify and its recent issue on free speech and misinformation is the application area of this paper. As a supplementary, a demographic analysis of the current statistics of podcast streamers is outlined to give an overview of the target audience of possible deception attacks in the future. As for the conclusion, this paper confers a recommendation to policymakers and experts in preparing for future mis-affordance of the features in social environments that may unintentionally give the agents of mis/disinformation prowess to create and sow discord and deception.

Keywords—*Fake News, Misinformation, Disinformation, Technology Policy, Podcast, Spotify*

I. INTRODUCTION

Information disorders, misinformation and disinformation, are still continuously evolving in digital communities. Colloquially known as *fake news*, their forms vary, but the most prevailing ones are presented through news headlines and fabricated articles. Additionally, visually manipulated media content magnifies the intensity of deception provided by misinformation and disinformation. However, an unusual but classic form of medium, audio communications, and radio broadcasts are recently emerging and exhibiting a very high potential in functioning as falsehood dissemination machines. Mis/Disinformation are still both types of information, and naturally, they can pollute any social platform that is grounded on information sharing, be it of any format, including audio.

The recent discourse on mis/disinformation on audio communication recently came to light when a group of 270 experts, scientists, and medical doctors called out Spotify to establish a clear and concise public policy on misinformation propagated in their platform. Spotify, as a tech company and an audio streaming provider, is bestowed by Section 230 of the U.S Communication Decency Act of 1996 to have the regulatory authority of the content on their platforms. In essence, like any other tech platform, this gives Spotify the

prerogative, *the right but not the responsibility*, to regulate all content in their environments, including the deceptive ones.

The inclusion of audio-formatted cyber deceptions is virtually underrepresented in the existing studies revolving around *fake news*, its properties, and even societal effects. The common misconception that the blanket term *fake news* is exclusive to textual content is paradoxically misleading [1], for the umbrella term *fake news* encompasses and includes non-textual media content such as *deepfakes*, altered images, and even legitimate audio broadcasts contextually spreading lies.

This paper examines the current landscape of audio-anchored information environments, their difference from that of the ones built on general multimodal format, and how they possibly amplify or de-amplify mis/disinformation campaigns. Platforms of this nature, such as Spotify and Apple Music, have more than 400 million active subscribers [2], and their capability to spread information, legitimate or misleading, is, without question, solidly robust. Furthermore, the recent event surrounding Spotify, a music app with no explicit messaging and communication system between its users, left scholars and experts with a sudden interest in these environments as information creation and dissemination machines.

This is an exploratory work grounded on the primal research question, “*What are the similarities and differences of audio-based social networks with the general multimodal platforms with respect to information creation and dissemination processes?*” This will be explored through a benchmarking of information creation and dissemination feature analysis with the latter as the reference. A supplementary demographic vulnerability analysis on the existing statistical data on their users will be further performed to compare the existing podcast audience with that of the prevailing mis/disinformation studies.

The literary contribution of this paper is through the exploratory analysis it confers on the under-investigated particular domain of audio-based information environments. This paper offers insights on the dissemination features of these current environments so that future controls may be projected based on their affordances. As social media

technologies evolve rapidly, unintended consequences beyond their promised features should be mitigated to better promote the well-being of digital citizens depending on these for their information source.

More than its literary significance, the practical implications of this paper rests with the hope that it influences the current and future regulations involving misinformation and disinformation, particularly to audio-based platforms. A coordination in policies across all social networking platforms is highly critical at this point in time. A deceptive content appropriately controlled in one platform but still persists in another will still reverberate in public discourse and can still likely wrongfully shape perception. A carefully shaped policy, particularly for audio-based platforms, will shield these environments from being used as the loophole for *fake news* creation.

The format-wise of this exploratory paper is as follows. The next section, literature review, will provide a quick summative precis of the fundamental background on the topic of *fake news* predictive modeling (vulnerability analysis) used in projecting the cyber risk of individuals, the role of information environments, their design and structure, and how it contributes and prevent to the persistence of *fake news*. The literary section concludes with the seminal gap that this paper will fill in the subsequent chapters. It will then be followed up by the outright comparison of audio-based platforms with multimodal ones. After the establishment of these literary backgrounds and theoretical underpinnings, a case study on the recent issue of Spotify will be the *application area* of this paper, including a demographic analysis on the users (i.e., streamers) of podcast shows. Finally, the conclusion section of this paper bestows its recommendation on this domain and introduces the next stream of empirical research on the area explored by this paper.

II. LITERATURE REVIEW

A. Predictive Modeling of Mis/Disinformation Vulnerability

Mis/Disinformation cyber risk modeling is the mathematical quantification of the projected risk of social media users to massive computational propaganda [3]. It is an application of predictive modeling where the results are interpreted to forecast the likelihood of certain users and segments in the population to fall prey to mis/disinformation attacks [4]. In humans, the metrics (i.e., dependent variables) used to measure the effectual damages are usually sourced from psychological literature such as the perceived doubt and the actual deception ignited by falsehoods campaigns [4]. The purpose of such endeavor is to strengthen the capabilities of the users, especially the revealed vulnerable groups, to such attacks of deception so that proper educational conditioning and interventions can be used to build their resistance to the effects of mis/disinformation.

The independent variables, on the other hand, are spread across multiple domains. The existing studies have exhaustively tested the most optimal configurations on which

are the predictors, moderators, mediators, and control variables. The most visible factors are the characteristics of social media users as humans, such as their demographic and socioeconomic status [3], native language [6], veteran status [7], personal history of being deceived [8], and even psychological and political perceptions [4]. Outside the human conditions, this cyber risk of being deceived by *fake news* may be due to environmental stimuli such as time of the day [5], metadata describing the content [9], and even the way the information flow of an environment based on a platform's structure and design [10]. These are all hypothesized to contribute to the cyber risk of an individual in being mis/disinformed; This stream of research is currently open since the current predictive models have not yet perfected (100% accuracy) the forecasting of such cyber risk/vulnerability.

B. The Information Environment as Cyber Risk Factor

One of the most significant predictors of the vulnerability of social media users to mis/disinformation attacks is the very design of the platforms themselves [10]. In a quick recap, Caramancion (2021) highlighted that this is because the design and policies of an environment dictate how information flows across the medium. The designation on who may create, share, or exclusively receive information (in the form of content) creates a system dynamic on who will be the information (or mis/disinformation) consumers and who has the authority or power to approve or invoke censorship [4]. Caramancion (2021) further raised the difference between the two major types of information environment designs, taxonomic (top-down) and folksonomic (bottoms-up). The importance of this factor is even more pronounced when [10] suggested that all the other remaining factors, human and non-human, are merely secondary to the way an environment is shaped.

Absolute taxonomically designed environments are highly authoritative due to the strict entry and flow of content [11]. Traditional library systems are examples of such design where the classifications used in indexing are usually standardized. The dawn of folksonomy [12], on the other hand, paved the way for the rise and pervasiveness of social networking platforms. Unlike taxonomic systems, the ability to create and disseminate information has been extended even up to the users [13]. For the longest time, this design has been the strength of these networks, but the price that comes with it is the creation and persistence of mis/disinformation [10]. Modern social networking platforms are not dichotomously restricted to either of these but rather made from the combination of both taxonomic and folksonomic influences. For instance, even though individuals may create and share any content as they wish, the privilege of labeling its legitimacy and censoring it still rests with regulators of an environment through the help of independent fact-checkers [14].

C. *The Literary Gap: The Missing Case of Audio-Based Environments*

With the above mentioned as the foundation, the following corollaries are evident:

a. That the current analyses on the information environments and their design are based on the context of mostly textual resources and general-purpose multimodal platforms. Exclusively audio-based social networks are, on their own, operating at a specialized locus, which warrants these networks an inquiry of their own distinct that of the context of general-purpose multimodal platforms.

b. That an analysis on the merits of both taxonomic and folksonomic features on these audio-based environments is virtually *missing* in scientific and commercial literature. As a significant predictor of mis/disinformation vulnerability, an information environment is only grounded on the sum of all its features and the affordances they offer. These include both intended and unintended consequences of such features.

c. That podcast, as the medium of misinformation and disinformation, warrants an inquiry *particularly focused on its context*. Podcasts, by their very nature, are different from textual news headlines and video clips; thereby, the mis/disinformation magnitude and flow that proceeds from them will naturally behave differently. The challenges and opportunities in podcast regulations may or may not resemble that of the typical content format of social platforms.

d. That the demographic and socioeconomic factors as predictors of mis/disinformation vulnerability may or may not be applied on audio-based environments. The existing studies of predictive modeling are mostly (if not all) based on general multimodal platforms, and the demographics of podcast listeners may or may not be in congruence with that of the general multimodal platforms.

III. FEATURE ANALYSIS OF AUDIO-BASED PLATFORMS

A. *Similarities with General Multimodal Platforms*

1. *The Presence of Social Feeds and User Profiles*

One hallmark characteristic of social platforms is the ability of information consumers to have their own social profiles (or user profiles). This, in essence, allows them to be a node in these networked social environments and create their identities. As nodes, the information flow can be traced, and the roles of being a sender or receiver can be technically defined. In the context of mis/disinformation attribution, this is essential, especially in tracing the source of falsehood attacks, the enforcers who spread the deception (i.e., amplifiers), and finally, the intended or unintended targets.

2. *The Presence of Behavioral and Engagement Metrics*

Content-wise, the metrics used to quantify the effects and reach of content, legitimate or not, is an important indicator of its influence on an audience. The number of hits, engagements, and even user views are all examples of such quantifiers. The purpose for such metrics may be used outside the usual projected monetary value they attempt to measure. For instance, in the context of mis/disinformation, the social

reach and virality of deceptive content may indicate how it compares to a truthful one. Information scientists and experts try to investigate the properties of such content for the purpose of making sense of it.

3. *The Presence of Collaborative Tools*

Collaboration features dictate the capability of users in social networks, through collective acts, to work on a common task. Note that these may be in the form of groups productivity tools or group messaging features in multimodal platforms. The focus, however, is not on what they do but what they exhibit—a network in enforcement. In the context of mis/disinformation, this exhibits the abilities of threat agents to perform networked adversarial attacks of deception. Most of the prevailing nation-sponsored massive propaganda (information warfare) rely on network infrastructures to release payloads.

4. *High Interoperability (as Sender) with other Social Apps*

The ability of content to be exported to another social networking platform is a hallmark of intra-environment connectivity and content transfer. With the serialization-and-deserialization construct as inspiration, platform-to-platform interoperability increases the ease of use on the part of users, especially when types of content that are usually shared can be easily migrated. These content—such as videos, music, website links—when shared from another social platform doesn't need a re-instantiation in the new platform. In the context of mis/disinformation, this design exhibits how a polluted platform can echo deceptive content to other platforms with weaker mis/disinformation policies.

5. *The Folksonomic and Taxonomic Influences are Present*

Information organization and its hallmark constructs of folksonomy and taxonomy are present. This can be seen in the way content sorting and categorizations are designed. Audio-based environments and their content can be retrieved and sorted alphabetically based on a resource's title or its associated stakeholders, such as artists and producers. Other related folksonomic metadata such as user's taste of music, preferred artists, and related crowd preference usually triggers recommendations to a user. The biggest implication of this to the vulnerability of users to mis/disinformation attacks is the creation of filter bubbles through hyper-personalization.

B. *Differences with General Purpose Multimodal Platforms*

1. *Lack of Direct User-to-User Communication*

The most visible lacking feature of audio-based platforms is the absence of explicit means to communicate, textual messages and call functions, in them. Unlike multimodal platforms where feedback in the form of comments or even the ability of a user to privately send a message to another user is virtually missing. With this absence, as an applied analysis on the domain of *fake news*, preliminary conception may lead one to believe that this may contribute to the non-promotion of *fake news*.

2. *Approval Required for Content Creation*

Influential and official channel sources of communicative audio broadcasts are usually subject to verification by the moderators of tech platforms. A verified status implies that the legitimacy of the claimed title is sustained. The important note to consider, however, is this verification does not imply or extend to the content disseminated by a verified account. Instances where accounts of such verifications have spread and are currently disseminating harmful, deceptive propaganda remain existing.

3. Peer Activity Monitoring

An audio-based platform, Spotify, allows users to explicitly reveal their listening activity to the people who follow them. This feature, previously included in prevailing multimodal platforms such as Facebook and Instagram, was removed due to the privacy concerns they pose to users. With regards to mis/disinformation attacks, there is a close correlation between privacy and vulnerability to attacks of deception—agents of propaganda create particularized content depending on the applicability of a topic to users and populations.

4. Lack of Personal Broadcasts

The personal broadcast here refers to the ability of a non-authoritative user (e.g., streamer, listener, etc.) to be the source, either producer or creator, of audio information. Unlike the multimodal platforms where users have the prerogative to create virtually any content, be it of any format, users in audio-based platforms at most can create personalized collections such as playlists or saved resources for their personal use, to which in few circumstances can be shared to their connections. As a hypothetical foundation, one may lead to believing that this leads to fewer and weaker instances of *fake news* on these platforms.

5. Exclusively Receiving Node for Interoperability

In the previous section of this chapter, it was noted that the audio-based environment's contents are easily transferrable to other platforms—the reverse, however, is not the same. This is due to the restrictions in the formatting of the audio platforms and the limited capabilities the users are authorized to perform. This characteristic, when superficially analyzed, can lead to the assumption that audio-based platforms are shielded from external injections of mis/disinformation attacks. The case study in the latter chapter examines this *a priori*.

C. Challenges and Opportunities

1. Need for Audio-Based Mis/Disinformation Detection Technologies

Should audio-based environments proven to be a potential breeding ground of mis/disinformation networks, the most visible danger this poses to the scientific and technological community is that most of the deployed AI and ML-based *fake news* technologies are all based on semantic, linguistic, and visual benchmarks. The challenge is translating these technologies to their audio counterpart. This is elusively

challenging due to the current limitations of processing audio resources in real-time monitoring.

2. Consider the Demographics of Audio-Based Environments

The interest in audio-based environments, although emerging, is attracting distinct demographics (as discussed in the next chapter) from general-purpose multimodal platforms. This difference is highly important to consider because the predictive models that forecast the vulnerability of social media users to mis/disinformation attacks are experimented based on multimodal platforms such as Facebook, Twitter, or even YouTube—which is also distinct from audio-based platforms. Such difference will reveal the impact of an environment's format on the way users perceive information.

3. The Role of Labels

Labels on audio content metadata have always been authoritative. However, the label confirming the legitimacy of content, however controversial, is not just ethical but also necessary. Labels are created not for the purpose of necessarily assigning legitimacy judgment on content but rather to be the guide to the users that may interact with these. For instance, simple reminders or warning that content may be disputed is enough for this endeavor. Although this approach sounds conservative compared to its counterpart of outright labeling content as false, this shows the responsibility of the platform in maintaining the integrity of their environments.

4. Simplify the Crowd Reporting

The simplest yet most effective method to tag questioned content is to allow users to report it. This has been, for the most part, present in audio-based environments, but the particular focus on deceptive content, especially in podcasts, should be promoted. This is due to the reason that most algorithmic detections of *fake news* are not deployable to audio content, and as such, the dependency on the role of users will be of high significance. Without such capability, audio-based environments have virtually no remedial or detection mechanism to deceptive content.

5. The Role of Policies Particularly Made for Audio Content

One of the important, if not most, in the non-promotion of misinformation and disinformation in any social platforms, is the establishment of well-crafted policies for their control. Without explicit policies or even acknowledgment of the plausible formulation of deceptive content, a platform implicitly enables falsehood information to persist in its environment. Clear policies that stipulate the categorizations, processes, and remedial response to such occurrences are robust means in building resistance against the agents of deception.

IV. APPLICATION & DISCUSSION

A. The Case of Spotify and COVID-19 Vaccine Mis/Disinformation

In early 2022, Spotify was at the center of debate on free speech and misinformation when one of the most influential

podcast channels hosted by Joe Rogan had given a speaking platform to an infamous medical physician, Dr. Robert Malone, on promoting and spreading COVID-19 debunked conspiracy theories. Such falsehood includes the claim of mass formation psychosis, where the public is hypnotized, similar to the point of compulsion, to act against their will in vaccinating themselves and follow related mandates such as masking and social distancing. Included in the claim that was raised in the podcast was the conspiracy that hospitals and medical providers get incentives when falsely diagnosing patients with positive results. This discourse trended on other social platforms such as Facebook and Twitter, with the medical experts calling out Spotify to act on the brazen and deliberate misinformation coming out on the said podcast channel. Further amplifying the discourse is when other artists pressured Spotify to censor the channel or else they would withdraw their content from the platform.

This case highlights several findings, and they are as follows:

Discussion 1: Audio-Based environments, through Podcasts, can be a Potent Source of Mis/Disinformation

The channel, with hundreds of millions of subscribers and frequent listeners, is currently considered a top podcast on the platform. At the point of the interview, it relayed unrelentless conspiracy theories already debunked on other platforms. This event, as an incident, left unsuspecting advocates surprised that a music application can be (and did) become a dissemination machine of public deception.

Discussion 2: Deceptive Content in a Platform Echoes All Throughout the other Platforms

The interoperability of the whole information ecosystem is highlighted in this case when an agent who is censored (i.e., banned) in other platforms was given an opportunity to create and spread mis/disinformation on Spotify. It yielded the remedial actions of other platforms ineffectual, the topic coming from Spotify, nonetheless trended on Reddit, Twitter, and Facebook. On the side of the spectrum, this interoperability has been used by advocates to call out Spotify using other platforms to act on the deception that transpired on its platform.

Discussion 3: Lack of Clear Policies Against Mis/Disinformation is a Vulnerability

At that point of the incident, Spotify has virtually no remediation or response in place to such occurrence. Thus, no warning or label was present to give cues to the listeners that the podcast content may be misleading or at the very possibility of it currently being disputed. Furthermore, the fact that the medical experts and other artists called out Spotify using other platforms to act on the issue displayed that there is no recourse (or acknowledgment even) that misleading content may exist on Spotify's platform.

B. Demographic Analysis of Audio-Based Platforms

As a supplementary analysis, this paper adds an overview of the demographics of the streamers (or listeners) of podcasts [15] [16]. This is due to the fact that the target audience

considered by the existing predictive models is based on the users of multimodal platforms. The most significant implication of this is that the weights of the factors considered in the current models will not necessarily be accurate when applied to audio-based environments. The vis-à-vis comparison, however, of the demographics between the two types of platforms will not be within the scope of this paper. The focus of this section is to identify potential statistics that may have significant implications to the future cyber risk models of mis/disinformation when audio-based environments are accounted for.

Discussion 1: Most Podcast Listeners are Aged 35-54

Age has always been a considered factor when user data are entered into regression models or ANOVAs to predict the vulnerability of people against mis/disinformation. This is a significant deviation from the usual multimodal platforms where younger populations are the dominant age groups [15][16] in content creation and consumption. The effects of this composition, if there is any, on the system dynamics and interactions with users remain unknown.

Discussion 2: Comedy is the Most Popular Podcast Genre

Unlike multimodal platforms where users have variations in their preference of content, the most dominant choice of genre in podcasts is comedy. This choice may or may not contribute to the cyber risk of populations, especially since satire and humorous posts are often associated with frequent misleading perceptions. Furthermore, the motivations and purpose of a user's information retrieval may dictate the echo chamber one belongs to.

Discussion 3: At least 80% of Podcast Listeners Finish Most of the Episodes

Interestingly, most listeners finish the content of the podcast that they are streaming. This behavior, under the category of information consumption, should be further compared to how information is consumed in multimodal platforms. The commitment of podcast streamers to finish content may be suggestive of the depth of deceptive content that may potentially reach into a person's cognition.

Discussion 4: Over 1/4 Podcast Listeners Have a College Degree

Although the effects of *advanced* academic achievements in *fake news* detection have been widely refuted, the lack of basic information/media literacy training [20] and background in discerning fact from fiction can be a potential cause of vulnerability of a user falling prey to deception. A college degree alone is a weak indicator of vulnerability, but it nonetheless may still be suggestive of basic training in fact-checking and the objective reliability of information sources across academic disciplines.

V. CONCLUSION, RECOMMENDATIONS, & FUTURE WORKS

Like a true villain, the omnipresence of misinformation and disinformation reverberates across all platforms regardless of the scheme of their environments. These cyber

deceptions [17][18][19], and their agents, exploit the weaknesses in the guards in place to protect the platforms from falsehood propaganda. This paper, through an in-depth examination of audio-based environments, unequivocally affirms that podcasts exhibit a high potential to be factories of *fake news*. This is due to the mis-affordance of the features used to disseminate authoritative information and the lack of explicit policies outlining the remediation and response to such misuses, including proper educational training [20] to counter these information warfare.

At this point, total annihilation of mis/disinformation is elusive; however, simple measures such as the establishment of clear policies that lay out the regulations for deliberately misleading content will significantly reduce the opportunities for agents of deception to pollute the audio-based environments. Moreover, timely response from the tech providers, once a feature is misused for purposes outside its intended objectives, can never be overemphasized. The inherent characteristic of technologies to be constantly evolving will be used by threat actors to find newer exploits.

This paper's hope is to call out the attention of the experts to consider unusual but potential surface attacks of mis/disinformation agents. Future iterations of this work will be the analysis of other platforms that may possibly be a new environment for exploitation once the loopholes for audio-based environments are closed. Finally, a new research stream for podcast streamers as the intended targets of deception and as the subjects for mis/disinformation vulnerability and risk modeling [21] will be looked out for.

Abstract—This paper offers a comparative vector assessment of DDoS and disinformation attacks. The assessed dimensions are as follows: (1) the threat agent, (2) attack vector, (3) target, (4) impact, and (5) defense. The results revealed that disinformation attacks, anchoring on astroturfs, resemble DDoS's zombie computers in their method of amplification. Although DDoS affects several layers of the OSI model, disinformation attacks exclusively affect the application layer. Furthermore, even though their payloads and objectives are different, their vector paths and network designs are very similar. This paper, as its conclusion, strongly recommends the classification of disinformation as an actual cybersecurity threat to eliminate the inconsistencies in policies in social networking platforms. The intended target audiences of this paper are IT and cybersecurity experts, computer and information scientists, policymakers, legal and judicial scholars, and other professionals seeking references on this matter.

Keywords—Disinformation, DDoS, Cybersecurity, Threat Assessment, Standardization

I. INTRODUCTION

Disinformation attacks, the deliberate method of injecting wrongful information to certain targets, are usually deployed at a massively public scale [1]. Distributed denial of service (DDoS), on the other hand, is the intrusive and forceful disruption of networks and systems by unauthorized hosts through resource exhaustion [2]. The latter, DDoS, is formally classified as an actual cybersecurity attack by the virtue of its very nature to operate at multiple lower layers of the OSI model. While the former, disinformation attacks (or campaigns), are typically considered as mere disorders [3] of social networking platforms and may touch only the highest layer of the OSI, the application (layer 7).

The proposed classification of disinformation to be considered as an actual cyber threat has recently emerged for the purpose of standardization [4]. The world has realized that social networks operate without geographical boundaries. The variations in user policies on the social platforms may indirectly contribute to or even amplify disinformation attacks and their ramifications.

A uniform approach in its prevention and response, is without a doubt, one of the solid prerequisites to winning the battle against this harmful phenomenon.

The prevailing calls for classification of disinformation, although highly compelling, lack any concrete comparison with an actual cyber threat *per se*, a move that will further strengthen the claims for such advocacies. First, if this phenomenon is proven to exhibit the same elements that of an actual cyber threat, it passes the elemental *presence* test. Or suppose should the case has proven to be otherwise; in that case, a new referenced cyber threat can just be comparatively benchmarked until the aggregate results from the plural comparisons suggest and reveal disinformation's rightful nature.

There are several potential actual cyber threats in the computing industry that can be benchmarked from this *presence* test that will fall outside the scope of this paper but will nonetheless be considered for future works and iterations of this research. This paper's in-depth referenced cyber threat focus is distributed denial of service (DDoS), as per the author's *a priori*. As such, for the constitutive research objective, the main question that this paper seeks to give illumination to is: "What are the similarities and differences of disinformation and DDoS?". This will be achieved through an in-depth analysis of the elements (i.e., threat agent, attack vector, target, impact, defense) of each phenomenon. This juxtaposition will be concluded with a recommendation based on the referenced cyber threat of this paper, DDoS.

The literary significance of this work is through its contribution to the existing research on the interdisciplinary reach of fake news (particularly disinformation), including but is not strictly limited to technology and social media policies, cybersecurity, digital forensics, the social sciences, behavioral and predictive modeling. All these involved domains are currently affected by the ramifications of fake news and both of its forms—misinformation and disinformation. An interdisciplinary approach to its phenomenon, drawing from the learnings of each of the involved fields, can be a promising blueprint of a robust policy to control these deceptions effectively. As a novel initiative, may this paper's structure

serve as a model for comparing disinformation attacks with other cyber threats.

There are multiple practical significance and implications of this paper. First, the influence it hopes to confer on social networking platforms their usage policies, specifically on the response to actors and content of disinformation. As it currently stands, there are differences in the responses of the prevailing platforms on how they deal with deliberate deception made by users. This very variation is a weakness and contributes to the growth and reach of disinformation. *A disinformation attack censored by one platform but nonetheless persists in another will still cascade throughout the whole information ecosystem.* The very nature of the information ecosystem to disseminate information, regardless of language, geographical, cultural, and demographic barriers, applies to the stratum of tech companies or the brand of the platform. A coordination in policies gives remedy to this limitation, which can be achieved through technical standardization at the computing industry-wide level.

Additionally, the epistemological provenance of disinformation attacks compared to the existing established cyber threats is relatively new. Thus, this dimension requires a thorough probe to better understand its nature. This paper will attempt to fill that gap by dissecting the anatomy of disinformation attacks, followed by a comprehensive analysis of its parts/elements.

This paper, format-wise, will (1) provide the literary constructs/background in understanding the narrative points explained in this paper, including the fundamentals of cyber threats, the anatomies of (a) disinformation attacks, (b) DDoS, (c) the literary gaps in this stream of research including a recap for the current calls for standardizations. It will be followed by the (2) discussion of the seminal methodology used in this research, the comparative threat analysis, including its controls and limitations. The latter part includes the (3) presentation of findings, (4) discussion and analysis of findings, before finally (5) highlighting the conclusion, prospectus for future research, and bestow recommendations based on the findings discovered.

II. LITERATURE REVIEW

A. Fundamentals of a Cyberthreats and Cyberattacks

Although the key terms *cyberthreat* and *cyberattack* are closely related, they are distinct from each other and are not interchangeable [4]. The former is a vulnerability that has the potential to be exploited; it is distinct from an ongoing attack that may be passive or active [5]. Due to this definition, it can be logically inferred that a cyberthreat is often a *prerequisite* of a cyberattack. This distinction in their definition is essential to keep in mind because the approach to them depends on their form; A cyberthreat is better prevented in escalating to an actual cyberattack where when there is already an ongoing cyberattack, the response is typically more aggressive to mitigate its effects and damages.

Form-wise, the Open Group (2009) defined cyberthreats as anything that is capable of causing an unwanted or harmful

consequence in computer systems [6] or in digital life in general [7]. On the other hand, a cyberattack has the presence of an *agent* [8] with the intent of exploiting the vulnerability through a particularly sophisticated method (or technically called *vector*) [9] aimed at a specific *target(s)* [10]. Due to their frequency, cyberattacks have an established protocol of response through either mitigation techniques or *defense* [10] for their counter. Most importantly, their historical occurrences have allowed the security industry to project their *impact* [10].

B. Anatomy of Disinformation Attacks

Disinformation, as an information disorder, is distinct from misinformation [3]. Disinformation is the deliberate act of creating and spreading untruthful content on social networking platforms, whereas misinformation typically happens by accident due to outdated information, miscaptioned images, and mislabeled headlines [11]. The prong that separates these two phenomena is the *intent* that comes with the act. Although these terms are commonly associated with the colloquial phrase *fake news*, they are more particular in their technical definitions. As a matter of truth, the very phrase *fake news* itself is misleading and may mean different contexts depending on the usage and applications, so it is typically not recommended to be used in more formal settings [12].

Advocates call for the classification of disinformation as an actual cybersecurity threat [4] and consequently, its more mature and dangerous form, *disinformation attacks*, should be classified as an actual cyberattack. A disinformation attack is a massive injection of deceptive propaganda in social platforms, typically state-sponsored [13]. These attacks are carefully engineered to influence and shape public opinion. Unlike mere disinformation, disinformation attacks are typically cascaded by astroturfs (bot accounts) and radical user accounts. When an entity (person or organization) is targeted, consistent untruthful narratives about the target will be bombarded across all social networking platforms.

C. Anatomy of Distributed Denial of Service (DDoS)

Denial of service (DoS) is the phenomenon characterized when a system or resource situated in a network is unable to provide its usual services and functions to other hosts. This is due to the strain induced on the resources by the gibberish requests that appear legitimate [14]. The distinctive attribute of DoS is the originating point of the exploit, as it is usually a single node in a network [15]. Although the current exploits of this kind are usually of malicious nature, it is important to note that at the technical level, DoS is a cyberthreat rather than a cyberattack because it can happen by mistake or unintentionally.

When the disruption, however, is sourced from multiple end devices and networks, it escalates to an even more serious cyberattack, distributed denial of service (DDoS) [15][16]. Compared to mere DoS, DDoS attacks are more complex and challenging to mitigate due to the involvement of botnet, end devices that are usually hijacked connected to the internet to enforce the attack for a controller [16]. The controller of these

hijacked devices is usually situated in a remote and difficultly untraceable network. Interestingly, the dual role of the hijacked device as unknowing perpetrators put them as unsuspecting victims too.

D. Importance of Threat Classification and Role of Standardization

Beyond the technical strategies in detecting and combatting these cyberthreats and cyberattacks, an equally important dimension for their holistic control is the correct applications of regulations. *Standardization* [17] allows uniformity in the approach to the remediation of all threats and attacks. Key stakeholders, when imbued with variation in their perceptions and policies, will result in inconsistencies and even outright polarization on the ethicality of a certain threat or attack. This very inherent resulting discord at the minimum will make the threat persist or may even amplify the effects of any threat or attack. A formal classification and elevation of a phenomenon to a threat is the first move in recognizing, industry-wide, that it is unacceptable to all the involved entities.

More importantly, *threat classification* [18] allows all the fields involved to contribute to solving the complexities of these threats and attacks, not just in a multidisciplinary but also in an interdisciplinary format. Finally, threat classification allows a richer context and more thorough understanding of these through the accounting of existing threat architecture, which may have directly or indirectly contributed to the emergence of the newer ones, which are typically more sophisticated. By tracing its origins, the possibility of eradicating them, not just at the surface but in their roots, can be achievable.

E. The Literary Gap: Comparison with an Actual Cyberattack

With these underpinnings, the seminal corollary is evident: That the existing calls for the classifications of disinformation and disinformation attack as an official cyberthreat and cyberattack, respectively, are not uncalled for. In their forms, they mimic the typical characteristics for their appropriate considerations. However, tangible evidence of such is missing in the existing literary works. There are multiple threat classification models that may be used to meet; however, a simple yet explicitly robust method of assessment is surprisingly virtually missing in these classificatory proposals, *a direct comparison of the proposed phenomenon with an actual cyberthreat/attack*. This paper fills this gap by outright doing so with an actual comparative vector analysis of cyberattack DDoS and disinformation attacks as the phenomenon in question. If they closely resemble each other, the affirmation it confers to the existing proposals will strengthen their claims. If not, a new benchmarked threat can be referenced, or the reasons for rejection will finally come into the picture. Either way, this will make the stream on this research domain move forward, a hope this paper aims to achieve.

III. METHODOLOGY

A. Summary, Overview, and Format

This paper explicitly compares two phenomena, DDoS and disinformation attacks. The former is an actual cyberattack as recognized in authoritative standards and manuals, while the latter is a candidate cyberattack speculated to contain the key elements congruent with the prevailing cyberthreats and cyberattacks.

On one end, DDoS and its substantial elements will function as the benchmark. On the other, disinformation attacks will be carefully analyzed and thoroughly probed if it meets the substantial *presence* (or absence) test per each threat/attack element. The substantial elements are exhaustively and systematically compiled by [19] in their work and will be each individually discussed in the following subsections. The number of elements present is directly proportional to the strength of indication that disinformation attacks should be classified as actual cyberattacks.

Cyberattack Component	Indicator(s) of Presence / Absence
Agent	A cyberthreat/vulnerability triggered by an <i>entity</i> (user, organization, or nation)
Vector	An established <i>pathway</i> of the payload from the agent to the target/s
Target	Documented past and current <i>impairments</i> in at least one layer of the OSI model
Impact	Evidence of the ability to affect systems, users, and organizations
Defense	Documented preventative controls and remediation strategies

Table 1: Summary of the Prong Applied to the Candidate Phenomenon

B. Agent

The agent of an attack is the entity that exploits a particular threat and triggers it to initiate the vector sequence. As it currently stands, an agent is always a human source. Institution and state-sponsored agents also fulfill this requirement. Albeit their sophistication, mechanical enforcers like bots and zombie computers are mere helpers of the agent. To further clarify this distinction, two prongs that are used to examine if an entity can be classified as the agent are (a) motivation and (b) goals or objectives. Enforcers will fail at these two prongs and, as such, are not considered agents but mere tools of amplification. The malice in motivation and goals is insignificant since intrusion tests meet the criteria of attack classification, albeit the objective of testing the cybersecurity posture of a subject. Tracing the agent is one of the most important (if not most) substantial elements of threat/attacks since most of the accountability is attributed to the sourcing agent. Existing laws and regulations, to the best of their prowess, usually prosecutes the agent more than the enforcers, should they happen to be human too.

C. Attack Vector

The vector of an attack, in essence, is the method of delivering the payload to the intended targets. It is the totality of the steps undertaken by the agent alongside the tools and strategies to exploit an attack surface. The vulnerability, at this point, has been used, and the transition of a cyberthreat to a

full-blown cyberattack has taken place. It is important to note, however, that cyberattacks have the distinguishing characteristic of the established pathway (i.e., the *vector*) connecting the sourcing agent to the target(s) discussed in the next subsection. Both active and passive cyberattacks meet this requirement. After an attack vector has been initiated and established by an agent, the payload will then flow to the target(s) internally or externally. The determination of the direction of the payload flow, as directed by the structure of the vector, is of utmost importance to the response of attack as it'll dictate the appropriate structure of mitigation techniques that will be used to minimize the effects of the attack; These are further discussed in the last subsection of this chapter.

D. Target

In the context of computer systems, the target(s) of cyberattacks are technically NOT directly humans or users. They are often directly and indirectly affected, but the attacks technically impair component(s) of the OSI layer model. For instance, malware and ransomware may make data unusable, rendering users unable to make something out of it; a simple denial of service attack may hinder users in accessing a resource but in all technicalities, what is broken is the access and authorization components of an application or the network hosting it.

Unlike a physical hazard that physically puts a human in danger, the commonality of cyberattacks is their natures are all concentrated in the cyberworld. This is not to say that humans will not be affected as they will certainly be. The prong of a candidate attack will be examined if it causes mostly a physical or cyber effect. It has to be primarily concentrated on the latter and affecting the users thereafter directly or indirectly.

E. Impact

The impact is the dimension where the humans or users come in. However, users are not exclusively the only impacted components of cyberattacks; for instance, they can be whole systems or even organizations (nations, vulnerable groups). Impacts are usually measured on several metrics, including but are not strictly limited to: (a) the gravity of their disruption scope and length, (b) novelty or precedence, (c) economic value, and even (d) psychological effects.

The *presence* test applied on this paper is a dichotomous test as it checks only the binary value (absence or presence) of any of these stipulated forms of impact to answer the research question of this paper. It is essential to note, however, that further quantification of these impacts is possible and is performed in many research streams and fields. This sub-area is outside the scope of this paper and one of this paper's limitations.

F. Defense

The defense mechanisms against a cyberattack fall under two categories, mitigation and remediation. Mitigation refers to the procedures employed *prior* to an attack as preventative measures and *during* an actual attack to limit the damages produced after its deployment. Forms of mitigation

procedures are often detection technologies that alert stakeholders of a possible attack, such as intrusions in a perimeter-based on a given set of indicators.

Remediation, on the other hand, is the act of correction *after* an attack has taken for the purpose of closing the loops that allowed it to happen and persist in the first place. Remediation strategies are equally as important as mitigation. It can include policy changes, hardening the skill set of users involved, and more. Types of defense mechanisms vary and are often used in conjunction with each other. For this paper's test, an examination of the current preventative and remediation if it currently exists is the success-and-failure metric for this component.

IV. RESULTS

A. Overview

The table below is the comparative summary assessment of DDoS against the candidate phenomenon, disinformation attacks. The values per element are dichotomous and non-scaled. Further discussions and explanations on the important points are included in the next chapter to interpret and make sense out of the findings presented below.

	DDoS	Disinformation Attacks
Agent	Cybercriminals, State-sponsored Organizations, Vendors (<i>Stresser Services</i>)	Radical Extremists, State-sponsored Organizations, Vendors (Ads)
Vector	Invalid authentication requests amplified by Zombie computers, TCP/IP Protocols as the attack surface (DNS, UDP, NTP, etc.)	Content Duplicators and Spreaders primarily through and amplified by astroturfs and bot accounts, appearing in any legitimate format (text, images, audio, video)
Target	Networks, Websites, Systems (technically OSI Layers 7, 6, 5, 4, 3)	News Headlines Manipulation, Article Fabrication, Content Miscalcaptioning, Deepfakes, Misleading Graphics, and Incomplete Videographic Creation (technically & exclusively OSI Layer 7)
Impact	Operational Disruption, Financial and Productivity Loss, Brand and Reputational Damages	Reputational Damages, Financial Loss (through Stocks and Securities Depreciation), Social Polarization
Defense	Web Application Firewalls, Intrusion Prevention Systems (IPS), Intrusion Detection Systems (IDS), Access Control Lists (ACL), Load Balancers (as backup)	Fake News Detection Technologies (mainly powered by Machine Learning models), Censorship on Agents and Secondary Actors, Content Demotion and Appropriate Labelling

V. ANALYSIS & DISCUSSION

Discussion 1: There is a Thin Line Between Radical Extremists and Cybercriminals

An in-depth look at the comparative table reveals that the usual agents for both disinformation attacks and DDoS are almost the same except for radical extremists. Agents of DDoS are, as per the existing US laws, considered cybercriminals since DDoS is officially sanctioned as an illegal activity. Radical extremists and their acts, on the other hand, are currently protected by the First Amendment (or Free Speech). Nonetheless, the usual motivations and deliberate intention of a threat agent are visibly present in disinformation attacks.

Discussion 2: The Vector of Disinformation Attacks Closely Resembles that of DDoS's

The vector structures, styles, and patterns of both DDoS and disinformation attacks are essentially the same. They both rely on amplification to undertake their respective payloads. To contribute to its acts of disruptions, DDoS actors harness the zombie computers. These computers and their respective users are often unaware of their inclusion. Furthermore, zombie computers are often situated in foreign countries, remote to both the agent and the targeted networks, rendering them elusive to trace. Disinformation attacks, on the other hand, harnesses troll farms and automatically generated *astroturfs* to successively inject social networking platforms with deceptive information. To add to these attacks, uninformed users [20-27] may further unknowingly share these to their feeds, reverberating the falsehood attacks mirroring a zombie computer's behavior.

Discussion 3: Unlike DDoS, Disinformation Attacks Targets Exclusively the Application Layer

The most visible difference between DDoS and disinformation attacks is the various OSI layers affected and reached by the former. The attack surface of DDoS is wider due to the mechanism of networking models and protocols to assure reliability. This may be due to acknowledgment requests and message trace bounce backs. Disinformation attacks, on the other hand, exclusively pollute the application layer through the content at the social networking platforms. Although the formats of deception highly vary, including text, image, audio, and video graphics—there is no attempt at intrusion at the networked elements and protocols. Agents and their enforcers carefully follow the rules and policies set by the social networking platforms.

Discussion 4: The Impacts of Disinformation Attacks are Congruent with that of DDoS's

Additionally, the impacts of both DDoS and disinformation attacks are both operating at a systemic and networked level. DDoS aims to disrupt resources and deny users of access; in the CIA triad of cybersecurity, this is the last abbreviation, **Availability**. While disinformation attacks, on the other hand, pollute and reduce the overall quality of information lurking around social networking platforms, making the users doubt content legitimacy, even the truthful

ones, which exactly represents the I in the CIA triad of cybersecurity, **Integrity**. Although they target different aspects of protocol stacks, they both ultimately bring dangers and inconvenience to society and users alike.

Discussion 5: Defense for Both DDoS and Disinformation Attacks are Primarily Mitigative rather than Preventative

As it currently stands, the prevailing responses and measures against both DDoS and disinformation attacks are mostly deployed after they have occurred or activated only at the time of their discovery. While it makes sense due to their design, advanced predictive technologies that may forecast when phenomena of such nature will most likely arrive may be needed to fully protect users from their effects. While the current detection and prevention systems are not completely impregnable, they are the essential controls that are put in place for basic defenses. Finally, increasing user awareness [28] and modification of policies after an attack is a reasonable practice currently implemented for both DDoS and disinformation attacks.

VI. CONCLUSION AND FUTURE WORKS

This paper examined the phenomenon of disinformation attacks through a comparative analysis with distributed denial-of-service (DDoS) attacks. The analysis revealed that the two are strongly similar in terms of all elemental criteria. Importantly, the vectors, amplification methods, styles, and structures of their forms are indistinguishable. The only trivial difference is the payload each injects, whereas DDoS mainly massively disrupts operations, disinformation attack massively deceives users.

With these compelling findings, this paper concurs and highly recommends that disinformation be classified as an actual cybersecurity threat. Its more advanced form, disinformation attacks, exhibits the presence of the notable elements that of an actual cyberattack. This warranted classification will compel common remediation approaches and instill unified philosophies across all social networking platforms against this phenomenon. Without such classification, the current architecture of social networks will allow the platforms to have their own policies in limiting misinformation and disinformation, yielding inconsistencies. This renders the war against *fake news* difficult to triumph over.

This paper, as a stream of research, introduced a novel approach to assess how a candidate phenomenon can be tested of its eligibility to a formal classification of a cybersecurity threat. By using an existing cyber threat as a benchmark and individually comparing their properties through an absence/presence test, their congruence can be examined. Future iterations of this study will use other cyber threats as benchmarks to further strengthen the claims and validity of the recommendation conferred by this paper. Projected benchmark cyber threats include advanced persistent threats (APTs), phishing, and adware.

Abstract—In this article the issues of further improvement of the credit system in order to ensure the implementation of the Decree of the President of the Republic of Uzbekistan dated May 12, 2020 No 5992 "On the Strategy of Banking Reform in the Republic of Uzbekistan for 2020-2025" studied. Problems of information security in the credit system and their solutions, issues of secure storage of personal data of borrowers through blockchain technology, as well as effective modeling of lending and borrower relations, lending institutions on the basis of established criteria recalculation model and quantitative analysis of the assessment, the application of the Monge-Kantorovich problem in the development of the credit scoring model, the process of forming a credit scoring model based on the model applied to the Monge-Kantorovich transport problem. The credit scoring model based on the Monge-Kantorovich problem is similar to the Bayesian network-based credit scoring model, and calculations are performed using elements of probability theory. Borrowers were evaluated using optimal evaluation criteria. As a result, the process of deciding whether or not to grant a loan to a borrower has been completed. The results obtained were analyzed and a credit scoring model based on the Monge-Kantorovich problem was proposed.

Index Terms—bank, lending, borrower, blockchain, credit scoring, transport task, rating, minimization, maximization, client, empirical, information security, confidentiality, lending, borrower

I. LITERATURE REVIEW

The banking system is one of the most important sectors of the country's economy. Today, in many developed countries, much attention is paid to the introduction of modern banking services, efficient customer service and the implementation of secure lending. The lending process is one of the main departments of a bank or other lending institution, and the implementation of secure lending increases the efficiency of the organization. Secure lending process includes proper assessment of borrowers, prevention of threats to the customer's customer data, ie protection against such actions as cyber attacks, physical destruction of data, violation of confiden-

tiality. In many developed countries, blockchain technology is widely used to secure modern banking services. These include automatic payments, P2P payment systems, and P2P lending systems based on blockchain technology [4], [5], [6].

The financial security of a lending institution depends on the correct assessment of borrowers and the risk of default. The higher the number of reliable borrowers in the lending process, the lower the risk of non-repayment. Therefore, the issue of effective evaluation of borrowers is a topical issue. Borrower evaluation models are generally referred to as credit scoring. Currently, economists, mathematicians and cybernetic scientists are conducting research on mathematical modeling of the credit scoring process and the development of effective scoring models [7]. Credit scoring models are based on machine learning and statistical analysis methods.

Several credit scoring models have been developed based on machine learning methods. There are currently many publications devoted to the study of machine learning models. In particular, evaluation models based on machine learning appeared in 1941 in the scientific work of David Durand. In David Durand's scientific work, the borrowers are divided into groups such as good or bad borrowers, which are evaluated by statistical methods in the allocation of loans to enterprises, firms, organizations of the banking organization [3]. Borrower assessment models were improved in the second half of the 20th century, and linear probability models and discriminatory methods based on statistical methods began to be used to solve credit scoring problems [2]. Crook, J. N., Edelman, D. B. and Thomas, L.C. In his works, models of assessment of borrowers by the method of logistic regression are presented [8].

Alternatively, B. Baesens et al. In a 2003 article, Benchmarking state-of-the-art classification algorithms for credit, looks at support vector machines, neural network, decision trees, k-nearest neighbor, linear programming, and Bayesian network classifier [9], [10]. This paper aims to mathematically model a credit scoring system based on the problem of machine learning by analyzing the above methods. We propose a system based on the Monge-Kantorovich problem in modeling

a credit scoring system [11], [12].

II. METHODOLOGY

Suppose there is a certain bank engaged in lending to individuals. Customers apply to banks for loans. The decision to issue a loan is made by the bank based on information about the client. The bank receives information about the client from various sources: from the client himself, from the credit bureau and from other sources [28], [29]. We will consider the information provided by the client himself. The bank receives it through a questionnaire filled out by the borrower. In the questionnaire, the borrower indicates the following data: gender, age, marital status, presence of children, monthly income, availability of real estate, etc. Based on these data, we will divide customers into groups in which they are similar in certain respects. [30], [31]. For each client, using the Bayesian method, we will find a rating - the empirical probability that the client will repay the loan, provided that he belongs to this group. Having found the distribution of ratings, we thereby construct a scoring model [13], [14], [15].

To apply the method, the data must satisfy the following conditions:

- independence clients do not collude to repay the loan;
- homogeneity data are taken from the same general population;
- equiprobability clients are equally likely to be distributed into groups.

The Kantorovich problem is linear in contrast to the complex Monge problem: it is required to find the minimum of a linear functional on a convex set. If the Monge problem has a solution, then the Kantorovich problem has a solution. In some special cases, it is possible to construct a solution to the Monge problem by solving the Kantorovich problem, but this is quite rare [16], [17], [18].

However, there is a close relationship between the Monge and Kantorovich problems. In this regard, the term Monge-Kantorovich problem has become generally accepted. Linear programming begins with the Kantorovich problem [19], [20], [21]. The problem of finding the distribution of ratings comes down to finding the joint distribution of the probabilities that the client will repay the loan and the probabilities that he will fall into a specific group [22].

Thus, we have reduced the problem of finding a joint distribution to a transport problem solved by linear programming methods. However, in this case, the problem can be solved more elegantly. In this case, we immediately proceed to finding the ratings. Consider a discrete version of this problem. It is called the transport problem of linear programming. The resulting problem is typical for linear programming. It is solved by the simplex method of linear programming. We will not give an algorithm for solving it here, but note that there is a procedure in the MATLAB environment that finds a solution to the transport problem [37].

III. INTRODUCTION

It is known that the improvement of information systems around the world, the widespread use of digital technologies

and the development and improvement of methods and algorithms for information protection are important. In particular, the consistent penetration of information technology in many areas in the Republic of Uzbekistan contributes to the growth of the country's economy.

The growth of business entities in a market economy requires the improvement of financial relations between them. Therefore, the country is undergoing many reforms to develop the banking sector, which is one of the most important sectors of the economy. To this end, the Government of Uzbekistan has adopted a number of decrees and resolutions. In particular, great attention is paid to the implementation of the Decree of the President of the Republic of Uzbekistan dated May 12, 2020 No 5992 On the strategy of reforming the banking system of the Republic of Uzbekistan for 2020-2025.

The role of credit systems in the development of business entities is undoubtedly of great importance. However, at the same time, the imperfection of the existing lending systems in the Republic of Uzbekistan leads to some conflicts. In this situation, the issues of improving the country's credit system are of great practical importance.

The lending system is one of the most important links of a bank or other lending institution. The implementation of effective lending processes is the basis for the effective operation of lending institutions [32], [33], [34]. Effective lending is the maximum benefit of the lending institution's lending process and ensuring the confidentiality of borrowers' information. By reducing the risk of non-repayment of loans in lending institutions or by providing loans to reliable borrowers, banking institutions can achieve maximum profit. The confidentiality of customers' financial information is ensured using modern information security mechanisms [35], [36].

One of the most effective ways to eliminate defaults in a bank or other lending institution is to assess the creditworthiness of borrowers. There are classic and machine-based methods of evaluating borrowers.

Classic methods credit scoring models

- Models of scoring (rating) evaluation
- Statistical assessment of the borrower
- Altman Model
- Chesser Model

Credit scoring models based on machine learning

- Linear regression
- Logistic regression
- Discriminant Analysis
- Decision Trees
- Support Vector Machine
- Bayesian networks
- Neural networks
- Genetic algorithms
- Combined methods
- Methods based on fuzzy logic

Today, machine-based methods that are more effective than the classic scoring methods listed above are widely used. In this paper, we propose a credit scoring mole based on the Monge-Kantorovich problem. This model is similar to

the Bayesian-based credit scoring model and is based on an intellectual analysis of data from a bank or other lending institution. The Monge-Kantorovich problem is presented as follows.

IV. MONGE-KANTOROVICH PROBLEM

Monge's problem. Given two probability spaces (X, A, μ) and (Y, B, ν) and a non-negative measurable function h on $X \times Y$, called the cost function. It is required to find a mapping $T : X \rightarrow Y$ that is measurable with respect to the pair (A, B) , etc., $T^{-1}(B) \in A$ for all $B \in \mathcal{B}$, that takes the measure μ to ν and delivers a minimum to the expression

$$M_h(\mu, T) := \int_X h(x, T(x))\mu(dx) \tag{1}$$

among all such mappings. The condition that μ goes into ν means that it ν coincides with the image of the measure μ when displayed T , which is given by the formula $\mu \circ T^{-1}(B) := \mu(T^{-1}(B)), B \in \mathcal{B}$. If some $T \in T(\mu, \nu)$ gives a minimum, then this is T called the optimal mapping of the measure μ or ν optimal transportation [1].

In the interpretation of Monge himself, it was about the transfer of soil for construction work, i.e. both measures were the usual volumes, the function was the usual distance, and the work done was minimized. Outwardly, the task looks like an applied one, but it is not. This formulation is not the only economic formulation of the transport task. A discrete version of the Monge and Kantorovich problems arises in many modern fields.

Kantorovich problem. In 1942 major L.V. Kantorovich submits his note for publication, in which a problem is posed that is close to the Monge problem, but with one fundamentally important nuance: in the Kantorovich problem, instead of searching for the mapping T (optimal transportation), it is proposed to find only the optimal transportation plan, i.e. such a probability measure σ on $(X \times Y, A \otimes B)$, that its projection on X and Y are μ and ν , respectively, and σ delivers a minimum to the expression

$$K_h(\sigma) := \int_{X \times Y} h(x, y)\sigma(dxdy) \tag{2}$$

over all probability measures σ from the class of (μ, ν) probability measures on the product $(X \times Y, A \otimes B)$, giving μ and ν when projecting on X and Y .

The Kantorovich problem is linear, in contrast to the complex Monge problem: it is required to find the minimum of a linear functional on a convex set. If the Monge problem has a solution, then the Kantorovich problem has a solution. In some special cases, it is possible to construct a solution to the Monge problem by solving the Kantorovich problem, but this is quite a rarity. [23]

However, there is a close relationship between the Monge and Kantorovich problems. In this regard, the term Monge-Kantorovich problem has become generally accepted. Linear programming begins with the Kantorovich problem. Consider

a discrete version of this problem. It is called the transport problem of linear programming. Let's formulate it [24].

Departure points given A_1, \dots, A_m in each of which there are a_1, \dots, a_m units of cargo, and destinations B_1, \dots, B_n with the needs b_1, \dots, b_n of units of cargo. The cost of transporting a unit of cargo is known $c_{i,j}$ from A_i to B_j . You need to make a transportation plan. In this case, the total need for cargo coincides with the total amount of cargo at the points of departure, etc.

$$\sum_{i=1}^m a_i = \sum_{j=1}^n b_j \tag{3}$$

Let us construct a mathematical model of this problem. Need to find x_{ij} the amount of cargo transported from the point of origin A_i to the destination B_j . Obviously, the following conditions must be met:

$$\sum_{j=1}^n x_{ij} = a_i, i = 1, \dots, m \tag{4}$$

$$\sum_{i=1}^m x_{ij} = b_j, j = 1, \dots, n \tag{5}$$

$$x_{ij} \geq 0 \tag{6}$$

In this case, the total cost of transportation should be minimized.

$$\sum_{j=1}^n \sum_{i=1}^m c_{ij}x_{ij} \tag{7}$$

The resulting problem is typical for linear programming. It is solved by the simplex method of linear programming. We will not give an algorithm for solving it here, but note that there is a procedure in the MATLAB environment that finds a solution to the transport problem.

V. BUILDING A CREDIT SCOURING MODEL BASED ON THE MONGE-KANTOROVICH PROBLEM

The content of the issue is similar to the Bayes problem, and the following conditions must be met:

- independence - clients do not collude to repay or not repay a loan;
- homogeneity - data are taken from one general population;
- equiprobability - customers are equally likely to be distributed into groups.

The task of finding the distribution of ratings comes down to finding the joint distribution of the probabilities that the client will repay the loan and the probabilities that he will fall into a specific group. It boils down as follows: knowing the joint distribution and the probability of getting into each group $P(X_{i,j}, Y_j)$ and $P(Y_j)$, we can find the rating

$$P(X_{i,j}|Y_j) = \frac{P(X_{i,j}, Y_j)}{P(Y_j)} \tag{8}$$

Let us reduce the problem of finding a joint distribution to a transport problem. denote $p_{i,j} = P(X_{i,j}, Y_j)$. At the same time, the marginal probability distribution is $P(Y_j)$ defined in Chapter 2. Let us indicate the marginal distribution $P(X_i)$ calculated as the ratio of the number of customers who repaid (not repaid) the loan to the total number of customers [23], [24].

We will build it as the ratio of the number of clients satisfying a pair of values of random variables (X, Y) to the total number of clients. Fix the number of clients corresponding to each possible pair (X, Y) .

TABLE I
THE NUMBER OF CLIENTS WHO REPAID AND DID NOT REPAY THE LOAN IN EACH GROUP

	X_i	Y_i		X_i	Y_i		X_i	Y_i		X_i	Y_i
No	0	1	No	0	1	No	0	1	No	0	1
1	20	12	16	19	5	31	10	5	46	49	14
2	45	22	17	34	25	32	21	17	47	69	27
3	44	20	18	45	15	33	20	13	48	58	18
4	21	10	19	21	4	34	16	3	49	27	9
5	15	10	20	11	3	35	8	4	50	20	3

15	12	6	30	28	10	45	14	2	60	1	1

$P(X_1) = 0.716742$, $P(X_2) = 0.283257$. X_1 - the number of those who repaid the loan, X_2 - the number of those who did not repay the loan [36], [37].

It is required to find a joint distribution $p_{i,j}$ such that: Minimizes the linear shape,

$$\sum_{i=1}^2 \sum_{j=1}^{60} |X_{i,j} - Y_j| p_{i,j} \tag{9}$$

$$0 \leq p_{i,j} \leq 1 \tag{10}$$

$$\sum_{i=1}^2 \sum_{j=1}^{60} p_{i,j} = 1 \tag{11}$$

$$\sum_{i=1}^2 p_{i,j} = P(Y_j), \quad j = 1, \dots, 60 \tag{12}$$

$$\sum_{j=1}^{60} p_{i,j} = P(X_i), \quad i = 1, 2 \tag{13}$$

As a cost function, $h(x, y)$ we choose the modulus of the difference between $X_{i,j}$ and Y_j : $h(X_{i,j}, Y_j) = |X_{i,j} - Y_j|$.

Thus, we have reduced the problem of finding a joint distribution to a transport problem solved by linear programming

methods. However, in this case, the problem can be solved more elegantly. In this case, we immediately proceed to finding the ratings [27], [28].

Consider the 1st condition for $p_{i,j}$. Since it is necessary to minimize the sum of non-negative elements, we can proceed to minimizing the sum over i , while fixing the specific j :

$$\sum_{i=1}^2 |X_{i,j} - Y_j| p_{i,j} \rightarrow \min \tag{14}$$

Using the fact that $P(X_{i,j}|Y_j) = \frac{p_{i,j}}{P(Y_j)}$, let's move on to

$$\sum_{i=1}^2 |X_{i,j} - Y_j| P(X_{i,j}|Y_j) \rightarrow \min \tag{15}$$

What is equivalent to minimizing

$$\sum_{i=1}^2 \left| 1 - \frac{X_{i,j}}{Y_j} \right| P(X_{i,j}|Y_j) \tag{16}$$

From minimization, we can make an equivalent transition to maximization:

$$\sum_{i=1}^2 \left| 1 - \frac{X_{i,j}}{Y_j} \right| (1 - P(X_{i,j}|Y_j)) \rightarrow \max \tag{17}$$

Denote

$$\tilde{P}(X_{i,j}|Y_j) = 1 - P(X_{i,j}|Y_j) \tag{18}$$

$$\tilde{c}_{i,j} = 1 - \frac{X_{i,j}}{Y_j} \tag{19}$$

$$\tilde{P} = \begin{pmatrix} \tilde{P}(X_{1,j}|j) \\ \tilde{P}(X_{2,j}|j) \end{pmatrix} \tag{20}$$

$$\tilde{c} = \begin{pmatrix} \tilde{c}_{1,j} \\ \tilde{c}_{2,j} \end{pmatrix} \tag{21}$$

Thus, the problem is reduced to maximizing the scalar product $\langle \tilde{P}, \tilde{c} \rangle$.

We use the Cauchy - Bunyakovsky inequality, which says that $\langle \tilde{P}, \tilde{c} \rangle \leq \sqrt{\langle \tilde{P}, \tilde{P} \rangle} \sqrt{\langle \tilde{c}, \tilde{c} \rangle}$. Equality is achieved when the vectors are collinear. Hence we get that $\tilde{P}(X_{i,j}|Y_j) = \tilde{c}_{i,j}$.

From here we obtain the solution of our problem:

$$P(X_{i,j}|Y_j) = \frac{X_{i,j}}{Y_j} \tag{22}$$

Thus, the transport problem was solved clearly. We have received customer ratings.

Table 2 calculates the rating scores for 60 pairs of clients. Based on these rating points, decisions are made based on the criteria in Table 3 for borrowers.

Based on the ratings, we can classify clients according to the empirical probability of their repayment of the loan.

Based on the evaluation criteria outlined in Table 3, the decision to grant a loan to a borrower is made as follows.

TABLE II
CUSTOMER RATINGS

	Rating score		Rating score		Rating score
1	0.625	21	0.75	41	0.803279
2	0.671642	22	0.765957	42	0.670103

Fig. 1. Ratings graph

- 1) The client's rating lies in the half-interval $(0.7, 1]$. The client is considered reliable. You can give him a loan.
- 2) The client's rating lies in the half-interval $(0.5, 0.7]$. The client is considered medium-risk. If the credit conditions are revised, then this client can be granted a loan.
- 3) Customer Rating The customer $(0, 0.5]$ is considered risky. Such a client should not be given a loan.

Based on the above evaluation criteria, we classify the assessments of borrowers in Table 2 by reliability levels. The indicators of the classified estimates are shown in the following tables.

TABLE III
CRITERIA FOR EVALUATING BORROWERS

Evaluation criteria	The level of confidence of borrowers
High level	$(0.7, 1]$
Medium level	$(0.5, 0.7]$
High level	$(0, 0.5]$

TABLE IV
BORROWER GROUPS WITH LOW RELIABILITY

Groups	Low reliability indicators
55	0.4925525

VI. RESULTS

Thus, we analyze the data tables classified above. The tables are divided into 60 groups, and calculations were performed using 1997 customer data.

Fig. 2. Borrowers with a medium level of reliability

As a result, in Table 4, groups 55 \rightarrow 0.4925525 and 60 \rightarrow 0.4525265 were assessed, of which 55 and 60 customer groups are **low levels** of reliability borrowers. These borrowers are considered insolvent and will not be given credit. According to the results given in Table 5, 5, 7-12, 15, 17, 25, 31, 32, 33, 35-37, 39, 40, 42, 54,56, 58 groups of borrowers have

Fig. 3. Borrowers with a high level of reliability

an **medium levels** of reliability can be granted a loan by re-analyzing their data. In addition, Table 6 lists 6, 13, 14, 16, 18-24, 26-30, 34, 38, 41, 43-53, 57, 59 groups of borrowers with **high levels** of reliability. Allocating loans to borrowers with a high level of reliability will lead to effective results. Now, we analyze the market share of customers in terms of reliability levels Figure 2, Figure 3, Figure 4, Figure 5.

From the above graphs, we can see that in the credit market we are analyzing, the share of groups of borrowers with a high risk of default is 3.3%, borrowers with a medium level of reliability 43.3% and trustworthy borrowers 53.4%. The results of this analysis show that the credit institution is effectively lending process.

VII. CONCLUSION

In short, the effectiveness of lending by banks or other lending institutions depends on lending to reliable borrowers. Therefore, many lending institutions face the problem of attracting customers and verifying customer trust.

In solving this problem, a new credit scoring model based on the Monge-Kantorovich problem was proposed. The credit scoring model based on the Monge-Kantorovich problem is distinguished by the fact that it is mathematically based and the conditions for its application are defined. Using this credit scoring model, the process of evaluating borrowers using data from lending institutions is presented, and scientific results are obtained.

Currently, credit scoring systems are widely used by banks or other lending institutions of the Republic of Uzbekistan. This shows that credit scoring models are an effective tool in evaluating borrowers as well as profitable lending. Using this credit scoring model, we can obtain the estimates of borrowers who are most likely to be involved in retail lending and micro lending. This leads to an efficient implementation of the lending process. Therefore, research is being conducted around the world to improve effective credit scoring models and develop new models. Therefore, in order to further develop the credit system in the Republic of Uzbekistan, it is necessary to improve credit scoring mechanisms.

Abstract: The advent of industry 4.0 has seen a massive increase in the connectivity of electronic devices to the internet. It also results in the implementation of data gathering schemes for environmental factors. One such field is the agricultural sector. In Sri Lanka, where this research was conducted, agriculture accounts for one fifth of the country's gross national production. The introduction of wireless sensor networks in the field of agriculture has shown some of the underlying factors that affect the crops and by extension, the harvest and yields. Recoding of environmental factors such as soil moisture, temperature, humidity, sunlight, etc. has enabled the modeling of the conditions in the plantations and nurseries. Thereby, delivering an understanding of what suboptimized factors can be improved. Also, two models are utilized to forecast the next-step moisture content at Boralanda town in Sri Lanka based on previous read values: Seasonal Autoregressive Integrated Moving Average (SARIMA) and Long-Short Term Memory (LSTM) Neural Network. It is shown that the LSTM model is superior with much lower error when predicting many time steps.

Keywords; Precision agriculture, LSTM, SARIMA, Wireless sensor networks

I. INTRODUCTION

Agriculture still remains on the main sources of income for developing countries like Sri Lanka. Over 25% of the work force in Sri Lanka is engaged in the agricultural sector [1-3]. Developing technologies in the fields of wireless connectivity and machine learning have given rise to new ways of managing agriculture and optimizing the processors, with maximizing the yields and reducing production costs. Precision agriculture delivers the means of observing the environmental features of the area, assessing and predicting the inputs needed for the short-term and long term in the future. In order to improve the crop yields and by extension agricultural production of the country, the gathered information and the prediction reached by the computer simulations can be delivered

to the farmer to adjust the input to the plantations and take better care of the crops. In the long term this could save a large amount of money, since the inputs to the plants are precisely controlled and the wastage and over use can be drastically reduced.

Another aspect of this implementation is for horticultural nurseries. Horticulture uses the knowledge of growing plants to intensively produce plants. The process is done not only to generate food, but mostly to propagate ornamental and flowering plants. In a market like Sri Lanka, the horticultural industry accounts for 20% of the total agricultural output of the country [4, 5]. It can be seen as very lucrative emerging market mainly for exportation.

One important aspect of this paper is introducing a suitable forecasting model for forecasting soil moisture content by several steps based on the captured data of the moisture sensor itself. The experiment data includes moisture content captured within 18 days in October 2019 with 1351 samples (sample rate of about 10 minutes) at Boralanda town in Sri Lanka. The data set is then shown to be non-stationary, where trend and seasonality components exist. A stationary series is a series where its mean and variance don't change over time and covariance function is not a function of time. A trend makes a series become non-stationary by adding an increasing or decreasing trend component, which changes the mean overtime. Also, seasonality is present when there is a repeated pattern in a same time period while the other time periods don't include the pattern, which changes the mean and variance overtime [6]. We will overcome these problems by introducing and comparing two different forecasting model – Seasonal Autoregressive Integrated Moving Average (SARIMA) and Long-short Term Memory (LSTM) Neural Network [7]. SARIMA is a well-known and simple forecasting model that takes cares of both non-seasonal and seasonal components in a series. LTSM

is a prevailing neural network structure that can be used to fit sequential data and a high degree of complexity [8].

The paper presents the observation and modelling of the environmental conditions in a controlled green house. The main focus has been analysis of soil moisture in the plant pots. Section II-precision agricultural systems; is an in-depth explanation on the different stages in a general precision agricultural system. Section III-data gathering electronics; will give a briefing on the electronics behind the data gathering process. Section IV-forecasting models; introduces the machine learning algorithms and software used to create the predictive model. Section IV will be an explanation of the model generated. Section V presents the results of this experiment and the advantages of using such a system. Finally, Section V would be the conclusions and future work.

II. PRECISION AGRICULTURAL SYSTEMS

This application of wireless networks that measure environmental conditions for automated control of resources or predicting and/or estimating the approximate depletion time of resources is known as precision agriculture [9]. Furthermore, this concept expands as, to create an maintain a complex system, typically controlled through electronic computation for adjusting resources and nutrients in the soil to attune to a specific composure suited for a plant variety [10].

The stages of precision agricultural system can be described as follows [11]. The initial and most important step of setting up a precision agricultural infrastructure is locating the wireless sensor network. The sensor nodes will act as the feelers in the system to gauge in sudden changes in environmental conditions. These sensors are used to measure vital information such as [12, 13]; soil moisture, pH level of soil, air temperature (if within a greenhouse), humidity, sunlight levels, etc. the next stage of the infrastructure is the data gather and accumulation. The data gathering includes the gauged parameter as well as the location of the sensing instrument. This data is transferred to a local route to then be recorded on a server. Finally, control decisions are made by humans or artificial intelligence based on the sensor data [14].

III. DATA GATHREING ELECTRONICS

One of the major issues in this application of IoT (Internet of Things) is the maintenance of the sensor network and electronics. Two challenges in managing the electronics are; exposure of physical components

to harsh environmental conditions, and the battery life of nodes.

Since the sensors need to be in physical contact with the elements to obtain readings, their internal components should be shelled for damage. Ultimately, this is a role that is passed on to the manufacturer.

Secondly, the nodes/sensor modules are required to operate with minimum interaction or maintenance by the humans. Typically, the deployment of such networks is vast and covers a large area. Therefore, the number of planted nodes could easily reach up to hundreds. In such an installation, retrieval of nodes for periodic maintenance such as battery recharging would be cumbersome. Therefore, optimization for energy efficiency is of the utmost importance. [15], has conducted their own research as well as presented past research on the energy consumption of wireless sensor networks designed for agricultural purposes. Accordingly, the devices transmit data to the routed periodically. In the meantime, in between transmissions, the electronics are forced into a sleeping mode so the current draw off the battery is low (in microampere range) [16, 17].

For reference, the data gathering instruments used in this research record and transmit data every 10 minutes. During test the electronics system only drew 56 microamperes during forced sleep mode. One single node in this implementation has enough energy to run for approximately one year without recharging. This is not to say that unexpected maintenance issues will not arise.

A. Embedded Hardware design

In this specific application we have adopted a simple embedded system with a microcontroller attached to wireless communication module for data transmission and a capacitive soil moisture sensor for gather information on the moisture level on the soil as shown in the Fig. 1.

The data measured by the soil sensor is converted internally in the MCU to a percentage moisture value. The moisture within any sample will not drop significantly, instead it will gradually decrease under natural conditions. Therefore, multiple reading for one sample is not required.

The NRF24 wireless communications module was selected to transmit the data from the node to the router placed within each green house. The module and their communication protocol were selected for its capability to transmit the data packages securely while also consuming a very low amount of power. The gathered data within each green house is transmitted

Fig. 1 – Embedded hardware system

by the router to the cloud over Wifi/ethernet, where it was subjected to the following analysis as described on this paper.

IV. FORECASTING MODELS

A. Seasonal Autoregressive Integrated Moving Average

Seasonal Autoregressive Integrated Moving Average (SARIMA), an extended version of ARIMA, is one of the most popular forecasting methods for univariate time series data. ARIMA, while having the capability to deal with trend components of data, lacks the consideration of seasonal components in its own algorithm. SARIMA expands its capability by adding autoregression (AR), differencing (I) and moving average (MA) for seasonal components as part of its equation.

Here, the autoregression (AR) model is the regression of time-series values to itself. In particular, the concurrent values of the series is considered to depend on its previous values, called lags. The maximum lag is denoted as p . The initial value of p is determined by using a partial auto-correlation function (PACF) plot. The Moving Average (MA) model presents the error of time series, with the argument that the current value of error also depends on some of its own lag, referred to as q . The initial value of q can be determined using an auto-correlation function (ACF) plot. Finally, I is the order of integration, which is the number of non-seasonal differences needed to make the time series become stationary [7]. The general

model is denoted as $SARIMA(p, d, q) \cdot (P, D, Q)^S$, where: p, d, q are AR, I and MA orders of trend elements, respectively; P, D, Q are AR, I and MA orders of seasonal elements, respectively. In 1970, Box and Jenkins introduced a multiplicative model of SARIMA, provided in [18].

$$\phi_p(B)\phi_p(B^S)\nabla^d\nabla_s^D X_t = \theta_q(B)\theta_q(B^S)\epsilon_t \quad (1)$$

Here, B is the backward shift operator.

The ordinary AR and MR components are presented as the polynomials $\phi_p(B)$ and $\theta_q(B)$ of the order p and q , respectively.

$$\phi_p(B) = 1 - \phi_1 B - \phi_2 B^2 \dots - \phi_p B^p \quad (2)$$

$$\theta_q(B) = 1 - \theta_1 B - \theta_2 B^2 \dots - \theta_q B^q \quad (3)$$

The seasonal AR and MA components are presented as the polynomials $\Phi_P(B^S)$ and $\Theta_Q(B^S)$ of the order P and Q , respectively.

$$\Phi_P(B^S) = 1 - \Phi_1 B^S - \Phi_2 B^{2S} \dots - \Phi_P B^{PS} \quad (4)$$

$$\Theta_Q(B^S) = 1 - \theta_1 B^S - \theta_2 B^{2S} \dots - \theta_Q B^{QS} \quad (5)$$

The non-seasonal and seasonal difference components:

$$\nabla^d = (1 - B)^d \quad (6)$$

$$\nabla_s^D = (1 - B^S)^D \quad (7)$$

Finally, X_t is observed value at time t ($t = 1, 2, 3 \dots, n$) and ϵ_t is residual at time t

The approach of Box and Jenkins requires four phases [19]:

Model identification. This phase involves analyzing and verifying the stationarity of the time series using various methods. There methods can be using ACF and PACF plots; Mann-Kendall trend test; unit root test. In addition, the type of the model (non-seasonal or seasonal) and its orders (p, q, P, Q) are determined using ACF and PACF plots, as discussed.

Model Estimation. This phase involves reviewing the model (as well as its orders) defined in previous phase and using a common error metric to determine the best one. Some popular error metrics are Mean Absolute Error (MAE) and Root Mean Square Error (RMSE)

$$MAE = \frac{\sum |error|}{n} \quad (8)$$

$$RMSE = \sqrt{\frac{\sum (error)^2}{n}} \quad (9)$$

Model Diagnostic. This phase uses the ACF and PACF plots of residuals to check if the residuals follow white noise or not. If it doesn't, we need to choose another model.

Model Forecasting and evaluation. This last phase involves using the model to forecast the future outcome. Moreover, testing data can be used to verify the performance of the model using suitable error criteria (MAD or MSE).

Four phases are iterated until a satisfactory model is achieved.

B. Long-short Term Memory Neural Network

Recurrent neural network (RNN) is an artificial neural network architecture specialized for sequential data such as handwriting, speech etc. Therefore, it is capable of handling time-series data as well. Here is the general structure of RNN

We can observe that the network feedback to itself at each time step. Hence, it can be unfolded as multi layers feed forward neural network. The formula for hidden state s_t of network and its output y_t are given in [20]

$$s_t = f(Ux_t + Ws_{t-1}) \quad (10)$$

$$y_t = g(Vs_t) \quad (11)$$

Fig. 2 shows x_t as the input to the system at time t , s_t is the hidden state of the cell at time t , which is stands for memory of the network; f is an activation function for the hidden state (\tanh or ReLU); U, V, W are parameters of network, which is shared across all time steps; y_t is the output of the network at time t and g is its activation function (SoftMax function).

Fig. 2 - Recurrent Neural Network

It can be observed that with such an enormous number of layers as the number of input increases, the gradients propagate all the way back to initial values will either suffer from vanishing gradients or exploding gradient. In particular, the deeper of the layers, the more matrix multiplications have to be applied because of the chain rule. Therefore, if they are small, the

The gradient will shrink exponentially to an extremely small value, such that the model cannot learn more. This phenomenon is called vanishing gradient. On other hand, if they are large, the gradients get exponentially larger and eventually crash the model. This phenomenon is called zn exploding gradient. Long-short Term Memory (LSTM) Neural Network solves these problems by introducing the concept of using different activation function layers called “gates” [8]. The proposed structure of one cell of LSTM is given as [21] (Fig. 3).

In Fig. 3 showing one cell of LTSM, x_t is current input at time t ; h_{t-1} and c_{t-1} are the previous cell output and state, respectively; h_t and c_t are previous cell output and state, respectively. f_t is the forget gate.

This sigmoid layer determines which data is irrelevant and should be forgotten. It takes x_t and h_{t-1} as input and give Boolean value as output for each piece of information (0 is giving up the information while 1 is keeping the information)

$$f_t = \sigma(x_t * U_f + h_{t-1} * W_f) \quad (12)$$

i_t is the input gate. This sigmoid layer determines which new data is to be written to cell state. Similar to the forget gate, its outputs are Boolean values that decide which piece of new information should be written

$$i_t = \sigma(x_t * U_i + h_{t-1} * W_i) \quad (13)$$

\bar{c}_t is the candidate gate. This \tanh layer regulates the vectors created by x_t and h_{t-1} to be in the range from -1 to 1 , which provides faster convergence.

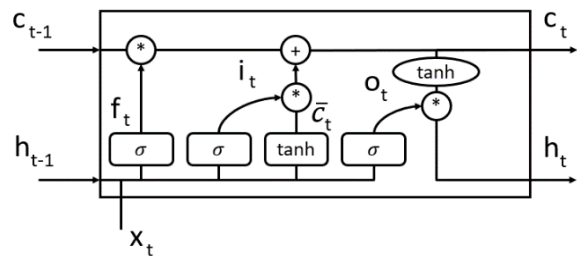

Fig. 3 – One cell of LTSM

$$\bar{c}_t = \tanh(x_t * U_c + h_{t-1} * W_c) \quad (14)$$

The multiplication between i_t and \bar{c}_t provides new regulated chosen values.

Next, the new value of current state c_t is calculated using previous state c_{t-1} along with calculated f_t , i_t and \bar{c}_t

$$c_t = f_t * c_t + i_t * \bar{c}_t \quad (15)$$

Finally, the output h_t of the cell is generated using 2 components: are regulated version of current cell state c_t using \tanh function and filtered values of h_{t+1} and x_t .

$$o_t = \sigma(x_t * U_o + h_{t-1} * W_o) \quad (16)$$

$$h_t = o_t * \tanh(c_t) \quad (17)$$

V. FORECASTING RESULTS

A. Development of SARIMA model

The data set consists of 1351 data points of moisture content (percentage) of the soil within the greenhouses located in Boralanda town in Sri Lanka with a sample rate of 10 minutes. As we have 6 observations per hour and one day (24 hours) is a full cycle, the frequency that we choose to decompose the data into additive components is 144 (6 multiplied with 24) and shown on Fig. 4.

Here, we can observe the presence of trending and seasonality in the data. Hence the data shows strong correlation to each other as in Fig.5 and is non-stationary. This implies that the current data set is inappropriate since a linear model like SARIMA requires the observations to be independent [19].

We also deduced the ACF and PACF plots of the original data in Fig. 5 and Fig. 6.

Fig. 4 – Decomposed additive components

In order to make the data stationary, the first seasonal difference was taken, as shown on Fig. 7 and Fig. 8.

Fig. 5 - ACF of original data

Fig. 6 – PACF of original data

Fig. 7 - ACF of D=1

Fig. 8 – PACF of D=1

We can observe that after the first seasonal difference, there is a very little correlation between the data. Thus, the series is considered to be stationary.

In the ACF plot, the positive significant spikes at lag 1 and 3 suggest a non-seasonal MA(2) component, and two negative significant spikes at lag 25 and 26 might suggest a seasonal MA(2) component. Also, in PACF plot, the positive significant spikes at lag 1 and 3 suggest a non-seasonal AR(2) and the negative significant spikes at lag 25 suggest a seasonal AR(1) component. Consequently, our final model for SARIMA is: $(2, 0, 2) \cdot (1, 1, 2)^2$.

After this, the SARIMA model will be trained with the original data.

B. Development of LSTM model

The training of the LSTM model involves the following steps:

- **Difference the series.** As discussed, a stationary series is very easy to predict and fit well in training model. The difference series is performed with one lag, similar to SARIMA. Also, this implementation is used to facilitate overfitting due to the correlation between the data.
- **Scale the data.** The data will be scaled down to the range from -1 to 1 in order to achieve fast convergence.
- **Train the model with training data.** Here, 4 neurons are used for LSTM network with a batch size of 1. The training iteration is chosen as 30.
 - **Predict the next steps with inversed scaling and inversed difference.** After training the model, we use it to predict the next steps where the predicted value will be used to predict the next step. Also, we need to scale back the predicted data to its intended value and apply back the non-stationarity.

C. Forecasting results and discussion

The results of two model with 48-step prediction for a duration of 8 hours are given in Fig. 9. The output prediction of the models compared to the raw test data is discussed with the corresponding inputs to the system. Table 1 gives the RMSE and the MAE values of the two compared networks to the original raw data.

Table 1 – RMSE and MAE of forecasting model

Model	RMSE	MAE
SARIMA	10.3617	6.27421
LSTM Network	1.98741	1.26152

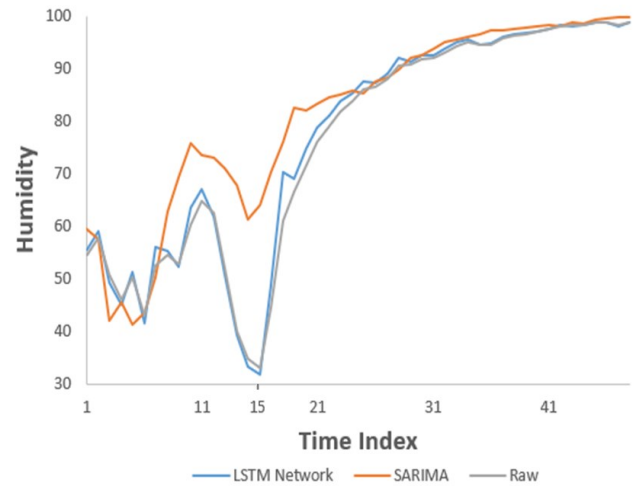

Fig. 9 – Comparison of SARIMA and LSTM network in forecasting moisture data

Although, two models exhibit a fairly small amount of error, compared with SARIMA, LSTM network performs significantly better for our data set of humidity with a much smaller RMSE and MAE. Therefore, we choose to use LSTM in forecasting the content of moisture.

The graph proves how close the LSTM Network follows the raw data compared to the SRIMA Network. Even at sudden changes, for example around 15-time index (which corresponds to the period of excessive evaporation in the morning), the LSTM Network prediction is acceptably accurate. Whereas, the SARIME Network shows a significant deviation from the real case.

VI. CONCLUSION AND FUTURE WORK

In conclusion, we have tested two different networks for forecasting the required data for a selected amount of time. We have successfully defined and compared two forecasting models: SARIMA and LSTM. By observing the results, it is evident that the LSTM network is much more versatile and performs outstandingly better than the controlled network. Due to lower error in predicting many time steps ahead, LSTM is considered to be more suitable for our model.

For future work, the models can and will be expanded for multiple parameter analysis. The correlations of humidity, sunlight, air temperature and weather forecasts with soil moisture can be taken into account in the future. The collection of larger sets of data and different combinations of SAMRIMA would potentially lead to the discovery of better models to predict resource availability and requirements for the plant ahead of time. By precise control of the inputs

needed for the plant growth, the cost due to wastage can be significantly reduced, and by extension, lift the financial burden on the farmers and planters of Sri Lanka.

Abstract—*Fragaria ananassa*, a member of the rose family's flowering plants, commonly recognized as strawberry, is prone to *Diplocarpon earlianum* infection that causes leaf scorch. Assessment via visual inspection of strawberries by farmers is normally ineffective, destructive, and laborious. To address this challenge, the use of integrated computer vision and machine learning techniques was done to classify a healthy from a scorch-infected strawberry leaf image and to estimate the leaf region infection rate (LRIR). A dataset made up of 204 normally healthy and 161 scorch-infected strawberry leaf images was used. Images were initially preprocessed and segmented via graph-cut segmentation to extract the region of interest for feature extraction and selection. The hybrid combination of neighborhood and principal component analysis (NCA-PCA) was used to select desirable features. Multigene genetic programming (MGPP) was used to formulate the fitness function that will be essential for determining the optimized neuron configurations of the recurrent neural network (RNN) through genetic algorithm (GA), and cuckoo search algorithm (CSA), and artificial bee colony (ABC). Four classification machine learning models were configured in which the classification tree (CTree) bested other detection models with an accuracy of 100% and exhibited the shortest inference time of 14.746 s. The developed ABC-RNN₃ model outperformed GA-RNN₃ and CSA-RNN₃ in performing non-invasive LRIR prediction with an R² value of 0.948. With the use of the NCA-PCA-CTree₃-ABC-RNN₃ hybrid model, for crop disease detection and infection rate prediction, plant disease assessment proved to be more efficient and labor cost-effective than manual disease inspection methods.

I. INTRODUCTION

Detection and identification of plant diseases is a commonly experienced problem in the agricultural crop production industry since it directly affects the quality of products being sold to local food markets. Researchers found that while these diseases show symptoms through different

parts of a plant, leaves tend to be the most frequently observed part for the detection of infection [1]. Various studies have been conducted that use digital image processing methods to detect and classify leaf diseases [2, 3]. Using a vision-based approach to detect the disease by utilizing leaf images is one of the best options researchers tend to go to [3].

Fragaria ananassa which is a common type of strawberry species that bears strawberry fruit is a good source of vitamin C for the improved immune system, potassium for lowering blood pressure, antioxidants for eliminating free radicals, and reducing inflammation, flavonoids such as anthocyanins, quercetin, and kaempferol for cancer prevention. It also promotes healthy eyesight because it contains ellagic acid and phenolic phytochemicals. The fruit has a low glycemic index and, it contains dietary fiber that helps regulate blood sugar levels [4]. However, it is prone to *Diplocarpon Earlianum* infection which is also known as leaf scorch. It is characterized by small purplish blemishes that appear on the top side of the leaf. Scorched-infected strawberry farms typically suffer from a decline in their strawberry produce's quality and taste. Late diagnosis of scorch infection is one of the main reasons for this. Moreover, monitoring and visually inspecting these fruits are typically done manually which is quite ineffective due to its dependence on the observer's bias, expertise, and observation skills.

A study conducted by [5] used the hybrid model utilizing linear discriminant analysis and decision tree to detect and quantify the damage of bacteria-infected grape leaves, [6] used a gaussian quantum-behaved particle swarm and recurrent neural network to assess the disease of corn leaves suffering from leaf spots, and [7] classified three rice leaf disease using a hybrid machine learning and deep neural network. Genetic programming, genetic algorithm, and machine learning models were implemented by [8-12] with the utilization of lettuce features to monitor the growth stages of lettuce. *Musa acuminata*'s post-harvest analysis was done by [13] using hybrid machine learning and deep transfer networks. Meanwhile, research by [14] used an adaptive

neuro-fuzzy inference system to classify three different lettuce seed varieties. On the other hand, research by [15] examined the use of lettuce images to indirectly predict the amount of nitrate present in aquaponic water flowing in a crop chamber system of a vertical farm with the use of a recurrent neural network that is optimized by genetic algorithm.

In this research, machine learning (ML) algorithms such as support vector machine (SVM), Naive Bayes (NB), classification tree (CTree), and linear discriminant analysis (LDA), were implemented to detect a scorch-infected leaf. This detected leaf is then examined to quantify the leaf region infection rate (LRIR) in terms of the area of the whole leaf with the use of a three-layered recurrent neural network (RNN) that is optimized by three bio-inspired optimization algorithms: genetic algorithm (GA), cuckoo search algorithm (CSA), and artificial bee colony (ABC). These models are responsible for the infection rate prediction process of the study. This study contributes to the: (1) development of an efficient and non-invasive vision-based detection of strawberry scorch leaf disease that would help the farmer to employ better agricultural practices; (2) development of an innovative and accurate technique in predicting the leaf infection rate that would help plant pathologist on how to treat strawberry leaves with such severity of infection; and (3) determination and analysis of most significant leaf phenotypes in terms of morphological, texture and spectral traits that have high relevance to leaf scorch disease.

II. MATERIALS AND METHODS

For this study, the realization of the model framework design is presented in Fig. 1. Input images of two classes of leaves (healthy and scorched-infected) were enhanced with the use of contrast improvement to make a distinct identity between the two and, to make the segmentation procedure much simpler. Two types of the strawberry leaf are being initialized as an input for image processing: healthy leaf and scorch-infected leaf. These images were segmented to extract the leaf area of both classes (whole and scorched area) for the calculation of the scorch infection rate. Once features are extracted, an optimized recurrent neural network will do the job of infection rate prediction. To accomplish such a challenging task, MATLAB R2020b software was used to perform vision-based leaf inspection, computational processing, model creation, optimization, classification, and estimation.

A. Strawberry Leaf Dataset Information

The dataset is composed of 365 images with a 1:1 aspect ratio and 256-by-256-pixel density. The number of the healthy leaf is 204 images while the scorched-infected leaf is 161 images. The dataset can be found on [16].

B. Image Enhancement (Contrast Improvement)

Completely raw images of the strawberry leaf (healthy and scorched) were enhanced by adjusting the contrast of the images through histogram equalization. By applying the *imadj* built-in command of MATLAB, the images' top 1% and bottom 1% of all pixel values were adjusted from a default value of 0 to 1 for low-in, high-in, and low-out, high-out values. By doing this, the color map of the image histogram

will stretch from a 0 to 255 range. The contrast settings used were as follows: (0.2, 0.9), (0, 1). An image output sample together with its corresponding histogram is presented in Fig. 2. To make the image enhancement task easier, a looping program was designed to preprocess all 365 images simultaneously with the use of an image batch processor, a built-in application inside MATLAB software.

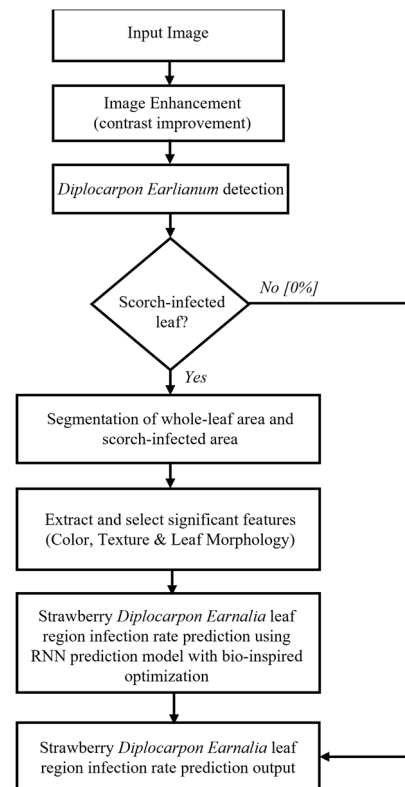

Fig. 1. Methodological framework for the strawberry leaf scorch classification and infection rate prediction using bio-inspired (population-based) optimization of recurrent neural network

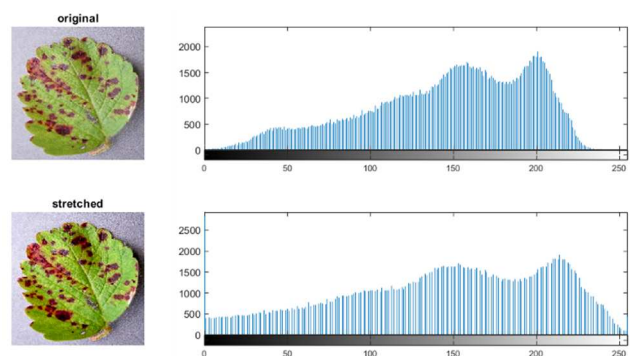

Fig. 2. Image histogram stretching of scorch-infected strawberry leaf for better segmentation results

C. Strawberry Leaf Feature Extraction, Selection, and Dataset Normalization

To establish a model capable of detecting and computing the amount of infection, eighteen features were extracted from the input images. It consists of color features (RGB,

HSV, L a*b*, YCbCr), textural features (correlation, contrast, energy, entropy, homogeneity), and morphological features (leaf vegetative pixel area) (Fig. 3). These features are the primary basis for the prediction model capable of estimating the leaf region infection rate of a strawberry leaf infected by *Diplocarpon Earlianum*. Using the extracted morphological area of the scorch-infected leaf ($A_{scorched}$) and the whole leaf area ($A_{whole\ leaf}$), the leaf region infection rate (LRIR) can be solved using (1).

$$LRIR = (A_{scorched} / A_{whole\ leaf}) \times 100 \quad (1)$$

Fig. 3. Segmentation of the scorched-infected strawberry leaf (a) raw leaf image (b) pre-processed leaf image (c) lazy snapping annotation for the scorch-infected area (d) lazy snapping for the whole leaf area (e) scorch-leaf masked region (f) whole-leaf masked region (g) binary masked image of leaf scorched areas (h) binary masked image of leaf whole area

Since there are 18 features, the model might take quite some time to predict the correct output, hence, only significant features should be considered for the model development. The most significant leaf features were selected by using a hybrid approach. It is done by using neighborhood and principal component analysis (NCA-PCA). PCA will give the number of significant features that need to be included. On the other hand, NCA is used to rank the features based on a particular feature's variability and impact on the prediction results. This process gave out a three-feature vector of R, G, and a*. After extracting the important features, they were further improved by applying data normalization. This step is implemented to promote proper scaling of data and, to prevent the unequal scattering of data. The normalization method, Z-score data normalization [17], was used. It is primarily based on getting column vector data's mean and standard deviation (Fig. 4). To do this, the data (x) of a certain feature (e.g., contrast) is subtracted by the mean derived from that column vector (\bar{x}). Lastly, the value is divided to the standard deviation of that column vector (σ).

$$Normalized\ value = \frac{x - \bar{x}}{\sigma} \quad (2)$$

D. Strawberry Leaf Health Status Identification using Machine Learning Model

For the detection task, machine learning algorithms such as support vector machines (SVM), Naïve Bayes (NB), classification tree (CTree), and linear discriminant analysis (LDA) were considered. Optimization parameters for each algorithm are as follows. SVM has a box constraint (1.6545), kernel (3.507), bias (1.0384), and solver (sequential minimal

optimization). NB has a 0.0512 kernel and cosine distance. LDA was configured with a delta of 0.0293 and gamma of 0.6766. Also, Bayesian optimization was used for the hyperparameter tuning for all the machine learning algorithms mentioned. To make the classifier model robust and unbiased, the image dataset was partitioned into three subparts: training data (56%), validation data (24%), and testing data (20%). This data partitioning technique is called stratified sampling in statistical jargon. The purpose of this step is to lower the error rate in the classification task of the model.

The assessment of each of these models will be based on the following criteria: accuracy, inference time, Matthew's correlation coefficient (MCC), precision, recall, fall-out, and hamming loss.

Fig. 4. Characterization of color-texture-morphological features based on NCA-PCA feature selection

E. Objective Function Creation using Genetic Programming

One of the ways to create an objective function for unconstrained optimization problems is using genetic programming (GP). It is a type of computational evolutionary algorithm that combines the use of a regression tree and a genetic algorithm. This union of two powerful algorithms is also known as multiple-gene symbolic regression. This is used to define the mathematical model to be minimized by the optimization algorithms to define the best possible combination of a three-layered neural network which will be used to predict the infection rate that a strawberry leaf contains. GPTIPsv2, a genetic programming tool that has built-in compatibility with MATLAB, is utilized to generate the objective function. The hyperparameters used are as follows: population size of 50, maximum generations of 50, training instances of 25, tournament size of 50, elite fraction of 0.1, Pareto tournament probability of 0.2, maximum genes of 10, maximum tree depth of 5, infinite number of total nodes, crossover probability of 0.84, mutation probability of 0.14 and expressional complexity measure.

The fitness function (3) is based on three input variables, represented by N_1 , N_2 , and N_3 for each layer of a three-layered neural network. The output parameter is a single variable that will provide the root mean square error (RMSE) value which will help the optimization algorithms figure out the right combination of neurons in consideration with the smallest RMSE value.

$$\text{Root Mean Square Error} = f(N_1, N_2, N_3) \quad (3)$$

F. Population-based Optimization of Neurons in Recurrent Neural Network

1) Genetic Algorithm (GA)

Genetic algorithm (GA) is one of the well-known bio-inspired algorithms recognized in the field of artificial intelligence. It is derived from the biological evolution theory called Darwinism, which is primarily based on population growth reproduction that introduces the concept of gene combination and mutation. The hyperparameters are as follows: population size is 50, the number of generations is 50, and the number of runs is 10. The selection parameters are as follows: tournament size of 50, Pareto tournament probability of 0.2, the mutation rate of 0.1, crossover rate of 1, constraint tolerance value of $1e^{-6}$. Moreover, a nonlinear constraint algorithm and selection roulette were implemented. The fitness limit is set to zero with a functional tolerance of $1e^{-6}$. The maximum generation allowed is set to 100.

2) Cuckoo Search Algorithm (CSA)

The cuckoo search algorithm (CSA) is a type of bio-inspired algorithm that mimics the behavior of cuckoo birds in population reproduction [18]. This algorithm utilizes the Levy flight theory to generate a new candidate solution (eggs). The concept is based on the way some particular cuckoo bird species engaged in obligate brood parasitism. The way they do it is by laying their eggs on the nest of a different species of bird (host bird). They simply rely on other host birds to take care of their offspring. The algorithm relies on the fact that there is at least a 10% probability that the host bird will discover that the cuckoo bird's egg is not of its own and thus, has a two-choice: to remove the cuckoo egg from its nest or carry its eggs (excluding the cuckoo egg) and bring it to a newly created nest. The survivability of the cuckoo bird solely depends on their eggs not being discovered by the host bird and, for the host bird to consider the cuckoo egg as its own. The ideal scenario is that the cuckoo egg is not discovered and, the cuckoo egg will hatch and grow together with the host bird's real offspring. Here, the population size for the algorithm is set with a value of 20, the discovery rate probability of alien eggs (or solutions) of 0.25, and the maximum iteration of 100 as the convergence criteria. The population stated is the number of host nests per generation. This means that a nest can contain only one cuckoo egg.

3) Artificial Bee Colony Algorithm (ABC)

The artificial bee colony algorithm (ABC) is a swarm-based metaheuristic algorithm that is primarily based on the honeybees' intelligent foraging behavior [19]. The algorithm can be explained on the principle of how bees coordinate with other bees to find the best possible food source they could find that is close to their beehive. The main components of this algorithm are food sources, employed foragers, and unemployed foragers (scout bees and onlooker bees). In selecting a food source, forager bees evaluate several

properties related to the food source such as nectar taste, energy richness, the difficulty of energy extraction, and closeness to the beehive. The hyperparameters for the implementation of the algorithm are as follows: food source is 100, maximum iteration of 100, the population size of 50, and a limit of 150 for the scouting phase.

G. Strawberry *Diplocarpon earlianum* Leaf Region Infection Prediction using Computational Intelligence

The leaf region infection rate (LRIR) is numerically computed using the developed recurrent neural network (RNN) with three types of optimization methods: GA-RNN, CSA-RNN, and ABC-RNN. The RNN model was built through MATLAB by using the built-in function *newelm*. For the configuration of this network, the training algorithm used is scaled conjugate gradient (SCG), 10,000 iterations (epoch), goal parameter is set to $1e^{-7}$, and the transfer function designation was 'tansig', 'purelin', and 'log'.

To evaluate the computational intelligence models, parameters such as root mean square (RMSE), coefficient of determination (R^2), and mean absolute error (MAE) were recorded. An ideal value of 1 for R^2 is desired while a value of 0 is targeted for MAE and RMSE.

III. RESULTS AND DISCUSSION

A. Strawberry Leaf Health Status Identification using Machine Learning Models

It can be seen in the confusion matrix summary in Fig. 5 that SVM, NB, and CTree were able to classify the scorched strawberry leaf from the healthy ones with 100% accuracy. LDA has the lowest accuracy of 97.37%. In terms of the amount of inference time, CTree outperformed all other three algorithms. CTree is 66.53% quicker compared to SVM, 39.80% quicker compared to NB, and 9.62% faster than LDA. This result is based on the testing phase of the model developed with the use of stratified sampling. It is quite noticeable that the reduction of features used resulted in much less computational time as seen in Table 1. By doing so, the improved performance of the models was able to recognize *Diplocarpon earlianum* leaf infection with much lesser time and computational cost without sacrificing the level of accuracy.

B. Objective Function Based on Genetic Programming

To create a robust model, function settings for the GPIPSv2 were set to times, plus, minus, square, sqrt, sin, cos, add3, mult3, cube, log, abs, and neg. These were utilized to generate a function. The parameters for the programming process were set to 0.1, 0.84, and 0.14 for the ERC probability, crossover probability, and mutation probability respectively.

The derived fitness functions were ranked based on their coefficient of determination (R^2) in descending order. There were 500 models generated in this process. Seventeen models were shown based on highest R^2 values (model 351, 370, 380, 379, 378, 262, 276, 294, 257, 192, 185, 285, 12, 37, 437, 72, and 87). Model 351 fitness function was the one chosen among other models based on its R^2 value of 0.939. The equation presented below in (2) with the use of variable N

represents the number of neurons needed. Additionally, the subscripts (1, 2, and 3) added under the variable N specify what layer is being identified.

$$RMSE = 0.00407N_1 + 0.0223N_2 + 0.0262N_3 + 9.42e-6N_3^2N_2^2 - 0.00112N_1N_2 + 6.34e-4N_1N_3 - 0.00497N_2N_3 + 1.98e-5N_1N_2^2 - 9.96e-6N_2N_3^2 - 8.49e-5N_2^2N_3 - 1.78e-6N_2^3N_3 + 4.24e-5N_1^2 + 0.00466N_2^2 - 9.86e-5N_2^3 - 0.00521N_3^2 + 6.46e-7N_2^4 + 9.42e-6N_3^4 - 1.63e-5N_1N_2N_3 - 0.0209 \quad (4)$$

C. Recurrent Neural Network Configuration based on Optimization Results

Based on the optimization results, GA-RNN has a three-layered-hidden-layer combination of 95.9915, 32.3209, 13.9978 (rounded off to 96, 32, 14), CSA-RNN has a three-layered-hidden-layer combination of 109.9901, 40, 15.2434 (rounded off to 110, 40, 15), and ABC-RNN has a three-layered-hidden-layer combination of 96.0986, 33.3731, 16.4391 (rounded off to 96, 33, 16). The fitness value for the GA-RNN is -0.0017, CSA-RNN has -0.5729, and ABC-RNN has -0.5605. The fitness curve of each algorithm is presented in Fig. 6, Fig. 7, and Fig. 8.

D. Strawberry Diplocarpon Earlianum Leaf Region Infection Prediction using Computational Intelligence

A three-layered recurrent neural network (RNN₃) is responsible for the quantitative prediction of the amount of prediction. The subscript of three indicates the number of layers used inside this type of neural network. Based on Table 2, it can be noted that the ABC-RNN₃ has the lowest MAE and RMSE for the testing phase. It also has the highest R² value which is closer to 1. It bested all other machine learning models used in this study. To compare ABC-RNN₃ has the highest R²: 1.328% higher than GA-RNN₃, and 3.834% higher than CSA-RNN₃. Additionally, ABC-RNN₃ has the lowest RSME: 11.238% lower than GA-RNN₃, and 19.490%

lower than CSA-RNN₃. Moreover, ABC-RNN₃ has the lowest MAE: 0.584% lower than GA-RNN₃, and 9.415% lower than CSA-RNN₃. Among the developed models, CSA-RNN₃ performed the least while GA-RNN₃ is the second-best among the three algorithms in predicting the leaf region infection rate (LRIR) of a *Diplocarpon earlianum* infected strawberry leaf.

Leaf scorch detection and infection rate prediction were explored to develop a vision-based approach to identifying a strawberry leaf's health condition and quantifying the amount of severity the *Diplocarpon earlianum* fungus had caused. Strawberry leaf health status was classified as good or infected with the help of machine learning models such as SVM, NB, CTree, and LDA which are all found to be highly accurate. These machine learning models were also examined by [5] to classify the leaf health status of grapes infected with black rot; [6] on the other hand, used these models to identify a corn leaf that is exposed to *Maize Cercospora* leaf spot; and [7] to classify three different rice leaf diseases. Among the four classification algorithms, CTree showed a 100% accuracy for this study. Using population-based optimizers such as GA, CSA, and ABC, the recurrent neural network was calibrated

to the ideal combination of three-layered hidden neurons for which ABC-RNN₃ gave out the highest R² value and lowest RMSE and MAE values. Given the reports from [9] that explored bio-inspired optimization with the firefly algorithm, exploring these population-based optimizers opens more options for innovation of computationally inexpensive intelligent models that plant pathologists can consider when it comes to quantitative assessment of leaf infection rate in strawberry leaves. Extracting and selecting the top three features which are R, G, and a* proves that among morphological, textural, and spectral traits, the most significant leaf phenotype that is directly relevant in determining a scorch-infected strawberry leaf is the spectral feature. Using the combination of NCA-PCA, which was also explored by [7, 13], for a contrast-improved strawberry leaf

image, the accuracy of the classification results had drastically improved while the computational cost was lessened, which is beneficial to farmers looking to improve their farming practices without spending too much money. Reducing the features needed for the model development significantly decreases the computational time and cost as observed by the results comparing an eighteen-feature vector to a three-feature vector [8], an eighteen-feature vector to a two-feature vector [13], and a twenty-two-feature vector to a seven-feature vector [14] respectively. Thus, the NCA-PCA-CTree₃-ABC-RNN₃ hybrid algorithm configuration provides a cost-effective approach for strawberry leaf scorch detection and infection rate quantitative assessment which can aid farmers in detecting the crop disease at an earlier stage which will significantly reduce widespread bacterial infection across the farm. Additionally, it will also give plant pathologists an idea of how the infection should be treated given that the amount of infection severity is numerically determined.

IV. CONCLUSION

This study proposed a new technique for detecting and predicting the *Diplocarpon earliarum* infection rate of strawberry leaves using recurrent neural network (RNN) integrated with population-based optimizers, namely genetic algorithm (GA), and cuckoo search algorithm (CSA), and artificial bee colony (ABC). The raw images containing scorched strawberry leaves were segmented using graph-cut segmentation through lazy snapping algorithm. Hybrid neighborhood component analysis (NCA) and principal component analysis (PCA) was done to select the 3 most significant morpho-spectro-textural features of leaves resulting in red, green, and a* components. A genetic programming-based RMSE model was constructed as a function of neuron density on each of the three RNN layers. After a series of explorations in the hyperparameters of GA-RNN, CSA-RNN, and ABC-RNN, the ABC-RNN model with inputs of the 3 most significant features outperformed other models in performing non-invasive leaf region rate infection with an accuracy of 94.8%. Four classification machine learning models were configured in which the classification tree (CTree) bested other detection models with an accuracy of 100%. Hence, this study was able to introduce a technique of integrating NCA, PCA, CTree, ABC and RNN for crop disease detection and infection rate prediction. For plant disease assessment, it was proven to be more efficient and labor cost-effective than manual disease inspection methods. For future studies, the inclusion of other strawberry leaf disease variants caused by other fungal bacteria is highly recommended to expand the range of diseases that can be determined by the model. Moreover, applying the developed model to an actual strawberry farm for leaf health analysis as extended research to further improve the model's efficiency is also suggested.

ACKNOWLEDGMENT

The authors would like to express their sincerest gratitude for the support bestowed by Engineering Research and Development for Technology (ERDT) of the Department of Science of Technology (DOST) of the Philippines as well as

the De La Salle University - Intelligent Systems Laboratory (DLSU-ISL), Manila, Philippines.

Abstract— Disability is a condition that directly affects the natural performance of human abilities such as movement due to diseases such as cerebrovascular accident (CVA), spinal cord injury (SCI), among others. According to the World Health Organization (WHO), more than a billion people, about 15% of the world's population, experience at least one form of disability caused by aging and the onset of multiple diseases. Lower limb exoskeletons are a set of links connected by joints that are used for multiple applications, including rehabilitation and/or assistance, especially for the elderly. In this recent review, several lower limb exoskeletons are analyzed in categories that are common requirements to propose conceptual designs of new exoskeletons such as the commercial name, the degrees of freedom (DoF), the mechanism that covers the part of the lower limb, the biosignal that controls the functions of the exoskeleton of the lower limbs, the characteristics of the test subjects that participated in the clinical evaluations, the pathology of the end users or potential clients, the application for which they are being designed and the Technological Readiness Level (TRL) which is a NASA measurement scale.

Keywords—*Lower-limb, exoskeletons, rehabilitation, assistance, hip, ankle, knee, biomechatronic, biomechanics*

I. INTRODUCTION

Disability is a condition that directly affects the natural performance of human capacities such as vision, movement, thinking, memory, learning, hearing, mental health and social relationships due to diseases such as paralysis brain, Down syndrome, among others. According to the World Health Organization (WHO), more than one billion people, about 15% of the world's population, experience at least one form of disability caused by aging and the onset of multiple diseases [1]. In 2014, the Economic Commission for Latin America and the Caribbean (ECLAC) determined that more than 70 million people live in conditions of disability [2]. In 2012, the National Specialized Survey on Disability (ENEDIS) and National Institute of Statistics and Informatics (INEI) identified that 5.2% manifested some type of disability in Peru [3]. Due to the COVID-19 pandemic, people with disabilities have become the most affected population due to their economic situation, age, gender, others. Also, although there is no evidence that shows the profile of people who died during the COVID-19 pandemic, it is estimated that people with disabilities were affected [4].

Physical disability is caused by multiple factors which are presented below. The dysfunction of the physical capacity of the lower limbs can be caused by genetic, accidental or acquired causes over time. The most frequent causes are pathologies such as stroke, spinal cord injury (SCI), traumatic brain injury (TBI), cerebrovascular accident (CVA), cancer, amputation, musculoskeletal injury or neuromuscular disease. These conditions are the main cause of the deficiencies recorded in patients who have reduced or no mobility in their lower limbs. [5]. People with this type of disability in the lower extremities show the consequences of their condition when they try to carry out their Activities of Daily Living (ADL). Besides, people with disabilities are economically affected, the majority being the economically inactive population. For this reason, it is people with disabilities who have the highest unemployment rates. Unfortunately, those who manage to get a job seek minimum remuneration or are informal jobs [6]. In addition, it has been recorded that households that have a person with a disability tend to have the highest expenses because basic needs include services such as rehabilitation therapies, personalized education, medications, maintenance of medical equipment used for transportation or medical assistance, care service and among others [3]. Given the above, the technical-scientific community has developed multiple devices as possible solution mechanisms such as mechatronic systems called exoskeletons. Exoskeletons are systems that consist of an electronic, mechanical and control part. These devices are what are commonly known as robots. The exoskeletons are a set of links connected by joints that are capable of executing different actions assigned by the actuators that compose it. José L. Pons [7] in the book *Wearable robots: biomechatronic exoskeletons* originally defines exoskeletons as extensors because they are considered a type of robot whose function is to provide force as support to the human body to carry out activities where the natural capacities of the body are not enough to do them. Therefore, José L. Pons. [7] defines the exoskeleton as a structure that corresponds to the anatomy of the human body to supply external force [7]. These devices are designed for areas such as the military, work and even health. In this last aspect, exoskeletons have positioned themselves in rehabilitation and assistance related to the improvement of motor capacity, being the lower limb exoskeletons most studied by researchers.

II. BIOMECHANICS OF LOWER-LIMB

By evaluating the relationship between each movement of a living organism, and the energy expenditure involved in the forces to generate that movement, we can say that we are fulfilling the objective of the study of biomechanics. This analysis includes the study of the characteristics of human movement from the point of view of kinematics, using parameters such as velocity and direction, and kinetics, observing how the forces applied inside and outside the body generate the movement [8]. The lower limbs are sequentially connected to the trunk of the body through the pelvic girdle, maintaining the weight load of the trunk and upper limbs, as well as to a constant generation of forces by the contact between the foot and the ground. The lower limb can be subdivided into three main parts, the thigh with its hip joint, the leg with its knee joint and the foot with its ankle joint; each with different degrees of freedom and types of movements as seen in Fig. 1.

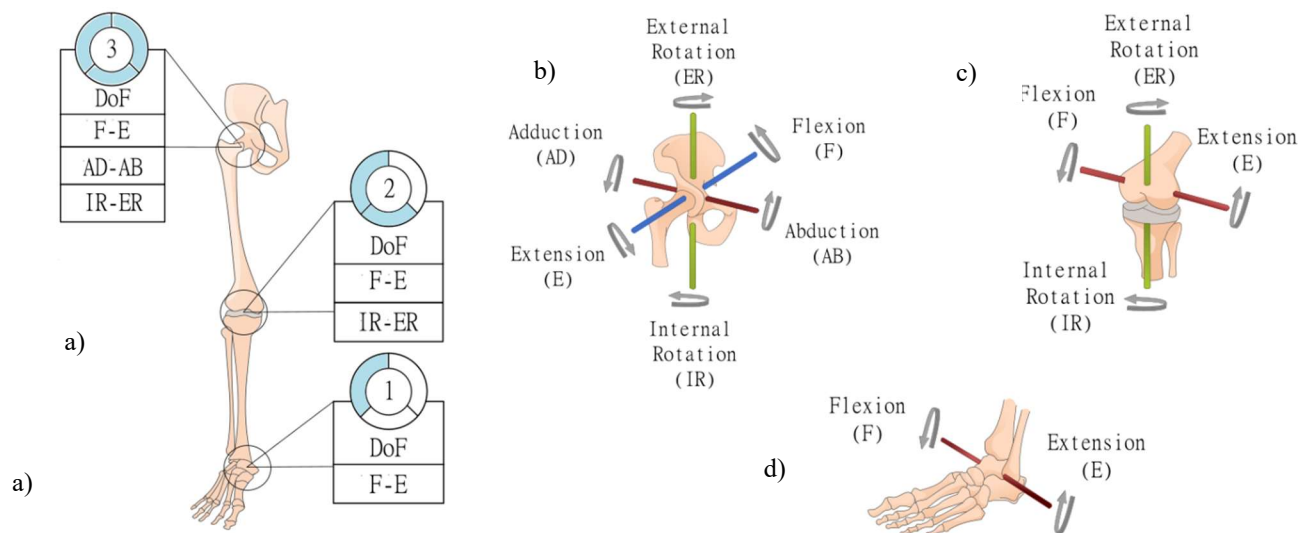

Fig.1. Biomechanics of Lower-Limb. a) Lower Extremity [10] b) Hip [10] c) Knee [10] d) Ankle [10]

A. Biomechanics of the Hip

The hip joint exhibits triaxial motion caused by its coxofemoral joint and acetabulum of the coxal. This type of joint is commonly called enarthrosis. The femur and shaft join the hip at an angle called the cervicodiaphyseal. Its common value varies between 125° and 135° in a healthy adult, increasing to 145° in the first years of life and decreasing to approximately 120° in old age. On the other hand, the hip has 3 DoF, as seen in Fig. 1. First, flexion and extension allow the thigh to move in the sagittal plane. Hip flexion with the knee extended can reach 90° while with the knee flexed it varies between 140° and 160°. In contrast, hip extension with the knee flexed forms an angle of 10° and with the knee extended it reaches 20°. The second one is called the abduction-adduction movement which has an amplitude of 15° in the normal state. Abduction can be increased by 90° by changing the position of other joint movements. The last one is the internal-external rotation where the amplitude is 90° distributed in 60° for external rotation and 30° for internal rotation [9].

B. Biomechanics of the Knee

The knee is a joint that connects the leg with the thigh, and allows cushioning loads between the upward forces of the ground and the weight of the body. This joint fulfills the function of giving stability and mobility to the body; internally it has three joints that involve the femur, the tibia, the fibula and the patella at the bony level, among them it is found the patellofemoral, the tibioperoneal and the most representative, the tibiofemoral, since the movement that it allows is the most notorious in the knee. When aligning the lower extremity, a flat angle between the leg and thigh is not achieved; it generally ranges between 170° and 175°. The knee has 2 DoF as seen in Fig.1. It allows flexion and extension movements on a lateromedial axis where flexion is 135° and extension is 0°. The other movement is internal and external rotation which is only performed when the knee is in semi-flexion which is 45° to 50° for external rotation and 30° to 35° for internal rotation [10].

C. Biomechanics of the Ankle

The ankle joint is located within the structure that connects the foot to the leg. This joint allows, like the others, to perform various movements that enable the gait cycle of the human lower extremity, which is recorded by a motion capture system to analyze the biomechanics of the ankle. Although at first glance it appears that it allows a great variety of movements, the truth is that it only has 1 DoF. As seen in Fig.1, this joint is commonly called the tibiotarsal. It involves contact of the tibia and fibula with the tarsus and provides stability during specific movements. To understand the movement of the ankle, it is important to correctly locate its axis of rotation. This part of the ankle joint crosses the malleoli obliquely to the tibia and forms an angle of 8° with the horizontal plane and 6° with the frontal plane. On the one hand, the pair of movements that the ankle allows are flexion and extension, although for the ankle it is usually called flat flexion and reaches an amplitude of 50°. On the other hand, the ankle joint is capable of dorsiflexion reaching 20° [10].

III. LOWER-LIMB EXOSKELETONS

Currently, lower limb exoskeletons are mechatronic systems that usually work with parts of the human body such as the hip, knee and/or ankle, which are frequently used for assistance and/or rehabilitation. This type of exoskeletons were classified in Table I. in the following categories: commercial name or references, the Degrees of Freedom (DoF) that allow identifying the Range of Motion (RoM), the mechanism that covers the selected part of the lower limb, also considered the biosignal used to control the actions of the exoskeletons,

characteristics of the test subjects who participated in the clinical evaluations to assess the effectiveness and feasibility of the exoskeleton, the pathology of the users for which each of the exoskeletons is intended, application and Technology Readiness Level (TRL) according to NASA [11]. The last one indicates the level of maturity of the lower exoskeleton system, which are levels from 1 to 9 where the first means that it is starting as research and the last means that they have already approved as commercial devices through organizations such as the Food and Drug Administration (FDA) [12] and others.

A. Description

Lower limb exoskeletons are a set of links connected by joints that work with different parts of the human body, depending on the application and pathologies for which they were designed. Fig.2 shows examples of several lower limb exoskeleton systems, such as EICOSI [14], Wake-Up [15], HUMA [16], among others. According to Table I., 63.38% do not have a commercial name. So, the majority identify themselves with the name of the main author. Therefore, 36.62% of them have commercial names such as EICOSI [54], Wake-Up [15], HUMA [16], XoSoft [84], EXiO-A [23], ANKUR-LL II [24], E-ROWA [25], ARKE [27], LOPES III [42], BioKEX-II [36], Symbitron [76], among others. Regarding the degrees of freedom of the exoskeletons, the exoskeleton Monaco *et al.* [19] stands out for having the highest number of DoF. This exoskeleton has 42 DoF covering the hip, knee and ankle joints, although others have only 1 DoF were also found, such as EICOSI [14], Khamar *et al.* [26], Al-Ayyad *et al.* [46] and Marsi Active Knee (MAK) [61], which encompass mechanisms such as the knee, leg, ankle, and foot. These latter exoskeletons are smaller compared to Monaco *et al.* [19] which is larger and encompasses the entire lower limb. It is worth mentioning that the number of DoF most used in the design of exoskeletons are 2 and 6, found in 7 and 6 articles, respectively. On the one hand, within the exoskeletons that have 2 DoFS, 5 of them cover only the hip and the knee, among them we have EXiO-A [23], Zhou *et al.* [55], Zhao *et al.* [75], Sun *et al.* [78], and Chen *et al.* [82]. In addition to the two remaining exoskeletons, Amiri *et al.* [43] and Yang *et al.* [58] cover the entire lower limb. On the other hand, within the exoskeletons that have 6 DoF, 5 of them cover the entire lower limb such as ARKE [27], EHTE [72], Vinoj *et al.* [41], Campbell *et al.* [49], and Ezhilarasi *et al.* [80]. Finally, there are the lower limb exoskeletons that cover only the hip as the application of robotics developed by Llorente-Vidrio *et al.* [57].

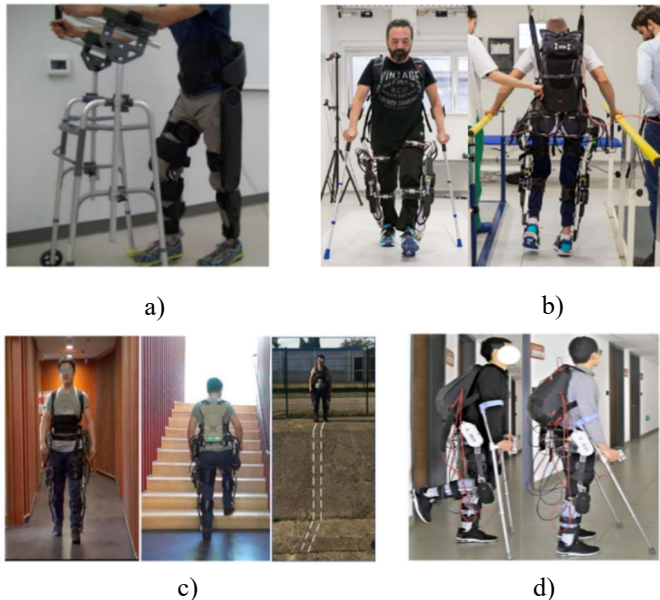

Fig.2. Lower-Limb Exoskeletons. a) Indego [33]. b) Symbitron [76]. c) E-ROWA [25]. d) Li *et al.* [48].

B. Pathologies and Applications

This review identified articles employing 1 to 45 test subjects, generally healthy males (age: 6-40 years, weight: 55-95 kg, height: 1.60-1.82 m) who assisted in the design, revision and fabrication of lower limb exoskeletons. These subjects simulated the physical structure and/or motor function of people who have suffered CVA or SCI that totally or partially affect the lower limbs, generating in them pathologies such as hemiplegia, paraplegia and/or paralysis. In this sense, it was found that 24 of the 71 articles reviewed seek to resolve the pathologies generated by cerebrovascular accidents, and 14, SCI. In addition, pathologies associated with the aging of the population were found, such as reduced movement, problems in maintaining balance, Sit-To-Stand (STS) limitation, among others where 20 articles dealt with the aforementioned pathologies. Of the exoskeletons reviewed, 37 were used for gait assistance, flexion-extension and STS, 30 were used for gait rehabilitation and STS, and 4 of the exoskeletons reviewed were used for both assistance and rehabilitation. The most frequently repeated application is gait rehabilitation and/or assistance, which is presented in 47 articles.

C. Biosignals or Bioelectrical Signals

Biomedical signals are identified by means of transducers that transform the carriers of ionic charges present in the cell membrane, which is found in the skin of the body, into electrical currents that we know as biosignals or bioelectric signal. These are ionic signals, when they are transformed into electrical signals, they are generally positioned on very small voltage scales; that is, they are between microvolts (uV) or millivolts (mV). For application purposes, biomedical signals are conditioned and amplified. In this way, it is possible to use it for different purposes such as the control of a lower limb exoskeleton. According to Table I., it is shown that the most used control signals are the electromyographic (EMG) while only one of them uses the electroencephalogram (EEG) signal. This means that 38.03% of the analyzed exoskeletons prefer to use the EMG signal to control their functions, while 60.53% still do not use biosignals in the proposed devices or choose not to use them yet. Of the 71 exoskeletons analyzed, it was found that only one chose to use the EEG signal.

D. Technology Readiness Levels (TRLs)

According to NASA, the Technology Readiness Level (TRL) is a measurement scale that researchers and engineers use to classify technology at different levels of development [11]. It means that it indicates the level of maturity of the lower exoskeleton system, which are levels from 1 to 9 where the first means that it is starting as research and the last means that they have already been approved as commercial devices through bodies such as the Food and Drug Administration (FDA) [12] and others. According to Table I., most lower extremity exoskeletons are found at TRL 5, TRL 6, or TRL 5/6. This means that around 12.7% of them are in the prototype stage. Furthermore, it was identified that TRL 7 and TRL 8 were the least frequent of the 71 exoskeletons analyzed. That means that ultimately few devices are being tested as prototypes in case studies with test subjects.

IV. CONCLUSION

In conclusion, this research article presents relevant information regarding the characteristics that are taken into consideration when proposing a new design for mechatronic systems such as lower limb exoskeletons. In this review, 71 research articles about lower limb exoskeletons were classified in the categories such as the commercial name, the degrees of freedom (DoF), the mechanism that covers the selected part of the lower limb, the biosignal that controls the functions of the exoskeleton of lower limbs, the characteristics of the test subjects who participated in the clinical evaluations, the pathology of the end users or potential clients, the application for which they are being designed and the Readiness Level (TRL) established by NASA [11]. It was determined that 63.38% do not have a commercial name assigned by their inventors. On the contrary, the minority of the exoskeletons found receive a commercial name, with 36.62% of them specifically as EICOSI [54],[14], Symbitron [76], among others. Regarding the degrees of freedom of the exoskeletons, the exoskeleton Monaco *et al.* It stands out for having the highest number of DoFs, which is 42 DoF, covering the hip, knee and ankle joints. That is, the entire lower limb. Exoskeletons with 1 DoF were also found, such as EICOSI [14], Khamar *et al.* [26], Al-Ayyad *et al.* [46] and Marsi Active Knee (MAK) [61], which encompass mechanisms such as the knee, leg, ankle, and foot. That is, only a specific part of the lower limb. It is important to mention that the number of DoF most used for the design of lower limb exoskeletons are usually in the range of 2 and 6 DoF. Lower limb exoskeletons with 2 DoF such as EXiO-A [23], Sun *et al.* [78], and Chen *et al.* [82] They prefer mechanisms that cover only specific parts of the lower extremity, such as the hip and knee. Regarding lower limb exoskeletons with 6 DoF such as ARKE [27], EHTE [72], Vinoj *et al.* [41], Campbell *et al.* [49] and Ezhilarasi *et al.* [80] they opt for mechanisms that cover almost the entire lower limb. This review identified articles employing 1 to 45 test subjects, generally healthy men (age: 6-40 years, weight: 55-95 kg, height: 1.60-1.82 m). These subjects simulated the physical structure and/or motor function of people who have suffered cerebrovascular accidents in their majority and SCI in their minority that totally or partially affect the lower limbs, generating in them pathologies such as hemiplegia, paraplegia and/or paralysis where these pathologies were related to the aging of the population, such as decreased movement, problems maintaining balance, for which it was determined that the most repeated application is rehabilitation and/or walking assistance. In addition, it was found that 38.03% of the exoskeletons analyzed use the EMG signal to control their functions, while 60.53% still do not use biosignals in the proposed devices or choose not to use them yet. On the other hand, only one of them use Electroencephalography (EEG) signals to control this devices. Finally, most lower extremity exoskeletons are found at TRL 5, TRL 6, or TRL 5/6. This means that around 12.7% of them are in the prototype stage. Furthermore, it was identified that TRL 7 and TRL 8 were the least frequent of the 71 exoskeletons analyzed. That means that few devices are ultimately being tested as prototypes in case studies.

Abstract— Deep learning has a large interest in medical image analysis as studies have shown several machine learning algorithms were successful in predicting disease. However, more work is needed to better understand the batch size, epoch, and learning rates. An empirical study of image processing with deep learning was conducted on the KIMIA path24 dataset. The rotation, width shifting, height shifting shear range, horizontal flip, and fill mode was used. The network was trained and validated by a total of 22,591 images from the KIMIA path24 dataset. ReLU was used for the convolution layer and softmax for the fully connected layer. Results found the batch size is inversely proportional to the network accuracy, the accuracy of a deep learning network is directly proportional to the number of epochs it passes through, and the learning rate does not bring any change to the network. The network performs best within a preferred learning rate.

Keywords—deep learning, machine learning, deep convolutional networks, image classification

I. INTRODUCTION

For several decades, pathology has been described as the archiving of microscopic information of specimens. This microscopic information is organized by storing specimens on glass slides. The problem with glass slides is that they are fragile and require a very large specially prepared storage room to store the specimens in. This kind of storage requires a lot of logistical infrastructures.

In 1999, whole slide imaging (WSI) was introduced by Wetzel and Gilbertson [1]. WSI can provide high image quality that doesn't decay over time, along with a range of other benefits. WSI can be used by multiple researchers to investigate multiple slides at the same time, and this kind of data is more useful in order to retrieve information and maintain quality control.

Pathology bounded by the WSI system is emerging into an era of digital specialty. WSI is providing solutions for centralizing diagnostic by improving the quality of diagnosis, patient safety, and economic concerns. [2].

The diagnosis of WSI is still difficult. The gigapixel nature of WSI scans makes it difficult to store, transfer, and process samples in real-time. One also needs tremendous digital

storage to archive them [3]. A diagnostic system aided by digital pathology scanned data would allow for a more objective approach and increase our ability to predict an individual's pathological diagnosis and treatment response.

The most common form of machine learning is supervised learning. In computer vision, deep convolutional networks have now become the technique of choice [4]. Deep learning is making major advances in solving problems in the artificial intelligence community. Deep learning deals with the problem of data representation by introducing simpler intermediate representations that allow them to combine in order to build complex concepts [5]. Deep learning methods are multiple levels of representation. These representations are obtained by composing simple but non-linear modules that transform the representation at one level into a representation at a higher abstract level. Recent studies have shown that machine learning algorithms were able to predict disease more accurately than experienced clinicians [6]. Deep learning has a large interest in medical image analysis. It is expected that deep learning will hold \$300 million for the medical imaging market by 2021 [7]. It is of great interest to develop and improve such prediction methods. The goal of this paper is to conduct an empirical study of image processing with deep learning using the KIMIA path24 dataset.

II. RELATED WORKS

A. Deep Learning

Deep learning-based image super-resolution (SR) models have been actively explored and often achieve the state-of-the-art performance on various benchmarks of SR. A variety of deep learning methods have been applied to tackle SR tasks ranging from the early Convolutional Neural Networks based method to recent promising SR approaches using Generative Adversarial Nets [8]. Dong, et al. [9] proposed a deep learning method for a single SR. In this study, the authors contributed three aspects: 1) presented a convolutional neural network for image super-resolution, 2) established a relationship between the deep learning-based SR method and the traditional sparse coding-based SR methods, and 3) demonstrated the usefulness of deep learning in the classical computer vision problem with super-resolution. The method of this study directly established an end-to-end mapping between the low/high-resolution

images. The mapping is represented as a deep convolutional neural network (CNN) that takes the low-resolution image as the input and outputs the high-resolution. With a lightweight structure, the Super-Resolution Convolutional Neural Network (SRCNN) has achieved a superior performance above other state-of-the-art methods. The authors conjectured that an additional performance could be further gained by exploring more hidden layers/filters in the network using different training strategies [9].

Chen, et al. [10] introduced the concept of deep learning into hyperspectral data classification. They introduced the deep learning-based feature extraction for hyperspectral data classification. Their method focused on applying an autoencoder (AE). At first, the authors verified the eligibility of stacked autoencoders by following classical spectral information-based classification. After that, a new way of classifying with spatial-dominated information was presented. Finally, they proposed a deep learning framework by merging the two features. Chen, et al. [10] exploited a single layer autoencoder (AE) and a multi-layer stacked AE (SAE) to learn shallow and deep features of hyperspectral data. AE-extracted features are useful for classification. AE and SAE deep feature extraction models increased the accuracy of SVM and logistic regression while obtaining the highest accuracy when compared with other feature extraction methods.

Chetlur, et al. [11] created a library with optimized routines for deep learning workloads with a similar intent to Basic Linear Algebra Subroutines (BLAS) [12]. They presented a novel implementation of convolutions that provided a reliable performance across a wide range of input sizes, and they took advantage of the highly optimized matrix multiplication routines to provide a high performance without requiring any auxiliary memory. Integrating Nvidia CUDA Deep Neural Network's (cuDNN) library into Caffe improved the performance by 36% on a standard model with a reduced memory consumption. NVIDIA cuDNN's performance is 86% of the maximum performance, with a small mini-batch size of 16. This implementation performed well across the convolution parameter space. NVIDIA cuDNN's library ranged from 23-35% of peak performance on the Tesla K40 and from 30-51% of peak performance on the GTX 980. NVIDIA cuDNN's library provided a performance portability across GPU architectures with no need for users to retune their code as GPU architectures evolve [11].

A large body of the work in deep learning can be classified into: (1) generative, (2) discriminative, and (3) hybrid categories. A deep autoencoder is used for learning efficient encoding or dimensionality reduction for a set of data. It is a non-linear feature extraction method classified as generative. Deep architecture, consisting of both pretraining and fine-tuning stages in its parameter learning, is classified as a hybrid. The concept of stacking, where simple modules of functions are composed first and then they are "stacked" on top of each other in order to learn complex functions, is classified as discriminative [13].

Algorithm-level noise tolerance can be leveraged to simplify underlying hardware requirements. Noise tolerance can lead to a co-optimized system that achieves significant improvements in computational performance and energy efficiency. Deep networks can be trained using only 16-bit wide fixed-point number representation using stochastic rounding with little degradation in classification accuracy [14].

Deep learning methods have dramatically improved the state-of-the-art speech recognition, visual object recognition, object detection, and many other domains, such as drug discovery and genomics. Deep convolutional nets have brought about breakthroughs in processing images, video, speech, and audio; whereas, recurrent nets have shined the light on sequential data, such as text and speech. Deep learning has beaten other machine-learning techniques by predicting the activity of potential drug molecules, analyzing particle accelerator data reconstructing brain circuits, and determining the effects of mutations in non-coding DNA on gene expression and disease. The 2012 ImageNet competition success has brought about a revolution in computer vision. ConvNets are now the dominant approach for almost all recognition and detection tasks. ConvNets also enhanced human performance on some tasks. The combination of ConvNets and the recurrent net modules generate stunning demonstrative image captions [15].

Cross modality feature learning can achieve a better feature for one modality (e.g., video) if multiple modalities (e.g., audio and video) are present at the feature learning time [16]. Ngiam, et al. [16] presented a series of tasks for multimodal learning showing how to train deep networks to learn features that address these tasks. These models were validated on the CUAVE and AVLetters datasets on audio-visual speech classification, demonstrating the best published visual speech classification on AVLetters and effective shared representation learning. Learning a canonical correlation analysis (CCA) with a shared representation of raw data results in a good performance. Learning the CCA representation on the first layer results in a significantly better performance compared to the original modalities for supervised classification.

Papernot, et al. [17] formalized the space of adversaries against deep neural networks (DNNs) and introduced a novel class of algorithms to craft adversarial samples based on a precise understanding of the mapping between inputs and outputs of DNNs. This experiment formally described a class of algorithms for crafting adversarial samples misclassified by DNNs using three tools: the forward derivative, adversarial saliency maps, and the crafting algorithm. These tools were applied to a DNN and used for a computer vision classification task: handwritten digit recognition. The crafting algorithm can reliably produce samples correctly classified by human subjects but misclassified in specific targets by a DNN with a 97% adversarial success rate while only modifying on average 4.02% of the input features per sample.

B. Deep Learning in Medical Images

Brosch and Tam [18] described a novel method called multi-scale structured convolutional neural networks (MS-CNN) for learning the manifold of 3D brain images. The method does not require the manifold space to be locally linear, and it does not require a predefined similarity measure or a prebuilt proximity graph. This manifold learning method was based on deep learning, a machine learning approach that uses layered networks (called deep belief networks, or DBNs). The authors proposed a computationally efficient training method for DBN. The proposed method performed manifold learning by reducing the dimensionality of the input images using a DBN. This method used deep learning to discover patterns of similarity and variability within a group of images. The learned manifold coordinates captured shape variations of the brain that correlated with demographic and disease parameters. The MS-CNN algorithm was much more efficient than traditional, convolution-based methods,

Plis, et al. [19] used deep learning to analyze the effect of parameter choices on data transformations. The authors demonstrated their results in the application of deep learning methods to structural and functional brain imaging data. They also described a novel constraint-based approach to visualize high dimensional data. These methods included deep belief networks and the building block of the restricted Boltzmann machine. The main goal was to validate the feasibility of this application by: (1) investigating if a building block of deep generative models a restricted Boltzmann machine, (2) examining the effect of the depth in deep learning analysis of structural magnetic resonance imaging (MRI) data, and (3) determining the value of the methods for discovering the latent structure of a large-scale. Deep learning has a high potential in neuroimaging applications. The depth of the DBN helped classification and increased group separation. DBNs have a high potential for exploratory analysis.

Payan and Montana [20] used deep learning methods, sparse autoencoders, and 3D convolutional neural networks to build an algorithm that can predict the disease status of a patient based on an MRI scan of the brain. This study demonstrated that the 3D convolutional neural networks outperformed several other classifiers. The authors compared the performance of 2D and 3D convolutional networks. This study took a two-stage approach. The authors used a sparse autoencoder to learn filters for convolution operations, and then built a convolutional neural network in which the first layer uses the filters with the autoencoder. The 3D approach had a superior performance for the 3-way comparison. The 3D approach had the potential to capture local 3D patterns, which may boost the classification performance, albeit only by a small margin.

Deep learning has been applied to medical images and demonstrates promising results in multiple instances including computerized prognosis for Alzheimer's disease [21], tumor segmentation [22], and histopathological diagnosis [23, 24]. Neuroimaging analysis is oftentimes employed to improve diagnostic abilities; furthermore, deep learning models and methods are being increasingly utilized to discover patterns and

rules within patient data as seen in [25-28]. The implementation was done for this classifier using a deep neural network initialized by a DBN (DBN-DNN).

Pinaya, et al. [29] trained a deep learning model, known as DBN, to extract features from brain morphometry data. The deep learning models excel at neuroimaging-based prediction methods and can be useful for demonstrating complex and subtle associations, as well as enabling more accurate individual-level clinical assessments. The strength of deep architecture came from multiple levels of non-linear processing that are well-suited to capture highly varying functions with a compact set of parameters. The deep architecture provided superior performance in classification tasks. The DBN highlighted differences between classes, especially in the frontal, temporal, parietal, and insular cortices and in some subcortical regions, including the corpus callosum, putamen, and cerebellum.

Bao and Chung [30] stated that specific architecture is designed to capture discriminative features for each sub-cortical structure. To improve the performance of CNN, two intuitive ways are generally utilized. Apart from the straightforward enlargement of network architecture, some elegant micro-structures have also been designed to enhance the capability recently. To evaluate the performance of the proposed method, the comparison with other methods has been carried out. As several different voxel resolutions exist in each dataset, affine transformations between atlases and the target image were first conducted as pre-processing. The initial structural surface used in label consistency (Blue Curve at Iteration 0) was generated by fusing the warped label maps with majority voting (MV). The results of MV were also employed as a baseline for comparison. The results indicated that, with a multi-scale strategy, more discriminative features can be captured, and the labeling result can be improved. Due to the lack of constraints among testing patches, embracing learning method alone often led to a rough boundary and desultory segmentation result. Experimental results demonstrated that the proposed method obtained a better performance as compared to other state-of-the-art methods.

de Brebisson and Montana [31] proposed a methodology based on a deep artificial neural network that assigned each voxel in an MR image of the brain to its corresponding anatomical region. The inputs of the network captured information at different scales around the voxel of interest: 3D and orthogonal 2D intensity patches captured a local spatial context while downscaling large 2D orthogonal patches and distances to the regional centroids enforce global spatial consistency. The combined use of three 2D orthogonal patches dramatically improved the segmentation performance compared to 2D or 3D patches. The distances to centroids, in addition to their invariance qualities, significantly outperformed the coordinates. For already manually segmented brains, using estimated centroids yield equivalent results as using the true centroids. It has a mean dice coefficient of 0.725 and an error rate of 0.163 when evaluated on the 20 testing MRIs of the MICCAI challenge. Good validation results were

obtained by training huge networks, sometimes composed of tens of millions of parameters, with a relatively small amount of data. The trained networks overfit the training data; however, they still generalize fairly well to unseen MRIs.

Chen, et al. [32] explored the deep residual learning on the task of volumetric brain segmentation. First, they proposed a deep voxelwise residual network, referred to as VoxResNet. Second, an auto-context version of VoxResNet is proposed by seamlessly integrating the low-level image appearance features, implicit shape information, and high-level context together for improving the volumetric segmentation performance. The results of combining multi-modality and auto-context information give more accurate results visually than only multi-modality information. The proposed algorithm has an application beyond brain segmentation, and it can be applied in other volumetric image segmentation problems.

Choi and Jin [33] developed a fast and accurate method for the striatum segmentation using deep convolutional neural networks (CNN). The delicate segmentation process performed by Local CNN used small portions of the image rather than the whole image. This method suggested that FreeSurfer segmentation included slightly more true-positive voxels and much more false-positive voxels than the CNN-based approach, which resulted in lower Dice Similarity Coefficient (DSC). This approach depended on training using manual segmentation, another recently developed automatic segmentation tool based on multimodal images (MIST), did not require a manually labeled training set, which could be flexible for various types of data.

III. BACKGROUND

A. Single Neural Network

The basic unit of every single network is the neuron. This basic unit is also known as a node. The main computational principle of a neural network is that it receives inputs from any external sources and generates an output.

Fig. 1: Single Neuron

Each input has an associated weight which is assigned based on its source, as shown in Fig 1. The node applies a function to the weighted sum of the input. The function that is used for calculating output is called the activation function. The above network, shown in Fig. 1, contains 2 input nodes X_1 and X_2 . The associated weights are W_1 and W_2 . There is another input with weight 1 and value b , which is known as bias.

The output of this neuron is calculated as shown in Fig. 1. The function used to calculate the value of the neural network is known as the activation function. This function is a non-linear function, which is used for introducing the non-linearity to the output of the neural network. According to most of the real-world dataset, the inputs are discrete and non-linear, and our main target is to train our network with this non-linear representation.

Every activation function takes a single number and performs a specific fixed mathematical operation [34]. There are several activation functions that can be used based on the input of the neural network.

B. Feed Forward Neural Network

The feed forward neural network was the first and simplest type of artificial neural network devised [35]. This network model contains multiple basic units referred to as nodes arranged in layers, followed by the same type of adjacent layer. Nodes from adjacent layers have a connection between them, but nodes from the same layer have no connection among them. These connections are called edges. Each adjacent edge has an associated weight with it.

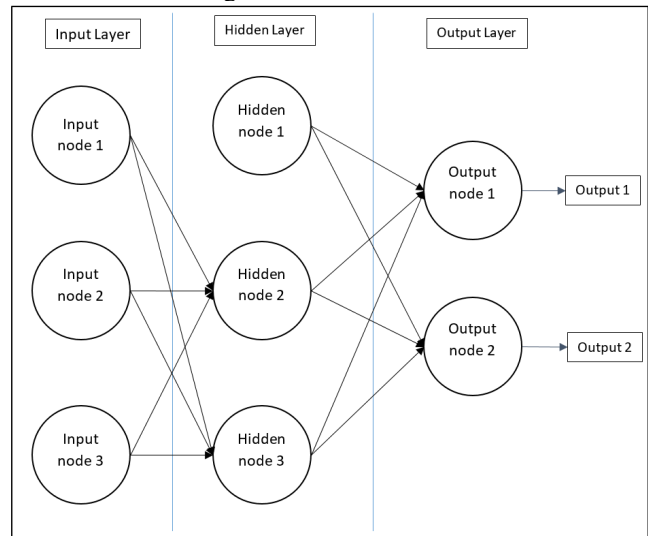

Fig. 2: Feed Forward Neural Network

There are three types of node layers in a feed forward neural network. These are: 1) input nodes, 2) hidden layers, and 3) output node. Three types of nodes in a network are shown in Fig. 2.

- 1) **Input layer:** The input nodes gather the information from the outer world. The combination of input nodes is known as the input layer. These nodes are primarily responsible for receiving inputs from the dataset. No computations are performed in this layer.
- 2) **Hidden Layer:** Hidden layers are those that take inputs from the previous input layer. For each input layer, first, the input and weight of the connections are multiplied, and then all the input weight multiplication products are summed up. After that, the result of the summation is put through an activation function and the output is forwarded

to the next layer. Equation (1.1) shows the output calculation for each node [4]. Here, the function in equation (1) is called an activation function.

$$f(\text{summation}) = f(w_0 * 1 + W_1 * X_1 + W_2 * X_2) \quad (1)$$

- 3) **Output Layer:** The output nodes also works the same way as the hidden nodes. These nodes take inputs from the previous hidden layer. For each output node, they first take the multiplication of the output of the previous node and the weight of the connection. Then, they sum up the multiplication results of all connections and put the summation on an activation function. The final step is to publish the outcome of the activation function as the output of the network.

C. Activation Function

Sigmoid: Equation (2) shows the sigmoid activation function. This takes a real value input and returns a value between 0 and 1.

$$\sigma(x) = \frac{1}{1 + e^{-x}} \quad (2)$$

Tanh: Equation (3) shows the Tanh activation function. It takes a real value input and returns a value between -1 and 1.

$$\tanh(x) = 2\sigma(2x) - 1 \quad (3)$$

ReLU: ReLU stands for Rectified Linear Unit. It takes a real value input and thresholds it between the max and cuts the negative values to 0. Equation (5.4) shows the ReLU activation function.

$$f(x) = \max(0, x) \quad (4)$$

Softmax: The softmax activation function turns the numbers into possibilities that sum to one. Softmax activation function changes the outcomes to a vector, which represents the probability distribution of a list of potential outcomes. Equation (5) shows the sigmoid activation function [4].

$$S(x_i) = \frac{e^{x_i}}{\sum_{j=1}^k e^{x_j}} \quad (5)$$

D. Back Propagation

1) Calculating the Total Error

Once the result for each output node is obtained, the next goal is to calculate the error for each node. It can calculate the error for each output node using the squared error function and sum them to get the total error. Equation (6) shows how to calculate the error for back propagation. Here, target is the expected value from the output node, and actual is the calculated result after forward propagation using the activation function.

The goal with back propagation is to update each weight of the network connections, so they cause the actual

output to be closer to the target output. This helps minimize the error of each node and the network as a whole.

$$Error_{total} = \sum \frac{1}{2} (\text{target} - \text{actual})^2 \quad (6)$$

E. Reducing Loss

Gradient Descent: Calculating the loss function for every single input is not a very efficient approach to find the convergence point. The convex problems have only one minimum data place where the slope is exactly 0. That is the minimum function where the loss function converges. The best approach to obtain the convergence point is called the gradient descent. The first step is to pick a random number between 0 and 1. The gradient descent algorithm then calculates the gradient of the loss curve at the starting point. Something that should be noted is that our gradient needs to have the property of moving both forward and backward. So, we pick our gradient as a vector, which has both direction and magnitude. The gradient always points towards the increase of the loss function. The gradient descent algorithm takes a step in the direction of the negative gradient in order to reduce loss as quickly as possible.

Stochastic Gradient Descent: In gradient descent, the whole dataset on a single iteration is not used. Only a certain amount of data at a single time, making it flow through the network and calculating the gradient is used. This a single iteration. When the dataset is large, then a single portion of data may take a long time to complete computation. A large dataset with randomly sampled examples probably contains redundant data. In this case, a large amount of data is certainly not carrying much productive value. The stochastic gradient descent uses only a single example per iteration from the dataset to calculate the gradient descent. The term stochastic indicates that one data example data is picked randomly per iteration.

An artificial neural network is a machine learning computational model. This model is inspired by the biological neural network in the human brain. This model processes the information the same way the human brain processes the information. Artificial neural networks brought some breakthrough in machine learning research. Some of them are image recognition, computer vision and text processing.

IV. METHODOLOGY

The deep learning network depends on multiple parameters that is useful for tuning our network. These parameters help to increase the performance of the model, reduce the memory allocation and training time. These parameters are: 1) batch size, 2) number of epochs, and 3) learning rate.

The batch size determines the number of inputs that is fed into the deep learning network for one iteration. The batch size depends on the memory of the machine. When the batch size is too high, it consumes a lot of memory.

The number of epochs determines how many times the whole input set is fed to the neural network. Thus, if there

is an increase in the number of epochs, then the accuracy of the network will increase.

Finally, the learning rate determines how frequently the deep learning network changes decision. If the learning rate is too high, then the deep learning network changes decisions very frequently. In most cases, a high learning rate doesn't bring any drastic changes to the accuracy. Also, a low learning rate may take too long to make a change in decision.

The goal of this research is to examine the following hypotheses:

H₁: The batch size is inversely proportional to the network accuracy. If we increase the batch size, then accuracy is decreased.

H₂: The accuracy of a deep learning network is directly proportional to the number of epochs it passes through.

H₃: Lower and higher learning rate do not bring any change to the network. The network performs best within a preferred learning rate

A. Dataset Description

This research utilized the dataset from Kimia Path24 [3]. This dataset has a total of 22,591 training images from 24 different categories. This dataset has a total of 1,325 testing images that include all categories. The image size is 1000 x 1000 for all the images.

B. Data Preparation

The Keras library from python was used to build the neural network. First, the image was loaded using the OpenCV library and then resized the image to 28 x 28. Then, the dataset was divided into two parts: 1) training and 2) testing. The training set contained 75% of the data, and the testing set contained 25% of the data. The testing set is used for validating the network. The labels were converted from integer to vectors and data augmentation was performed. The rotation range was set to 30, width shift range to 0.1, height shift range to 0.1, shear range to 0.2, zoom range to 0.2, horizontal flip to true, and fill mode to nearest.

C. Building Network Model

After completing the data augmentation, the neural network was built. Fig. 3 contains the code snippet of the neural network. Our deep learning model contains 3 convolution networks. A small portion of the convolution layer is used as the input of each node, and the size of the small portion is often 3 x 3 or 5 x 5 [36]. The activation function is the rectified linear unit followed by a flat layer, and finally, two dense layers. The first layer has the activation function rectified linear unit (ReLU) and the output layer has the softmax. The softmax helps to keep the output between zero and one. Next, the adam optimizer was set with a learning rate of 10⁻³ and the model with a batch size of 32, the number of epochs as 25 was set.

```
class LeNet:
    @staticmethod
    def build(width, height, depth, classes):
        # initialize the model
        model = Sequential()
        inputShape = (height, width, depth)

        # if we are using "channels first", update the input shape
        if K.image_data_format() == "channels_first":
            inputShape = (depth, height, width)

        # first set of CONV -> RELU -> POOL layers
        model.add(Conv2D(20, (5, 5), padding="same",
            input_shape=inputShape))
        model.add(Activation("relu"))
        model.add(MaxPooling2D(pool_size=(2, 2), strides=(2, 2)))

        # second set of CONV -> RELU -> POOL layers
        model.add(Conv2D(50, (5, 5), padding="same"))
        model.add(Activation("relu"))
        model.add(MaxPooling2D(pool_size=(2, 2), strides=(2, 2)))

        # Third set of CONV -> RELU -> POOL layers
        model.add(Conv2D(64, (5, 5), padding="same"))
        model.add(Activation("relu"))
        model.add(MaxPooling2D(pool_size=(2, 2), strides=(2, 2)))

        # first (and only) set of FC -> RELU layers
```

Fig. 3: Building Deep Learning Neural Network with Keras

D. Training the Model

After setting all the parameters, we ran the model with the fit_generator. Then, we saved the model and the learning curve plot with loss, accuracy, validation loss, and validation accuracy.

E. Tesingt the Model

After we finished training our model, we used a different script to test the model. We loaded the saved model and ran the prediction methods with the test data and generated the confusion matrix to find the accuracy, recall, precision, and f1-score.

V. RESULTS

The change of accuracy with respect to the batch size is displayed in Table 1. From the table, we can see that the accuracy decreases when we increase the batch size, which is satisfying our first hypothesis. Fig. 4 shows that the decrease in accuracy is linear with respect to the batch size.

TABLE 1. CHANGE OF ACCURACY WITH BATCH SIZE

Epoch	Batch size	Learning rate	Accuracy
50	16	0.001	0.6491
50	32	0.001	0.6204
50	64	0.001	0.5585
50	128	0.001	0.4989
50	256	0.001	0.4777
50	512	0.001	0.4438
50	1024	0.001	0.4513

Fig. 4: Change of Accuracy with Batch Size

The change of accuracy with the change of epoch is displayed in Table 2. From the table, we can see that the accuracy increases with the number of epochs, which satisfies our second hypothesis. Fig. 5 shows that the accuracy is not linearly correlated with the number of epochs when the value is small. With a larger epoch size, the accuracy increases linearly with respect to the number of epochs.

TABLE 2. CHANGE OF ACCURACY WITH NUMBER OF EPOCHS

Epoch	Batch size	Learning rate	Accuracy
10	32	0.001	0.5668
15	32	0.001	0.5970
25	32	0.001	0.5298
35	32	0.001	0.6128
50	32	0.001	0.6204
70	32	0.001	0.6491
100	32	0.001	0.6732

Fig. 5: Change of accuracy with number of epochs

From Table 3, we can see that the accuracy increases when we increase the learning rate from 0.1 to 0.001. Then after 0.005, the accuracy starts decreasing. At the learning rate of 0.0001, the accuracy is 45.6%, which is less than the accuracy of the learning rate of 0.001 (61.9%). The accuracy starts decreasing after the learning rate of 0.0001. This experiment validates our third hypothesis that the higher learning rate and lower learning rate do not always bring better changes to the accuracy.

TABLE 3. CHANGE OF ACCURACY FOR LEARNING RATE

Epoch	Batch size	Learning rate	Accuracy
50	32	0.1	0.0528
50	32	0.05	0.0302
50	32	0.01	0.0566
50	32	0.005	0.5925
50	32	0.001	0.6189
50	32	0.0005	0.6272
50	32	0.0001	0.4558

Fig.6: Change of Accuracy for Learning Rate

Fig. 6 shows the change in accuracy, with respect to learning rate. The relation between learning rate and accuracy is not linear. The accuracy does not increase or decrease linearly with the change in learning rate.

VI. DISCUSSION

In this experiment, we have done an empirical study of image processing with deep learning. We have conducted the experiments on the KIMIA path24 dataset. We have simply designed the architecture and used the feature selection. The image processing mechanism was used for manipulating the dataset. We have used rotation, width shifting, height shifting shear range, horizontal flip, and fill mode. The network was trained and validated by a total of 22,591 images from the KIMIA path24 dataset. The running time of the network was 6-7 hours depending on the parameters. We used a Google collaboratory training environment equipped with two core Intel's @2.3 GHz Xeon processor with a NVIDIA Tesla K80 (GK210 chipset) [37].

In this experiment, we used two serial 2-dimensional CNN architectures for segmentation. We used ReLU for the convolution layer and softmax for the fully connected layer. During the compilation, we used the adam optimizer and set loss to binary_crossentropy. The learning rate, the batch size, and the number of epochs was set according to hypotheses testing.

As a limitation of our experiment, various types of network architecture for the segmentation are possible. As

proof of the concept to test those hypotheses of our deep learning network parameter, the structure of the architecture was empirically designed after studying the image prototype. An adjustment of our proposed network, including the number of convolution layers, the number of nodes, the activation function, and other parameter upgrades, are possible. As a future work, an optimization of the network architecture and the parameter upgrades could increase the runtime and improve the performance. As our architecture and other parameters were set to test those hypotheses against the KIMIA path24 dataset, this design can be optimized and retrained for other image datasets.

One of the issues of the deep convolutional neural network is sample images. The number of images required to test and validate the network is not always available. The scale of the medical data available for studies is insufficient for machine learning and computer vision. This can affect the performance of deep learning for medical data [38]. In general, the convolutional neural network requires a large number of training data for each specific category. In our current dataset, we have a total of 24 categories. Some categories have more than 1,000 images for training, whereas few categories have less than 100 images for training and validation. These categories decline in accuracy and affect the overall performance. Using a proper dataset for all categories can improve the performance and provide more degree of freedoms.

VII. CONCLUSION

In this experiment, we built a simple deep convolutional neural network and conducted hypothesis testing on three hypotheses on the Kimia Path24 dataset. 2D convolutional neural networks were used for image classification. Our three hypotheses were proved correct. We used an image feature selection and image processing mechanisms for moderating the dataset. The parameter tuning and network structure designs provide essential outcomes, which ensures the credibility of our model.

Abstract — In the present work, a biomechanical prosthesis with the acquisition of EMG signals will be designed for patients who have lost their right upper extremity due to a transradial forearm amputation, with a short stump before the elbow and an affected psychological factor. For these reasons, the EMG signal acquisition circuit will be designed from operational amplifiers (OPAMPs), which will obtain, filter, and amplify the electromyographic signals acquired from the stump and encoded on the Arduino nano board. being these used to perform the main movements with Maxon motors of pronation and supination in the biomechanical wrist, as well as the movements of the fingers to release and grab an object of the biomechanical hand, where the motor stops turning when it grabs an object if it meets the thermoresistor included in the tip of the index finger. Then, this research will serve for the development of right upper limb prototypes that have the same morphology and modeling of this biomechanical prosthesis, to improve the quality of life of patients who, due to this type of amputation, have been affected in their motor capacity. and psychological.

Keywords—*Biomechanical prosthesis, transradial forearm amputation, EMG, OPAMPs, motor capacity.*

I. INTRODUCTION

Today people are suffering various very severe accidents in their daily lives, which may have repercussions in the not so distant future or at that very moment, they may already lose some part of their body as a result of these incidents, is this, that many times doctors and surgeons come to have the decision to amputate the affected limb and if it is from the forearm to the hand, the so-called "transradial forearm amputation" will be performed, which is a type of amputation where "the extirpates the upper limb from the union between the middle third and the distal third of the forearm, leaving a small stump at the end of the amputated part" [1], therefore this amputation is the most frequent, since "Within of major upper-limb amputations, transradial amputation and radiocarpal disarticulation are performed in about 35% of surgical interventions" [2].

However, sometimes, when patients learn of the loss of their upper limb, they can be psychologically affected by this new lifestyle that they have to live, because "The amputation of an upper limb at any level will have repercussions decisive in the life of the person and most cases it will be unexpected, causing serious functional, aesthetic, psychological and socio-occupational repercussions" [3], then it must be taken into account that a patient who has come out of an intervention surgery like this, apart from having motor deficiencies, it will

be psychologically affected in his daily life, "making prosthetic devices fall into the so-called Uncanny Valley, which can be defined as a feeling of strangeness and non-belonging that users have when they see or use a device that is very similar to something human but that behaves unexpectedly" [4].

Therefore, the objective of this article is to design a biomechanical prosthesis with EMG signal acquisition for patients who have lost their right upper extremity due to a transradial forearm amputation, therefore, by leaving a small stump before the elbow, it is known that "a myoelectric prosthesis is very influential in a transradial level amputation because it makes a greater functional contribution" [2], then this circuit will be composed of operational amplifiers OPAMPs, which by obtaining the various electromyographic signals emitted by the muscles of the forearm, they will carry out various filtering stages to obtain a completely clean and functional signal.

For the acquisition of the EMG signals, a certain process must be followed to obtain them, since "the EMG signals are captured by electrodes on the surface of the skin and are generated by the contraction of the muscles, they range between 5 to 20 mV, and require a signal filtering and amplification system" [5], therefore, it begins with the first stage of initial amplification, where a gain for the input signal will be determined, then in the second stage a Notch filter will be performed, in which the noise in the input signal is rejected, as a third stage, a bandpass filter was used to attenuate the signals that exceed the established frequency ranges, so that the final amplification of the signal is then carried out without inverting it and therefore, as the last stage Offset was established for the interaction of the EMG signals and the Arduino Uno board, achieving the main movements in the biomechanical wrist of pronation and supination. and the finger movements of releasing and grasping an object of the biomechanical hand.

Being for this reason, that in this way it will be possible to support the patient to improve his motor capacity when using the biomechanical forearm prosthesis daily with the acquisition of EMG signals and when presenting an aesthetic finish, it will be able to function normally in his daily life without being affected. for a psychological factor.

II. MATERIALS AND METHOD

For the development of the biomechanical prosthesis, various materials will be used within its structure and composition whose main characteristics are light, resistant,

flexible, and easy to find today, therefore, the materials that are recommended for use in The construction of prostheses are like our prototype must be thermoplastic sheets, silicone, linings, and covers, which will be used in various parts of our biomechanical prosthesis, as described below:

1. Nylon Filament (Polyamides):

This filament is going to be used in 3D printing of the biomechanical hand and forearm since this material is made up of semi-crystalline structures, in addition to this, the filament has a good balance of chemical and mechanical characteristics that offer good stability, rigidity, flexibility, shock resistance and offers a high level of detail.

- Fingers of the hand: The design of each of the fingers (see Fig. 1), was made from the anthropometric measurements obtained, through the following Table I:

TABLE I. AVERAGE VALUES AND DEVIATION OF THE LENGTH OF THE PHALANXES OF THE ADULT HAND

	Phalanx lengths (mm)		
	Proximal phalanx	Medial Phalanx	Distal Phalanx
Little finger	37 ±10	23 ±5	20 ±3
Cancel	45 ±11	30 ±6	23 ±3
Means, medium	57 ±13	37 ±8	26 ±2
Index	50 ±11	32 ±7	25 ±3
Thumb	43 ±6	NA	32 ±4

Fig. 1. 3D design in AutoCAD of the five fingers of the biomechanical hand – Type of view: X-Ray

- Hand: Developing the 3D modeling of the hand (see Fig. 2), was made from the data obtained from the following Table II:

TABLE II. HAND AND FOOT DIMENSIONS OF ADULT MEN AND WOMEN

		I	J	K	L
95	in.	8.07	4.63	3.78	9.11
	cm.	20.5	11.8	9.6	23.1
5	in.	7.00	3.92	3.24	7.89
	cm.	17.8	10.0	8.2	20.0

Fig. 2. Hand and foot dimensions of adult men and women, in inches and centimeters, according to percentile selection, with data from (Binvignat et al., 2012)

Fig. 3. 3D AutoCAD design of the palm and screw-type socket for the biomechanical wrist – View Type: X-Ray

- Forearm joint: Developing the 3D modeling of the forearm (see Fig. 4):

Fig. 4. AutoCAD 3D design of the forearm and accessories for biomechanical wrist movement – View Type: X-Ray and Realistic

2. Polyethylene plates:

This type of material will be used in the connection of the prosthesis with the stump, since having a low density it is a soft and flexible thermoplastic, which can be remodeled by applying hot air to achieve the necessary temperature in the

pressure area that is you want to shape it into a socket for the biomechanical prosthesis.

Fig. 5. AutoCAD 3D drawing of the forearm junction and residual limb socket – View Type: X-Ray

3. Silicone - Type Iceross 3S:

It is going to be used as a filler material since it has resistance to humidity, radiation, and ozone, in addition to that, it has great resistance to compression deformation, therefore, a suspension system for the socket will be developed. silicone suction for gripping the prosthesis with the stump.

4. Lining -Pelite:

This material is going to be used as a soft socket for the contracting limb since it is a closed-cell polyethylene foam material available in various durometers, which can be molded in a plaster mold with heat to make a better fit. residual limb comfort.

5. Sheath – Latex, and nylon:

The nylon sheath will be used outside the prosthesis for a more aesthetic finish by coloring the prosthesis according to the patient's skin type and the latex sheath will be used to provide suspension, since being a sheath non-porous, the suspension will be achieved by a combination of suction and mechanical friction between the stump and the prosthesis socket.

6. 3D design of the forearm prosthesis:

Fig. 6. 3D design in AutoCAD of the reinforced forearm prosthesis – Type of view: Realistic

On the other hand, within the prosthesis, the use of a silver-silver chloride electrode will be taken into account due to its availability, non-invasiveness, and ease of use, since it will be located in the muscle called flexor carpi radialis to perform the main movements in the biomechanical wrist of pronation and supination, utilizing a Maxon 12 mm DCX motor, which is

considered the most suitable actuator for this type of prosthesis, since its movements are carried out without jerks, in addition to presenting high power densities, a wide range of speed values and a long useful life.

Besides, a thermoresistor was used in the tip of the index finger for the control and displacement of the fingers of the biomechanical hand, concerning the signals received and encoded from the voice interface through the Nano Arduino board, these movements are performed by another Maxon 12 mm DCX motor, which according to the rotation mode will be doing the movements of the fingers to release and grasp an object employing industrial rubber bands, used for their high resistance to deformation and a very influential elasticity constant for this type of work.

Fig. 7. 3D design in AutoCAD of the reinforced forearm prosthesis – Type of view: X-Ray

III. EMG SIGNAL ACQUISITION CIRCUIT

To develop the EMG signal acquisition circuit, it was made from OPAMPs and calculations mathematical, to determine the gains that we want, thus being able to estimate the values of both the resistors and the capacitors that are going to be included and the cutoff frequencies determined for the various filters that are going to be used, for which it is going to divide to the circuit into six stages, which will be represented in a flow chart.

- **First Stage, Initial Amplification:** As is known, "the amplitude of the EMG signals (electromyography) varies from μV to a low range of mV (less than 10 mV)" [6], therefore, to perform good filtering in the following stages of the circuit and there is not much distortion in the input signal, an instrumentation application stage was carried out, which was done with a Gain (G) of 100. Then, to calculate the gain resistance (R_{G1}), the following formula was used:

$$G = \frac{49,4K\Omega}{R_{G1}} + 1 \tag{1}$$

Using (1), the value of the resistance gain is equal to 498.98 Ω .

- **Second Stage, Notch Filter:** It is designed to reject a frequency that interferes with the circuit, since "myoelectric signals are of low value, noise, or artifacts such as ambient noise or, to a greater extent, line noise (50Hz – 60Hz) can cause a false interpretation of the results" [6], therefore, this filter will reject frequencies of 60 Hz using a cut-off resistor:

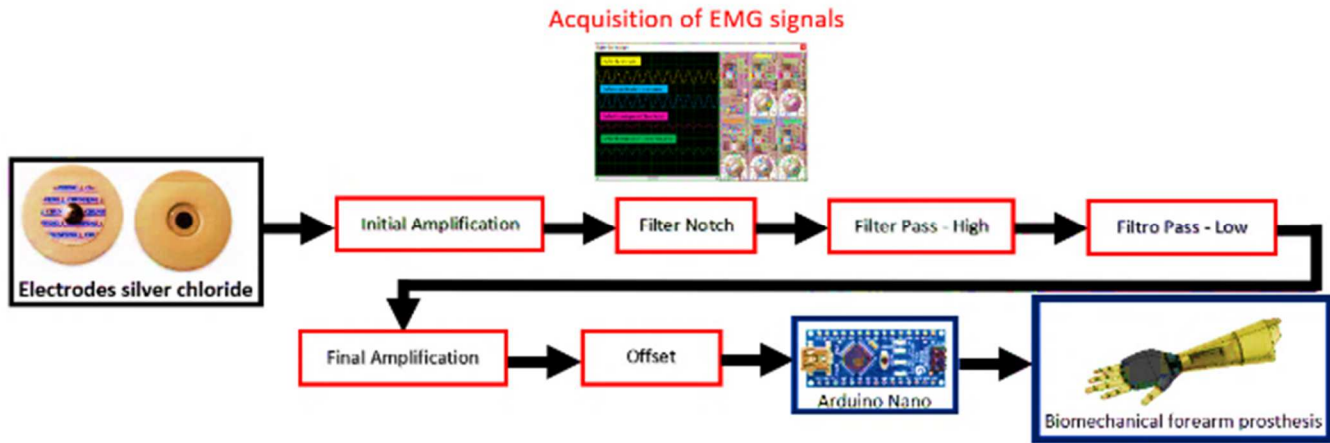

Fig. 8. Flow chart for the acquisition and acquisition of EMG signals for the biomechanical forearm prosthesis

$$F_c = \frac{1}{2\pi RC} \tag{2}$$

Knowing the cutoff frequency (Fc) is 60 Hz, a value of 100 nanofarads (C) is assumed for the two capacitors. Using (2), the values of R₂ and R₃ are 26.52KΩ.

- Second Stage, Bandpass filter:** Here you have to take into account that a “Clean” EMG signal must be obtained, therefore, a bandpass filter will establish a certain range of frequencies and attenuate the rest, since a bandpass “Allows the passage of frequencies between two frequencies ω₁ and ω₂ (ω₁ < ω₂), called lower cutoff frequency and upper cutoff frequency, blocking the rest”[8], then a “ Sallen-Key ” arrangement for this filter would be very valuable due to its simplicity and being established as second-order, not too much noise is generated and with a Butterworth type curve the Butterworth type frequency (Q) was determined, Q = 0.7071.
- Third Stage, High-pass filter:** In this stage, the caps let the high frequencies pass and the resistors are the ones that absorb the low frequencies, having a cutoff frequency (Fc) of 5Hz of Butterworth type and second-order.

$$K = 3 - \frac{1}{Q} \tag{3}$$

To obtain the value of the filter gain (K), in (3) was used which indicates that the value of K = 1.5858. Considering a value of R₅ as 1KΩ.

$$K = \frac{R_5}{R_6} + 1 \tag{4}$$

Using (4), the value of R₆ is 585.8Ω. Knowing the cutoff frequency (Fc) is 60 Hz and the value of 1 nanofarad (C). Using (2), the value of R is 31.831KΩ.

- Fourth Stage, Low-pass Filter:** In this stage, the opposite happens, the resistors allow the low frequencies to pass, and the capacitors are the ones that absorb the high frequencies,

having a cutoff frequency (Fc) of 1.3 kHz and a Sallen-Key arrangement of second-order and Butterworth type.

The value of the filter gain (K) is 1.5858 in (3). Considering a value of R₁₁ as 680Ω in (4), the value of R₁₂ is 394.34Ω. Knowing the cutoff frequency (Fc) is 1.3 KHz and the value of 1.2KΩ (R). Using (2), the value of C is 0.102 nanofarads.

- Fifth Stage, Final Amplification:** For the final amplification stage in the calculation, all the resistances found in the circuit will be needed, and a gain according to it, using a non-inverting amplifier, since it does not want the signal waves to be inverted and it determines the resistance that will be used for the gain.

Considering a value of R₁₄ as 10KΩ in (4), the value of R₁₃ is 3.3KΩ.

- Sixth Stage, OFFSET:** The Arduino is working in a range from 0 to 5 volts, therefore, it is necessary to raise the signal, since this circuit is in a signal of 2.5V in a positive and negative value, for this it will be added to a DC signal, using a potentiometer to introduce 5V to the source and be able to regulate the offset, to the necessary signal, with a gain (G) of 1.

Considering a value of reference resistor (R_f) as 10KΩ, the values of the resistance in parallel (R_p) is 5KΩ and of the design resistance (R_d) is 10KΩ.

Therefore, after having obtained the filtered and amplified EMG signals, they will be transferred from these to the Arduino Uno board, where the voltage ranges will be defined to perform the movements in the biomechanical wrist of pronation and supination, therefore both thanks to the offset, the average voltage that should be exceeded were determined, at the moment that the muscle is contracting and the motor begins to rotate 90° to perform the supination movement, putting the biomechanical hand in a gripping position, therefore, the estimated voltage is 3V or 6mV and in analog value, within the Arduino programming, it was 154.

- H-bridge circuit for Maxon motor:** The main function of this circuit is to allow our Maxon motors to rotate in both directions utilizing BJT transistors and diodes, which will allow the passage of current concerning the digital outputs established by the Arduino Uno board to define the rotation that it wants. and this would be expressed in the following Table III.

TABLE III. Digital values applied to each of the H-bridge inputs

S1	S2	Turn Orientation
1	0	Horary
0	1	Counterclockwise
1	1	Short circuit
0	0	Short circuit

Then, by joining all these simulations, the following EMG signal acquisition circuit would be obtained as a result:

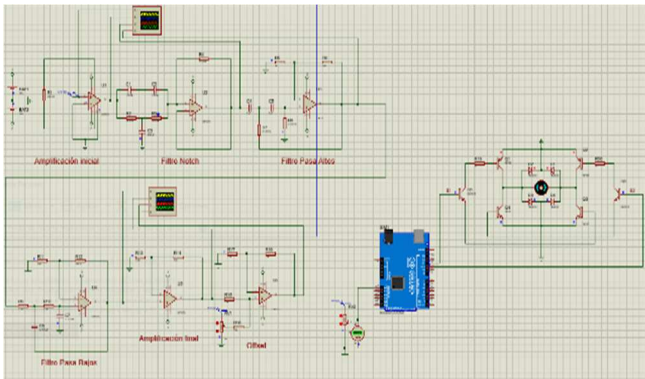

Fig. 9. Design of the entire acquisition circuit processing of simulated EMG signals in Proteus.

IV. DISCUSSION

For a biomechanical design of a prosthesis with the acquisition of EMG signals, it must be considered that “There are two methods to acquire this type of biological signals, the first is the invasive method that requires surgery that involves risks such as pneumothorax, hematoma, and discomfort. The second approach is a non-invasive method or surface EMG.” [9], then by considering the second method as the best approach and incorporating a series of previously stipulated filters into the biomechanical prosthesis, it will be possible to develop more accurate anthropometric movements.

Therefore, the developed prototype managed to analyze the pulses of the stump and amplify them so that they can be analyzed by the microcontroller, this was achieved by using the operational amplifiers that allowed the filter of the pulses since the interference of the environment does not allow an adequate analysis to achieve an appropriate anthropomorphic movement performing proper supination and pronation of the arm, then the correct operation of the following filters can be seen:

- Notch filter:** To attenuate the unwanted signal, the NOTCH filter was used. In one of the tests carried out on this circuit with a signal of 5mV and 60 Hz, it is verified in the red wave, when it is with a frequency of 60 Hz, it was attenuated and therefore the following signals will also be attenuated.

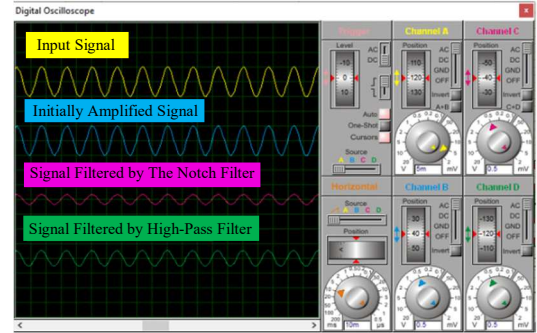

Fig. 10. EMG signals attenuated by the Notch filter and emitted in the oscilloscope simulation in Proteus

- High-Pass Filter:** To attenuate the low-frequency pulses, the High-Pass filter was used, so in this case, a 5 mV and 3 Hz signal was used to test the behavior of this circuit, in the green pulse shown by the oscilloscope such behavior is observed.

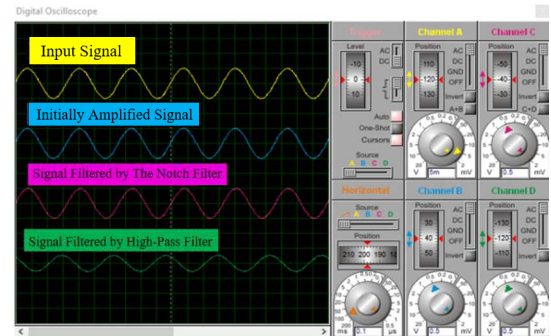

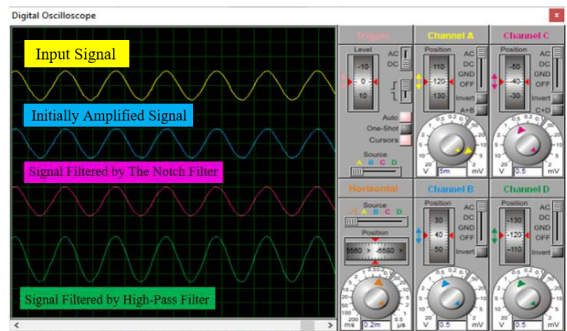

Fig. 11. EMG signals attenuated by the High-Pass filter and emitted in the oscilloscope simulation in Proteus

- Low-Pass Filter:** To attenuate the highest frequencies of the EMG pulses, its low-pass filter behavior was verified by applying a 5mV and 1.6kHz signal and the oscilloscope showed us such behavior in the celestial pulses

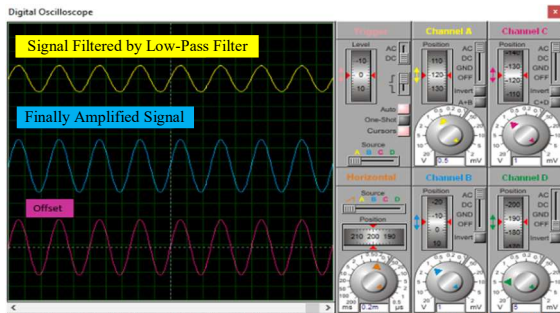

Fig. 12. EMG signals attenuated by the Low-Pass filter and emitted in the simulation of the oscilloscope in Proteus

V. CONCLUSIONS

The acquisition of EMG signals by the forearm prosthesis was established through five stages, the initial amplification stage, Notch filter, bandpass filter, final amplification, and an offset, which together managed to establish filtering optimal for processing these signals on the Arduino Nano board.

The aesthetic design that was used in the forearm prosthesis will allow the patient to restore his psychological state affected by the loss of his right upper limb due to this type of transradial amputation, therefore, the patient will be able to rejoin and carry out his daily life. as if nothing had happened.

This work will undergo possible changes in the future since when this situation improves, EMG signal acquisition tests can be carried out on real patients who have suffered a transradial amputation of the forearm, in addition to this work will be done on the incorporation of a voice interface with IA that will provide the patient with a rapid recovery from the psychological condition suffered by this type of amputation.

Abstract— Recognizing and extracting handwritten character information is still a challenge in the scanning process. This research describes a method for OCR applications where Bengali handwritten characters can be recognized effectively. This method mainly focuses on post processing steps like feature extraction and building classification model to find a favorable accuracy rate. For feature extraction LBP method is used. Local Binary Pattern is a coming of age feature extracting method which is applied very few times in Bengali Language. This work is also an experimental approach of confirming what occurs when LBP is used in Bengali Characters. To classify Random Forest algorithm is applied, which is also a unique classification method. The datasets are gathered by collecting Bengali characters written in various fashions. Initially, scanned images of Bengali characters are given as input and by applying LBP required features are extracted. Principal Component Analysis (PCA) is applied on the collected feature vectors to reduce the dimension. Finally, RF algorithm is implied on the output to generate a recognition rate. Support vector machine (SVM) is also used as a classifier to evaluate and compare.

Keywords—Local Binary Pattern (LBP);Random Forest Algorithm (RF);Feature Extraction;SVM;Principle Component Analysis (PCA)

I. INTRODUCTION

The method of recognizing handwritten input from photographs, documents and other images by computers is known as handwriting recognition systems. There are online and offline hand writing recognition methods. Online is when characters are recognized at the time of writing. In this method, the pen trajectories and direction of movements are recorded by touch pads and later the writing and recorded directions are used to recognize characters or words. But offline method on the other hand is quite hard ,as the trajectories or directions of the cursives are not available to detect characters. To determine offline characters some factors must be considered like: Aspect ratio, Percent of pixels above the horizontal half way point, Percent of pixels above the vertical half way point ,Number of strokes ,Reflected by Y axis , reflected by X axis and distance away from center.. Postal automation, bank cheque, drafting and all sorts of documentation can be made easier by hand writing recognition systems.

Bengali is the seventh most spoken native language in the world with 205 million speakers. Despite that Bengali language has poor number of machine recognizer for its vast database, complex and look alike characters. It consists of 50 basic characters including 11 vowels (Shoroborno) and 39 consonant (banjonborno) characters and 10 numerals. In Bangla, the concept of upper case or lower case letter is not present. Bangla basic characters have characteristics that differ from other languages [1] It has horizontal lines over some characters called “matra” also it has symbolic forms of consonants which are used alongside the consonants. Since the 80’s the journey for inventing an efficient and accurate handwriting recognition system has begun. It achieved a milestone by creating CEDAR-FOX, first automatic writer recognition system. The trials have not stopped since then by the researchers to establish an almost accurate recognizer for most spoken languages. This thesis paper offers post preprocessing method that can recognize Bengali character from an image. It is an effort to better the Bengali recognition system.

As mentioned earlier, after the basic scanning of image, here Local binary pattern known as LBP method is applied for feature extraction. The reason behind choosing LBP is mainly because the texture based classifications have been an eye catcher lately. This research attempts to discover the outcome of LBP as feature extraction method on Bengali Language. Then the extracted features’ dimensions are reduced using Principle component analysis process. PCA is able to take out the core structures of an image and can quicker the execution time. Then, SVM and Random forest algorithm is applied to build a classification model and generate an accuracy rate. Though both the methods are efficient, Random forest algorithm has shown a better upshot than Support vector machine here.

Thus the present section introduces the problem addressed in this research, while literature review is elaborated in the Section II. Methodology is described in section III. The results are presented in Section IV and Section V concludes the paper.

II. LITERATURE REVIEW

Generous amount of effort has been dedicated for robust BHR methods .The known methods are mostly by using neural networking , HMM, etc. Some unique approaches are in the following: MLP based recognition scheme using stroke features for Bangla basic characters by Bhowmik et

al.[2], here, a stroke-feature-based recognition scheme was proposed, where character images are identified and 10 certain features are extracted from each of them. MLP classifier is trained using back propagation algorithm. Respectively, 350 and 90 sample images are used for 50 Bangla basic characters. Bhattacharya et al.[3] also designed a two-stage MLP based recognition system using shape based features with a large dataset, in 2006. A novel multi stage approach by A.F.R. Rahman in 2001[4], the analysis shows the features, how to detect various high-level features might help to formulate successful multistage OCR designs by proposing multistage scheme for the recognition of Bengali handwritten characters. Super imposed matrix for character recognition by Ahmed Shah Mashiyat in 2004[5] was proposed.

In this system, the Bengali text accepted as an image file and after segmented into each character boundary of each character is determined. The characters are then stored in a 32*32 matrix and the matrix is compared with a knowledge base where all recognized character is stored in superimposed form. Finally depending on the similarity, the system recognizes the character and the accuracy.

III. METHODOLOGY

.Fig.1 illustrates the overview of Bengali handwritten recognition procedure.

This research work is form on the post processing method of Bengali character recognition. After preprocessing conduct the scanned character image is taken as input. Then the features are extracted implementing LBP (Local binary pattern) algorithm and for better features PCA (Principle component analysis) is activated which reduce the dimension of the feature vector

For classification process Random forest algorithm is applied which produce a satisfactory accuracy rate. A diagram is given to explain the procedure of this research in a nutshell. Every step is described into 3 phases

1. Pre-processing
2. Feature extraction.
3. Recognition

It is suggested that the procedure with standard datasets can lead to a favorable output for a Bangla OCR system

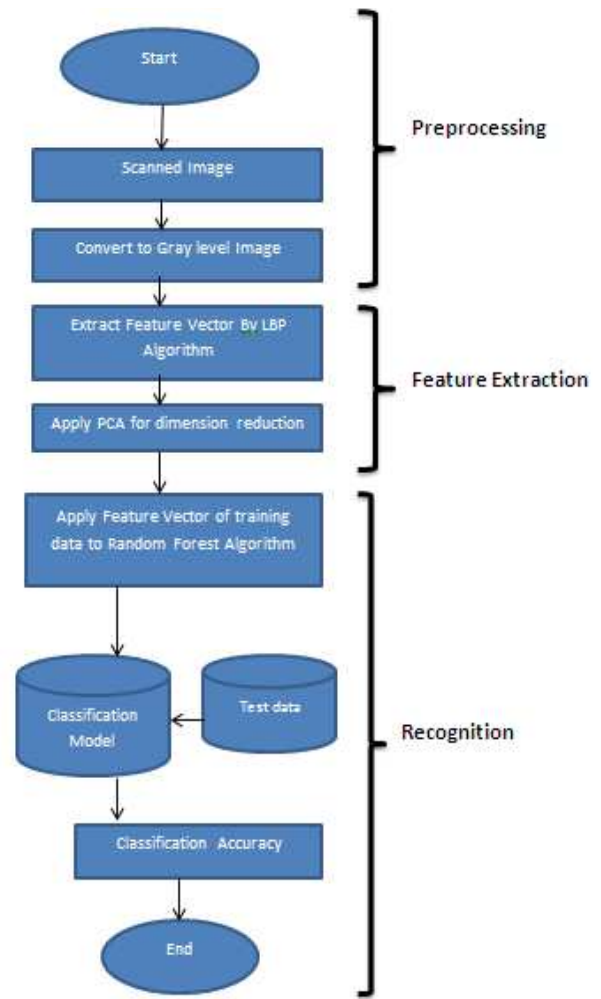

Fig.1.Flowchart of Bangla Handwritten Character recognition

A. LBP

This algorithm is applied here for the required feature extraction phase. It is a method that reconstructs an image into an array that interprets the small scale emergence of the image. Images are possessed of micro patterns and the LBP algorithm works with the uniform patterns of image. The important distinctive of LBP is its heftiness to monotonic gray scale transpose. It is also easy to compute which makes it preferable for real time applications. In this work the basic LBP is applied which works in a 3*3 pixel block by thresh holding its bordering pixel with the value of the center pixel. The output comes into binary 0s that point out the neighboring gray scale value is less than the center value and 1 indicates the opposite. After comparison the binary 8 bit string is converted to decimal number which length is 256, This process is explained with the following mathematical expressions:

IV. RESULTS

A. Datasets

Dataset refers to a collection of images used by researchers to evaluate programs.[11].In this process, the Bengali handwritten character images written in various styles are added and later put into training. Both vowels and consonants are taken also to apply in the system.

The datasets are gathered in a well-organized and systematic manner. Dataset are collected from online Bangla Lekha-Isolated [13], which contains sample images of numeric digits, Bangla characters and compound characters. We used 50 basic Bangla character with 3000 samples of each characters .After preprocessing 1,50,000 handwritten character images were selected. Moreover collection of Bengali characters of different handwriting styles are collected and put into the database. In training phase 70% data are used and 30% are used for validation.

The vowels and consonants have been casted-off separately for recognition. The vowels of Bengali Characters have less differences. So, the classification gets rougher in that zone. The data are tested by choosing random characters and storing them. Later the better given results are taken for observation.

B. Summary of Findings

This paper evaluated the datasets of Bangla handwritten characters by applying into 2 separate classification methods: SVM (support vector machine), Random Forest Algorithm. A Support Vector Machine (SVM) is a discriminative classifier formally defined by a separating hyperplane. In other words, given supervised learning data.[12] the algorithm outputs an optimal hyperplane which categorizes new examples. Support vectors are the data points nearest to the hyperplane, the points of a data set that, if removed, would alter the position of the dividing hyperplane. Because of this, they can be considered the critical elements of a data set. However, like most machine learning algorithms, they are generally applied using a randomly selected training set classified in advance. But in this field so far, the Random forest algorithm has given the most productive results. The foremost reason behind SVM’s poor performance is perhaps the nature of the datasets here. SVM works better with binary classification. In this experiment every character is identified as different classes itself, which is a disadvantage for SVM. On the other hand, RF algorithm’s strongest suit is to work with categorized data.

Fig.4.Some fragments of the Datasets.

Some sample data are given in fig 4 and fig 5.

Fig.5. Some portions of training sets.

Hence, the result has gone in the favor of Random Forest algorithm here. Findings are explained in the following table I.

Table I. Accuracy rate by applying SVM.

Class	Accuracy rate
39(consonant)	60%
11(vowel)	77%

Here, five-fold cross validation for the classifier using the parameters C = 100 and gamma = 0.1

Table II. Accuracy rate by applying RF algorithm

Class	Cross validation	Accuracy Rate
39(consonant)	2	78%
11(vowel)	2	80%
39(consonant)	5	80%
11(vowel)	5	85%

C. Interpretation

Despite having an optimistic consequence, the results could be uplifted with better resolution of the character images, vast samples and different values of cross validations.

D. Comparative Study

Every research has their own collection of data sets. So, comparative analysis does not harvest an evocative outcome. There are pre-conditions like addressing noise detection and cleaning phase in some papers. However, a comprehensive solution for leaving zero noise in images is not obtained yet. In the discussed paper, SVM and Random forest algorithm both are applied as classification method to compare and examine which method produce a better result. Same set of data sets are implied to them and cross validated using number of testing and training sets.

Fig.6. Comparing SVM with RF algorithm for various datasets

Comparison between the SVM and RF algorithm while using same feature extraction and dataset is given above in fig 6.

E. Accomplishments:

The aim of this paper is to assist a OCR system for developing an operative recognition model, and it can be said that, the objective was successfully met. In this effort, a new and completely unique choice of methods is used. Previous works on Bengali character recognitions use methods like HMM (Hidden Markov Model), Free chain code for feature extracting, and ANN (Artificial neural network), MLP (Multi-layer Perception) for classification. But here for feature extraction LBP (Local Binary Pattern) is used and Random Forest Algorithm is used for classification schemes. RF algorithm is used for recognizing handwritings

of various international languages but perhaps not for Bengali Language. The purpose of this exertion is to observe

what outcomes they could bring combined. 85% accuracy is gained applying LBP and RF method with a minimum error.

V. CONCLUSION AND FUTRE WORK

Regardless of being one of the most spoken languages, Bengali language has poor number of machine recognizer for its vast database, cursives and similar nature symbols. Bengali handwritten character recognition can facilitate the progress in: Postal automation, Bank draft, Passport verification, Signature approving etc. In fine, all types of documented works that needed to be computerized can be recognized with Bengali Language also, if sufficient progress in this field has been made. There is ample of works done already on English, Chinese and Hindi. Despite of being one of the most spoken languages the digitalization of Bengali language is yet to be made fully. The aim of this thesis is to achieve satisfactory recognition rate to narrow down this gap. In future we will work on Compound Characters and also attention can be compensated for angular alphabets.

The Iso-RSA Cryptographic Scheme

Mamadou I. Wade
 Department of Electrical Engineering and Computer Science
 Howard University
 Washington, DC, U.S.A
 wademamadoui@gmail.com or mamadou.wade@howard.edu

Abstract—This paper shows one way that can be used to strengthen the RSA cryptographic scheme which was published in 1978 by Ron Rivest, Adi Shamir, and Len Adleman. We use the isonumber theory of the first kind which was developed by Santilli where the unit one of normal arithmetic is replaced with a new unit called an isounit. The proposed cryptosystem possesses both characteristics of symmetric and asymmetric encryption and therefore can be seen as a hybrid public-key and private-key cryptographic system that benefits from both types of the cryptographic method with a substantial increase in security of the associated ciphers. Additionally, applications and implementations of the Iso-RSA cryptosystem for the encryption and decryption of information encoded into positive integers or binary digits of 0s or 1s are implemented, and simulation results show that our proposed cryptographic system produces highly secure encrypted information. A wide range of other applications in security mechanisms and security services which include data confidentiality, authentications, data integrity, digital signature, key exchange, and others can be implemented using our proposed Iso-RSA cryptographic scheme.

Index Terms—Iso-RSA, Iso-RSA Cryptographic Scheme, RSA, Iso-RSA Encryption Function, Iso-RSA Decryption Function, Isonumber Cryptosystems.

I. INTRODUCTION

A Number of public-key cryptographic schemes have been proposed in the literature during the past few decades. One of the ideas behind a public-key cryptographic system is to have two keys, one made public and accessible to anyone and can be used to encrypt a secret message, while the other key is kept private and can be used for decryption to recover the original message. Among the public-key cryptographic schemes, one can find the RSA cryptographic scheme which was published in 1978 by Ron Rivest, Adi Shamir, and Len Adleman. The RSA is one of the most widely used public-key cryptographic systems, and it is a block cipher whereby both the plaintext and ciphertext consist of integers in the range 0 to $n - 1$ for some positive integer n [9], [11]. Another public-key cryptographic scheme proposed in 1984 is the ElGamal cryptographic system; it is based on the Diffie-Hellman key exchange protocol [8], [10], and its security rest on the

difficulty of solving a Discrete Logarithms (DL) problem over finite fields. Among public-key cryptographic schemes, one can also include the Paillier cryptographic system proposed in 1999, and it is based on the composite residuosity class problem [5]. This paper also includes concepts of the number theory of the first kind which was proposed by Santilli [6], [7], whereby the unit 1 of normal arithmetic is replaced by a new unit called an isounit.

In our proposed cryptographic approach, we set the isounit to be both an encryption and decryption secret isokeys as is the case in symmetric cryptosystems. In addition, when the secret isokey is randomly generated, the Iso-RSA cryptographic scheme is a probabilistic and asymmetric cryptographic scheme with a public encryption isokey and a private decryption isokey; therefore, can be seen as a hybrid public-key and private-key cryptographic system. Because of its extremely large isokey sizes, which can be more than 3,000 digits or about 10,000 bits, with a minimum added computational cost, the Iso-RSA cryptosystem produces highly secure encrypted information.

II. SANTILLI'S THEORY OF ISONUMBERS

A brief introduction to Santilli's Theory of Isonumbers is provided in this section. This theory was discovered and used by Santilli in his representation of antiparticles as particles moving backward in time, and it provides a rigorous foundation for an idea proposed by Feynman [1], [6], [7].

The real numbers is a field where 0 is the unit for addition and 1 is the unit for multiplication, and it can be represented by a five-tuple $(\mathbb{R}, +, \cdot, 0, 1)$. Santilli observed a sense of direction from left to right for \mathbb{R} that mathematicians implicitly use, so it could be represented as a six-tuple $(\mathbb{R}, +, \cdot, 0, 1, \rightarrow)$. So, practically our real number system is not symmetric. In the Isonumber Theory of the Second Kind, Santilli's proposed a new representation of the real numbers $(\hat{\mathbb{R}}, +, *, 0, \hat{1}, \leftarrow)$ which he called the isotopic dual representation of the real numbers, where the unit for addition remained 0, but the new unit for multiplication also called isounit is $\hat{1} = -1$ and is in the field (i.e. $(-1) = \hat{I} \in \mathbb{R}$). Thus,

$$\hat{a} * \hat{b} = (-a)(-1)(-b) = -ab = \hat{ab}. \quad (1)$$

Our interest in this paper is in Santilli's Isonumber Theory of the First Kind, where the new unit or isounit \hat{I} is not in the field (i.e. $\hat{I} \notin \mathbb{F}$). Let the field be given by $\mathbb{F}(a, +, \cdot)$ (for instance, Z_p , with p prime) and let the isounit $\hat{I} = \hat{T}^{-1} \notin \mathbb{F}$ be an invertible quantity. Let a new definition of multiplication be defined on the field \mathbb{F} using $*$ = $\hat{T} = \hat{I}^{-1}$ [1]. Now we can define a new field which is an isofield of the first kind $\hat{\mathbb{F}}(\hat{a}, +, *)$, with elements called isonumbers and rules for multiplication and addition given by:

$$\begin{aligned} \hat{a} &= a\hat{I}, \\ \hat{a} * \hat{b} &= (a\hat{I})\hat{I}(b\hat{I}) = ab\hat{I} = \widehat{ab} \\ \hat{a} + \hat{b} &= (a\hat{I}) + (b\hat{I}) = (a+b)\hat{I} = \widehat{a+b}. \\ \hat{0} &= 0\hat{I} = 0 \end{aligned} \quad (2)$$

III. UNDERLYING MATHEMATICS

This section provides explanations about the underlying mathematics needed to develop and construct the Iso-RSA cryptographic scheme. It includes the Isodivision Algorithm, the Euclidean-Senegalese Algorithm, the Extended Euclidean-Senegalese Algorithm, and the Euler-Senegalese Isototient Function.

A. Isodivision Algorithm

Recall that the division algorithm describes the relation obtained when a nonnegative integer a is divided by a positive integer n . This relation is given by $a = q \times n + r$, where the remainder r and the quotient q satisfy $0 \leq r < n$ and $q = \lfloor \frac{a}{n} \rfloor$, the symbols $\lfloor x \rfloor$ gives the largest integer less than or equal to x , which is also called the Floor of x .

The isodivision algorithm is an equivalent version of the division algorithm using isonumbers.

Proposition 1: Isodivision Algorithm

Let \hat{n} be a positive isointeger and \hat{a} be any nonnegative isointeger, and let \hat{I} be the isounit, if \hat{a} is isodivided by \hat{n} , we obtain an isointeger quotient \hat{q} and an isointeger remainder \hat{r} satisfying the following equation:

$$\hat{a} = \hat{q} * \hat{n} + \hat{r} = \hat{q}\hat{I}\hat{n} + \hat{r} \quad (3)$$

where

$\hat{0} \leq \hat{r} < \hat{n}$; $\hat{q} = \lfloor \frac{\hat{a}}{\hat{n}} \rfloor \hat{I}$ and $*$ = $\hat{T} = \hat{I}^{-1}$. The symbol $\lfloor \hat{x} \rfloor$ represents the largest isointeger less than or equal to \hat{x} . Eq. (3) can also be written as

$$\begin{aligned} \hat{a} &= \hat{q} * \hat{n} + \hat{r} \\ \hat{a} &= \hat{q}\hat{I}^{-1}\hat{n} + \hat{r} \\ \hat{a} &= \lfloor \frac{\hat{a}}{\hat{n}} \rfloor \hat{I}\hat{I}^{-1}\hat{n} + \hat{r} \\ \hat{a} &= \lfloor \frac{\hat{a}}{\hat{n}} \rfloor \hat{n} + \hat{r} \end{aligned} \quad (4)$$

Note that the isodivision algorithm is a generalization of the division algorithm whereby the unit 1 for multiplication is replaced by the isounit \hat{I} . If the isounit \hat{I} in (3) and (4) is replaced by 1, and the $*$ operator is replaced by the regular

multiplication operator \times , we obtain the traditional division algorithm.

B. Euclidean-Senegalese Algorithm

The Euclidean-Senegalese algorithm can be used to find the greatest common isodivisor (*gcd*), \hat{d} , of two isointegers \hat{a} and \hat{b} .

Definition: mod Operator

Given an isointeger \hat{a} and a positive isointeger \hat{n} , the remainder \hat{r} when \hat{a} is isodivided by \hat{n} is defined as $\hat{a} \bmod \hat{n}$. we write

$$\hat{r} = \hat{a} \bmod \hat{n} \quad (5)$$

Using mod operator, the isodivision algorithm in (4) can be written as

$$\hat{a} = \lfloor \frac{\hat{a}}{\hat{n}} \rfloor \hat{n} + \hat{a} \bmod \hat{n} \quad (6)$$

TABLE I: The Euclidean-Senegalese Algorithm

Assume that $\hat{a} \geq \hat{b} > \hat{0}$

$\hat{r}_1 = \hat{a} \bmod \hat{b}$	$\hat{q}_1 = \lfloor \frac{\hat{a}}{\hat{b}} \rfloor \hat{I}$	$\hat{a} = \hat{q}_1 * \hat{b} + \hat{r}_1$ $= \lfloor \frac{\hat{a}}{\hat{b}} \rfloor \hat{b} + \hat{r}_1$; $\hat{0} < \hat{r}_1 < \hat{b}$
$\hat{r}_2 = \hat{b} \bmod \hat{r}_1$	$\hat{q}_2 = \lfloor \frac{\hat{b}}{\hat{r}_1} \rfloor \hat{I}$	$\hat{b} = \hat{q}_2 * \hat{r}_1 + \hat{r}_2$ $= \lfloor \frac{\hat{b}}{\hat{r}_1} \rfloor \hat{r}_1 + \hat{r}_2$; $\hat{0} < \hat{r}_2 < \hat{r}_1$
$\hat{r}_3 = \hat{r}_1 \bmod \hat{r}_2$	$\hat{q}_3 = \lfloor \frac{\hat{r}_1}{\hat{r}_2} \rfloor \hat{I}$	$\hat{r}_1 = \hat{q}_3 * \hat{r}_2 + \hat{r}_3$ $= \lfloor \frac{\hat{r}_1}{\hat{r}_2} \rfloor \hat{r}_2 + \hat{r}_3$; $\hat{0} < \hat{r}_3 < \hat{r}_2$
⋮	⋮	⋮
$\hat{r}_{n-1} = \hat{r}_{n-3} \bmod \hat{r}_{n-2}$	$\hat{q}_{n-1} = \lfloor \frac{\hat{r}_{n-3}}{\hat{r}_{n-2}} \rfloor \hat{I}$	$\hat{r}_{n-3} = \hat{q}_{n-1} * \hat{r}_{n-2} + \hat{r}_{n-1}$ $= \lfloor \frac{\hat{r}_{n-3}}{\hat{r}_{n-2}} \rfloor \hat{r}_{n-2} + \hat{r}_{n-1}$ $\hat{0} < \hat{r}_{n-1} < \hat{r}_{n-2}$
$\hat{r}_n = \hat{r}_{n-2} \bmod \hat{r}_{n-1}$	$\hat{q}_n = \lfloor \frac{\hat{r}_{n-2}}{\hat{r}_{n-1}} \rfloor \hat{I}$	$\hat{r}_{n-2} = \hat{q}_n * \hat{r}_{n-1} + \hat{r}_n$ $= \lfloor \frac{\hat{r}_{n-2}}{\hat{r}_{n-1}} \rfloor \hat{r}_{n-1} + \hat{r}_n$ $\hat{0} < \hat{r}_n < \hat{r}_{n-1}$
$\hat{r}_{n+1} = \hat{r}_{n-1} \bmod \hat{r}_n$ $= \hat{0}$	$\hat{q}_{n+1} = \lfloor \frac{\hat{r}_{n-1}}{\hat{r}_n} \rfloor \hat{I}$	$\hat{r}_{n-1} = \hat{q}_{n+1} * \hat{r}_n + \hat{0}$ $= \lfloor \frac{\hat{r}_{n-1}}{\hat{r}_n} \rfloor \hat{r}_n + \hat{0}$ $gcd(\hat{a}, \hat{b}) = \hat{d} = \hat{r}_n$

Using (6) result, (5) can also be written as

$$\hat{r} = \hat{a} \bmod \hat{n} = \hat{a} - \lfloor \frac{\hat{a}}{\hat{n}} \rfloor \hat{n} \quad (7)$$

Proposition 2:

Given a nonnegative isointeger \hat{a} , a positive isointeger \hat{b} and assuming that $\hat{a} \geq \hat{b} > \hat{0}$, we have the following relation:

$$gcd(\hat{a}, \hat{b}) = gcd(\hat{b}, \hat{a} \bmod \hat{b}) \quad (8)$$

Proposition 3: Euclidean-Senegalese Algorithm

The Euclidean-Senegalese algorithm allows us to find the greatest common isodivisor (*gcd*), \hat{d} , of two isointegers \hat{a} and \hat{b} , or $\hat{d} = gcd(\hat{a}, \hat{b})$. To find \hat{d} , the isodivision algorithm in (3), or its equivalent version in (5), or (8) can be applied until a zero remainder is obtained at some iteration $n+1$. This process of finding $\hat{d} = gcd(\hat{a}, \hat{b})$ is summarized in Table I. As can be seen in Table I, when a zero remainder is obtained at iteration $n+1$, we have found the *gcd* of \hat{a} and \hat{b} , and is given by

$$gcd(\hat{a}, \hat{b}) = \hat{d} = \hat{r}_n. \quad (9)$$

This approach is a systematic way of finding the *gcd* of two isointegers \hat{a} and \hat{b} , and it is very useful when isointegers are encrypted using the Iso-RSA cryptographic scheme.

Note that the traditional Euclidean algorithm is a special case of the Euclidean-Senegalese algorithm when the isounit \hat{I} is set to 1 and the $*$ = $\hat{T} = \hat{I}^{-1}$ operator is replaced with the multiplication operator \times , and the isonumbers are replaced with integer counterparts.

C. Extended Euclidean-Senegalese Algorithm

The Extended Euclidean-Senegalese algorithm allows us to find not only the greatest common isodivisor (*gcd*), \hat{d} , of two isointegers \hat{a} and \hat{b} , but also two isointegers \hat{x} and \hat{y} satisfying the following equation.

$$\hat{a} * \hat{x} + \hat{b} * \hat{y} = \hat{d} = gcd(\hat{a}, \hat{b}) \quad (10)$$

The Extended Euclidean-Senegalese algorithm is a generalization of the classical Extended Euclidean algorithm whereby unit 1 is replaced by the isounit \hat{I} and the traditional multiplication operator \times is replaced by the operator $*$ = $\hat{T} = \hat{I}^{-1}$, in addition to other minor adjustments.

In order to find the two isointegers \hat{x} and \hat{y} satisfying (10), assume that at each iteration step, i , of the Euclidean-Senegalese algorithm in Table I, we can compute \hat{x}_i and \hat{y}_i satisfying the following equation,

$$\hat{r}_i = \hat{a} * \hat{x}_i + \hat{b} * \hat{y}_i \quad (11)$$

The recurrence relations for \hat{x}_i and \hat{y}_i needed to construct the Extended Euclidean-Senegalese algorithm are given by

$$\hat{x}_i = \hat{x}_{i-2} - \hat{I}^{-1} \hat{q}_i \hat{x}_{i-1} \quad (12)$$

and

$$\hat{y}_i = \hat{y}_{i-2} - \hat{I}^{-1} \hat{q}_i \hat{y}_{i-1} \quad (13)$$

Equations (12) and (13) provide the relations we need in order to find \hat{x}_i and \hat{y}_i at each iteration step on the Extended Euclidean-Senegalese algorithm that will be discussed next in Table II.

Similar to the approach used to construct the Euclidean-Senegalese algorithm described in Table I, (8) can be applied until a zero remainder is obtained at iteration $n+1$. One of the goal is to find \hat{x}_i and \hat{y}_i at each iteration.

At iteration $i = -1$.

We initialize $\hat{r}_{-1} = \hat{a}$. So, (11) can be written as

$$\hat{r}_{-1} = \hat{a} * \hat{x}_{-1} + \hat{b} * \hat{y}_{-1} = \hat{a} \quad (14)$$

Eq. (14) implies that $\hat{y}_{-1} = \hat{0}$ and $\hat{x}_{-1} = \hat{I}$ since $\hat{a} * \hat{I} = \hat{a}$. At iteration $i = 0$.

We initialize $\hat{r}_0 = \hat{b}$. So, (11) can be written as

$$\hat{r}_0 = \hat{a} * \hat{x}_0 + \hat{b} * \hat{y}_0 = \hat{b} \quad (15)$$

Eq. (15) implies that $\hat{x}_0 = \hat{0}$ and $\hat{y}_0 = \hat{I}$ since $\hat{b} * \hat{I} = \hat{b}$.

The results for iterations $i = 1$ through $i = n+1$ are summarized in Table II.

Note that columns 3 and 4 of Table II are calculated using (12) and (13), respectively; while column 5 is obtained from (11).

As can be seen on the results on the last row of Table II, the iteration process ends when a remainder of zero is obtained at some iteration $i = n+1$. At this iteration, we have found the *gcd*(\hat{a}, \hat{b}) which is equal to $\hat{d} = \hat{r}_n$, the isointeger $\hat{x} = \hat{x}_n$, and $\hat{y} = \hat{y}_n$, all satisfying (10).

In addition if $gcd(\hat{a}, \hat{b}) = \hat{I}$, then we also have found the isomultiplicative inverse of \hat{b} in (10), which is given by $\hat{b}^{-1} \text{ mod } \hat{a} = \hat{y} = \hat{y}_n$.

In order to illustrate the use of the Euclidean-Senegalese algorithm in Table I, and the Extended Euclidean-Senegalese algorithm presented in Table II, consider the following example. Given $\hat{a} = \hat{20}$, $\hat{b} = \hat{7}$, and $\hat{I} = \hat{30}$, find the *gcd*(\hat{a}, \hat{b}) = \hat{d} , the value of \hat{x} , \hat{y} , and the isomultiplicative inverse of $\hat{b} \text{ (mod } \hat{a})$ if applicable(when $\hat{d} = \hat{I}$). Results of this example is summarized in Table III .

Also, note that the isointegers $\hat{a} = \hat{20}$ and $\hat{b} = \hat{7}$ are relatively isoprime, so we would expect their *gcd* to be equal to \hat{I} as shown in the result obtained in Table III.

Also note that $\hat{a} \text{ mod } \hat{b} = a\hat{I} \text{ mod } b\hat{I} = (a \text{ mod } b)\hat{I}$ implies that $gcd(\hat{a}, \hat{b}) = gcd(a, b)\hat{I} = d\hat{I} = \hat{d}$, where $d = gcd(a, b)$.

D. Euler-Senegalese's Isototient Function

The Euler-Senegalese's isototient function is the equivalent version of the Euler's totient function when using isomubers. The Euler-Senegalese's isototient function generalized the Euler's totient function when the unit 1 is replace by the isounit \hat{I} and the multiplication operator \times is replaced with the operator $*$ = $\hat{T} = \hat{I}^{-1}$. So, the Euler's totient fuction is a special case of the Euler-Senegalese's isototient function. We can recall the Euler's totient function as follows:

Definition: Euler's Totient Function ($\phi(n)$)

The Euler's totient function is defined as the number of positive integers that are less than n and relatively prime to n . Its notation is $\phi(n)$, and we define $\phi(1) = 1$ [10].

Note that if p and q are two distinct prime numbers and $n = p \times q$, then

$$\phi(p) = (p - 1) \quad (16)$$

$$\phi(n) = \phi(p \times q) = \phi(p)(q) = (p - 1) \times (q - 1) \quad (17)$$

Definition: Euler-Senegalese's Isototient Function ($\phi(\hat{n})$)
 Given the isounit \hat{I} , we define the Euler-Senegalese's isototient function as the corresponding isonumber of the number of positive isointegers that are less than \hat{n} and relatively isoprime to \hat{n} . Its notation is $\phi(\hat{n})$, and we define $\phi(\hat{I}) = \hat{I}$.

Proposition 6

Consider the following relations:

It \hat{p} is an isoprime number, then

$$\phi(\hat{p}) = \hat{p} - \hat{I} \quad (18)$$

If \hat{p} and \hat{q} are two isoprime numbers that are distinct, and $\hat{n} = \hat{p} * \hat{q}$, then

$$\phi(\hat{n}) = \phi(\hat{p} * \hat{q}) = \phi(\hat{p}) * \phi(\hat{q}) = (\hat{p} - \hat{I}) * (\hat{q} - \hat{I}) = (\hat{p} - \hat{I})\hat{I}^{-1}(\hat{q} - \hat{I}) \quad (19)$$

If $\hat{n} = \hat{p} * \hat{q}$, where \hat{p} and \hat{q} are two isoprime numbers, then the Euler-Senegalese's Isototient function $\phi(\hat{n})$ is related to the Euler's Totient $\phi(n)$ by

$$\phi(\hat{n}) = \phi(n)\hat{I} \quad (20)$$

The cost of implementing (20) is less than the cost implementing (19).

IV. THE ISO-RSA CRYPTOGRAPHIC ALGORITHM

This section describes our proposed Iso-RSA cryptographic algorithm, as well as the traditional RSA Algorithm. We introduce the traditional RSA encryption scheme and the extensions that lead to the Iso-RSA scheme.

A. *Traditional RSA Cryptographic System*

The traditional RSA cryptographic system was published by Ron Rivest, Adi Shamir, and Len Adleman in 1978. The RSA algorithm has stood the test of time in terms of security and efficiency of computation, especially when implemented using the fast exponentiation algorithm or other similar methods; it is one of the most widely used public-key cryptographic systems. The RSA is a block cipher whereby both the ciphertext (C) and plaintext (M) consist of integers between 0 and $n - 1$. The RSA algorithm consists of a key generation step, an encryption step, and a decryption step. Each of these steps is as follows [9], [10].

1) **The RSA Public and Private Key Generation:** Two prime numbers p and s are randomly selected in order to compute the public key $n = p \times s = ps$. For the encryption scheme to be computationally secure, p and s must be as large as possible so that factoring n to obtain p and s is computationally infeasible. This value of n is used to compute the Euler's Totient function defined by (17) as $\phi(n) = \phi(p \times s) = \phi(p) \times \phi(s) = (p - 1) \times (s - 1)$. Another integer e greater than 1, relatively prime to $\phi(n)$, and less than

$\phi(n)$ is randomly selected. So, we have the greatest common divisor (gcd) of $\phi(n)$ and e is 1; or $gcd(\phi(n), e) = 1$ and $1 < e < \phi(n)$. Now, the public key needed for encryption is a pair of positive integers given by $\{n, e\}$. It is important to note that the greatest common divisor of two integers can be computed using the Euclidean algorithm.

To find the private key needed for decryption, we compute the integer f that is the multiplicative inverse of $e \pmod{\phi(n)}$; which can be written as $e \times f \equiv 1 \pmod{\phi(n)}$, or $f \equiv e^{-1} \pmod{\phi(n)}$, where the symbol \equiv represents the congruent relation. We also note that $f < \phi(n)$, and is relatively prime to $\phi(n)$, meaning that $gcd(\phi(n), f) = 1$. The private key needed for decryption is given by the pair of positive integers $\{n, f\}$. We can also point out that f can be computed using the Extended Euclidean algorithm.

2) **The RSA Encryption Function:** The RSA encryption function is used to encrypt a message or plaintext represented by an integer M between 0 and $n - 1$. The encryption of the message M using the encryption function, E , the modulo operator $\pmod{}$, in conjunction with the public key $\{n, e\}$, to obtain the cipher C , is given by

$$C \equiv E(M) \equiv M^e \pmod{n} \quad (21)$$

3) **The RSA Decryption Function:** The RSA decryption function is used to decrypt the ciphertext represented by integer C between 0 and $n - 1$. The decryption of the ciphertext C using the decryption function, D , in conjunction with the private key f to obtain the message M , is given by

$$M \equiv D(C) \equiv C^f \pmod{n} \quad (22)$$

B. *Iso-RSA Cryptographic System*

This subsection presents in detail the Iso-RSA Cryptographic System. It is also a three steps process consisting of a key generation step, an encryption step, and a decryption step. At this point, we have developed the mathematical tools needed to carry out our cryptographic process in the context of isomubers; these mathematical tools could not be found anywhere in the literature, leading us to develop and apply them to our cryptographic problem. These mathematical tools are discussed in the underlying mathematics section, and they include Euclidean-Senegalese Algorithm, Extended Euclidean-Senegalese Algorithm, and the Euler-Senegalese's isototient function, and others.

1) **The Iso-RSA Public and Private key Generation:** The public and private isokeys generation for the Iso-RSA cryptographic system are described in this section. First, we randomly generate two prime numbers p and s , and randomly generate the isounit \hat{I} greater than the largest values of the message to be encrypted. After computing $\hat{p} = p\hat{I}$ and

$\hat{s} = s\hat{I}$, we calculate the public encryption isockey \hat{n} as

$$\hat{n} = \hat{p} * \hat{s} = \hat{p}\hat{T}\hat{s} = \hat{p}\hat{T}^{-1}\hat{s} = p\hat{I}\hat{T}^{-1}s\hat{I} = (ps)\hat{I} = n\hat{I} \quad (23)$$

If \hat{n} is known, the RSA public encryption key n can be obtained by $n = \hat{n}\hat{I}^{-1}$. Now we compute the Euler's isototient function given by (19) and summarized as

$$\phi(\hat{n}) = (\hat{p} - \hat{I})\hat{I}^{-1}(\hat{s} - \hat{I}) \quad (24)$$

Another way of computing $\phi(\hat{n})$ is $\phi(\hat{n}) = \phi(n)\hat{I}$ given by (20). When $\phi(\hat{n})$ is known, $\phi(n)$ can be obtained by $\phi(n) = \phi(\hat{n})\hat{I}^{-1}$.

To obtain the public encryption isockey, \hat{e} , we can randomly select the integer e and calculate $\hat{e} = e\hat{I}$ such that the following greatest common isodivisor (*gcid*) is verified, that is $gcid(\phi(\hat{n}), \hat{e}) = \hat{I}$, and $\hat{I} < \hat{e} < \phi(\hat{n})$. The $gcid(\phi(\hat{n}), \hat{e})$ can be calculated using the Euclidean-Senegalese algorithm summarized in Table I. Or, \hat{e} can simply be computed as $\hat{e} = e\hat{I}$, where e is the RSA public key.

On one hand, the encryption isokeys of the Iso-RSA cryptographic scheme is given by the triplet $\{\hat{n}, \hat{e}, \hat{I}\}$, where pair of isointegers $\{\hat{n}, \hat{e}\}$ is made public, while the isounit \hat{I} is the secret encryption and decryption isockey. On the other hand, the encryption isokeys of the Iso-RSA cryptographic scheme can be computed using the triplet $\{n, e, \hat{I}\}$, where n and e are the previous RSA public encryption keys. The values of \hat{n} and \hat{e} can be computed as $\hat{n} = n\hat{I}$ and $\hat{e} = e\hat{I}$, where again the isounit \hat{I} is the secret encryption and decryption isockey. Now, we can compute the private decryption isockey \hat{f} , which is the isomultiplicative inverse of $\hat{e} \pmod{\phi(\hat{n})}$. We can write

$$\hat{e} * \hat{f} \equiv \hat{I} \pmod{\phi(\hat{n})} \quad (25)$$

Equation (25) implies that

$$\hat{f} \equiv \hat{e}^{-1} \pmod{\phi(\hat{n})} \quad (26)$$

Three different methods can be used to calculate \hat{f} .

Method 1: The Extended Euclidean-Senegalese Algorithm. The Extended Euclidean-Senegalese Algorithm summarized in Table II is a systematic way that can be used to calculate \hat{f} given by the relation described in (25) or (26).

Method 2: Trial and Error

When the isonumbers are large, it is not the best method to compute \hat{f} because it involves a search of an isointeger \hat{q} satisfying (28). Equation (25) implies

$$(\hat{e} * \hat{f}) \pmod{\phi(\hat{n})} = \hat{I} \pmod{\phi(\hat{n})} = \hat{I} \quad (27)$$

Equation (27) implies that there exist an isointeger \hat{q} such that

$$\hat{e} * \hat{f} = \hat{q} * \phi(\hat{n}) + \hat{I} \quad \text{or} \quad \hat{e}\hat{T}\hat{f} = \hat{q}\hat{T}\phi(\hat{n}) + \hat{I} \quad (28)$$

Using (28), the goal is to use trial and error or search for the value of \hat{q} that will make \hat{f} to be an isointeger given by

$$\hat{f} = (\hat{q}\hat{T}\phi(\hat{n}) + \hat{I})\hat{T}\hat{e}^{-1} = \frac{\hat{q}\hat{I}^{-1}\phi(\hat{n}) + \hat{I}}{e}, \quad (29)$$

where $\hat{e}^{-1} = \frac{\hat{I}}{e}$ and $e = \hat{e}\hat{I}^{-1}$. Note that $\hat{T}\hat{I} = \hat{T}\hat{T}^{-1} = 1$.

Method 3: Direct method

Assuming that the value f describe in the traditional RSA Cryptographic system is available, \hat{f} is computed as

$$\hat{f} = f\hat{I} \quad (30)$$

The isointegers needed for decryption are $\{\hat{n}, \hat{f}, \hat{I}\}$, where \hat{f} is a private decryption isockey, and \hat{I} a secret encryption and decryption isockey, and \hat{n} is the public isokeys previously used for encryption.

For the encryption to be computationally secure, the values of \hat{p} , \hat{s} , \hat{e} , and \hat{f} must be as large as possible.

2) **The Proposed Iso-RSA Encryption Function:** Similar to the RSA encryption function used to encrypt a message or plaintext represented by an integer M between 0 and $n - 1$, the Iso-RSA encryption function is used to encrypt a message M with corresponding isointeger $\hat{M} = M\hat{I}$ between $\hat{0}$ and $\widehat{n-1}$. Using the RSA public key e , or given the public encryption isockey \hat{e} , one can compute the the public key $e = \hat{e}\hat{I}^{-1}$. So, assuming the secrete encryption and decryption isockey (isounit) \hat{I} is known to both sender and receiver, the encryption of \hat{M} using the encryption function, E , to obtain the ciphertext \hat{C} is given by

$$\hat{C} = E(\hat{M}) = E(M\hat{I}) = (M^e)\hat{I} \pmod{n\hat{I}} = (M^e)\hat{I} \pmod{\hat{n}} \quad (31)$$

Note that \hat{C} can also be computed as $\hat{C} = E(\hat{M}) = E(M)\hat{I}$, where $E(M) = C = M^e \pmod{n}$ is given by Eq. (21) and corresponds to the RSA encryption function using the public key $\{n, f\}$. So, the sender can encrypt the message M using either (31) or $\hat{C} = E(\hat{M}) = E(M)\hat{I}$ since it has access to the shared secrete isockey \hat{I} . If \hat{I} is a different randomly generated positive integer during each encryption operation, the encryption function $E(\hat{M})$ contains a random variable; therefore, it is probabilistic compared to the RSA encryption function described in (21). This will ensure that the encryption of the same message M using the same isockey $\{\hat{e}, \hat{n}\}$ with a different random isounit or secret isockey \hat{I} , will produce different results and make the associated ciphertext more secure.

3) **The Proposed Iso-RSA Decryption Function:** The Iso-RSA decryption function is used to decrypt the ciphertext represented by the isointeger \hat{C} between $\hat{0}$ and $\widehat{n-1}$. One can decrypt the ciphertext \hat{C} using the decryption function, D , in conjunction with the private isockey \hat{f} , to obtain the original message \hat{M} . Using the private isockey \hat{f} , we can compute the private key $f = \hat{f}\hat{I}^{-1}$, or f can be directly computed from the RSA algorithm, and we calculate the cipher $C = \hat{C}\hat{I}^{-1}$. The message M is given by

$$\hat{M} = D(\hat{C}) = D(C\hat{I}) = (C^f)\hat{I} \pmod{n\hat{I}} = (C^f)\hat{I} \pmod{\hat{n}} \quad (32)$$

The original message M can be obtained from (32) as

$$M = \hat{M}\hat{I}^{-1} = \frac{\hat{M}}{\hat{I}} \quad (33)$$

TABLE II: The Extended Euclidean-Senegalese Algorithm

Assume that $\hat{a} \geq \hat{b} > \hat{0}$				
Compute Remainder (\hat{r}_i)	Compute Quotient (\hat{q}_i)	Compute (\hat{x}_i)	Compute (\hat{y}_i)	Which Fulfills
$\hat{r}_{-1} = \hat{a}$	—	$\hat{x}_{-1} = \hat{I}$	$\hat{y}_{-1} = \hat{0}$	$\hat{r}_{-1} = \hat{a} * \hat{x}_{-1} + \hat{b} * \hat{y}_{-1} = \hat{a}$ $\hat{r}_{-1} = \hat{a}\hat{I}^{-1}\hat{x}_{-1} + \hat{b}\hat{I}^{-1}\hat{y}_{-1} = \hat{a}$
$\hat{r}_0 = \hat{b}$	—	$\hat{x}_0 = \hat{0}$	$\hat{y}_0 = \hat{I}$	$\hat{r}_0 = \hat{a} * \hat{x}_0 + \hat{b} * \hat{y}_0 = \hat{b}$ $\hat{r}_0 = \hat{a}\hat{I}^{-1}\hat{x}_0 + \hat{b}\hat{I}^{-1}\hat{y}_0 = \hat{b}$
$\hat{r}_1 = \hat{a} \text{ mod } \hat{b}$ Or $\hat{a} = \hat{q}_1 * \hat{b} + \hat{r}_1$ $\hat{a} = \lfloor \frac{\hat{a}}{\hat{b}} \rfloor \hat{b} + \hat{r}_1$ $\hat{0} < \hat{r}_1 < \hat{b}$	$\hat{q}_1 = \lfloor \frac{\hat{a}}{\hat{b}} \rfloor \hat{I}$	$\hat{x}_1 = \hat{x}_{-1} - \hat{I}^{-1}\hat{q}_1\hat{x}_0$ $\hat{x}_1 = \hat{x}_{-1} - \hat{0}$ $\hat{x}_1 = \hat{I}$	$\hat{y}_1 = \hat{y}_{-1} - \hat{I}^{-1}\hat{q}_1\hat{y}_0$ $\hat{y}_1 = \hat{0} - \hat{I}^{-1}\hat{q}_1\hat{I}$ $\hat{y}_1 = -\hat{q}_1$	$\hat{r}_1 = \hat{a} * \hat{x}_1 + \hat{b} * \hat{y}_1$ $\hat{r}_1 = \hat{a}\hat{I}^{-1}\hat{x}_1 + \hat{b}\hat{I}^{-1}\hat{y}_1$
$\hat{r}_2 = \hat{b} \text{ mod } \hat{r}_1$ Or $\hat{b} = \hat{q}_2 * \hat{r}_1 + \hat{r}_2$ $= \lfloor \frac{\hat{b}}{\hat{r}_1} \rfloor \hat{r}_1 + \hat{r}_2;$ $\hat{0} < \hat{r}_2 < \hat{r}_1$	$\hat{q}_2 = \lfloor \frac{\hat{b}}{\hat{r}_1} \rfloor \hat{I}$	$\hat{x}_2 = \hat{x}_0 - \hat{I}^{-1}\hat{q}_2\hat{x}_1$ $\hat{x}_2 = \hat{0} - \hat{I}^{-1}\hat{q}_2\hat{I}$ $\hat{x}_2 = -\hat{q}_2$	$\hat{y}_2 = \hat{y}_0 - \hat{I}^{-1}\hat{q}_2\hat{y}_1$ $\hat{y}_2 = \hat{I} - \hat{I}^{-1}\hat{q}_2(-\hat{q}_1)$ $\hat{y}_2 = \hat{I} + \hat{I}^{-1}\hat{q}_2\hat{q}_1$	$\hat{r}_2 = \hat{a} * \hat{x}_2 + \hat{b} * \hat{y}_2$ $\hat{r}_2 = \hat{a}\hat{I}^{-1}\hat{x}_2 + \hat{b}\hat{I}^{-1}\hat{y}_2$
$\hat{r}_3 = \hat{r}_1 \text{ mod } \hat{r}_2$ Or $\hat{r}_1 = \hat{q}_3 * \hat{r}_2 + \hat{r}_3$ $= \lfloor \frac{\hat{r}_1}{\hat{r}_2} \rfloor \hat{r}_2 + \hat{r}_3;$ $\hat{0} < \hat{r}_3 < \hat{r}_2$	$\hat{q}_3 = \lfloor \frac{\hat{r}_1}{\hat{r}_2} \rfloor \hat{I}$	$\hat{x}_3 = \hat{x}_1 - \hat{I}^{-1}\hat{q}_3\hat{x}_2$ $\hat{x}_3 = \hat{I} - \hat{I}^{-1}\hat{q}_3(-\hat{q}_2)$ $\hat{x}_3 = \hat{I} + \hat{I}^{-1}\hat{q}_3\hat{q}_2$	$\hat{y}_3 = \hat{y}_1 - \hat{I}^{-1}\hat{q}_3\hat{y}_2$ $\hat{y}_3 = -\hat{q}_1 - \hat{I}^{-1}\hat{q}_3\hat{y}_2$	$\hat{r}_3 = \hat{a} * \hat{x}_3 + \hat{b} * \hat{y}_3$ $\hat{r}_3 = \hat{a}\hat{I}^{-1}\hat{x}_3 + \hat{b}\hat{I}^{-1}\hat{y}_3$
\vdots	\vdots	\vdots	\vdots	\vdots

TABLE III: The Extended Euclidean-Senegalese Algorithm Example

Given: $a = 20; b = 7; I = 30$				
Compute Remainder (r_i)	Compute Quotient (q_i)	Compute (x_i)	Compute (y_i)	Which Fulfills
$r_{-1} = a = 20$	-	$x_{-1} = I = 30$	$y_{-1} = 0$	$r_{-1} = aI^{-1}x_{-1} + bI^{-1}y_{-1} = a$ $r_{-1} = 20I^{-1}I + 7I^{-1}0 = 20$
$r_0 = b = 7$	-	$x_0 = 0$	$y_0 = I$	$r_0 = aI^{-1}x_0 + bI^{-1}y_0 = b$ $r_0 = 20I^{-1}0 + 7I^{-1}I = 7$
$r_1 = a \bmod b$ $r_1 = 20 \bmod 7$ $r_1 = 6$	$q_1 = \lfloor \frac{a}{b} \rfloor I$ $q_1 = \lfloor \frac{20}{7} \rfloor (30)$ $q_1 = 2$	$x_1 = I = 30$	$y_1 = -q_1 = -2$	$r_1 = aI^{-1}x_1 + bI^{-1}y_1$ $r_1 = 20I^{-1}I + 7I^{-1}(-2)$ $r_1 = 20 - 14 = 6$
$r_2 = b \bmod r_1$ $r_2 = 7 \bmod 6$ $r_2 = 1$	$q_2 = \lfloor \frac{b}{r_1} \rfloor I$ $q_2 = \lfloor \frac{7}{6} \rfloor (30)$ $q_2 = 30 = I$	$x_2 = -q_2$ $x_2 = -I$	$y_2 = I + I^{-1}q_1$ $y_2 = I + I^{-1}I(2)$ $y_2 = I + 2$ $y_2 = 3$	$r_2 = aI^{-1}x_2 + bI^{-1}y_2$ $r_2 = 20I^{-1}(-I) + 7I^{-1}(3)$ $r_2 = -20 + 21$ $r_2 = I$
$r_3 = r_1 \bmod r_2$ $r_3 = 6 \bmod 1$ $r_3 = 0$ STOP (We Got a 0 Remainder)	-	-	-	$n = 2$ $d = \text{gcd}(a, b) = a * x + b * y = r_n$ $\text{gcd}(20, 7) = 20 * x + 7 * y = r_3 = I$ $x = x_2 = -I$ and $y = y_2 = 3$ Since $d = I$, we have $b^{-1} \bmod a = 7^{-1} \bmod 20 = y_2 = 3$

There is another way the receiver who already has access the public isokeys $\{\hat{n}, \hat{e}\}$, the private isokeys $\{\hat{n}, \hat{f}\}$, and the secrete isokey \hat{I} , can recover the original message or plaintext M from the ciphertext \hat{C} . Using the received Iso-RSA ciphertext \hat{C} , the receiver can compute the RSA ciphertext C as $C = \hat{C}\hat{I}^{-1}$, and then compute M using the RSA decryption function as $M = D(C) = C^f \pmod n$ given by (22), where $f = \hat{f}\hat{I}^{-1}$, $n = \hat{n}\hat{I}^{-1}$ or $n = p \times s$.

V. APPLICATIONS OF THE ISO-RSA CRYPTOGRAPHIC SCHEME

This section shows some possible applications and implementations of the Iso-RSA Cryptographic scheme. The results from this section are obtained using simulation programs that we have written using a MATHEMATICA 12 software package. Examples 1 and 2 are for illustration purposes with smaller values of the encryption and decryption isokeys. These examples give insight through simple computations using the Iso-RSA cryptographic scheme. In example 3, the encryption and decryption isokeys have extremely large number of digits and therefore making the corresponding ciphertext computationally secure.

The Iso-RSA Cryptographic scheme can be used to encrypt any data or information that are numbers or bits, or that can be encoded/mapped into numbers or bits. These two major cases are described in the next two subsections.

A. Binary Encryption/Decryption Case Applications

The Iso-RSA Cryptographic scheme can be used to encrypt a binary digit or bit represented by 0 or 1. Recall that the encryption of the message M and its corresponding isonumber $\hat{M} = M\hat{I}$ to produce the ciphertext \hat{C} is given by (31) as $\hat{C} = E(\hat{M}) = E(M\hat{I}) = (M^e)\hat{I} \pmod{\hat{n}}$.

On one hand, we can obviously observe that if message M takes the value of bit 1 or $M = 1$, the corresponding ciphertext

$\hat{C} = (1^e)\hat{I} \pmod{\hat{n}} = \hat{I} \pmod{\hat{n}} = \hat{I} \pmod{n\hat{I}} = \hat{I}$. To avoid having the same results when encrypting bit 1, we can change the value of \hat{I} when encrypting each bit value of 1. Or/and, M can be mapped to a positive integer before encryption, for example we can set $M = 3$. So, it is not recommended to map M to integer 1 because it will lead to having $\hat{C} = \hat{I}$ which will be easy to infer by a hacker.

On the other hand, when M takes the value of bit 0 or $M = 0$, the corresponding ciphertext $\hat{C} = (0^e)\hat{I} \pmod{\hat{n}} = 0 \pmod{\hat{n}} = 0 = \hat{0}$. To avoid having the same result of 0, when encrypting bit 0, before encryption each bit zero is map to a different value such as 2 for example, and/or we can also change the value of \hat{I} for each bit value of 0 encryption as shown in next example.

(1) Original Data Byte
(2) Data Encoding, bit 0 mapped to 2, bit 1 mapped to 3
(3) Encrypted data using corresponding isounit \hat{I}_i

(a)

Fig. 1: Data byte Encryption using the RSA-Senegalese Cryptographic Scheme

Example 2: Binary Encryption/Decryption Case

Encrypt the data byte 01001101 using the Iso-RSA cryptographic scheme, then decrypt the corresponding ciphertext to obtain the original data byte.

We randomly generate our private keys (prime numbers) $p = 59$ and $s = 41$ and compute the associated isokeys \hat{p} and \hat{s} , \hat{n} , and then select the public key $e = 181$. Also, each corresponding isounit \hat{I} is randomly generated. Before encryption, each bit 0 is mapped/encoded to integer 2, while each bit 1 is mapped to integer 3.

During the encryption step shown in Fig. 1, the first bit of 0 is mapped to integer 2 then encrypted. Using the isounit $\hat{I}_1 = 3$, we compute the public isokey $\hat{n} = (ps)\hat{I}_1 = 7257$, and use

(a)

Fig. 2: Data byte Encryption using the Iso-RSA Cryptographic Scheme.

the public isokey $\hat{e} = e\hat{I}_1 = 543$ to encrypt the message $M = 2$ and obtain the ciphertext $\hat{C}_1 = 6402$.

During the decryption step, we compute the private isokey $\hat{f} = 423$ and use the isounit \hat{I}_1 to decrypt the ciphertext \hat{C}_1 and obtain the message $\hat{M} = 6$ and compute $M = 2$, which is then mapped back to bit 0. Other bits are encrypted and decrypted in a similar way. Fig 1. summarizes the encryption results for all bits, while Fig. 2 provides the decryption results.

If there are more bytes to be encrypted, instead of choosing a different set of isounits from I_1 through I_8 , we can just rotate left or rotate right by a number of units $n > 1$ only known to legitimate users. This 8-bit binary encryption and decryption process can be extended to data with 16-bit, 32-bit, 64-bit length, or data with a higher bit length.

B. Integer Encryption/Decryption Case

The Iso-RSA cryptographic scheme can be also used to encrypt any data or information represented by a positive integer. For illustration purposes, we can revisit example 1, but this time we use encryption and decryption isokeys with large number of digits making the associated ciphertext highly secure.

Example 3: Encrypt the message $M = 5$ and decrypt the corresponding ciphertext using the Iso-RSA cryptographic scheme.

Isokeys Generation Phase:

We randomly generate a 1000 digits integer for the isounit which is the secret encryption and decryption isokey given by $\hat{I} = 6705642340830151337605366935497966688761425655519559843828657577090172913994408414332899431464255251388681687534843573142127832857164988057162140679344430849550623415758144002805955676539779144413081666427672244649977065294448511646168508466258719140780943313500356137350913117761841587541072046842140628578142955389931592357685235132792156575417572258336611013384887932596891993802189171620277603372515155995685792629671939427207687000922309664920659259876090557494905671340147267632922771751460911880985048796749243916894295401320178931291607476629090848825487365429867396914733651503131872003548735801648508726573810037409657943941822983944431554434714883289287312299035367249105842302709469538697906678497506604733618656495369998344420895459600227346026009124090746307330643089753441656918158490417608926105825031300108627198097128996366457145879916542747941929967421611549556420177407112578351666448385326256147185085435692846830946101537995091381866029559339800844475788961790423761031689997212.$

We also randomly select the private prime numbers p and s with 600 digits each, and then compute $\hat{p} = p\hat{I}$ and $\hat{s} = s\hat{I}$ with each 1600 digits. We calculate the public isokey \hat{n} using (23) as $\hat{n} = \hat{p} * \hat{s} = (ps)\hat{I}$ and obtain an integer with 2200 digits and 7306 bits given by

$\hat{n} = 1109216243454912743255660804559755004992834351052549014434500755060694914920200996577882430565433539641869697102491569052297674823868086998199560135651691594957298370714132063739061821791803207988321495979594408956545176572589015144119810493695404488904405680564916683333596928393294898786558701309102221401712780094412140704909038502539457683582022798068290980535955553785180716488393563018578881751094343338891584052410147809531282088123538394726280171016082963794320734360516317648813962962780800934399476222188432466539146061878670708207983647501856537882288556013464631705390717255749584465337016401836697427890195826459762916456895516754030118458581092636520574931526905190381332479492206946367964630058601133769052759298783996249265509806842618411084857843882914028275819081096379797089087208855906639572410927479993381334712064914730146796662143649287774856712317316238345712123544747990816502245187292759305394322350447786369389086618768325272946484626068871128067323130629977878745318556925894051661536006947697179977737828205566141809076529221828083227500120615169946942131168434714020481311823501180969554575520869268523087616789521121148550329632524419438461296544170303432877039617079928717113711859746417811$

 092.

So, we now have the public encryption isokey $PU = \{\hat{n}, \hat{e}\}$ and the secret encryption isokey (isounit) $PR = \{\hat{I}\}$.

We calculate the private decryption isokey \hat{f} which has 2199 digits but not shown here because of number of pages limitations.

So, the private decryption isokey is $PR = \{\hat{f}, \hat{I}\}$

Encryption Phase:

The message $M = 5$ is encrypted using (31) to obtain the ciphertext \hat{C} with 2199 digits given by

$\hat{C} = 383331694654418271994382897533298668520133104$

 580.

This value of \hat{C} represents the secure encrypted value that is transmitter or/and store.

It only takes 0.0547881 seconds to encrypt the message M using a regular desktop computer.

Decryption Phase:

The above ciphertext \hat{C} is decrypted using (32) to obtain \hat{M} with 1001 digits.

The corresponding message M is computed using (33), and is given by

$$M = 5.$$

It only takes 0.040612 seconds to decrypt the ciphertext \hat{C} using the same regular desktop computer.

As can be seen in the final result, the original message $M = 5$ is obtained after decryption.

The Iso-RSA cryptographic scheme produces highly secure encrypted information because of its isokeys sizes that can be extremely large, and other characteristics.

The number of digits for \hat{p} , \hat{s} , \hat{n} , \hat{e} , and \hat{I} is arbitrary, but the higher the number of digits for each, the more computationally secure the public isokeys and ciphertexts become, but also the computational cost is higher.

Also, note that the ciphertext \hat{C} produced by the Iso-RSA encryption scheme has a very large number of digits, and therefore will require more memory for storage and a longer transmission time. This large size of \hat{C} can be overcome with extra processing that will be discussed in our next paper.

VI. CONCLUSIONS

This paper introduces the Iso-RSA cryptographic scheme which possesses characteristics of symmetric and asymmetric cryptographic approaches, and therefore can be seen as a

hybrid private-key and public-key cryptosystem. It consists of a key generation step, an encryption step, and a decryption step. An isounit represented by a positive integer replacing the unit one of normal arithmetic is used as both secret encryption and decryption isokey, and it provides an additional degree of freedom of unit. Because the encryption and decryption isokeys can be extremely large, for example, more than 3000 digits or about 10,000 bits or more, the Iso-RSA cryptographic produces highly secure encrypted information. The paper also presents examples of possible applications of the Iso-RSA cryptosystem. The scheme can be used to encrypt and decrypt any information that can be encoded into positive integers or bits such as a binary 0 or 1. The Iso-RSA cryptographic scheme can also be used in a wide range of other applications in security mechanisms and security services which include data confidentiality, authentications, data integrity, digital signature, key exchange, and others. Our contribution includes the strengthening of the RSA cryptosystem using an isounit as a secret encryption and decryption isokey, leading to a hybrid public-key private-key cryptosystem that produces highly secure encrypted information. Our future work includes investigating how well the Iso-RSA cryptographic scheme can resist quantum computing-based attacks.

Abstract—In this paper, we use Santilli's isonumber theory of the first kind to add a new degree of freedom of unit to the ElGamal cryptographic system leading to a new encryption scheme. In this scheme, the key generation, encryption, and decryption steps are performed in an isofield with an isounit replacing unit one of normal arithmetic. This isounit is used as a shared secret isokey for encryption and decryption as is the case in a symmetric cryptographic system. In addition, our proposed cryptographic system is asymmetric with a public isokey used for encryption and a private isokey used for decryption. We thus obtain a hybrid public-key private-key cryptographic system with a substantial increase in security due to this additional freedom of unit. The private isokeys and ciphertexts produced by this scheme are highly secure. In addition, the ability to use isokeys of ten thousand bits or more with minimum additional computational cost makes this cryptographic scheme produce highly secure encrypted information. Also, applications and implementations of the Iso-ElGamal scheme on messages represented by positive integers and data or information encoded into binary digits or bits are presented. A wide range of other applications in security services and security mechanisms, which include authentication, data confidentiality, data integrity, digital signature, and others can be implemented using our proposed scheme.

Index Terms—Iso-ElGamal, Iso-ElGamal Cryptographic Scheme, ElGamal Cryptographic System; Isonumber Cryptosystems.

I. INTRODUCTION

A Wide range of public-key encryption schemes has been proposed in the past few decades. Using a public-key cryptographic system, one key can be made public for encryption, while a different key is made private for decryption, eliminating the key distribution problem encountered in symmetric encryption schemes, where the same shared secret key is used for both encryption and decryption. One widely used public-key encryption scheme is the ElGamal cryptographic system [9], [11] which was proposed by Taher ElGamal in 1984. This approach is based on the Diffie-Hellman key exchange protocol in which security

relies on the difficulty of solving the Discrete Logarithm (DL) problem over a finite field. Another widely used public-key cryptographic system is the RSA [10], [11] first introduced by Ron Rivest, Adi Shamir, and Len Adleman in 1978. The RSA is a block cipher where both the ciphertext and plaintext consist of integers. The Paillier cryptographic system [1], [5], [6], [11] is another highly favored public-key encryption scheme.

In this paper, we use Santilli's Isonumber Theory of the first kind to insert an additional degree of freedom of unit into the encryption process for the ElGamal system, which we call the Iso-ElGamal scheme. In this approach, the unit 1 of normal arithmetic is replaced by a new unit called an isounit. When the isounit is used as both encryption and decryption keys (isokeys), in addition to the public and private encryption and decryption isokeys, our proposed scheme becomes a hybrid public-private-key cryptographic system, providing the strengths of both asymmetric and symmetric schemes [3], [4]. Large isokey sizes of 3,000 digits (about 10,000 bits) or more can be used with minimal additional computational cost. This scheme can also be used for authentications, confidentiality, and data integrity.

The paper is summarized as follows: In Section II, we introduce Santilli's isonumber theory of the first kind. In Section III, we combine the ElGamal cryptographic scheme with isonumber theory to produce our new scheme which we called the Iso-ElGamal Cryptographic Scheme. In Section IV we look at the application of this system using integers and binary data. Section V is devoted to our conclusions.

II. SANTILLI'S THEORY OF ISONUMBERS

An important tool in science and engineering is symmetry. R. M. Santilli was the first to observe that new symmetry relations can be obtained for a fixed physical system via a change in the definition of multiplication in the underlying algebra. He called these new algebras Lie-isotopes, by analogy with a similar phenomenon in nuclear physics where the same atom can have a varying number of neutrons. In this section, we introduce Santilli's Theory of Isonumbers, which is among the tools for this paper (see [2], [7] and

[8]).

Let $(\mathbb{R}, +, \cdot)$ be the real numbers with addition and multiplication. We define the isodual numbers by inverting the direction of the real number line. Define \hat{a} by $\hat{a} + a = 0$. Let $(-1) = \hat{1}$ be the new unit, so that $\hat{1} * \hat{1} = \hat{1}$ and $\hat{a} * \hat{b} = (-a)(-1)(-b) = \hat{a}\hat{b}$. Thus, $(\hat{\mathbb{R}}, +, *)$ is also a representation of the same real numbers.

$$\leftarrow \hat{\mathbb{R}} : 0 : \mathbb{R} \rightarrow$$

A related example arises if we replace our unit 1 by any nonzero number $a = \hat{1}$. Since $\hat{1} * \hat{1} = \hat{1}$, we must have $*$ = a^{-1} . It is easy to check that $\hat{b} = ab$ and $\hat{b}^{-1} = ab^{-1}$. Thus, $(\hat{\mathbb{R}}, +, *)$ is yet another representation of the real numbers. However, now we have the option of choosing a in \mathbb{R} , in \mathbb{C} or any other field \mathbb{F} . In the first case, we obtain a theory of the second kind. In the other cases, we have Santilli's theory of the first kind.

Our scheme is based on the theory of the first kind, where the new unit is not in the field. Let a field $(F, +, \cdot)$ be given (e.g., Z_p , with p prime) and chose an invertible element $\hat{I} = \hat{T}^{-1} \notin F$ for our new the isounit. We introduce a new definition of multiplication on \hat{F} using $*$ = \hat{T} . This allows us to define a new field $(\hat{F}, +, *)$, isofield of the first kind, with rules given by:

$$\begin{aligned} \hat{a} &= a\hat{I}, & \hat{a} * \hat{b} &= (a\hat{I})\hat{T}(b\hat{I}) = ab\hat{I} = \widehat{ab} \\ \hat{a} + \hat{b} &= (a\hat{I}) + (b\hat{I}) = (a + b)\hat{I} = \widehat{a + b}. \end{aligned} \quad (1)$$

$$\hat{0} = 0\hat{I} = 0$$

III. THE ISO-ELGAMAL CRYPTOGRAPHIC SCHEME

This section describes our proposed Iso-ElGama cryptographic scheme. We first introduce the traditional ElGamal system and add the modifications that lead to the Iso-ElGamal scheme.

A. Traditional ElGamal Cryptographic System

The ElGamal cryptographic system is a widely used public-key system that was proposed by Taher ElGamal in 1984. It is based on the Diffie-Hellman key exchange protocol and its security depends on the difficulty of solving the Discrete Logarithms (DL) problem over a finite field, where the plaintext and ciphertext are integers less than some prime number q . The next few sections explain each of these steps [9], [11].

1) **The ElGamal Public and Private Key Generation:** We assume a communication session is taking place between a sender S and a receiver R . First, a large prime numbers q is

randomly selected on the receiver side, and a primitive root g modulo q is chosen. The receiver selects a private-key x such that $1 \leq x < (q - 1)$ to compute $a \equiv g^x \pmod{q}$, where the symbol \equiv represents the congruent relation; x is also later used for decryption. The public-key is given by $PU = \{q, g, a\}$, while the private is $PR = \{x, y\}$, where y represents the private encryption key selected by the sender such that $1 \leq y < (q - 1)$.

2) **The ElGamal Encryption Algorithm:** On the sender's side, let M be the message or plaintext to be encrypted using the ElGamal scheme with $M < q$. We encrypt the message M using the public-key a, g, q , and the private-key y , obtaining ciphertexts C_1 and C_2 . These values are used to compute:

$$K \equiv a^y \pmod{q}, C_1 \equiv g^y \pmod{q} \text{ and } C_2 \equiv M \times K \pmod{q}$$

3) **The ElGamal Decryption Algorithm:** The decryption of the ciphertext (C_1, C_2) using the private-key x and the public-key q to obtain the plaintext M is performed at the receiver side. If K^{-1} is the multiplicative inverse of K modulo q , the message M is obtained by computing $K \equiv (C_1)^x \pmod{q}$, and $M \equiv C_2 \times K^{-1} \pmod{q}$.

B. Iso-ElGamal Cryptographic System

The Iso-ElGamal cryptographic system is described in this section. Similarly, consider a communication session between a sender S and a receiver R . The Iso-Elgamal cryptographic scheme consists of key generation, encryption, and decryption phases described below.

1) **Iso-ElGamal Public and Private key Generation:** The public and private isokeys generated for the communication between sender S and receiver R uses a randomly chosen large prime number q and a primitive root g modulo q . In addition, a large positive integer isounit \hat{I} is chosen to represent the shared secret encryption-decryption isokey and used to compute the following:

$$\hat{q} = q\hat{I} \quad \text{and} \quad \hat{g} = g\hat{I} \quad (2)$$

After selecting a private decryption key x such that $1 \leq x < (q - 1)$ and computing $\hat{x} = x\hat{I}$ on the receiver side, one computes

$$\hat{a} = (g^x)\hat{I} \pmod{\hat{q}} \quad (3)$$

The sender selects a private encryption key y with $1 \leq y < (q - 1)$ and uses it to calculate the private encryption isokey $\hat{y} = y\hat{I}$. The public isokey is given by $PU = \{\hat{q}, \hat{g}, \hat{a}\}$, and the private and secret isokeys are $PR = \{\hat{x}, \hat{y}, \hat{I}\}$.

The values x, y , and \hat{I} can be selected to be large prime numbers in order the make the factorization of $\hat{x} = x \times \hat{I}$

to obtain x and \hat{I} from the private isokey \hat{x} more difficult for unauthorized users who have access to \hat{x} . Similar for the the factorization of $\hat{y} = y \times \hat{I}$.

2) **The Iso-ElGamal Encryption Algorithm:** The message $M < q$ with corresponding isonumber $\hat{M} = M\hat{I} < \hat{q}$ can be encrypted by the sender who has access to the public isokeys $\hat{a}, \hat{q}, \hat{g}$, the private key y and isokey \hat{y} , in addition to the secret isokey (isounit) \hat{I} . In addition, the sender can compute $a = \hat{a}\hat{I}^{-1}$ and $g = \hat{g}\hat{I}^{-1}$. With this information, the sender and calculate \hat{K} :

$$\hat{K} = (a^y)\hat{I} \pmod{\hat{q}} \quad (4)$$

With \hat{K} known and using $*$ = \hat{I}^{-1} , we obtain the ciphertext \hat{C}_1 and \hat{C}_2 :

$$\hat{C}_1 = (g^y)\hat{I} \pmod{\hat{q}} \quad (5)$$

and

$$\hat{C}_2 = (\hat{M} * \hat{K}) \pmod{\hat{q}} \quad (6)$$

The values of \hat{C}_1 in (5) and \hat{C}_2 given by (6) represent the pair of ciphertext (\hat{C}_1, \hat{C}_2) obtained using the Iso-ElGamal encryption algorithm.

Alternatively, if the values of K, C_1 , and C_2 obtained from the ElGamal encryption algorithm are first calculated, the values of \hat{K}, \hat{C}_1 , and \hat{C}_2 can be computed as

$$\hat{K} = K\hat{I} \text{ and } \hat{C}_1 = C_1\hat{I} \text{ and } \hat{C}_2 = C_2\hat{I} \quad (7)$$

3) **The Iso-ElGamal Decryption Algorithm:** The Iso-ElGamal decryption algorithm is implemented at the receiver side who has access to the private key x , isounit \hat{I} , and computed isokey \hat{x} , in addition to the public isokey $PU = \{\hat{q}, \hat{g}, \hat{a}\}$. We also assume that the ciphertext \hat{C}_1 and \hat{C}_2 have been transmitted to the receiver. The receiver already has access to the private key x and can compute the quantities

$$q = \hat{q}\hat{I}^{-1} \text{ and } C_1 = \hat{C}_1\hat{I}^{-1} \text{ and } C_2 = \hat{C}_2\hat{I}^{-1} \quad (8)$$

and use them to find

$$\hat{K} \equiv (C_1)^x \hat{I} \pmod{\hat{q}}. \quad (9)$$

Using \hat{K} , the receiver can calculate

$$K = \hat{K}\hat{I}^{-1} \quad (10)$$

and use it to compute

$$Z = K^{-1} \pmod{q} \quad (11)$$

and

$$\hat{Z} = Z\hat{I}. \quad (12)$$

The value of \hat{M} is given by

$$\hat{M} = (\hat{C}_2 * \hat{Z}) \pmod{\hat{q}\hat{I}} = (\hat{C}_2\hat{I}^{-1}\hat{Z}) \pmod{\hat{q}} \quad (13)$$

where $*$ = $\hat{I} = \hat{I}^{-1}$.

Finally, the original message is obtained as

$$M = \hat{M}\hat{I}^{-1}. \quad (14)$$

Thus, the original message M encrypted on the sender side is retrieved.

IV. APPLICATION OF THE ISO-ELGAMAL CRYPTOGRAPHIC SCHEME

In this section, we explore a few implementations of the Iso-ElGamal scheme. First, we consider the encryption and decryption of messages represented by positive integers less than the chosen isounit \hat{I} . Secondly, we consider information or data represented by bits. Results for each were obtained using simulation software we have written using Mathematica 12 software package.

A. Integer Encryption/Decryption Application Case

The Iso-ElGamal is used here to encrypt and decrypt information encoded into an integer less than the isounit \hat{I} . Consider the encryption and decryption of the message $M = 24$ using the Iso-ElGamal system.

Isokeys Generation Phase:

The generation of the public isokeys $PU = \{\hat{q}, \hat{g}, \hat{a}\}$ and the private and secret isokeys $PR = \{\hat{x}, \hat{y}, \hat{I}\}$ needed for encryption and decryption are shown here. They are extremely large with a number of digits generally around 3,100 digits corresponding to a number of bits around 10,298 bits. These large number of bits are necessary for highly computationally secure isokeys and ciphertext against attacks such as brute force. Displaying all values from $PU = \{\hat{q}, \hat{g}, \hat{a}\}$ and $PR = \{\hat{x}, \hat{y}, \hat{I}\}$ will take many pages because of their large sizes.

So, only the values of \hat{I}, q, g, x and y are displayed here. Other values such $\hat{q}, \hat{g}, \hat{a}, \hat{x}$, and \hat{y} can be computed from these values as explained above.

We randomly generate a large positive integer with 3,000 digits representing the secret isokey (isounit) \hat{I} used for encryption and decryption. It is given by

$\hat{I} = 61881370267169220159050077054207864289330937$

 7615850482318922471245844118671070132470742916.

A prime number q with 100 digits is randomly generated, and a primitive root g modulo q with 100 digits is selected.

The value of q is

$q = 9760942796514275765881544370070504554461264179752849592070224700654377607327139902694438634730098111$

The value of g is

$g = 2440235699128568941470386092517626138615316044938212398017556175163594401831784975673609658682524535$

The public isokey \hat{q} is calculated as $\hat{q} = q\hat{I}$, and it has 3, 100 digits and 10, 298 bits but not displayed here.

The public isokey $\hat{g} = g\hat{I}$ with 3, 100 digits and 10, 296 bits is also calculated but not displayed here.

The private key x with 99 digits and 3, 28 bits is randomly generated and given by

$x = 367119322642078637789512557541048667547257023148314118526182175382629287616953592747817873242399922.$

The private isokey \hat{x} is calculated as $\hat{x} = x \times \hat{I}$, and it has 3, 099 digits and 10, 293 bits, also not displayed here.

We also calculate $a = g^x \pmod{q}$, and it has 100 digits and 332 bits. It is given by

$a = 8670140956271752363721691551414417075934976627920447306324435831863875366409938603386352791932708352.$

The associated isokey \hat{a} is computed as $\hat{a} = a \times \hat{I}$, and it has 3100 digits and 10298 bits, also not displayed here.

The private encryption key y is randomly generated and has 99 digits and 329 bits, and it is given by

$y = 695946457771683057076364591958034612150810033638431945316822573781604326896217519115097920359131458.$

The corresponding private isokey \hat{y} has 3, 099 digits and 10, 294 bits, and it is computed as $\hat{y} = y \times \hat{I}$. Also, not displayed here. So, the public isokeys is $PU = \{\hat{q}, \hat{g}, \hat{a}\}$ and the private isokey $PR = \{\hat{x}, \hat{y}, \hat{I}\}$ are all computed and shown above.

Encryption Phase:

The message $M = 24$ is encrypted to obtain the ciphertext \hat{C}_1 given by (5) and \hat{C}_2 given by (6). The cipher \hat{C}_1 has 3100 digits and is given by

$\hat{C}_1 = 1714037909774206145505461105140523417249561350039986353561275336287536866609280839503888414711111059625655163348700768465667987236900261074357370323748859993359280657567931339004379094883734345930033424964532337140800538454009517906217429454282411897012849887271288537750813319644899978061163571842769671456170601013716821741717957125659538111473655636828821545250313215263073235$

The pair of ciphertext (\hat{C}_1, \hat{C}_2) represents the secure encrypted message that will be store or transmitted through a channel that may be unsecured.

It takes only 0.0022954 seconds to encrypt the message. The computational cost time-wise is not large despite the large number of digits associated with the isokeys. The isonumbers are formed by having generally about one extra multiplication by \hat{I} to an original value such as a key in order to produce an isokey, for instance. So, a very high security based on very large isokeys and ciphertext is achieved with minimum computational cost.

Note that the values of the ciphertexts \hat{C}_1, \hat{C}_2 , and others values are very large and require larger memory size to store, or larger transmission time. This problem can be overcome by further processing and reducing them to smaller sizes that will be discussed in our next paper.

Decryption Phase:

The decryption of the ciphertext (\hat{C}_1, \hat{C}_2) is achieved using (8) through (14) to obtain \hat{M} with 3,002 digits but not displayed here. The final decrypted message obtained is $M = 24$, which corresponds to the original message that was initially encrypted.

The Iso-ElGamal cryptographic scheme may possibly takes us one step closer to an encryption scheme that is resistant to quantum computing-based attacks because of its characteristics, isokeys and ciphertext with a very large sizes.

The number of digits for each of the public isokeys and private isokeys is arbitrary, but the higher the number of digits, the more secure the isokeys and associated ciphertexts, but also the higher the computational cost.

B. Binary Encryption/Decryption Case Applications

The Iso-ElGamal scheme can be used to encrypt a bit represented by 0 or 1. Before encryption, each bit must

be first mapped to a positive integer greater than 1 in order to avoid having the associated ciphertext \hat{C}_2 equals 0 when encrypting bit 0. The isounit \hat{I} can also be given a different value for each bit of encryption.

For illustration purposes, consider encrypting the data byte 10110011 and then decrypting the associated ciphertext to recover the original data byte.

The public keys q and g used for each bit encryption are the same, as well as the private keys x and y are also the same when encrypting and decrypting each bit. But the associated public isokey $PU = \{\hat{q}, \hat{g}\}$, private isokey $PR = \{\hat{x}, \hat{y}\}$, and \hat{a} are computed using each associated isounit $\hat{I}_i, i = 1, 2, \dots, 7, 8$ for each bit as shown in Fig. 1 and Fig. 2. Also, before encryption, a bit 0 is mapped or encoded into integer $M = 3$, while a bit 1 is mapped or encoded into $M = 2$ for example, other values different to 2 and 3 can be used as well. The mapping of bit 0 to a value not equal to zero will avoid obtaining the trivial value $\hat{C}_2 = 0$ for the encryption of all bit 0 as shown in (6). Similarly, the mapping of bit 1 to a value other than 1 will avoid having the same value of \hat{C}_2 for all bit 1, when the values of \hat{k} and \hat{q} are the same for each bit 1 as shown in (6).

The keys used for the encryption/decryption of each bit are $q = 17, g = 11, x = 6,$ and $y = 4$, and the corresponding isonumbers $\hat{q}, \hat{g}, \hat{x}, \hat{y}$ are computed using the associated isounit $\hat{I}_i, i = 1, 2, \dots, 7, 8$ shown in in Fig. 1 and Fig. 2. The values of these isokeys are small and only for illustration purposes, but they must be made as big as possible in order to produce secure ciphertexts \hat{C}_1 and \hat{C}_2 .

For instance, to encrypt the first bit of 1 in the data byte, it is first mapped to $M_1 = 2$ before encryption using $\hat{I}_1 = 5$ to obtain ciphertexts \hat{C}_{11} and \hat{C}_{21} , where the second index corresponds to the index of the isounit used, while the first index distinguishes between the first and second cipher. Using $\hat{I}_1 = 5$, the computed isokeys are $\hat{q} = q\hat{I}_1 = 85, \hat{g} = g\hat{I}_1 = 55, \hat{x} = x\hat{I}_1 = 30,$ and $\hat{y} = y\hat{I}_1 = 20, \hat{a} = a\hat{I}_1 = [g^x \pmod{q}]\hat{I}_1 = 40, \hat{C}_{11} = 20$ and $\hat{C}_{21} = 75$, as shown in Fig. 1. The corresponding decrypted value is $M_1 = 2$, which is then decoded as bit 1, as shown in Fig. 2. Other bit values in the data byte are encrypted and decrypted in a similar manner and results are summarized in Fig. 1 and Fig. 2. Results on Figs. 1 and 2 are obtained from the Mathematica 12 simulation program which we have written.

In case that more data bytes need to be encrypted, the isounits \hat{I}_1 through \hat{I}_8 can be rotated left or right by a number of units $n > 1$ instead of choosing difference random isounits.

V. CONCLUSIONS

In this paper, we have introduced the Iso-ElGamal cryptographic scheme which combines the traditional ElGamal Cryptographic System with Santilli's Isonumber Theory of the first kind to provide an additional degree of freedom of unit to the encryption-decryption of data encoded into positive integers or bits. Our approach includes both public-key or asymmetric encryption approach, and symmetric encryption using an isounit as share encryption and decryption isokey; therefore, leading to having a Hybrid public-key and private-key cryptographic system with a substantial increase in security of the associated ciphers. The cryptographic process which includes the key generation, encryption, and decryption phases is performed in an isofield whereby the new parameters are isonumbers. The paper also provides applications of the Iso-ElGamal scheme for the encryption of any data or information that can be encoded into positive integers, as well as bits. In addition, a wide range of applications such as confidentiality, data integrity, and digital signature can be implemented using this Iso-ElGamal cryptographic scheme. Our contribution includes the strengthening of the ElGamal cryptographic system using isonumber theory of the first through a mathematical description of the encryption and decryption approaches. Future work includes investigating how well the Iso-ElGamal scheme will resist quantum computing-based attacks.

Abstract—The proliferation of autonomous and connected vehicles on our roads is increasingly felt. However, the problems related to the optimization of the energy consumed, to the safety, and to the security of these do not cease to arise on the tables of debates bringing together the various stakeholders. By focusing on the security aspect of such systems, we can realize that there is a family of problems that must be investigated as soon as possible. In particular, those that may manifest as the system expands. Therefore, this work aims to model and simulate the behavior of a system of autonomous and connected vehicles in the face of a malware invasion. In order to achieve the set objective, we propose a model to our system which is inspired by those used in epidimology, such as SI, SIR, SIER, etc. This being adapted to our case study, stochastic processes are defined in order to characterize its dynamics. After having fixed the values of the various parameters, as well as those of the initial conditions, we run 100 simulations of our system. After which we visualize the results got, we analyze them, and we give some interpretations. We end by outlining the lessons and recommendations drawn from the results.

Index Terms—Security, Malware, Stochastic Model, Compartmental model, Autonomous and Connected Vehicle, CAV, Intelligent Transportation Systems.

I. INTRODUCTION

V2X is a generic term that specifies the interactions which a connected vehicle can have with its environment. The letter X in V2X can be V (V2V), I (V2I) or P (V2P). The V2V comprises the communication types occurring between vehicles. Whereas, V2I deals with the interactions that the vehicle can have with the infrastructure and vice versa. However, the last combination (V2P) represents the communication that can take place between the vehicle and the pedestrians.

All the X mentioned above can either be the target of one or more attacks, or their sources. Whatever the X in question, because it is part of an intelligent transport system, it is essential to protect it and protect oneself against it, otherwise the life of the human being is in danger [1]. However, apart from the human being, the autonomous and connected vehicle is both the most interesting and the most complex case to deal with. In addition to its mobile aspect, the complexity of such

a system, from the point of view of its security, lies in the extent of its attack surface that it presents [2] [3].

Despite all these fears, manufacturers are constantly producing new prototypes with increasingly sophisticated capabilities and functions [4]. Also, a segment of customers interested in this type of vehicle, not yet mature, is increasingly appreciated [5]. This means that converging towards a generation of society in which the word “driver’s license” would have no meaning is a certainty.

From what we have just said, implementing safety procedures and techniques dedicated to this new type of system, which will soon invade our roads, is a necessity. However, even if we have made enormous progress in this area, it is still insufficient [6]. Indeed, one can find works that have addressed the internal and local security of these systems as an isolated vehicle [7]. Others have addressed a more global aspect, given the local environment of such systems [8]. One can find other works which preferred to approach real cases [9]. Whatever the context of the work in question, it can be said that the conditions are not yet in place to draw definitive conclusions. Thus, researchers and engineers in such a situation always prefer to resort to modeling and simulation in order to predict what may happen in the future or in inaccessible situations (see sec. II).

The strength of the modeling and simulation approach is that, in most cases, we have tested them in areas relevant to the present for which we have enough experience. We can therefore think of reusing them, with precautions, to model phenomena relating to new domains for which we lack experience or access, as for the present work.

This work proposes to investigate the situation where most vehicles in circulation will be autonomous and connected vehicles. We consider the case of an environment where there is no trust. The problem that arises is, considering the conditions mentioned, what will be the dynamics of such a system if it is subjected to pandemic malware? To help answer this question, we propose in section III a stochastic model, based on what has been done for Covid-19, while adapting it to our case [10]. Solving the equations of the proposed model by simulation

will allow us to draw conclusions about certain requirements that a Connected and Autonomous Vehicle (CAV) system must meet in order to minimize the damage.

Besides the introduction, this article includes: (i) a section devoted to a review of the literature as close as possible to the subject treated (sec. II) and in which the research gap is expressed; (ii) a third section with several subsections all aimed at specifying quantities and operating the model (sec. III); (iv) the section (sec. IV) brings together everything concerning the simulation and the choice of the various parameters. Also, at the level of this section, one visualizes the results got after having numerically solved the model; (v) section V discusses the results got; (vi) In section VI, we end with a conclusion.

II. LITERATURE REVIEW

In our previous work [11], we studied a behavior of malware spreading over V2V channel by using a Multi-agent modeling approach. The results of the simulation show clearly that the density of traffic has a large impact in malware spreading. Then, the work on [12] presents an overview of the propagation of worm on the VANET network and refers to some research has dealt with the subject. The paper [13] examines the node movements in VANET's Network merged with the velocity dependent shadow fading model of wireless links between VANET nodes.

Besides, Authors of [14] provide an analytical study of the worm's propagation in the both static and dynamic traffic of urban system. They provide models for mobility, communication channel, Medium Access Control and worm propagation. And [15] focus on the spreading of worm and patches on highway corridor of 10km of length.

In [16], the authors discuss the parameters leading to active worm propagation on VANET. They describe a stochastic model based on the SIR epidemic model to define a worm's spreading on high and low traffic density. Although, other reseachers [17] propose a two-layer model named virus-traffic coupled dynamic model to study a virus propagation on V2V channel. this model combines the SIR model and cellular Automata.

Authors of [18] investigate the worm spreading through V2V communication and introduce a numerical model of worm spreading based on SIR model taking account Immunization. while those of [19] presents a SEIR-S Model based on VANET Network behavior and SIR Epidemic Model. A numerical analysis and Agent-based Modeling by Netlogo simulator are done to verify a proposed model.

To our knowledge, none of the previous work has solved the above problem using stochastic models reflecting more control measures. While the latter are widely used in the case of pandemic modeling, for example. We propose in this work to fill this gap by relying on epidemiologic modeling work while providing the necessary extensions and adaptations.

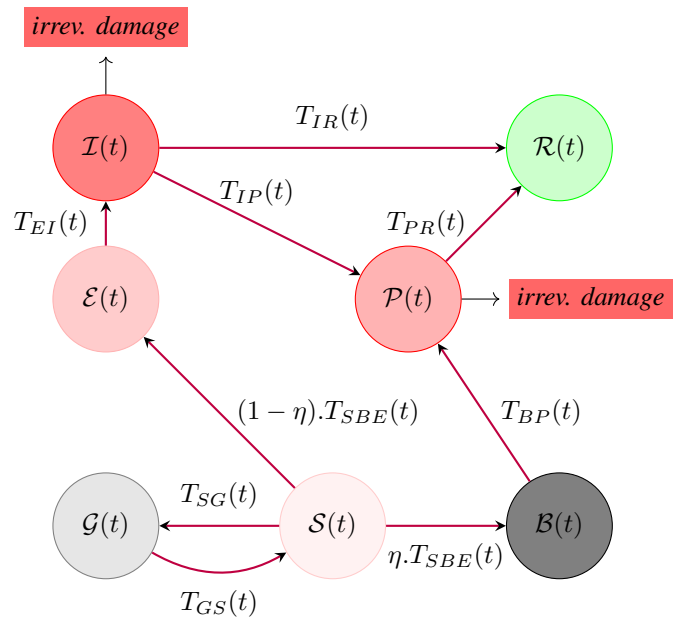

Fig. 1. Model dynamics graph

III. MODEL

A. Dynamics Graph

The vertices of the graph (Fig. 1) represent the sets in which a CAV could live. The *Susceptible* set, denoted \mathcal{S} , includes CAVs that are susceptible to certain malware-based attacks. This is the most populated set at the start of the malware spread. A CAV belonging to this set can evolve in three ways. Namely, it can transit to the *Blacklisted* set, denoted \mathcal{B} , if we can identify it as more likely to be infected than many other CAVs. Likewise, the *Graylisted* set, denoted \mathcal{G} , encloses CAVs facing moderate risk compared with the former which turned out to be false positives. Eventually, the exposed CAVs not belonging to either last both mentioned sets occupy the *Exposed* set, denoted by \mathcal{E} . Both the CAVs in the *Infected* set, denoted \mathcal{I} , and those in *Blacklisted* one can be members of the *Purging* set, denoted \mathcal{P} . The latest contains CAVs in sterilization stage. Upon achieving the purging process, and if the damage is reversible, the CAV becomes a new member of the *Recovered* set, denoted \mathcal{R} . we should mention that \mathcal{I} and \mathcal{B} are distinct from each other. On the one hand, the set \mathcal{I} comprises elements that are positively infected and under no control. Although \mathcal{B} may contain both infected and high-risk items, regardless of the situation, all of \mathcal{B} 's items are under control.

We labeled each vertex in the graph with the same letter of its underlying set as being a function of time. Indeed, it represents the cardinality of the considered set fixed at time t .

B. Inter-sets Transition Specification

A transition occurs from a set \mathcal{X} according to a stochastic process. We propose to model the number T_{ij} of CAVs leaving a set i and arriving at a set j , at time t , by a binomial

or Poisson process. In this work, we consider the progression of time t as a discrete sequence t_n . The following equations describe the transitions, as well as the various arguments and parameters involved.

Equation (1) gives the number of elements leaving set \mathcal{S} to arrive at set \mathcal{B} (resp. \mathcal{E}) at time t . Those who have probably been blacklisted. $\mathbb{P}_{S_{BE}}$ is the probability that a CAV leaves set \mathcal{S} and arrives at set \mathcal{B} (resp. \mathcal{E}).

The TABLE II gives the meaning of the other parameters.

$$T_{S_{BE}}(t) \sim Poisson(\mathcal{S}(t) \cdot \mathbb{P}_{S_{BE}}(t)) \quad (1)$$

Where

$$\mathbb{P}_{S_{BE}}(t) = 1 - \exp(-\beta \cdot c(t) \cdot h \cdot \mathcal{I}(t) / \mathcal{N}) \quad (2)$$

Equation (3) gives the number of elements leaving set \mathcal{S} to arrive at set \mathcal{G} at time t . Those who have probably been graylisted. \mathbb{P}_{SG} is the probability that a CAV leaves set \mathcal{S} and arrives at set \mathcal{G} .

$$T_{SG}(t) \sim Poisson(\mathcal{S}(t) \cdot \mathbb{P}_{SG}(t)) \quad (3)$$

Where

$$\mathbb{P}_{SG}(t) = 1 - \exp(\eta(1 - \beta) \cdot c(t) \cdot h \cdot \mathcal{I}(t) / \mathcal{N}) \quad (4)$$

Equation (5) gives the number of elements leaving set \mathcal{E} to arrive at set \mathcal{I} at time t . Those who have probably been infected. \mathbb{P}_{EI} is the probability that a CAV leaves set \mathcal{E} and arrives at set \mathcal{I} .

$$T_{EI}(t) \sim Bin(\mathcal{E}(t) \cdot \mathbb{P}_{EI}) \quad (5)$$

Where

$$\mathbb{P}_{EI} = 1 - \exp(-h \cdot \tau_{ei}) \quad (6)$$

Equation (7) gives the number of elements leaving set \mathcal{I} to arrive at set \mathcal{P} at time t . Those who have probably been purged. \mathbb{P}_{IP} is the probability that a CAV leaves set \mathcal{I} and arrives at set \mathcal{P} .

$$T_{IP}(t) \sim Bin(\mathcal{I}(t) \cdot \mathbb{P}_{IP}) \quad (7)$$

Where

$$\mathbb{P}_{IP} = 1 - \exp(-h \cdot \tau_{ip}) \quad (8)$$

Equation (9) gives the number of items leaving set \mathcal{I} to arrive at set \mathcal{R} at time t . Those who have probably been recovered. \mathbb{P}_{IR} is the probability that a CAV leaves set \mathcal{I} and arrives at set \mathcal{R} .

$$T_{IR}(t) \sim Bin(\mathcal{I}(t) \cdot \mathbb{P}_{IR}) \quad (9)$$

Where

$$\mathbb{P}_{IR} = 1 - \exp(-h \cdot \tau_{ir}) \quad (10)$$

Equation (11) gives the number of items leaving set \mathcal{G} to arrive at set \mathcal{S} at time t . Those who have probably been recovered. \mathbb{P}_{GS} is the probability that a CAV leaves set \mathcal{G} and arrives at set \mathcal{S} .

$$T_{GS}(t) \sim Bin(\mathcal{G}(t) \cdot \mathbb{P}_{GS}) \quad (11)$$

Where

$$\mathbb{P}_{GS} = 1 - \exp(-h \cdot \tau_{gs}) \quad (12)$$

Equation (13) gives the number of items leaving set \mathcal{B} to arrive at set \mathcal{P} at time t . Those who have probably been recovered. \mathbb{P}_{BP} is the probability that a CAV leaves set \mathcal{B} and arrives at set \mathcal{P} .

$$T_{BP}(t) \sim Bin(\mathcal{B}(t) \cdot \mathbb{P}_{BP}) \quad (13)$$

Where

$$\mathbb{P}_{BP} = 1 - \exp(-h \cdot \tau_{bp}) \quad (14)$$

Equation (15) gives the number of items leaving set \mathcal{P} to arrive at set \mathcal{R} at time t . Those who have probably been recovered. \mathbb{P}_{PR} is the probability that a CAV leaves set \mathcal{P} and arrives at set \mathcal{R} .

$$T_{PR}(t) \sim Bin(\mathcal{P}(t) \cdot \mathbb{P}_{PR}) \quad (15)$$

Where

$$\mathbb{P}_{PR} = 1 - \exp(-h \cdot \tau_{pr}) \quad (16)$$

Equations (17 and 18) represent the number of CAVs that experienced irreversible damage.

$$T_{Idam.}(t) \sim Bin(\mathcal{I}(t) \cdot \mathbb{P}_{Idam.}) \quad (17)$$

$$T_{Pdam.}(t) \sim Bin(\mathcal{P}(t) \cdot \mathbb{P}_{Pdam.}) \quad (18)$$

Where

$$\mathbb{P}_{Pdam.} = \mathbb{P}_{Idam.} = 1 - \exp(-h \cdot \delta) \quad (19)$$

C. Model Equations

Equations from (20) to (26) specify the dynamics of the proposed model. Being already mentioned that time is considered as a discrete variable, the step taken to solve them is Δt . It can be observed briefly that the evolution of the cardinality of each set is the difference between the number of CAVs having just joined this set at time t and that having just left it at the same time.

$$\mathcal{S}(t + \Delta t) = \mathcal{S}(t) - T_{S_{BE}}(t) - T_{SG}(t) + T_{GS}(t) \quad (20)$$

$$\mathcal{E}(t + \Delta t) = \mathcal{E}(t) + (1 - \eta) \cdot T_{S_{BE}}(t) - T_{EI}(t) \quad (21)$$

$$\mathcal{G}(t + \Delta t) = \mathcal{G}(t) + T_{SG}(t) - T_{GS}(t) \quad (22)$$

$$\mathcal{B}(t + \Delta t) = \mathcal{B}(t) + \eta T_{S_{BE}}(t) - T_{BP}(t) \quad (23)$$

$$\mathcal{I}(t + \Delta t) = \mathcal{I}(t) + T_{EI}(t) - T_{IR}(t) - T_{IP}(t) - T_{Idam.}(t) \quad (24)$$

$$\mathcal{P}(t + \Delta t) = \mathcal{P}(t) + T_{IP}(t) + T_{BP}(t) - T_{PR}(t) - T_{Pdam.}(t) \quad (25)$$

$$\mathcal{R}(t + \Delta t) = \mathcal{R}(t) + T_{PR}(t) + T_{IR}(t) \quad (26)$$

TABLE I
MODEL INITIAL VALUES

Symbol	Description	Value
\mathcal{N}_0	The Toatal Number of CAVs	10^6
\mathcal{E}_0	Initial Exposed CAVs	300
\mathcal{I}_0	Initial Infected CAVs	5
\mathcal{G}_0	Initial Graylisted CAVs	0
\mathcal{B}_0	Initial Blacklisted CAVs	0
\mathcal{P}_0	Initial Purging CAVs	0
\mathcal{R}_0	Initial Recovered CAVs	0

D. Isolation Function

Among the best strategies to adopt during an epidemic, or a pandemic, is the strategy of mobility restriction. We propose to adopt the same in the CAV community. However, as soon as we have not yet arrived at a generalist artificial intelligence comparable to that of humans, the isolation procedures may not be the same. One can, for example, think of memorizing all the CAVs with which the infected one has cooperated directly and repeat the same thing for a higher order of cooperation in order to apply the isolation. The questions that arise in this scenario and in others like it, with what latency should it be? And what impact will the choice of restriction time have on controlling the spread of malware? The injection of the function $c(t)$ specified in the equation (27), in the model allows us to know its usefulness.

$$c(t) = \begin{cases} c_0 & \text{if } t \leq t_{res} \\ (c_0 - c_{res})e^{-\kappa(t-t_{res})} + c_{res} & \text{if } t > t_{res} \end{cases} \quad (27)$$

IV. SIMULATION AND PARAMETERS ESTIMATION

A. Parameters and initial conditions Fixing

To simulate the model proposed in section III, we propose the values given in TABLE II and the initial conditions as specified in TABLE I. Because of the lack of data (futuristic scenario), we tried to fix the different values in the most rational way possible.

We implemented the simulation in a Python program. We have set the number of executions to 100. For each, we numerically solve the proposed model by specifying the potential evolution of each set or compartment. We plotted curves at the end of each simulation step (see Fig. 2). We should also mention that we automatically extracted the maximum values that appear in Fig. 2 and Fig. 3 from the simulation.

B. Simulation

Fig. 3 shows the evolution of the cardinality of the different sets considered in the model proposed in section III. The first remark which jumps to the eyes is that the evolution of the cardinality of the sets \mathcal{I} , \mathcal{E} , \mathcal{B} and \mathcal{G} on the one hand, and that of \mathcal{P} and \mathcal{R} have the same shape. However, the first family of these sets shows peaks, while the second tends towards a level from the thirtieth day. While we can clearly notice that the curve corresponding to the evolution of the cardinality of \mathcal{S} follows a completely different pace. In fact, the curve in question represents a degradation by oscillating until these oscillations attenuate and tend towards 0.

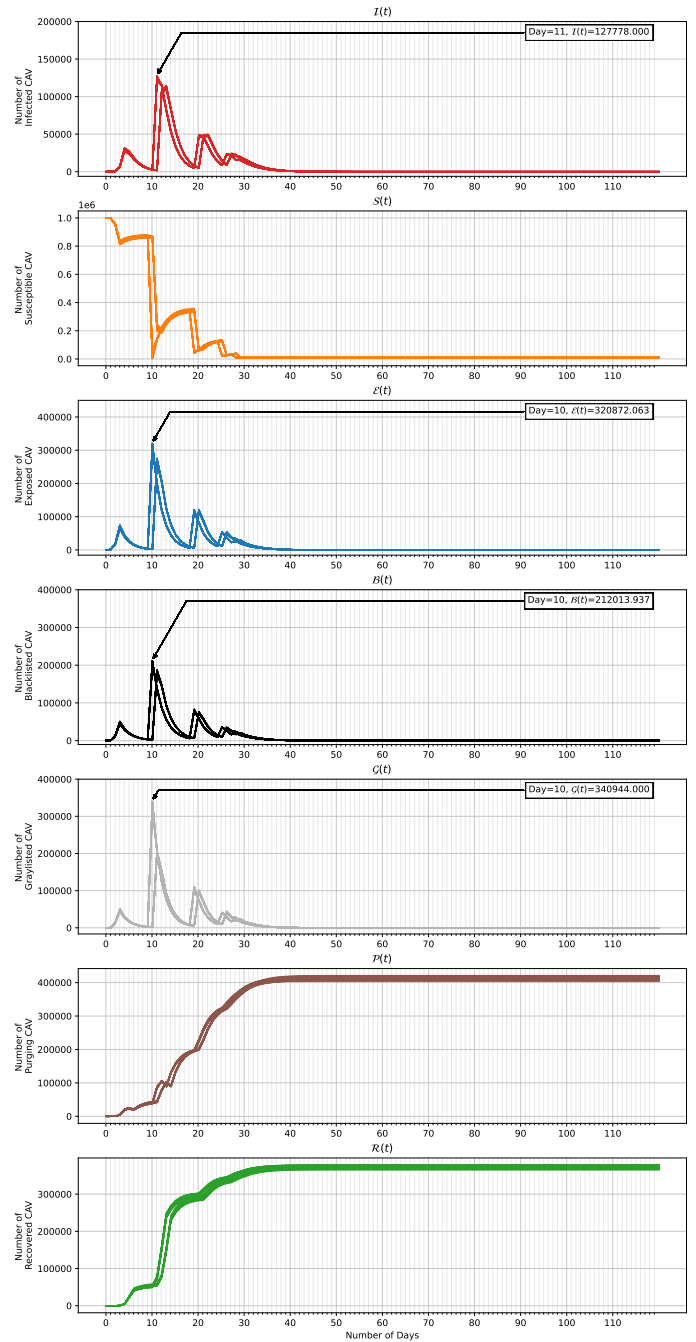

Fig. 2. Cardinality Evolution of the Sets \mathcal{I} , \mathcal{S} , \mathcal{E} , \mathcal{B} , \mathcal{G} , \mathcal{P} and \mathcal{R}

Let's inspect the collective behavior of the curves in Fig. 2. At time 0 until the third day, the curve $S(t)$ decreases so that it increases again until about the tenth day. Then, a sudden decrease is observed near this one. This pattern repeats until the set \mathcal{S} becomes empty. The drops are explained because the CAVs are leaving compartment \mathcal{S} to go towards \mathcal{G} , \mathcal{B} or \mathcal{E} . This corresponds to peaks in the curves of the latter. The increase in the cardinality of the host sets originates from a decrease at the level of the set \mathcal{S} , while the decrease of that of \mathcal{G} generates the increase observed in the curve of \mathcal{S} . The

TABLE II
MODEL PARAMETERS ESTIMATION

Symbol	Description	Range	Mean	Std	Baseline Value
c_0	Initial Cooperation Rate	[0, 800]	500	—	—
c_{res}	Cooperation Rate after Restriction	[0, 10]	0.9921	0.6468	1
k	Exponential decreasing speed of the cooperation rate	[0, 1]	0.0993	0.0101	0.1
β	Probability of Malware Injection	[0, 1]	0.5075	0.02908	0.5
η	Isolation Ratio of Exposed CAVs	[0, 1]	0.3975	0.0146	0.4
τ_{ei}	Transition Rate from Exposed to Infected State	[0, 1]	0.5000	0.0017	0.5
τ_{gs}	Transition Rate from Greylisted to Scuceptible State	[0, 1]	0.5	0.0023	0.5
τ_{ip}	Transition Rate from Infected to Purging State	[0, 1]	0.3001	0.0010	0.3
τ_{bp}	Transition Rate from Blacklisted to Purging State	[0, 1]	0.4501	0, 0009	0.45
τ_{ir}	Transition Rate from Infected to Restored State	[0, 1]	0.3	0.0010	0.6
τ_{pr}	Transition Rate from Purging to Restored State	[0, 1]	0.8000	0.0010	0.8
δ	Irreversible Damage Rate	[0, 1]	0.1999	0.0009	0.2

Fig. 3. Cardinality Evolution of Sets S , \mathcal{E} , \mathcal{I} , \mathcal{R} according to the worst scenario

cardinality of \mathcal{E} (resp. \mathcal{B}) generates an increase in that of \mathcal{I} (resp. \mathcal{P}). Set \mathcal{I} is unloaded in three ways: (i) The CAVs that have been detected as infected, transit to set \mathcal{P} to be purged, which explains the increase in $\mathcal{P}(t)$ in this period. (ii) the CAVs having been disinfected by means other than those recommended by the manufacturer or equivalent are found to belong to the set \mathcal{R} , which implies the increase of $\mathcal{R}(t)$. (iii) CAVs that have suffered irreversible damage are no longer part of the system. A part of \mathcal{P} can be lost forever while what remains is held by \mathcal{R} , hence the difference between the two levels, given the simulation parameters used.

The curves that we have just analyzed above are in fact families of curves corresponding to several simulation runs. The Fig. 3 represents the variation of the cardinality of the sets S , \mathcal{I} , \mathcal{E} and \mathcal{R} which are associated with the scenario manifesting the greatest peak of \mathcal{I} . This way of representing the curves supports the analysis that we made for Fig. 3. For example, the shift between the different curves shows the consistency that exists between the proposed model, more precisely, its dynamics, and the results got.

The reproduction number is widely used in epidemiologic [20]. In our context, it characterizes the power of propagation of a Malware within the framework of a CAV community. When we calculate this parameter in the presence of con-

Fig. 4. Evolution of the R_c

trol measures, we rather speak of the effective reproduction number R_c . In this simulation, we have adopted the equation (28) which is like those which have been widely used in the literature while respecting its compatibility with our proposed specific model.

$$R_c(t) = \frac{\beta(t).c(t).(1 - \eta(t))}{\tau_{ip}(t) + \delta(t) + \tau_{ir}(t)} \quad (28)$$

In Fig. 4, we represent a sample of the stochastic behavior of the number $R_c(t)$. We can say that under the values taken by the parameters (see. TABLE II), the number of reproduction under control is $R_c(t) < 1$ around day 50. Which corresponds to about half of the period set for the simulation.

V. DISCUSSION

The proposed model and the simulation results got to make it possible to deduce the importance of the safety of transport systems and CAVs in particular. Also, we should add that this type of model also allows the prediction of the resources that we must put in place in order to control such scenarios. We can summarize the lessons to be drawn from this work in:

- (i) We recommend minimizing the T_{ij} numbers contributing to lead a CAV towards irreversible damage, such as fatal accidents.
- (ii) Minimizing the cardinality of \mathcal{G} by minimizing misidentification of CAVs that were suspected to be exposed.

This corresponds to minimizing targeting uncertainty. (iii) Increasing η increases the cardinality of \mathcal{B} , which means going from a less controlled system to a more controlled one. In this way, we reduce the cardinality of \mathcal{E} and subsequently that of \mathcal{I} . (iv) The dynamic of the model shows us that the sterilization stage undergone by the CAVs in \mathcal{P} requires an infrastructure dedicated to this type of operation in sufficient quantity and according to an adequate dispersion pattern. (v) The number T_{ir} sheds light on the fact that migration to \mathcal{P} is not the one and only possible choice. In very specific situations, such as communication failures, the probability of transition to \mathcal{P} can tend towards 0, which does not leave several choices to our CAV. So encouraging manufacturers to adopt the Open-CAV model, the twin of Open Source in software context, can be very useful.

VI. CONCLUSIONS

Through this work, we have investigated the case where a system of autonomous and connected vehicles would undergo the spread of malware at a certain infection rate. The usefulness of this modeling lies because a transport system is as critical as the life of the human being is.

This type of problem has been addressed in the literature in several ways. Namely, we can cite, among others, approaches based on multi-agent models, those based on epidemic models, either deterministic or stochastic. Finally, other researchers and engineers have preferred to investigate more realistic scenarios on prototypes or based on real incidents that may have occurred because of the premature injection of such systems into public roads.

We based our model on the SEIR model. To which we added two new sets that we named \mathcal{G} for Graylisted and \mathcal{B} Blacklisted. We have specified the variation of the cardinals of the different sets by binomial or even Poisson stochastic processes.

Afterwards, we ran 100 simulations of the proposed model for a certain set of parameters and initial conditions. The visualization of the results shows that the model controls the infectious situation well and truly under the stated hypotheses.

Finally, In the discussion section (sec. V), we drew some lessons and gave some suggestions for future work, such as the development of standards allowing third parties to invest in autonomous and connected vehicle systems.

ABSTRACT

In this study, a clever plan to detect cassava leaves has been developed using a customized fine-tuned deep learning model. Five categories of diseases are used in this study: Cassava Brown Steak Disease (CBSD), Cassava Green Mite (CGM), Cassava Bacterial Blight (CBB), and Cassava Mosaic Disease (CMD) and Health. The results showed an accuracy on the test data obtained was over 77% on original problem using clever data augmentation without affecting the scope of this problem.

***Index Terms*— CNN; Convolutional Neural Network; Cassava Leaf**

I. INTRODUCTION

Cassava is a plant whose leaves are particularly rich in protein and vitamins[1]. Additionally, cassava is the key ingredient of rice. According to Bandar Lampung City's 2015, 2016 and 2017 Central Bureau of Statistics, cassava production totaled 5,323.00 tons, or second place with rice. Plants that produce 29,583.68 tons. However, output of cassava declined by 34.5 percent in 2018 compared to the previous year (Central Statistical Office of Bandar Lampung City, 2019). This is due to declining yields that occur due to disease outbreaks in cassava plants. Varieties The types of diseases in cassava leaves are caused by insects, viruses, bacteria and fungi [2]. This study investigated four common cassava leaf diseases, namely: Cassava Brown Steak Disease (CBSD), Cassava Green Mite (CGM), Cassava Bacterial Blight (CBB), and Cassava Mosaic Disease (CMD).

Infected leaves interfere with harvesting, as leaves are an important part of the plant that catalyzes photosynthesis, which is necessary process for plants, so that they can produce energy. Phloem tissues transport effects of photosynthesis in all other parts of plants. As long as the plant's leaves are in excellent condition and the photosynthetic process continues normally, the stems and clusters of the plant will reach maturity. However, when leaves become diseased and photosynthesis is disturbed, stem growth and root crops are also affected, reducing yields. Laboratory tests or plant help specialist is usually performed to diagnose cassava leaves. However, producers are unable of promptly and effectively combating cassava leaf disease. This is due to the fact that laboratory testing is often difficult due to cost constraints, and doctors cannot discover the sickness in time. Therefore, a clever solution to these problems is required as a pro-interactive python notebook pro, which can run on a browser using google

colab which is designed to work easily [3].

Previously, Adaptive Neural Fuzzy Inference System has been used in a number of research to detect flavonoid chemicals in guava leaves using artificial intelligence (ANFIS) [4]. Case-based reasoning[5], the Dempster-Shafer method[6], the separation of images using a soft computer[7], and comparable diagnostic techniques all utilise images. Alternatively, as these methods do not turn the training process into a database, they must be compatible with both the database training process and the network transformation in order to generate highly accurate results. Convolutional Neural Network is the name of the methodology proposed in this study (CNN)[8]. CNN's system has the most important effects on image perception. This is because the CNN method can process 2D data/images. A CNN's network has a special layer called a convolution layer. In this convolutional layer, the image input displays patterns in different parts of the image for easy separation. Based on this, the CNN method can read images easily and efficiently.

II. LITERATURE SURVEY

Authors	Description	Outcomes
Hany Elnashar et.al.	The author has used Resnet50, a pre-trained model to classify images into 5 given classes.	Using this pre-trained model, authors were able to achieve validation accuracy of around 64%[9].
H R Ayu, A Surtono, D K Apriyanto et.al.	The author has used MobileNetV2, a pre-trained model to classify images into 5 given classes.	Using this pre-trained model, authors were able to achieve validation accuracy of around 65.6%[10].
D.A. Bashish et.al.	The authors assumed that there should be a bad pixel in at least one of the clusters and used k-means clustering to divide the leaf image into 4 clusters.	Using this neural network, authors were able to achieve a classification accuracy of around 93%[11].
E.Kiani et.al.	Here, Two inputs were associated with iron deficiency and the other associated with fungal infections. If the leaves are sick, the output indicates two diseases.	Using this model, authors were able to achieve an overall system accuracy of 96% using the proposed algorithm[12].
M.Bhange et.al.	Clustering k-means is more efficient when applied to large data sets due to which they have used it in this research.	Using SVM model, authors were able to achieve an overall system accuracy of 82% using the proposed algorithm[13].

Authors	Description	Outcomes
G.Saradhambal, et.al.	Otsu's algorithm forms a bi-modal histogram with the foreground and background pixels. For feature extraction, shape and texture-oriented features were used.	The shape-oriented features used were area, color axis length etc whereas, contrast, homogeneity etc were the texture-oriented features.[14].
A Ramcharan, K Baranowski, et.al.	This article investigates transfer learning using a deep convolutional neural network (CNN) model for cassava picture datasets.	The Inception v3 model had the highest accuracies of 98% and 0.95% with the leaflet dataset for CBSD and GMD, respectively[2].
G Sambasivam, GD Opiyo et al.	This paper focuses on strategies like SMOTE (Synthetic Minority Over-sampling Technique) and focus losses with deep neural networks	This paper obtained more than 93% accuracy[1].
David Opeoluwa Oyewola, Emmanuel Gbenga Dada et al.	The research offers a unique deep residual convolution neural network (DRNN) for detecting CMD in photos of cassava leaf.	The DRNN model produced the best and achieved an accuracy of 96.75%[15].
Amanda Ramcharan, Peter McCloskey et al.	This paper proposes the "One-Vs-All" methodology for solving the multi-class classification problem of detecting disease in cassava plant's leaves.	The proposed model achieved an overall accuracy of around 85.64%[16].

III. DATASET AND EVALUATION METRIC

Pictures of cassava leaves found in the Kaggle competition, which includes five classes, namely: Cassava Bacterial Blight (CBB) (1087 photos), Cassava Brown Steak Disease (CBSD) (2189 photos), Cassava Green Mite (CGM) (2386) images, Cassava Mosaic Disease (CMD) (13158 images) and Healthy (2577 images). During the experiment, the database was divided into three parts: training data (80%) and testing data (20%). Fig 1-5. shows the examples of a cassava leaf images, which is a database by class. The main symptoms and pathogens that cause the appearance of cassava leaves are:

CBB is a disease caused by the bacteria *Xanthomonas manihotis*, which is typically found in humid environments[17]. The first symptoms of angular ulcers, tissue death at the site of infection shoots death. The whitefly virus *Bemisia tabaci* causes CBSD (Genn). There are two leaf symptoms that include yellow chlorosis in the bones of the upper extremities [2], another sign is chlorotic spots. The most common symptom of this disease is the development of dry sepia into brown, foam, and necrotic lesions in the nodular tissues. CGM is caused by the small leaf-eating insect *Mononychellus tanajoa*. This causes bleaching because chlorophyll enters the cells. As a result, the leaf turns into a dot, dies and becomes an abscissa. CMD is a virus caused by the begomovirus. Depending on the intricacy of the disease, the symptoms visible on the leaves contain a mixture of yellow and white sulphide particles. These particles can interfere with photosynthesis and plant growth. This causes a little decrease in the total yield[17].

Fig. 1. Cassava Bacterial Blight (CBB)

Fig. 2. Cassava Brown Streak Disease (CBSD)

Fig. 3. Cassava Green Mottle (CGM)

Fig. 4. Cassava Mosaic Disease (CMD)

Fig. 5. Healthy

Fig. 6. Frequency of each class in the dataset

As we can see in Fig 6. input data is highly imbalanced, which can cause bias in the network. If we augment all the classes except Cassava Mosaic Disease (CMD) to around 13000, then we can get a dataset which will have nearly zero class-imbalance.

Numerous researchers have used accuracy as a measure of model performance[18][19]. Accuracy is the proportion of predictions that the model made correctly, i.e. the number of correct predictions in all predictions.

$$\text{Accuracy} = (T P + F N) / (T P + T F + F P + F N)$$

IV. METHOD

After deeply analyzing the frequency graph, this can be noticed that the class imbalance in the input dataset is at it's extreme especially due to Cassava Mosaic Disease (CMD). Previous techniques [9][10] used for augmentation are defective, as augmentation is applied over the whole dataset. Whereas, class Cassava Mosaic Disease (CMD) already contains 13,000 images in the original dataset. These techniques are actually contributing to increased class imbalance as internal data augmentation of tensorflow augments each image by a factor of around 6, which means CBB class will have around 3000 images after augmentation, whereas CMD class will have around 75000 images, which is accountable for huge class imbalance. This paper proposes a technique to resolve this issue by use of a custom image augmentation once with certain filters in the included images that can directly benefit the model such as:

- Gaussian Blur [20]
- Thresholding[21][22]
- Sharpening kernel[23][24]

Once we get the filtered data, we can generate the augmented data using the following pseudo-code:

```

1 traindf = load_dataset()
2 X_data = array()
3 Y_data = array()
4
5 for i in 1...size(traindf):
6     img = load_img(traindf['image_id'][i],target_size
7                 =(64,64))
8     X_data.append(img)
9     Y_data.append(label(img))
10
11     if current label is not Cassava Mosaic Disease:
12         X_data.append(rot90(img))
13         X_data.append(rot270(img))
14         X_data.append(flip_horizontal(img))
15         X_data.append(flip_vertical(img))
16         X_data.append(scale_in(img))
17         Y_data.append(label(img)*4)

```

Once we get the augmented data, we can then feed it into a custom CNN(Convolutional Neural Network), Fig 7. shows the architecture of the CNN used for the training. The augmented dataset generated has nearly 70,000 images of 5 classes, nearly 14,000 of each class.

To implement the model, we utilized Keras (<https://keras.io/>) environment with TensorFlow [25]. Python version 3.6 is used including standard libraries like Numpy, matplotlib, PIL, cv2, pandas etc. We implemented the model via Google Colaboratory (<https://colab.research.google.com/>) which included computer specifications as follows:

- GPU: 1xTesla K80, having 2496 CUDA cores, compute 3.7, 12GB (11.439GB Usable) GDDR5 VRAM
- CPU: 1xsingle core hyperthreaded, i.e., (1 core, 2 threads) Xeon Processors @2.3Ghz (No Turbo Boost), 45MB Cache
- RAM: 15.6 GB Available

Layer (type)	Output Shape	Param #
conv2d (Conv2D)	(None, 64, 64, 256)	3328
average_pooling2d (AveragePooling2D)	(None, 32, 32, 256)	0

V. ANALYZING THE PREDICTIONS

Many researchers have used the level of accuracy as a determinant of model performance [18][19]. Fig 9. shows the graph for Training and Validation Accuracy and Fig 10. shows the graph for Training and Loss. The performance of the model over augmented dataset is quiet good with training accuracy of over 95% and validation accuracy of over 77% respectively, which is a significant improvement over the original 64%[9] and 65.6% [10] validation accuracy.

Authors	Description	Accuracy
Hany Elnashar et.al[9]	The author has used Resnet50, a pre-trained model to classify images into 5 given classes.	64%.
H R Ayu, A Surtono, D K Apriyanto et.al[10]	The author has used MobileNetV2, a pre-trained model to classify images into 5 given classes.	65.6%.
Proposed paper	This paper proposes a better method of data augmentation as compared to what is used in above research papers.	77%

VI. CONCLUSION AND FUTURE WORK

As we can see in the Accuracy and Loss graph, this model is suffering from Overfitting [26]. Overfitting is a mathematical mistake that arises when a small number of data points are firmly connected to a small number of characteristics. As a result, this model is very useful for referencing other datasets too which contain high level of class imbalance. So, next step in this research is to prevent overfitting as training accuracy is already over 95%. Therefore, an improvement on validation accuracy can be achieved by overcoming this overfitting.

Abstract— The fusion of widespread IoT devices, highly adopted cloud services, and advanced network technologies has laid the foundation of Cyber-Physical Systems. However, the architecture is highly vulnerable due to weak security bound to IoT devices. The IoT devices have played a significant role in launching DDoS attacks, thereby making the state of affairs catastrophic. The attacks are novel and traditional systems are not efficient enough to address high volume and diverse attacks. The roadblock to researchers is the unavailability of an adequate number of datasets that apprehends the diversity of attacks. The paper describes the specifications of cyber-physical systems, description of IoT-DDoS attacks, and highlights the research challenges. The paper further collates and elucidates the IoT-DDoS datasets with a comparative analysis of the test environment, features offered, and statistical details of datasets. At the end of the paper, based on the dataset study, recommendations are proposed for dataset standardization and extracting most out of the datasets.

Keywords— *Internet of Things; IoT-DDoS; Distributed Denial of Service; Dataset; Cyber Physical System*

I. INTRODUCTION

Internet of Things (IoT) and Cloud Computing are the keys in the electronic cosmos of connected living. The IoT devices are consistently ideated, innovated, and created for novel disciplines. The companion cloud computing paradigm offers software, platform, and infrastructure as services and is under high adoption because of its ability to offer on-demand services, broad network coverage, resource pooling, rapid elasticity, and measured services. It is predicted that predicted number of connected IoT devices will grow to 75.44 billion by 2025 from 42.62 billion in 2022 [1]. Gartner, a leading research company, has forecasted the cloud market to grow to 3.64 billion US dollars by 2022 [2] and COVID-19 has proven catalyst to the cloud growth.

The unprecedented growth of Internet of Things, transformation of communication layer, and cloud computing services amalgamated on a time-series to coined the term Cyber-Physical Systems (CPS).

In a cyber-physical system, a swarm of IoT devices and cloud services are deeply intertwined and are supported by a networking backbone to operate on different temporal and spatial scales. Fig. 1 shows Smart City as an illustration of the Cyber-Physical System. The US National Science Foundation

has perceived cyber-physical systems as a substantive realm of research. The key soup ingredients of the contemporary cyber-physical system are the physical sensors and actuators that are fabricated onto communicable and intelligent embedded devices, the dimensions of automation, integration at Spatiotemporal scales, dynamic configuration, and networking at divergent planes.

The proliferation of IoT systems and innovative cyber-physical systems have made society so much dependent on the digital epoch that even a dearth of any of the operational capability may lead to severe consequences. Naturally, any technological innovation that is widely embraced, allures the cyber attackers to exploit the implementation domain by employing advanced tools and techniques such as Botnets. The lack of uniformity in low-cost, low-power, and lightweight IoT devices has exacerbated the problem. There are shreds of evidence that attackers have exploited the IoT system fragility for botnet propagation to launch an unparalleled IoT-DDoS attack of magnitude 2.3 Tbps in 2020, which is the peak recorded in the last 10 years [3]. As manifested, the attackers can compromise IoT devices, snap out of it, orchestrate a zombie army, launch an IoT-based DDoS attack, and cause substantial damage to the cyber-physical systems or its components (such as IoT network, communication backbone, and cloud network) in atomicity. The IoT-DDoS attacks are geared towards disrupting the services of the server by aiming at the availability vertex of CIA (Confidentiality, Integrity, and Availability) triad.

The researchers have been investing substantial efforts in envisioning and devising an effective defense mechanism against IoT-DDoS attacks that can analyses such an enormous amount of data in real-time. In our previous research [4], [5], [6] we have presented the vulnerability retrospection of IoT-based DDoS attacks on cyber-physical systems. Though contemporary mathematical model-based machine learning and deep learning techniques are applied for an intelligent framework/solution, the major roadblock is the availability of benchmark datasets for research purposes. The IoT-DDoS attacks are novel, and the research is in inception.

A. The relevance of IoT-based DDoS datasets to the Cyber-Physical Systems

IoT devices are the key ingredients of a cyber-physical system. IoT devices form the perception layer and are the only layer where standardization has not happened. The reasons are perceptible that the devices are diverse, heterogeneous, fragile

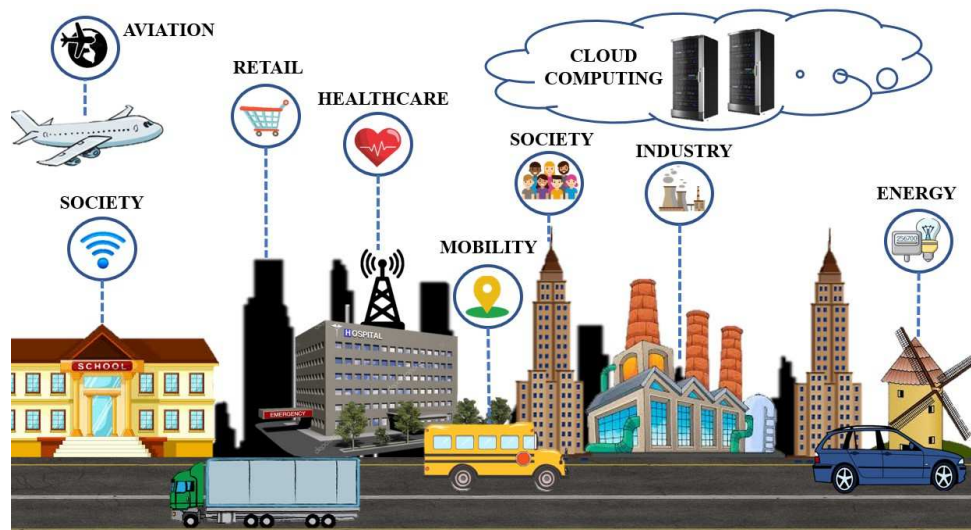

Fig. 1. Smart City - An example of Cyber-Physical System

to security issues. Though there are no direct datasets available for cyber-physical systems, IoT-based datasets make the closest relevance to the cyber-physical systems. Numerous datasets are available for the cloud layer with the detailed available literature, but no such literature is available for IoT-based attack datasets. Hence, the discussed IoT-based attack datasets are the missing piece to the jigsaw puzzle.

B. Our Contribution

The article has the following prime contributions to the research community: To our perception and awareness, the research community lacks the IoT-DDoS datasets because IoT-DDoS are at the inception stage. The paper offers comprehensive details of IoT-DDoS attacks datasets. The paper also presents the comprehensive challenges of IoT-DDoS attacks on the cyber-physical system. Furthermore, the paper proposes recommendations for dataset standardization.

C. Paper Organization

Rest of the paper is structured as follows: Section II puts forward the details of cyber-physical system, security issues with cyber-physical systems, most devastating IoT-DDoS attacks, and research challenges. Section III discusses about the details of publicly available IoT-DDoS datasets, dataset features for the purpose of preparing defense solution, and a comparative analysis of various datasets under discussion. Section IV highlights future prospects of the work. Section V concludes the study.

II. CYBER-PHYSICAL SYSTEM SECURITY

The Cyber-Physical System overview, security issues, and research challenges are described in the following sections.

A. Cyber-Physical Systems

The unprecedented growth of physical objects linked to the Internet has proven a boon for implementing the Internet of Things (IoT) concept. While developments such as the Internet of Things can be traced in the early 80s by connecting the Carnegie Mellon University Coca Cola vending machine to the internet. Likewise, cloud computing had been around

since 2000. A correlation between the real world (e.g. automobiles, wearable technology, medical instruments, sensor elements, etc.) and digital world has proven to be a boon to innovation in network domains. Interdependency and union of the Internet of Things (that represents the physical space) and cloud computing (that represents cyberspace) have given birth to an era of Cyber-Physical Systems (CPS).

However, the popularization of IoT, Cloud, and CPS has proven a battlefield for a new and more devastating form of DDoS attacks, i.e. IoT-DDoS [7]. The following section discusses more about IoT-DDoS attacks.

B. IoT-DDoS Attacks

The IoT-DDoS attacks frequently require millions of compromised IoT devices to exploit huge resources against a target. The Fig. 2 shows the modus operandi of IoT-based DDoS attacks. The recent high-volume DDoS attacks (recently reported 2.3 Tbps in Mar-2020 on U.S. Health Agency) from the millions of diverse and heterogeneous IoT devices has turned out that the traditional defense solutions are not sufficient enough to handle the modern-day IoT traffic [8]. The best known Mirai form of IoT-DDoS has evolved from compromising the MIPS based Linux devices to MIPS, ARM, PPC, and many-more CPU architectures. In its simplest form, IoT-based DDoS attacks are composed to have four primary elements. The core of the botnet is Command and Control Server (C&C Server), which provides the centralized management, tools, and commands to drive the IoT-DDoS attack. The supporting component is the loader system that diffuses the bot binary (Based on target CPU architecture) on the victimized device. Report Server keeps the specifics of the botnet army in the database. The Scanner and the Bot Dyad have the dual objective of spreading the infection to feebly configured devices and attacking the server once the attack command is received from the C&C server.

C. Research Challenges

The IoT devices were introduced only a decade ago and have been adopted by public in large in a short span of time.

Fig. 2. Modus operandi - IoT-DDoS

This popularity has, no doubt, attracted researcher's attention. The flip side of the coin is, attackers have also shown great interest in IoT devices and have leveraged IoT devices to prepare a zombie device army due to weak security of IoT device. The IoT devices have greatly been used to launch the most devastating security attack, IoT-based DDoS. Although, a very significant amount has been invested by research community, there are a number of research challenges faced by the community. The research challenges are highlighted as below:

1) *Unavailability of IoT-based Datasets*

The major roadblock for the researchers is unavailability of IoT-based datasets. As IoT devices are still under evolution, only a limited dataset is available for the research community. To the best of our knowledge, the publicly available IoT-dataset is still in scattered form, and no documentation is available for comparative analysis for the research purpose.

2) *High Volume Network Traffic*

With the dawn and exponential increase in IoT devices, there is a sky-scraping increase in network traffic. The traditional security solutions are not efficient enough to address the modern-day IoT traffic [9]. There is a strong need for the researchers to pay the primary attention to the defense solutions than spending significant efforts in locating an appropriate dataset to test with.

3) *Diversity in datasets*

As IoT devices are heterogeneous in nature, no dataset alone is enough to support a defense solution because of unavailability to capture the diverse scenarios. Hence, there is a strong need to collate the datasets available in IoT domain.

4) *Dataset Outlook*

The rapidly advancing technologies demand a shift in the way datasets are created. The available datasets don't address the surfacing technologies such as Big Data, Blockchain, Software-defined Networking (SDN), Network Function Virtualization (NFV), and the associated threats.

5) *Zero-day Attacks*

The attacks are evolving at a higher pace than the datasets are being generated. Hence, new techniques are required for dataset generation and benchmarking the datasets.

6) *Security-as-a-Service*

The cloud computing services have introduced the concept of availability of Everything-As-A-Service. For example, infrastructure, platform, software, and even machine learning and IoT platforms are available as services. With the technology focus on making everything realized as a service, the work towards realizing security-as-a-service is still in inception. Security-as-a-service can be an exceptional platform to test the available datasets thoroughly [10].

D. *Research Motivation*

To our acquaintance, there has been no research article that details contemporary traffic and datasets. The lack of information on modern-day IoT datasets poses a significant roadblock for researchers. Hence, we have summed up the article that offers in-depth details of several current datasets, the list of attacks covered, a description of the benign and attacks instances, etc. The benchmark datasets details will clear the roadblocks so that researchers can focus on the security solutions rather than simulate the scenarios.

III. BACKGROUND AND RELATED WORK

There is a decent effort in attack detection and mitigation in CPS and IoT systems. Karthick et al. [11] manifested a Fog layer-based solution which includes data processing, storage, and security, in a proposal for a Medical Cyber System (MCS) and uses IoT technologies for cardiovascular disease patients.

There are several benchmark datasets (such as NSL-KDD, CICIDS2017, CICDDoS2019, etc.) and detailed literature available for traditional attack scenarios. However, only limited datasets are available for IoT-DDoS attacks. Most of the datasets captures the real time traffic and are explained in the following section.

A. *IoT-DDoS Dataset Specifics*

The details of publicly available IoT-DDoS datasets are described as follows. Table 1 summarizes the statistical attributes of the contemporary IoT-DDoS datasets.

1) *IoT-23 Datasets*

IoT-23 dataset [12] dataset is a benchmark labelled IoT-dataset created by Stratosphere Laboratory, Avast AIC in association with Czech Technical University (CTU), Czech Republic with an aim to contribute to research community. The dataset is a recently published dataset in 2020, with captures extending from 2018 to 2019. The dataset consists of 23 scenarios (hence, named IoT-23) i.e., 20 malware captures from infected IoT devices, and 3 captures from benign IoT-devices. The scenarios were created after compromising the devices by Mirai, Torii, Trojan, Gagfyt, Kenjiro, Okiru, Hakai, IRCBot, Muhstik, and Hide & Seek malwares. The network traffic flows in the datasets have further been labelled to describe the possible malicious activity. The authors have categorized the traffic into attack traffic, benign traffic, C&C traffic, and file download traffic. When the traffic flows from the infected device to the target host, the traffic is attack traffic. The traffic is benign if no suspicious activity exists in the flow. The network communication between C&C and the infected device is the

C&C traffic. Furthermore, when the file is downloaded to the infected device, it produces the file download traffic. Moreover, the packets sent on a specific connection to check KeepAlive of the infected device by the C&C server are classified as HeartBeat traffic. The goal of the dataset is to prepare a dataset for malicious traffic and another for benign network traffic.

2) LITNET-2020 Dataset

The LITNET-2020 Netflow dataset [13] is a benchmark dataset created from real world academic research environment containing the attack as well as benign traffic. The dataset presents 12 attack types. The dataset was created

at Kaunas University of Technology (KTU), Lithuania and have captures ranging from 2019 to 2020. The network traffic was captured using nfcap tool and feature set was generated using Python Scripts, Nfsen, and MeSequel tools. The network topology used for collecting LITNET traffic consisted of senders and receivers. The CISCO routers and Fortige firewalls (FG-1500D) have been used as senders and high configuration server is used as collector. The malicious traffic is further classified into 12 classes based on the attack type.

TABLE 1. IoT DDoS DATASETS COMPARISON

Dataset	Year	Num Instances	Malicious Instances	Benign Instances	Num Attributes	Num IoT Devices	Attack Types / Protocols for Attack	Size of Dataset (GB)
IoT-23	2020	32,53,07,990	29,44,49,225	3,08,58,765	--	--	HTTP, DNS, DHCP, SSL, SSH, and IRC	21

BOT-IoT	2019	73,360,900	7,33,51,357	9,543	--	5 (Simulated)	Port Scanning, OS Fingerprinting, Dos/DDoS (HTTP, TCP, UDP), Metasploit (Data Theft, Key Logging) .	69.3
Sydney UNSW IoT	2019	Raw Data (.pcap files)	Raw Data (.pcap files)	Raw Data (.pcap files)	Raw Data (.pcap files)	28	DDoS	80.3
N-BaIoT	2018	70,62,606	65,06,674	5,55,932	115	9	BASHLITE (Scan, UDP, TCP, COMBO), Mirai (Scan, ACK, SYN, UDP, UDPPlain)	34
CTU-13	2011	2,06,43,076	4,32,755	3,69,806	22	Simulated	IRC, SPAM, ClickFraud, Port Scan, DDoS, Fast Flux, HTTP.	696.9

3) BOT-IoT

Unlike other traditional available benchmark datasets, Bot-IoT dataset [14] was created specifically for IoT-Botnet scenarios. The dataset was generated in Cyber Range Lab of UNSW Canberra Cyber, Australia. The authors performed feature selection is performed using Correlation and Entropy [15] methods. The dataset is classified into normal network traffic, probing attacks (Port Scanning, OS Fingerprint), DoS attacks (HTTP, TCP, UDP), DDOS attacks (HTTP, TCP, UDP), and Information Theft attacks (Key logging, Data theft).

4) Sydney UNSW IoT Dataset

The researchers from University of New South Wales (UNSW), Sydney [16] instrumented 28 unique IoT devices to collect the traffic traces spanning 26 weeks. The stage is set for further analysis and defense solutions against IoT-DDoS attacks.

5) N-BaIoT Dataset

The N-BaIoT [17] fills the gap in the publicly available botnet datasets, specifically for IoT. The data was collated from 9 commercially produced IoT devices that have been infected with Mirai and BASHLITE. in the controlled experimental setup and is multi-classified into 10 classes of

benign data and 1 category of benign data. The authors of the dataset originally used anomaly detection technique. They applied Deep Autoencoders and concluded with a 100% TPR rate.

6) CTU-13 Dataset

The CTU-13 dataset [18] was captured and published at Czech Technical University (CTU), Czech Republic in 2011. The dataset consisted of 13 scenarios, each one executed with different malware. A variety of bots such as neris, Rbot, Virut, Menti, Sogou, Murlo, and NSIS.ay were used to generate the attack traffic. CTU-13 is as old as hills and the most recent version, IOT-23, has been published by the laboratory.

B. IoT-DDoS Dataset Specifics

IoT traffic behavior is the key to distinguish the IoT devices contrast from non-IoT devices [19]. The IoT-device specific features are flow volume, flow duration, sleep time (time duration for which IoT device doesn't have active flow), etc. [16].

The characteristics possessed by an individual IoT device factors in concluding the association of generated traffic to specifics of network communication. IoT devices, despite

their heterogeneous purposes of existence, generate a predefined traffic pattern that can be used to generate clusters of IoT devices based on network traffic characteristics. Such features are used for IoT device identification [16], type of service being used by IoT devices [20], unauthorized device detection in the network [21], and detection of traffic anomalies [17][22]. The network traffic features generated by IoT devices are classified into following two categories:

1) Network traffic features at packet level

Notably, the features used in IoT traffic study, network intrusion detection systems, DDoS defense solution, or any

network security solution is comprised of network packet level features of the traffic transaction. The most commonly used network traffic features of IoT devices at network packet level are described in Table 2. The first five attributes form the primary tuple of a flow, i.e. $\langle IP.src, IP.dst, IP.proto, port.src, port.dst \rangle$. Other least commonly used packet level features are: *pkSeqID* (Packet Sequence Number), *Stime* (Flow start time), *flgs* (Flow state flags in transaction), *bytes* (Total number of bytes in a transaction) [23]. The network packet features are the prime keys to DDoS detection.

TABLE 2. NETWORK TRAFFIC PACKET LEVEL FEATURES OF IOT-TRAFFIC

Feature Label	Feature	Feature Description	Research References
IP.src	Source IP address	The IP address of the device originating the network traffic.	[23] [24] [17] [25] [26] [27]
IP.dst	Destination IP Address	The IP address of the destination to which the network traffic is targeted.	[23] [24] [25] [26][27]
IP.proto	Protocol for communication	The protocol used for communication between two entities.	[23] [24] [17] [25] [26] [27][28]
port.src	Source port	The port number of the source device.	[23] [17] [25]
port.dst	Destination Port	The port number of destination where the sought service is available.	[23] [24] [25] [29]
Ttl	Time to live	Time to live for the packet for preventing the packet from circulating in the network indefinitely.	[21]
psize	Packet Size	Size of each packet in the flow.	[23] [17] [25] [26]
Num_Pkts	Total Packets exchanged	Total number of packets exchanged during a flow	[23] [17]

TABLE 3. NETWORK TRAFFIC FLOW LEVEL FEATURES OF IOT-TRAFFIC

Feature Label	Feature	Feature Description	Research References
intensity	Traffic Intensity	Sum total of transmitted and received packets during a flow.	[24] [16]
S_dur	Session Duration	The length of duration during which session is established between two end points during a flow.	[24] [16]
Sleep_time	Device inactive time	Time duration between first and last packet during a flow	[24] [16][6]
Flow_vol	Flow Volume	Sum total of size of all incoming and outgoing packets during a flow	[24] [16]
Avg_flow_rate	Average Flow rate	Ratio of Flow Volume and Flow Duration	[24] [16]
Pkt_size_S	Additional Statistical Packet Size related Feature	Additional features added as a result of performing statistical analysis, such as mean, standard deviation and maximum values of traffic flow	[17] [30] [31]
IP.proto	Protocol for communication	The protocol used for communication between two entities	[23] [24] [16][17] [25] [26][27] [28]
Num_packets	Number of packets	Number of packets during a flow	[23][17]
Int	Packet inter arrival time a.k.a. packet jitter	Time difference between two consecutive packets arrival in a flow	[17]
DNS Query	DNS Query by IoT	DNS Query by IoT devices	[24] [16]
NTP Queries	NTP Query by IoT	NTP Query by IoT devices	[24] [16]
Cipher Suite	Cipher Suite for data encryption	Cipher suite used by IoT during secure communication	[24] [16]

2) Network traffic features at flow level

The selection of features is hand-picked based on the purpose of the study. For example, The authors of [23] inferred from the experimental results that the IoT devices exchange low volume of data per flow. They empirically

proved that 95% of the IoT devices generate less than 1000 bytes of data, with most devices transferring as low as 120 bytes per flow. The aforesaid researchers used other flow level attributes such as flow duration, average flow rate, and

inactive (sleep) pattern of IoT devices. The features identified at network flow level are described in Table 3.

3) IoT Dataset Comparison

The Fig. 3 summarizes the dataset and the type of attack covered in the dataset. The datasets from various researchers and laboratories have been published and are available for further study. In this section, we discuss the contrast between

the testbeds used for generating the datasets in the literature. A testbed is an experimental setup used for generating the network traffic. The comparative analysis of experimental testbeds used for generating IoT traces are shown in Table 4 as follows:

TABLE 4. COMPARATIVE ANALYSIS OF ENVIRONMENT FEATURES OF DATASETS

Dataset	Testbed Configuration (R: Realistic/ S: Simulated)	Traffic Type (R: Realistic/ S: Simulated)	Labelled Dataset (Y/N)	IoT Trace (Y/N)	Diverse Attacks Scenarios (Y/N)	Full Packet Network Capture (Y/N)
IoT-23	R	R	Y	Y	Y	Y
LITNET-2020	R	R	Y	N	Y	Y
BOT-IoT	S	S	Y	Y	Y	N
Sydney UNSW IoT	R	R	N	Y	N	Y
N-BaIoT	R	R	Y	Y	Y	Y
CTU-13	S	S	Y	Y	Y	Y

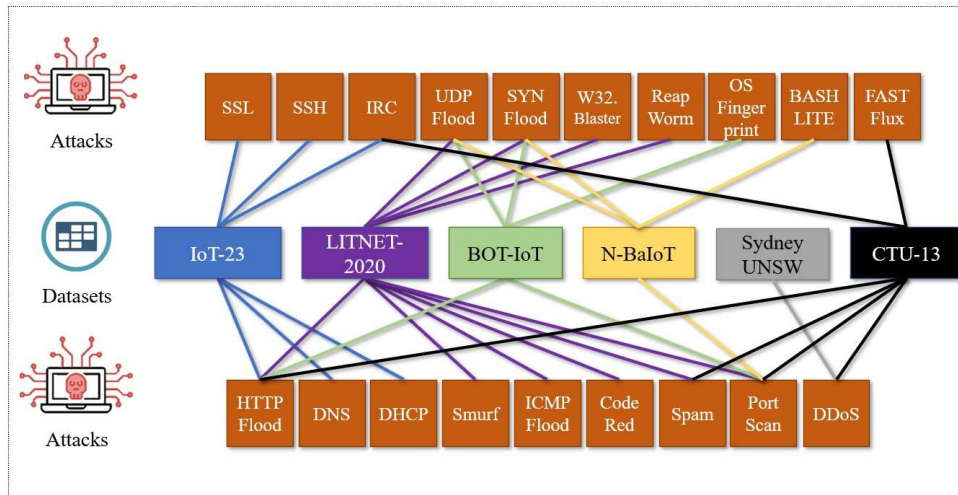

Fig. 3. Datasets and Attacks mapping

IV. FUTURE PROSPECTS

The following suggestions would help develop the next-generation cyber security framework for intelligent devices, driven by the strong reliance of datasets on the development of IoT-DDoS defense solutions. The outcome would be real-life deployments.

A. Generation of extensible and modular datasets

As aforesaid, diverse datasets are highly required to cover complex network architectures or to put forward zero-day attacks. To benefit the most from the datasets, they should be flexible to extend or to integrate with other datasets. This would make datasets agile and ready for frequently changing scenarios. That way, anomaly-based DDoS defense solutions could be trained for advanced machine and deep learning techniques to identify zero-day attacks.

B. Standardization of dataset generation, collection, evaluation and validation processes

One of the prime challenges faced by researchers is the lack of standard procedures for dataset creation and unavailability of detailed documentation associated with newly available datasets. Furthermore, the lack of benchmark tools and document templates makes the researchers use their own tailored methods. The datasets should be validated on the standard parameters and performance metrics. Large degree of researchers focuses on showcasing the accuracy of the defense solution/model/framework. However, the performance metrics, other than accuracy, should be considered to reflect the precise performance of the proposed model

C. Datasets resilience

To ensure dataset resilience, the datasets variations should be available. This may include variations in attack scenarios, diversity in traffic loads (daytime and inactive time). The datasets availability in raw format along with the standardized template format would make researchers apply their own tailored methods and have a choice between stateless or stateful features.

D. Close Collaboration

The study shows that there is no common platform used for dataset generation. Each of the generated datasets exist in isolation, and the community is continuously investing efforts in developing the modern-day datasets. The shared platform will also help in dataset standardization.

E. Dataset Publication Platform

We also recommend using a common standardized platform for datasets and the associated metadata for analysis. The research community can leverage the platform to focus on solution-oriented approaches rather than setting up the data generation environment.

V. FUTURE PROSPECTS AND CONCLUSION

This paper described the cyber-physical system and investigated the security issues associated with contemporary IoT-devices that form the perception layer of cyber-physical system. The paper also discusses IoT-DDoS as the most devastating version of DDoS attacks and then highlights the unavailability of IoT-datasets as a challenge to the research community. The available IoT-DDoS datasets are well collated in the paper which will serve as the base document for the researchers. Finally, the paper concludes that the lack of standardization of datasets are the roadblock to study and proposes the recommendation to the dataset standardization process.

ACKNOWLEDGMENT

The authors would like to pass-on gratitude to anonymous reviewers for their constructive feedback and valuable suggestions.

Abstract—Wireless communication is one of the most implemented solutions, allowing a high level of interconnectivity in different networks, including industrial critical systems responsible for production control and safety. Performance improvements with the increase in wireless connectivity between "things", however, are followed by the increase in vulnerabilities due to the risks related to the security of wireless networks. Thus, this study aims to provide a view of the wireless communication vulnerabilities in the context of applications for industrial environments, assess maturity of current technologies in critical systems and provide a map of resilience measures to be adopted to anticipate and mitigate risks.

Keywords—Industrial Internet of Things, Cyber Risks, Resilience, Digital Manufacturing, Wireless Hart, ISA100

I. INTRODUCTION

In a digital manufacturing era, new communication and control infrastructures are operating in cooperation and collaboration for optimized performance of process, equipment and devices [1]. The increasing in the systems interoperability with integration of IoT, cloud computing and other emerging technologies generated a hyperconnection of systems where it is imperative to define a role for cybersecurity area where risks and vulnerabilities should be considered and addressed throughout systems lifecycle [2]. In December 2010, a new worm (type of malware) called Stuxnet targeted a highly specialized industrial system with unprecedented sophistication and impacts, making this event a key milestone for cybersecurity in industrial systems. Due to the potential impacts, this event was considered the wake-up call for the industrial cybersecurity awareness [3].

II. INDUSTRIAL INTERNET OF THINGS SECURITY

A. IIoT Standards and Protocols

Wireless devices needs low power consumption to be integrated into IoT and WSN (wireless sensor networks) with hundreds or thousands of other devices. Typically, a wireless communication solution is defined based on the data transfer rate, required signal range, security and reliability required for the network [4]. As part of the IEEE 802 communication standards, the IEEE802.15 group of short-distance Wireless Personal Area Networks (WPAN) stands out. The WPAN working group was initially created as IEEE 802.15.1 standards for Physical Access and Medium Access Control (MAC) Layers based on Bluetooth technology. In 1999, the IEEE 802.15.3 WPAN group was included and in 2000 the IEEE 802.15.4 WPAN was introduced for low transmission rates [5].

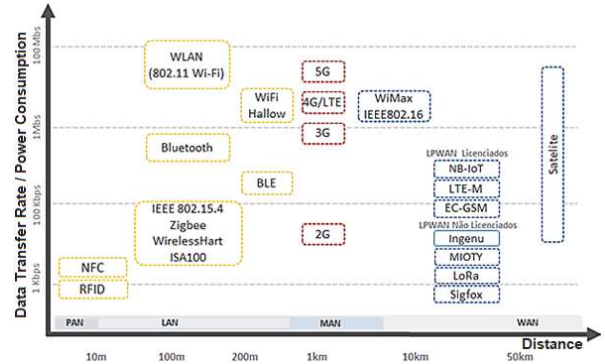

Fig. 1. Wireless Protocols Characteristics

IIoT networks might be affected by a variety of threats and vulnerabilities where attackers may take advantage of different mechanisms to cause interference or to intercept a communication. Industrial environments are also composed by a diversity of physical areas that adds important functional challenges for IIoT devices. As described in Figure 2, according to [11] wireless networks can be characterized as layered communication protocols following the Open System Interconnection (OSI) model. The communication stack consists of main 5 layers: Physical, MAC (Data-Link), Network Layer, Transport and Application.

Fig. 2. Wireless Network OSI Stack Layers

B. Systems Resilience

Although widely discussed in other areas of computer science, in the context of CPS (Cyber-Physical System) there are opportunities to discuss resilience mechanisms that can be applied for industrial systems, contributing to adapt to challenging scenarios and maintaining long-term reliability in interoperable and diverse systems. Considering the heterogeneity of equipment in these networks, reliability and security characteristics are essential for building an overview

of the state of the art of resilience of IoT in industrial environments [7].

For industrial services it is expected that components of a system are reliable and safe throughout system lifecycle, ensuring robustness for continuous operation even in the presence of failures of any of its components. [6] defines the dependability property of a system as the combination of some attributes such as availability (readiness for correct service), reliability (continuity of correct service), safety (absence of severe incidents), integrity (absence of undue changes) and maintainability (modifications and repairs with minimal effort). Availability, integrity and confidentiality (absence of unauthorized disclosures) are treated as features included in the sense of security.

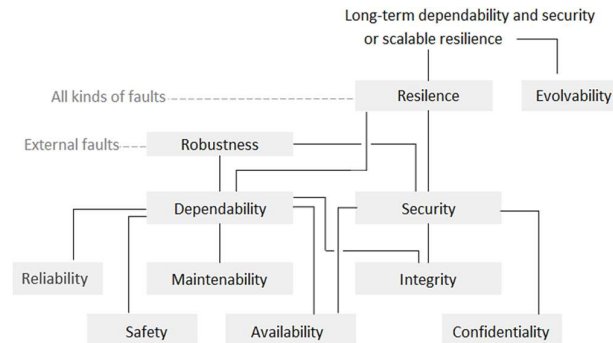

Fig. 3. System Attributes Relations in a Resilience Context [7]

The term resilience is often used by the security community to describe resistance to malicious attacks and crashes. In this context, two important properties contribute to cyber resilience and address security in different ways: safety and security [7]. [8] refers to safety as the property of a system to maintain the physical integrity of people and structures, in order to avoid damage, dangers and various risks. Resilient systems are characterized by having safeguards and security measures as part of the system architecture, with the ability to resist to attacks and failures, maintaining their operation even in a degraded or weakened state [9].

A system with a high level of security must comply with security standards and have failsafe mechanisms. The reliability and robustness of a system is also linked to its property relative to fault tolerance, that is, its ability to maintain its service continuously without significant impacts even in a scenario of device and components failures. The term resilience is often used by the security community to describe resistance to malicious attacks and crashes [7].

III. METHODOLOGY

This study was carried out by identifying security parameters on IIoT networks, including communication protocol technologies and risk management strategies important for a secure operation. This was initially performed through a systematic literature review in four main areas: (i) IoT Communication Protocols, (ii) IIoT vulnerabilities and attacks, (iii) IIoT Security and resilience measures, (iv) cyber risk management.

Literature findings were qualitatively explored and analyzed to create a map of vulnerabilities and attacks mechanisms to IoT networks. These vulnerabilities and challenges found were individually identified, classified,

prioritized, and treated to find actions to prevent or mitigate incidents in production systems in a digital manufacturing environment. These prior steps supported the mapping of risks involving the IoT on a huge diversity of scenarios, including industry environment.

Through an in-depth analysis of IoT technologies, applications and literature review, wireless sensor networks were assessed regarding its resilience properties considering all parts of the system, as well as the life cycle. The purpose is to provide a view of vulnerabilities and assess current maturity of IoT application in the industrial environment.

IV. IIoT RESILIENCE EVALUATION

A. Challenges and Cyber Attacks in IoT

The implementation of IoT technologies makes it possible to optimize operations through the application of previously unfeasible monitoring and controls, however it comes with several challenges in keeping thousands of devices coexisting and connected efficiently and securely. Some of the main technical challenges listed in the literature for the implementation of IoT networks are listed below [11]:

- Heterogeneity – IoT consists of a variety of devices belonging to the same network with gateways, switches, sensors, actuators, intelligent applications and mobile systems.
- Scalability – challenge in generating addresses, names, management and services from thousands of connected devices.
- Communication – Various technologies are used by IoT devices and networks, such as wired and wireless communications in different protocols.
- Energy Consumption – is one of the biggest challenges for IoT networks. Any kind of algorithm or mechanism running on IoT devices needs to be designed to operate with low processing load in order to extend life of its battery.
- Data Privacy – User data privacy when using IoT can be an issue in some specific cases. For example, in regular mode IoT devices can provide location information to system administrators or neighboring devices, but when in private mode, information such as this must be kept secret.
- Self-Awareness – IoT smart objects must organize themselves autonomously to perform some predetermined tasks in response to the real environment in which they are inserted, minimizing the need for human intervention.
- Interoperability – standardization of communication between different IoT devices, allowing heterogeneous objects and networks to communicate.

Other challenges related to IoT devices availability [12]:

- Fault Tolerance – The system must prevent an infected or problem node from affecting the entire system. This network must also be able to avoid the resource exhaustion attack against resource-limited devices.

- Availability – IoT devices and networks must be functionally available when needed, maintaining system operational continuity.

[13] demonstrated other challenging attributes for IoT communication:

- Trust Management – Objects and devices cannot communicate without at least having an established trust level. Building trust between devices coming from different entities is a challenge, especially in such a large-scale network.
- Latency and time constraint – objects in IIoT networks need to respond in real time to events and messages. For example, the SCADA system (Supervisory Control and Data Acquisition) must respond in real time to any variation in current, voltage or frequency values of electricity, in addition to other environmental parameter that influence the operation of the equipment.
- Mobility – the use of mobile devices, such as e-cars and mobile operations in the field, demand a continuous need for authentication and secure communication with a changing environment.
- Resource limitation – many IoT devices have restricted resources. Special care must be taken when developing security solutions to make sure that resources will meet the solutions as intended. This makes applying classic security solutions a challenge, especially those based on public-key cryptography.
- Bootstrapping – efficiently boot the thousands of IoT devices with resources required for encryption (cryptographic keys, parameters, functions and cryptographic algorithms, etc.).

Vulnerabilities and threats are important agents to be considered in the management of security risks for manufacturing systems. Security challenges change overtime and requires up-to-date information as a key part for addressing system vulnerabilities [10]. Figure 4 shows main attacks possible in wireless networks that should be considered to evaluate risks for IoT systems.

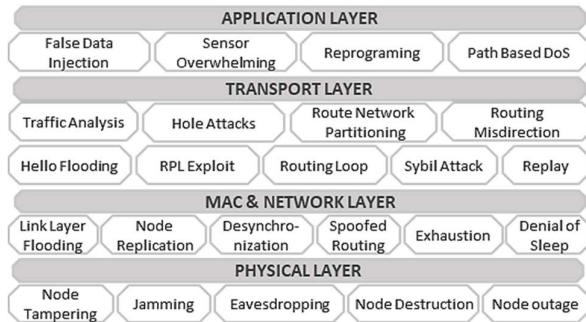

Fig. 4. Wireless Network Attacks [11]

B. IoT Resilience in the Industry Environment

The risk of cyberattacks to the wireless network is one of the most critical technical challenges of implementing this technology on the industrial environment. Vulnerabilities can be exploited by third parties and may cause critical security or safety issues. Passive attacks, which the attacker stays hidden

with no identification of intrusion in the system, normally target sensitive data, silently inserting himself into the network. In active attacks, the target is not only confidential data but also system integrity, causing disturbances to services [11].

In an industrial environment, wireless sensors need to operate securely and safely for a long period embedded in current process control systems. From this perspective, WirelessHART and ISA100 are considered reliable wireless protocols and provide means of path diversity, channel hopping and high reliability in message delivery. Zigbee protocol does not provide same tools to avoid issues with interference and obstacles, usually inherent in industrial environments, which is an issue for this protocol. For this reason, ZigBee is not suitable for critical industrial process applications as it does not meet requirements for industrial-grade network reliability and robustness. On the other hand, safety requirements and energy consumption are satisfactory in this protocol. Table I illustrate industrial WSN resilience for different cyberattack types.

TABLE I. WSN PROTOCOLS RESILIENCE TO ATTACKS

Attack	Layer	W. Hart	ISA100	ZigBee	Source

✗ - Vulnerability exploitability cited in the literature.
 ✓ - Found demonstration of security for the attack type in the literature.

WirelessHART and ISA100 protocols define a set of security keys that are used to ensure reliable communication. The strong encryption relies on both communication endpoints using the same key to communicate securely. Attackers who do not share keys cannot modify messages undetected and cannot decrypt encrypted payload information. Common to both standards is that a new device is provisioned with a connection key before attempting to connect to a network.

The connection key is used to authenticate the device to a specific network. Once the device successfully connects to the network, the security manager provide keys for further communication. While it is intrinsic in WirelessHART, the use of the join key is optional in ISA100.11a. A global key, a well-known key with no security guarantees, can also be used in the joining process for devices that do not support symmetric keys. ISA100.11a allows optionally encrypting

messages while WirelessHART does not allow security to be optional, which avoids errors that can compromise the system [12]. From general resilience perspective and considering native security in different WSN, Table II shows some resilience attributes for main protocols applied.

TABLE II. WSN PROTOCOLS RESILIENCE ATTRIBUTES

Attribute Resilience	WSN Protocol			Source
	ZigBee	ISA 100.11A	WirelessHart	
Security	High	Very High	Very High	[20]
Reliability	Low	Very High	Very High	[20]
Power Consumption	Medium	Low	Low	[20]
Scalability	Medium	High	High	[20]
Coexistence	Low	High	High	[21]
Channel Hopping	No	Yes	Yes	[21]

At the field level, ISA100.11a devices are not required to support the router function. For this reason, it is possible to see ISA100.11a networks that have a star topology while wirelessHART networks are inherently mesh. The choice for ISA100.11a devices still has a significant influence on the topology that can be deployed. If the user is forced to use a star topology, it is very likely that it will be necessary to perform an on-site test to ensure that the network will be created as designed and performance ensured.

Due to the wide diversity of applications, resilience and maturity of wireless networks, it is necessary to evaluate the types of native protections, additional security devices and usage policies that enable these protocols for safe and reliable use according to the system criticality. In order to identify possible safeguards for ensuring resilience of wireless networks against attacks, the literature findings were compiled and results illustrated in Figure 5.

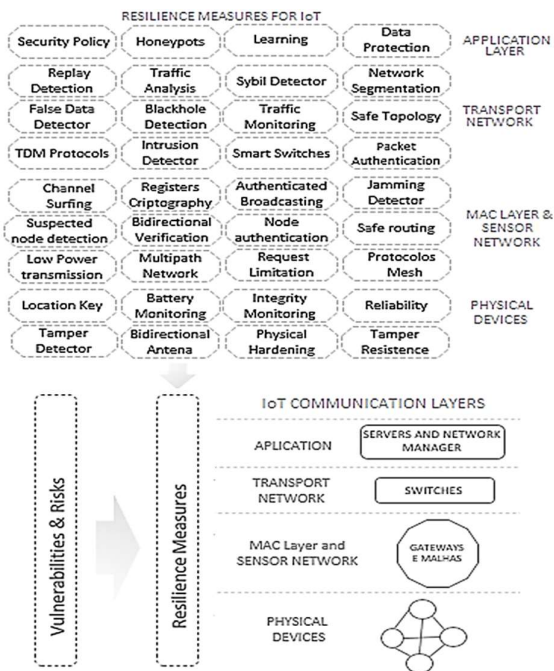

Fig. 5. Wireless Network Resilience Measures

The security and availability of IoT networks is directly linked to the treatment of vulnerabilities and challenges identified during the life cycle of these networks. In industrial environments, there are different types of networks with different criticality. Wireless sensing networks in ICS (Industrial Control Systems) zones must coexist with other technologies and systems in a corporate environment (outside ICS) that also use radio waves to connect to their databases and applications. ICS connected systems are normally critical and, for this reason, they must be implemented using a classification criterion to support resilience analysis required for these networks during their life cycle (accuracy, latency, integrity, and others).

[22] portray that as a vehicle for promoting discussion in the cyber resilience space, the American organization MITRE developed a framework for cyber resilience engineering (Cyber Resilience Engineering framework - CREF). This group is based on resilience engineering disciplines, network resilience, fault-tolerant systems, intrusion resilience in critical infrastructures with the objective of acting in the cyber space also including not cyber events like natural disasters, errors, and failures. Figure 6 illustrates cyber resilience goals, objectives and techniques proposed by MITRE organization.

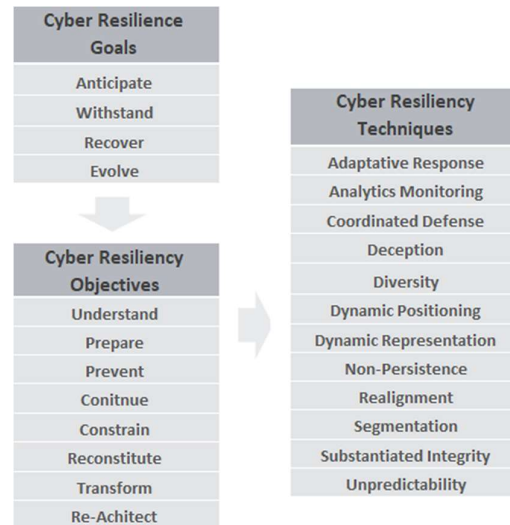

Fig. 6. Cyber Resiliency Engineering Framework [22]

Each wireless communication protocol has its own security features and maturity in terms of reliability and resilience. As shown in Figure 6 in the field of cyber resilience it is needed to apply a series of techniques and plans to ensure proper operation. A cyber risk management is not performed only by system features but as well as security policies, procedures, and culture. However, applying a system with a native secure protocol is still one of the main points for a resilient operation. Unfortunately, although there are protocols with considered high level of security, most of system features are not properly used or even disable during the operation. From the customer and vendors perspective, most of times the efforts during system applications are directed to implement, enable and operate the new wireless system from the functionality perspective and all performance benefits of this system, not specifically about security.

C. Cyber Risk Management

It is recommended that all the security elements for IoT (challenges, threats, vulnerabilities, and resilience techniques) discussed so far should be considered during the system lifecycle to address many types of risks such as ethic risks, technical risks, security risks and privacy risks [23]. To address proper treatment for risks present in system operations it was created important Cyber Security Risks Frameworks (CSRF) with different approach and considerations. Although the main frameworks widely used were not created specifically for IoT application security analysis, these can be used with an approach adjustment for IoT. Table III describes some of main frameworks used for system risk analysis.

TABLE III. MAIN CYBER SECURITY RISK FRAMEWORKS

CSRF		Description
CVSS	Common Vulnerability Score System	Standard for assessing the severity of cyber vulnerabilities on a scale of 1 to 10
FAIR	Factor Analysis of Information Risk	Methodology to quantify the factors related to your risk
OCTAVE	Operationally Critical Threat, Asset, and Vulnerability Evaluation	Comprehensive risk assessment and four-step assessment procedure, from selecting risk measurement criteria to identifying mitigation approach
CMMI	Capability Maturity Model Integration	5-level maturity model with guidance through the best case studies for the continuous improvement of production methods, especially in software development
TARA	Threat Agent Risk Assessment	Threat identification/classification and filtering methodology that prioritizes mitigations over threat importance
NIST SP800	National Institute of Standards and Technology, Special Publication	Cybersecurity risk framework. NIST SP800 is a comprehensive list of countermeasures/controls for cyber threats

Cyber risk can be considered as a relation with vulnerabilities, threats and consequences from intentional or unintentional events. It is necessary a comprehension of this three variables on an organizational environment to understand network resilience and drive measures. Tangible elements of risk in an information system can be listed like as assets, vulnerabilities and threats. The risk analysis process and definition of metrics to measure security maturity involves a sequence of steps like: (1) identification of vulnerabilities, (2) identification of threats, (3) determination of probability of occurrence, (4) determination of magnitude of the impact, (5) risk determination.

The implementation of IoT in industrial environments with different operation zones require wireless solutions with different levels of reliability and maturity. Information Systems (IT) and Operation Systems (OT) with different requirements must coexist safely in the airspace, requiring care during the implementation of new projects. To operate in automation and control networks, wireless protocols need high levels of security, reliability and maturity that can be achieved, for example, by the WirelessHART and ISA100 standards, which are used and approved by the main manufacturers of control and automation systems.

D. Wireless Sensor Networks for Critical Systems

Industrial systems are designed prioritizing reliability, safety of people and response time when defining requirements for the communication between sensors and systems. At this environment system communication must have mechanisms to ensure that data packets are exchanged in a determined time frame. Normally, safety systems use a periodic sensor data measure model to collect data to the safety controller [24].

Performance requisites for industrial sensors depends on the objective and criticality of the application to which it will be implemented. A user association for automation technologies in the process industries, NAMUR, defines 3 classes of industry wireless sensor applications in its standard NAMUR NE 124 for “Wireless Automation Requirements”. The International Society of Automation (ISA) also defined classes for the using of wireless industrial sensors in the specification ISA100.11a for field wireless devices. Table IV demonstrates types of industry application and classes defined by ISA and NAMUR.

TABLE IV. APPLICATION CLASSES OF INDUSTRIAL SENSORS

Application	Industrial Application Classes		
	NAMUR	ISA	Wireless Suitability
Safety	Class A Functional Safety	Class 0 Emergency Action	Lack of Maturity for Suitability
Control	Class B Process Management and Control	Class 1 Closed-Loop Regulatory Control	Suitable with considerations
		Class 2 Closed-Loop Supervisory Control	Suitable with considerations
		Class 3 Open-Loop Control	Suitable
Monitoring	Class C Display and Monitoring	Class 4 Alerting and Flagging	Suitable
		Class 5 Logging	Suitable

Process and machine safety systems shall comply with certain Safety Integrity Level (SIL) in order to ensure proper behavior when on safety demand. IEC 61508 standard defines the SIL from a set of safety and integrity requisites carried out by devices, software and the whole system. There are 4 levels of integrity for a safety loop (SIL1 to SIL4), where the level SIL4 is the most reliable. Neither WirelessHART nor the ISA100 directly support safety required mechanisms for SIL certification.

Then one alternative for using wireless communication for safety is combining these widely used WSN with safety certified protocols. There are few cases of SIL application with wireless networks like [16] mention that a SIL2 point to point communication between a machine safety controller and a wireless sensor was developed using ISA100.11a tunneled by PROFIsafe implemented for a hydrocarbon gas detection. WirelessHART current command limitation in the application layer still limits the implementation of a tunneling need to apply PROFIsafe with this protocol. Until a potential

modification in HART communication protocol specification is done it will not be possible to use PROFIsafe over wirelessHART.

The review of literature, vendors information and industry cases of WSN demonstrated that it is not possible to define a valid maturity level for the using of wireless networks for critical applications as functional safety. This lack of suitability for safety systems makes visible an opportunity to develop studies at this field. It is a call for manufacturers and for researchers to direct efforts to develop new approach and enhance technologies to enable the use of wireless devices in the field of people and machine safety, as well as SIL certification.

The benefit of expand wireless measurements in many fields of the industry is well known and brings elements to enhance operations performance. However, wide application of WSN is still recent and very dense networks are not a reality yet. Studies involving functional tests with application of hundreds, or thousands of devices are expensive and difficult to be accessible for independent researchers. Due to the lack of studies on real and dense scalability for WSN exists an opportunity for future studies to emulate conditions of scalability to high density networks to evaluate real performance of different protocols in expansion scenarios. Understand behavior of wide WSN scalability and scenario of future coexistence with dense networks is an important step to enhance resilience maturity that can enable secure application of this technology for more diversity of cases.

The review of vulnerabilities and threats in IoT networks when applied to critical systems demonstrated that it is still needed to enhance the level of maturity of these networks at industrial environment to deliver the secure and reliable operation required. Current WSN technologies like ISA100 and wirelessHART are mature for certain industrial applications however these networks should be designed and operated in accordance with security policies as defined by manufacturers and main wireless standards. These security requirements are not always native by the protocol and requires efforts to develop security culture and procedures for system maintenance.

V. CONCLUSION

The management of risks on wireless sensor networks in industrial environments depends on a deep comprehension of vulnerabilities during system lifecycle. Each network layer is differently affected by a huge number of threats which creates complex security management scenarios. The mapping of vulnerabilities and measures previously discussed as well as the application of resilience maturity models, are important tools to ensure proper level of network resilience during its lifecycle.

With the exploration of specific vulnerabilities, attack types, solution proposals described in the literature and specific issues when applying wireless sensor networks, it was possible to establish a path to increase maturity and resilience for wireless networks in critical systems. ISA100 and wirelessHART protocols demonstrated high level of resilience when using all security features available, but still need customized configuration to ensure high level of resilience.

With this article it was also possible to identify important gaps on the literature and with technologies to enable wireless

networks to be used for machinery and process safety carrying integrity level certification. Other literature gaps like performance analysis for high density wireless network in a real industrial environment was visualized, which enables opportunity for future studies.

Abstract—In this work, we design a bio-chemical sensor based on Optical Micro Ring Resonator (OMRR) by using the feature of Lithium Niobate ($LiNbO_3$) on Insulator (LNOI) to sense the various concentrations of Sodium Chloride ($NaCl$), sucrose, and glucose in water as well as different cancer cells. Some conventional methods that are used in laboratories and industries to detect the different bio and chemical samples are expensive, slow, and waste a large volume of samples. Recently, OMRR has become very popular for sensing applications to overcome those limitations of conventional sensing methods as it is compact, robust, and cheaper. Furthermore, LNOI has some particular properties; these are photorefractive, favorable optics, piezoelectric, and photoelastic properties. In the early stages, we implemented different geometric structures of LNOI based OMRR in COMSOL to perform the mode of analysis. After that, we designed ring resonators in Opti-FDTD using the associated information of geometric structures from COMSOL to evaluate the achievement of this bio-chemical sensor. Our proposed design is found for the rib height, rib width, thickness of $LiNbO_3$, ring radius, and space between waveguide and ring of $0.56 \mu\text{m}$, $0.5 \mu\text{m}$, $0.16 \mu\text{m}$, $15 \mu\text{m}$, and 80 nm , respectively. Simulation results prove that this bio-chemical sensor design shows better Quality (Q) factor, high sensitivity, sharp peak at resonance wavelength, and low transmission output.

Index Terms—Optical Micro Ring Resonator, Effective Refractive Index, Resonance Wavelength, Bio-Chemical Sensor, and Quality Factor.

I. INTRODUCTION

The sensing technology and mechanism based on photonics has great possibilities to enable the new measurement of different concentration of samples more precisely in medical, laboratory and other sensing fields. Photonic based sensors are the subject of effective research to detect a wide and variety of chemical and biological samples. This sensor is involved in different application fields; these are biomedical, chemical, electrical, temperature, magnetic, pressure, rotation, position, vibration, and acoustic sensors [1]. Nowadays the Mystery challenge is to detect and analyze different genres of cancer cells such as leukemia, brain, cervical, and breast cancer. Cancer creates one of the most leading causes of death now. The American society of cancer association showed a report on cancer which expresses that more than 50% of

Fig. 1. Single ring resonator coupling procedure

death is involved by cancer. This assertion indicates that these deaths can be reduced by detection of cancer at the primary stages [2]. Currently, the traditional techniques, which can detect different cancers at the early period, are very limited where these are not only low resolution but also less sensitive. In recent times, optical sensing mechanisms have greatly enhanced sensor performance, particularly in the field of light source, fluidic design, and analyte interaction. It also improves in bio-chemical sensor sensitivity, fewer sample consumption, detection limit, faster time of detection, and lower cost in each measurement which illustrate that the economic interest in many laboratories have grown significantly to optical sensors [1]. Therefore nanostructures with their unique sensing properties are capable of replacing the traditional sensing mechanism.

Though OMRR was widely used as wavelength frequency converters, filters, circuits, optical communication, and switches in the last decade. In recent times, most researchers emphasize developing this resonator in different sensing fields. A OMRR is a set of ring and straight waveguides among which the ring shape waveguide acts as the resonant cavity and the straight waveguide acts as different ports [3]. The basic coupling procedure of OMRR is depicted in Fig. 1. In terminal 1, multiple wavelengths are given as inputs among which those that satisfy the resonant condition are coupled with the ring through a coupler. From this figure, we can observe that wavelength λ_i can only satisfy the resonant condition and thus, coupled with the ring and remaining input wavelengths are suppressed. Therefore, only the wavelength λ_i will be dropped from terminal 2, while

other wavelengths will pass through terminal 4 which is through port [4]. When resonance wavelength takes place, Only these specific wavelengths that satisfy the resonance condition will be capable of passing through the ring resonator fully and traveling wave dielectric material mode of micro cavity is formed in ring resonator structure [5]. The sensor mechanism of the ring resonator depends on light confinement of the waveguides.

The innovative contribution of our work is to design an optimized LNOI based OMRR to achieve high Q factor, sharp resonance wavelength, high sensitivity, and low transmission output. Moreover, several other designs related to our work are shown in Table I. However, compared with these works, in terms of designing simplicity and sensing capacity, our optimized sensor shows better performance compared to the sensing applications. We have designed 5 different models by changing the value of different size parameters to find out the optimized structure. We have shown that our optimized model gives best sensing performance by comparing with our other models. We also take different bio-chemical samples such as various concentrations of NaCl, sucrose, and glucose in water and different cancer cells to indicate that our sensor can sense different samples more precisely.

Additionally, we have proposed LNOI as a base material as it shows high sensing performance and sensitivity only for the tiny change in refractive indices and others. LNOI has a high refractive index and widespread transparent window. It also capables the detection of extremely little analyte quantities with fast sample preparation. This enhanced the interaction of light-matter in a cavity that increases the sensitivity. In addition, it exhibits a very strong bulk photovoltaic and significant photorefractive effect which are very attractive properties of LNOI. The main advantage of photorefractive properties of LNOI is to induce the change in refractive index linearly and it can be very useful properties in sensing application [6]. Due to the difficulties of dry etching process of LNOI, we may apply different techniques like wet etching, diamond dicing, chemical mechanical polishing (CMP), and femtosecond laser direct writing to the nano-structuring of LNOI [7]. For the fabrication process, if crystal ion slicing technique is used, the process of radius bending of $LiNbO_3$ waveguides becomes more perfect. This can help to achieve the high quality sidewalls on the LNOI nano-photonics structures [8].

The rest of this research paper is organized as follows. We explain some of our related works and show an effective comparison table on different ring resonators and sensing applications in Section II. In Section III, we focus on the basic principle of bio-chemical sensor using OMRR. Section IV represents the description of different models, material, method, and our working procedure using different software. In Section V, We show the sensing results of our proposed design to detect various bio-chemical samples, we further choose our proposed design by observing the performance of our other structure. We also conclude our paper by providing some further research plan in Section VI.

II. LITERATUR REVIEW

In recent times, to detect various constituents of blood for biomedical applications using a photonic crystal based ring resonator (PCRR) was successfully demonstrated in [9]. A serially cascaded micro ring resonator based on a hybrid plasmonic waveguide to detect multiple analysts simultaneously is presented in [10]. Here, they used two ring waveguides with separate ring radiuses which are coupled serially through a silicon strip waveguide. This model shows best sensitivity when it is observed that ring radiuses are 2.0 μm and 1.8 μm , respectively. A planar sensor based on the prototype of microwave ring resonator is presented in [11] for sensing different biological tissues by observing high sensitivity. A dual and label free optical micro ring resonator biosensor based on LNOI technology is presented for bio sensing applications in [8]. In [12], a high-sensitivity complex refractive index sensing SWG micro-ring resonator is proposed. In [13], A chemical sensor is designed to achieve low confinement losses and high sensitivity for sensing various concentration of ethanol-water and benzene-toluene mixer at the wavelength range of 800 to 1600 nm using photonic crystal fiber (PCF).

From Table I it can be stated that the ring radius of our proposed glucose sensing resonator model is comparatively larger compared to other resonator models and only one ring. Therefore, our resonator can be easily fabricated and less complex for bio-chemical sensing applications. Furthermore our proposed model also shows the highest Q factor compared to all related works in Table I. Thus, to our knowledge, our proposed OMRR model for sensing different bio-chemical (NaCl, sucrose, glucose, and cancer cells) is less complex and easy to fabricate, and provides best sensitivity compared to the state-of-the-art works.

III. BIO-CHEMICAL SENSING

Sensing of different bio-chemical samples is one of the most effective and important sectors in laboratory, medical, and industry to detect various types of liquid concentrations. The structure of our OMRR sensor is designed in a way such that it confines light within a cavity by creating resonance. When a specific wavelength of incoming light or laser satisfies the condition of resonance, it couples into the ring waveguide from the input straight waveguide and continuously recirculates among it. By the same process, resonant light escapes from the ring waveguide to the output waveguide where

Fig. 2. Block diagram for bio-chemical sensing with micro ring resonator

the rest of all wavelengths of input light propagate into the through port. We can observe the resonance wavelength from the through port. By persuading these properties, OMRR for bio-chemical sensing has become more exoteric and popular. In this work, we take input light as 1550 nm and output is analyzed between 1250 to 1300 nm wavelength. Then, this input light is propagated through the in port of the OMRR. The different samples are deposited on the top of the straight and ring waveguides where we set up a photodiode detector on the through port for analyzing the sensing performance. Various samples contain different refractive indices which are specific and fixed for that material. And when we change the sample with various concentrations on the top of the ring resonator, their refractive index as well as effective refractive index will be changed. Therefore, the mode of propagation of this structure will be changed and these create a resonance wavelength shift. So more difference between two consecutive effective refractive indices, more resonance wavelength shift which is the attractive property for sensing. A block diagram of bio-chemical sensing procedure is presented in Fig. 2.

IV. METHODS AND MATERIALS

The main theme of our research work is to sense various samples by designing and simulating an LNOI based OMRR. At first, we designed the geometric structure of LNOI at COMSOL to get effective refractive indices of different solutions. Then, using these effective refractive indices as waveguide materials, we drew specific ring resonators in Opti-FDTD. We observed and analyzed all the sensing parameters from the wavelength vs. transmission curve to detect different concentrations of NaCl, sucrose, and glucose in water and various cancer cells. Therefore two software are needed for this observation, design, and simulation process i.e. COMSOL and Opti-FDTD. We have used COMSOL RF solver and transverse electric (TE) mode for resonance as TE shows better power confinement. In Opti-FDTD, we also use Gaussian continuous modulated waves as a propagation mode.

A. Comsol design

COMSOL multiphysics is a simulation based software that uses finite element analysis to calculate power confinement and effective refractive index. To draw a geometry structure of the ring resonator, we used COMSOL RF module-Perpendicular wave-hybrid analysis. Then from physics properties, we changed the frequency into wavelength. Then, we drew a LNOI based geometry structure which is a small portion of our ring resonator as shown in Fig.

Fig. 3. Layout of micro-ring resonator geometry

3. LNOI has three tiers where the base tier is made with Silicon ($n_{Si}=3.479$) [14]. The buffer tier is made with Silica ($n_{SiO_2}=1.444$) [15]. The upper tier is formed with Lithium Niobate ($n_{LiNbO_3}=2.211$) [15]. The rib structure with specific height and width is formed of $LiNbO_3$. The input light is set at 1550 nm wavelength [15]. Then, we set a specific refractive index of different concentrations of samples from the physics subdomain section. After that, we set up a boundary condition of our geometry structure. Next, we analyzed the mesh view which is a smaller triangle in the active region. Then, we selected the solve-solver parameter for getting mode solution and effective refractive index. All the refractive and effective refractive indices of different concentrations of samples using our optimized structure are shown in Table IV, V, VI, and VII accordingly.

B. Opti-FDTD design

Opti-Finite Difference Time-Domain (FDTD) is a very effective method for modeling Computational Electromagnetic (CEM) processes. We used FDTD software for drawing a ring resonator with a specific light source and analyzing all sensing parameters from the wavelength vs. transmission curve. To design a ring resonator in Opti-FDTD software, firstly we selected a "waveguide layout designer" for setting up the material properties from "profile and material". Now from the channel section, we find our proposed material to be selected with specific name, height, width, and thickness. By using the similar process, we also selected other waveguides and Si as a base wafer material. Then, we drew two linear waveguides and a ring waveguide from the draw section and selected a specific profile which is already created in the "profile and material" section. We inserted an input light as a vertical input plane from the draw section. We used a Gaussian modulated continuous wave with positive Z direction. The mode of one of the waveguides is a full vector along the Y axis where input light will be propagated for sensing operation. We added an observation point for analysis at the through port. After completing design, we simulated and observed wavelength vs. transmission curve for sensing application. The ring resonator design using Opti-FDTD software is presented in Fig. 4.

C. Performance parameters

1) *Quality factor*: It is defined as the ratio between the resonance wavelength and the half of the width of the curve

Fig. 4. Optical micro ring resonator layout design using Opti-FDTD

for which resonance wavelength is produced [16].

$$Q = \lambda_r / \Delta\lambda \quad (1)$$

Here, λ_r is called resonance wavelength where $\Delta\lambda$ is known as half of the width of the curve for which resonance wavelength is produced.

2) *Sensitivity*: It is defined as the ratio between the distance of resonance wavelength and difference between refractive indices [17].

$$S = \Delta\lambda_r / \Delta n_c \quad (2)$$

Here, $\Delta\lambda_r = \lambda_r - \lambda_0$ and $\Delta n_c = n_c - n_0$, where λ_0 and λ_r are initial and respective resonance wavelength, respectively.

D. Different designs

We have designed different LNOI based sensing models with several parameters and compared those designs to find out the optimized design. At first, we designed a LNOI based geometric layout using COMSOL software. The base tier of this structure is about 1 μm thick Silicon. The buffer tier is settled with 1 μm thickness of SiO_2 . The upper tier is made of 0.16 μm thick LiNbO_3 . The rib structure with specific width and height is formed of LiNbO_3 are 0.5 μm and 0.56 μm , respectively. The different samples with various concentrations are deposited 0.8 μm from the upper tier. In Opti-FDTD, the thickness and width of the straight and ring waveguides used are 0.5 μm , and 0.5 μm . The ring radius is calculated as 15 μm and the proper space between the ring and straight waveguide is about 80 nm and the length of each one straight waveguide is approximately 34 μm . We use these parameter's values in Design 1. By changing the size of LiNbO_3 thickness and ring radius, we designed 5 OMRR structures which are presented in Table II. We already fixed the rib height and width by analyzing the performance parameter with increasing and decreasing the size of rib height and width in [16].

V. RESULT AND DISCUSSION

A. Determining proposed design by performance analysis of different designs

Here, we determine the optimized design by observing the impact of LiNbO_3 thickness and ring radius. It is clear that if we increase or decrease the size of the parameters such as ring radius and LiNbO_3 thickness from the Design 1 of Table

Fig. 5. (a) Comparison of Design 1, 2, and 3 by varying ring radius (b) Comparison of Design 1, 4, and 5 by varying thickness of LiNbO_3

TABLE II
DIFFERENT DESIGNS BY VARYING VARIOUS SHAPE OF PARAMETERS

Design Name	LiNbO_3 Layer μm	Rib H μm	Rib W μm	Ring Radius μm	Distance between Waveguide to Ring (nm)
Design 1	0.16	0.56	0.5	15	80
Design 2	0.16	0.56	0.5	10	80
Design 3	0.16	0.56	0.5	20	80
Design 4	0.15	0.56	0.5	15	80
Design 5	0.17	0.56	0.5	15	80

TABLE III
THE OBSERVED RESONANCE WAVELENGTH, Q FACTOR, AND TRANSMISSION OUTPUT OF DIFFERENT DESIGNS

Design Name	Resonance Wavelength (nm)	Quality factor	Transmission (Output dB)
Design 1	1274.9	2450	-46.1946
Design 2	1270.75	290	-12.69
Design 3	1269.94	465	-7.83
Design 4	1269.92	1097.1	-31.6703
Design 5	1270.57	2173	-40.8231

II, none of the wavelength vs. transmission curves of these figures show sharp resonance and better Q factor than Design 1. Fig. 5(a) shows the comparison among Design 1, 2, and 3 only varying the ring radius while keeping other parameters permanent. By same process, in Fig. 5(b), we varied only the thickness of LiNbO_3 in Design 1, 4, and 5. In every design, we only change one specific size of parameter while keeping all other sizes of parameters permanent as well as fixed. From Table III, we can observe that Design 1 shows highest Q factor, lowest transmission output, and sharpest resonance peak among these designs. So we can state that the Design 1 is our proposed structure to sense different biochemical samples.

B. Bio-chemical samples (NaCl, sucrose, glucose, and cancer cell) sensing with proposed design

Here, we analyze and explore the capability of the optimized sensor by utilizing wavelength vs. transmission curves of Fig. 6 and 7 and Table IV, V, VI, and VII. From Fig. 6(a) and Table IV, when NaCl concentration in water is about 5%, a green curve is shown whose Q factor is 1438. Then we increase the NaCl concentration at 10%, after that, our

Fig. 6. Wavelength vs. transmission curve of our optimized design at various concentration of NaCl (a) and Sucrose (b) in water

Fig. 7. Wavelength vs. transmission curve of our optimized design at various concentration of glucose in water (a) and different cancer cell (b)

optimized design indicates the red curve of Fig. 6(a). The Q factor and sensitivity are 2345 and 133.4, respectively. All information on sensing using different NaCl concentration in water as shown in Fig. 6(a) are tabulated in Table IV. By similar process, the sucrose and glucose concentration sensing in water are depicted in Fig. 6(b) and 7(a), respectively and the related information is summarized in Table V and VI. For different cancer analysis, we observed normal cells and various cancer cells such as jurkat, HeLa, PC-12, and MCF-7 cells. From Fig. 7(b) and Table VII, when the cell is normal with refractive index 1.350, green curve is shown where effective refractive index and Q factor is 1.7150 and 1732, respectively. Then when we analyzed different cancer cell with refractive index (1.39 to 1.40), different curves are displayed where range of effective refractive index, Q factor, and Sensitivity are (1.7585 to 1.7617), (2252 to 4370), and (237 to 188), respectively. It can be clearly stated that the difference of resonance wavelengths of normal cell and cancer cells is 9.1nm. All sensing information using different cancer cells as shown in Fig. 7(b) are tabulated in Table VII. So, we can easily detect different cancer cells by using our proposed OMRR based bio-chemical sensor.

C. An effective analysis of our optimized bio-chemical sensor based on resonance wavelength, spectral Shift, quality Factor, and sensitivity

Fig. 8 shows the concentration vs specific resonance wavelength and spectral shift for different bio-chemical samples such as NaCl, sucrose, and glucose as well as various cancer cells. From this figure, due to the increment of NaCl, sucrose, glucose concentration in water, spectral shift increases and thus refractive and effective refractive indices of solution are also increased which are tabulated in Table IV, V, VI, and

TABLE IV
VARIOUS CONCENTRATION OF NaCl IN WATER WITH SENSING PERFORMANCE PARAMETERS

Concentration (%) [18]	Refractive Index [18]	Effective Refractive Index	Quality Factor	Sensitivity S
5	1.342	1.7130	1438	–
10	1.351	1.7157	2345	133.4
15	1.359	1.7170	4210	141.2
20	1.369	1.7193	2526	137.1

TABLE V
VARIOUS CONCENTRATION OF SUCROSE IN WATER WITH SENSING PERFORMANCE PARAMETERS

Concentration (wt%) [19]	Refractive Index [19]	Effective Refractive Index	Quality Factor	Sensitivity S
0.1	1.346	1.7114	1196	–
0.2	1.363	1.7780	1252	200
0.3	1.378	1.7214	3650	184.4
0.4	1.398	1.7262	2560	171.3

TABLE VI
VARIOUS CONCENTRATION OF GLUCOSE IN WATER WITH SENSING PERFORMANCE PARAMETERS

Concentration (gm/dl) [20]	Refractive Index [20]	Effective Refractive Index	Quality Factor	Sensitivity S
0	1.3155	1.7071	1564	–
5	1.3222	1.7086	1788	134.4
10	1.3279	1.7100	3795	137.1
15	1.3357	1.7117	2090	131.1
20	1.3421	1.7131	1780	132.2
25	1.3474	1.7143	1568	128.5

TABLE VII
VARIOUS CANCER CELL WITH SENSING PERFORMANCE PARAMETERS

Name of The Cell	Different Cancer Name	Refractive Index	Effective Refractive Index	Quality Factor	Sensitivity (S)
Normal	No	1.350	1.715	1732	–
Jurkat	Leukemia	1.390	1.759	2252	237
HeLa	Cervical	1.392	1.760	3350	205
PC-12	Brain	1.395	1.761	3840	194
MCF-7	Breast	1.401	1.762	4370	188

VII. The increment in the effective refractive index changes the mode of propagation and thus causes the shift of resonance wavelength through the positive direction. This indicates that the spectral resonance shift becomes wider with increasing

Fig. 8. Resonance wavelength (a) and Spectral shift (b) for different bio-chemical samples

Fig. 9. Quality factor (a) and Sensitivity (b) for different bio-chemical samples

concentration in samples. In Fig. 9, we observe the Q factor and sensitivity of different NaCl, sucrose, and glucose in water and various cancer cells. From this figure it is clearly stated that Q factors are increased in terms of sharp resonance wavelength by identifying the different curves of Fig. 6 and 7. The sharpest is the resonance peak and the highest is the Q factor. We can also observe the sensitivity of different samples. From this figure, we can state that the relative sensitivity increases with the decrease of concentration in water. These Fig. 8 and 9 give a clear indication that our proposed device has comparatively great capability to sense various concentrations.

VI. CONCLUSION AND FUTURE WORK

Now-a-days, OMRR is a very attractive field for research and implementation. Through this work, we showed 5 designs of OMRR by varying different ring sizes and $LiNbO_3$ thickness. We also compared our optimized model with some related works. Among all these, we proposed our optimized design which is Design 1 that can detect the various concentrations of NaCl, sucrose, and glucose in water as well as different cancer cells most precisely with respect to others. The optimized design contains ring radius and bus waveguides of $15 \mu\text{m}$ and $34 \mu\text{m}$, respectively. The height and width is $0.5 \mu\text{m}$ and $0.5 \mu\text{m}$ for both ring and bus waveguides. We also analyzed a small portion of this ring resonator as a geometry structure which shows wider change in effective refractive index. Simulation results also indicate that our optimized design is capable of sensing different samples more perfectly. In the future, we have a robust motive to fabricate our optimized LNOI based OMRR design and compare the practical result with the simulated one.

Abstract—Now-a-days, we are facing significant challenges as a result of food shortages and a lack of large-scale food production utilizing traditional methods. As a result, global food supply rivalry has become the most pressing issue of the world. Cloud computing based on Internet of Things (IoT) and Wireless Sensor Networks (WSN) have become a comforting part of the solution to overcome this situation by replacing traditional methods in food production and monitoring systems. In this work, we represent a consolidated farming system with LED, SMS, E-mail, and website-based monitoring using WSN and IoT. To monitor a smart farm, several effective sensors are utilized in various industries, such as agriculture, aquaculture, livestock, air quality, weather monitoring, and health monitoring. All sensor's data is reserved on the IoT cloud platform as well as our built website named Website for Consolidated Smart Farms Monitoring (WCSFM), allowing a concerned person to readily access all relevant data from anywhere on the planet. Our model notifies the end user of expected information based on predefined sensor values by sending SMS, E-mail notifications, and turning on LEDs. Moreover In remote places, our IoT and WSN-based approaches may be more useful.

Index Terms—Internet of Things, Cloud Computing, Wireless Sensor Networks, Consolidated Farms Monitor, and Sensors

I. INTRODUCTION

Agriculture is a vital sector in the economic development of improving countries like Bangladesh. It is impossible for a farmer to physically irrigate and fertilize the entire field while making the best use of these. As a result, a sophisticated agriculture infrastructure system is needed to take necessary steps across the entire field in order to increase crop yield [1]. Aquaculture will generate about 62% of all seafood produced for human consumption by 2030. Our ocean's and other natural resources overfishing is increasing year after year. Aquaculture is the answer to future generation's access to healthy, sustainable protein sources. The need for animal protein will increase about 52% by 2050 when the population of the world will reach 10 billion [2]. The livestock industry is an important part of the global food system that helps to alleviate poverty, ensure food security, and promote agricultural development. Livestock generates 40% of worldwide agricultural output and supports the livelihoods. Simultaneously,

Fig. 1. The fundamental IoT model for connecting different things.

there is a need to enhance livestock sector practices in order to make them more sustainable, equitable, and less hazardous to animal and human health [3]. Furthermore, in areas where the weather changes frequently, it is critical to managing the crop in accordance with the changing weather. We are expected to boost crop yields by employing the probability of climate change. There is substantial evidence that poor air quality can harm the respiratory health of numerous livestock species. Farm employees may be affected by long-term exposure to particles in barns. Livestock farming emits a wide range of pollutants, ammonia, methane, nitrous oxide, and particles such as dust and microbes are all examples of airborne emissions [4].

Due to lack of a proper monitoring system, a variety of obstacles to farming situations arise. Farming growth is inhibited by several problems like lack of environmental issues and effective decision making, resulting in the loss of certain food while they are still in the juvenile stage [5]. As the world's population expands, so does the amount of food needed. Traditional technologies have been used to address these issues, but they require a substantial amount of labor, so the investment is always significant. As a result, an automated method based on IoT and WSN will be a cost-effective and efficient way to deal with the problems. An IoT is a network which is connected with computing devices, digital and mechanical gear, and objects that can perceive, collect, and transmit data over the internet without human interaction. It has changed the society where we live now. Fig. 1 presents various things connected with the internet which support IoT. Smart farming is necessary to address the aforementioned is-

Fig. 2. IoT connecting different farming fields in an intelligent monitor.

sue. Weather, traditional agri-aquaculture techniques, climate change, and other environmental factors are all influenced by farming techniques. Nowadays, technology is a boon to the modern world. Internet-based technologies have recently made our lives easier and more comfortable in terms of power, size, and cost consumption. Those technologies could also be used in agriculture, communication, medicine, and other industries. Using IoT and WSN, it is feasible to improve and monitor food production more effectively. Fig. 2 depicted the IoT connecting different farming fields with an intelligent monitor.

By persuading these problems and necessity, we have developed an IoT, cloud computing, and website based intelligent consolidated farming technique that can effectively notify users or farmers of smart farming, air quality, weather, and health monitoring by using wireless sensor networks and environmental data. Our work contributes to the field of agriculture, aquaculture, air quality, weather monitoring, and livestock husbandry by developing an intelligent framework based on IoT and edge computing that delivers automated notifications. The unique contribution of our work is to develop a website which can be accessed from anywhere from the globe and get relevant all sensing information from farms for making proper decisions. In this manner, a person will be notified via not only SMS and E-mail, but also LED status. These combined notifications improve our farm monitoring system more effectively. To our knowledge, no research has looked at using IoT and cloud computing technology to create an intelligent consolidated agricultural technique.

The rest of the paper is laid out as follows: Section II examines similar studies in several fields. Section III shows an intelligent farming system based on IoT and Cloud Computing. The framework of our designed intelligent farming process is described in Section IV. Section V contains our created circuit schematic for sensing different farming parameters, as well as the seven-days notification results. Finally, Section VI brings the paper to a close.

II. RELATED WORK

The researchers developed a novel method for using sensors to monitor weather and climate so that the technology makes real-time data about temperatures, humidity, and wind velocity via the IoT [6]. Parra et al. suggested a smart irrigation

system which is made with a smart irrigation tube that uses humidity and water content sensors to work. [7]. Intensive aquaculture has been condemned for its negative impact on the environment and the usage of antibiotics. Integrated Multi-Trophic Aquaculture (IMTA) is the practice of cultivating a variety of species in such a way that uneaten food and waste can be captured [8]. Sensors, a processing unit, a gateway, and a cloud platform are the three main components of an IoT system. Sensors collect data and deliver it to a processing unit, which processes it according to the requirements and then sends the processed data to a cloud platform for air quality monitoring protocol as proposed by Gupta et al [9].

For successful cattle farming, Artificial Intelligence (AI) is a data-driven technology that can process and represent huge volumes of data acquired by sensors and IoT [10]. Other sensors, such as RFID sensors, body position sensors, respiration sensors, and CO2 sensors, are employed in some health monitoring systems. They also discuss smartphone-based and microcontroller-based health monitoring systems [11]. Using an IoT-based website and a smart umbrella, created a system for sending automated weather notifications. A person is notified by the smart umbrella turning on a light and sending an SMS to their phone [12]. Finally, Uddin et al. proposed an intelligent rice-fish farming process that can effectively notify users of water and fertilizer management events where different sensors are distributed to monitor environmental and physical factors including pressure and temperature [13].

III. SENSOR DEPLOYED CONSOLIDATED FARMING SYSTEM BASED ON IoT AND CLOUD COMPUTING

Different sensors are implemented in various sectors like agriculture, aquaculture, livestock, air quality, weather, and health monitoring. All sensing data is stored in a gateway node, which is passed to the end user through the internet. Different protocols are used to transmit data from node to node. The UDP protocol is widely used and we use this protocol for sending those sensing information from node to user end via the internet. Different fields that are monitored by end users via the internet are presented in Fig. 3. In fig. 4 depicts the block diagram of field deployed sensors connected to the smart IoT network. In this figure, various sensors are connected by a microcontroller, which is the LPC1768 [14]. All sensing information from different sensors are collected by this microcontroller and, based on the predefined values that are set for comparison with sensing parameters, information is passed to mobile SMS via GSM and E-mail via the internet. This network is designed based on full IP that creates it more easily to end users and minimizes the cost of maintenance and better monitoring in rural, suburban, and urban areas [15]. In rural areas, where the network is weak, the femtocell is more effective to transmit data from the internet to user [16].

Fig. 3. Data from field-deployed sensors is linked to the Internet for users.

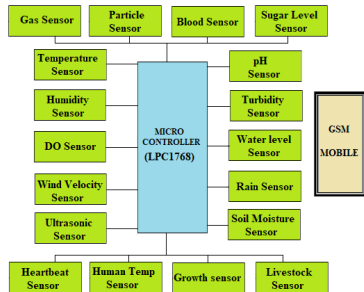

Fig. 4. Field deployed sensors are connected to the smart IoT network represented in the block diagram [13].

IV. THE FRAMEWORK OF OUR DESIGNED CONSOLIDATED FARMING SYSTEM

The main theme of our work is to propose an IoT and cloud-based consolidated farm monitoring system by using different sensors that are deployed in various fields. All sensing data is stored on our developed website, named WCSFM. Besides this, our model also sends SMS, emails, and turns on LEDs by comparing predefined values with sensing values, which makes this model more effective and feasible. For hardware design, we take different things such as Arduino UNO R3, Node MCU ESP8266, AC-DC 5V 2A power supply, LPC1768, SIM900A GSM, gateway node, access node, various sensors, LEDs, and jumpers. For website design, we use different software such as javascript, CSS, HTML, and python.

A. Establishing our proposed model with the intelligent consolidated farming model

The basic working process of our proposed model is shown in Fig. 5. In this figure, there are 3 main layers, where the first layer is called the collection layer. In this sector, all sensing information of different sensors from farming fields is collected by gateway nodes. This sensor information is placed in layer 2, which is the decision-making layer. In this layer, some specific values for different types of sensing information are predefined as threshold values. At a specific time, this layer checks all sensing information by utilizing threshold values and makes decisions by turning on different LEDs. At

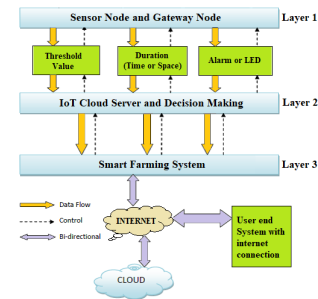

Fig. 5. Overall system architecture, from raw data sensing to intelligent decision making [17].

the final layer, which is called the application layer, a person can be notified by LEDs, SMS, E-mail, proposed website [17].

B. Presenting the work step-by-step to show the overall working process

The overall working process of our proposed model is depicted in Fig. 6. In this figure, different sensors are deployed in different monitoring places. All sensing information from different fields are collected and stored at the edge point by using WSN gateway nodes. To monitor the agriculture field, we deployed different sensors like temperature, humidity, soil moisture, water level, and pH sensors. To get the proper information about aquaculture, we inserted temperature, humidity, turbidity, water level, DO, and pH sensors. For the livestock farm monitor, we deployed gas, water level, count, temperature, and humidity sensors. To know the air quality of these farming areas, we also take temperature, pH, gas, humidity, and particle sensors. To monitor this, we connect temperature, humidity, wind velocity, and wind direction sensors. To track our health information, we use BP, sugar level, pulse rate, and body temperature sensors. IoT cloud servers collect all relative information from access points and check it by comparing it with predefined values that are stored in the decision making sector. Those associated decisions for individual fields are transmitted to the end user through SMS and E-mail. The user can also access all the sensing information by using our developed website named WCSFM from anywhere on the globe and may take effective decision for farm monitoring.

C. Developing a cloud-based website model that is compatible with the deployed sensor data store and distribution

WCSFM is a website developed using javascript, CSS, HTML, and python. On this website, all the sensing information is placed automatically by the gateway and node access point. We developed WCSFM where we can see all the sensing information from agriculture, aquaculture, livestock, air quality, weather, and health monitoring at a glance. Using this website, a concerned person can get all the sensing information from any place, which may boost our productivity. The proposed experimental homepages of different field-sensing data viewing website are shown in Fig. 7.

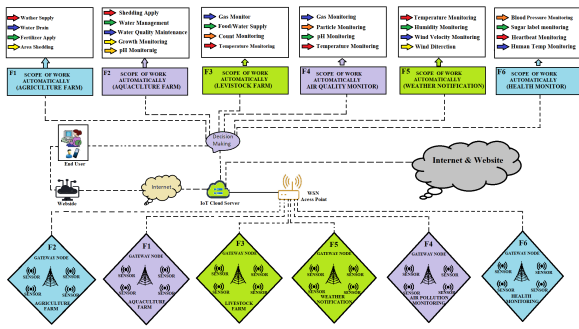

Fig. 6. Intelligent system models ranging from sensing to decision making, with a demonstration of the scope of work.

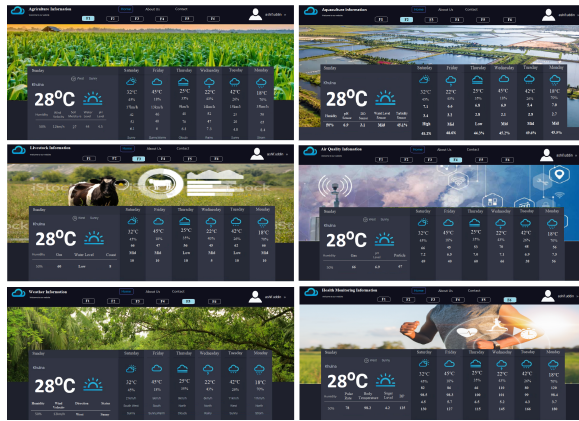

Fig. 7. A sample website view when system monitoring information is visible in a consolidated farming manner.

D. Proposed algorithm techniques for different farming field monitoring intelligently

The proposed algorithm for consolidated farm monitoring systems is presented in Fig. 8. Based on this figure for the agriculture monitoring, when the soil moisture sensed data is less than 40, turning on the red LED is satisfied and the white LED turns OFF. This indicates that water is needed at the farm. On the other hand, when this data is higher than 40, the red light is turned OFF and the white LED is turned ON, which indicates that there is no need to supply water at the farm. Analogously, when the water level is greater than 60 ppm, the blue LED turns ON and the associated white LED turns OFF. This LED status indicates that we need to drain water from the farm. In contrast, when the water level is less than 60 ppm, the blue LED turns OFF and the associated white LED turns ON, which represents that there is no need to drain water from the farm. Similarly, based on various sensor information in different fields and with individual algorithms, they are depicted in Fig. 8.

V. RESULTS AND DISCUSSION

The schematic circuit diagram of our intelligent consolidated farming model hardware connections is shown in Fig. 9. Our implemented sensor's sensed values, which are stored at

Fig. 8. A proposed algorithm for a consolidated brainy farming model ranging from monitoring to physical view.

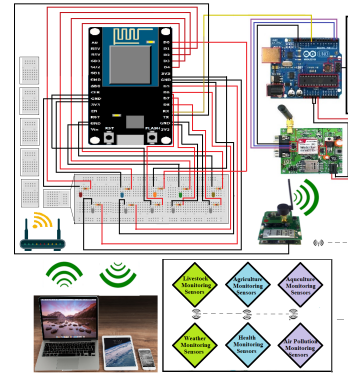

Fig. 9. The system circuit diagram for an consolidated farming model displays hardware connections.

the website, are tabulated in Table I and II. For observing agricultural information, From the first row of the first subtable of the Table I, the first temperature, humidity, soil moisture, water level, and pH level read from the website and IoT cloud server are 28°C, 50%, 27, 44, and 4.5. These are depicted in the first subtable of Table I. As long as the value of soil moisture and pH level are below the threshold, the condition for turning on the red and green LEDs is satisfied and they remain ON while the white LEDs associated with the red and green LEDs remain OFF. On the same day, the temperature is below, the humidity is higher, and the water level is also below the predefined value. Therefore, the blue and orange LEDs remain OFF and both white LEDs associated with the blue and yellow LEDs remain ON. This assembled LED status can clearly disclose to the user that it is needed to apply water and fertilizer. On the 4th day of the second subtable, the temperature, humidity, soil moisture, water level, and pH level are observed. In this case, the temperature is lower where the humidity, soil moisture, and pH are higher than the threshold value, so the condition of turning ON the red, green, and orange LEDs is not satisfied where the water level is higher than the threshold value, so the blue LED is satisfied. Therefore, the red, green, and orange LEDs are turned off while the blue LED remains on. This notifies the person that it needs to be drained of water. Other information for 7-days monitoring of the intelligent agriculture process is tabulated in the first subtable of Table I. Similarly, other information about aquaculture, livestock, air quality, weather, and health

monitoring systems are depicted in the second, third, fourth, fifth subtable of Table I, and Table II accordingly.

VI. CONCLUSION AND FUTURE WORK

Different field-deployed sensors are used in our IoT-based consolidated farming framework to measure diverse environmental and meteorological information on farms. For agriculture, aquaculture, livestock, air quality monitoring, weather monitoring, and health monitoring, we deploy temperature, humidity, wind velocity, soil moisture, pH, turbidity, DO, gas, particles, blood pressure, sugar level, BP, and human temperature sensors. A gateway called WSN connects all of the sensors from various fields. IoT cloud servers accept all sensing data from this gateway and transmit it on to a website as well as the decision-making sector, which is overseen by node MCU. Decisions are made in the decision-making sector based on specified values that are sent to the end user via GSM, and E-mail. The user can simply monitor all important information from any location on the planet and carry out physical tasks in smart and interconnected farming areas. This IoT-based consolidated combination farm system with access to data visualization via websites named WCSFM may help us increase production by requiring less labor and allowing us to operate more efficiently. It reduces the cost of crop production while speeding up the process. We intend to use Machine Learning (ML) to analyze vast amounts of farm field monitoring data in the future.

Abstract—Commercial electromagnetic (EM) simulator tools solve complicated Maxwell’s equations to design and optimize electromagnetic devices, which is computationally expensive and time consuming. There is a dire need to solve complex electromagnetic problems with least amount of computational resources in a short time. This work proposes the application of machine learning techniques in design process of electromagnetic problem. For the proof of concept, we demonstrated an optimum design process of an artificial magnetic conductor, which is a metasurface unit cell, by applying machine learning algorithms namely, artificial neural network (ANN), k-nearest neighbor (KNN), support vector machine (SVM), extreme gradient boosting (XGBoost), and least absolute shrinkage and selection operator (LASSO). The performances of these machine learning optimization models were evaluated on the test data set based on root mean squared error (RMSE) values. To the best of our knowledge, this is the first work that yields an excellent match with the original EM results from a commercial simulator tool with very small training dataset. Thus, it obviates the need of using computationally expensive and time-consuming electromagnetic simulators and massive training datasets for data-driven design approach of complex electromagnetic problems.

Index Terms—AMC, metasurface, XGboost, machine learning, gradient boosting

I. INTRODUCTION

Artificial magnetic conductor (AMC) belongs to the category of metasurfaces [1]. Metasurfaces are printed 2D electromagnetic surfaces consisting of periodically arranged unit cells. AMC can be used as the ground plane of microstrip patch antennas [2]. The advantage of using AMC as a ground plane is that it generates an image current in-phase of the radiating current, unlike a ground plane. Image current in antenna ground plane is 180° out of phase with respect to radiating current which can create ripples in the overall radiation pattern of the antenna, leading to bad design. Additionally, AMC can be used as a superstrate above the antenna to increase gain and reduce radar cross-section. Optimizing AMC unit cells by using a conventional CAD-based EM simulator requires time-consuming and computationally expensive efforts. Recently,

machine learning and deep learning techniques have been applied to solve different EM problems such as designing, and optimizing EM problems such as in designing metasurfaces [3] [4]. In [5], deep learning techniques have been applied to compute code in programmable metasurfaces. In [6], an AMC surface was designed by using particle swarm optimization (PSO) but the authors did not compare the performance between conventional EM simulation and PSO approach. In [7], a deep neural network (DNN) was proposed that predicts the corresponding scattering parameters given a geometrical feature of metasurface. However, the DNN model proposed in [7] requires considerable large amount of training dataset from prior computationally intensive EM simulations. At present, the solution to the design of complex EM problems with a small amount of training dataset is still challenging which requires careful selection of the appropriate machine learning approach. Often, trade-offs among the training dataset size, speed and accuracy are found in the existing literature.

In this work, we propose machine learning (ML) techniques for predicting the resonance frequency of an AMC unit cells given its geometrical features as input with very little amount of training dataset with significantly fast speed. We have considered artificial neural network (ANN), k-nearest neighbor (KNN), support vector machine (SVM), extreme gradient boosting (XGBoost), and least absolute shrinkage and selection operator (LASSO) algorithm in this work. We have chosen ANN, KNN, SVM and LASSO as these are some common ML algorithms that have been applied in the field of electromagnetic problems found in literature [1] - [7]. We have also decided to experiment with XGBoost as this is one of the most popular and powerful ensemble techniques in recent days and also one of the most successful algorithms in Kaggle competitions.

Moreover, we have compared the performance of these algorithms and chose the one that gives the most accurate prediction. The results have shown good agreement with the original EM simulation results. The main goal of our work is to reduce the time and computational expense in electromagnetic problem such as metasurface design. To the best of our

knowledge, this is the first demonstrative work that can predict the resonance frequency of artificial magnetic conductor unit cell, even with a smaller training datasets, thereby reducing the computational burden for electromagnetic researchers. Section II describes the necessary theoretical background. The ML algorithms used in this works are described in section III and the results are discussed and analyzed in section IV followed by conclusion in Section V.

II. IMPLEMENTATION

A. Theoretical Background

To implement the idea, we proposed an AMC unit cell as shown in Fig.1. AMC unit cell consists of a dielectric substrate, a metal ground plane beneath and a metal patch radiator with a rectangular outer ring on top.

Fig. 1. Artificial magnetic conductor(AMC) and a unit cell

Fig. 2. Reflection phase curve of an AMC unit cell

Together, this unit cell acts as a resonator like an electrical RLC resonator circuit. This implies that the unit cell has its own resonance frequency around 5.4 GHz at which it behaves as a metasurface i.e. artificial magnetic conductor, to say more precisely. Moreover, when a free-space electromagnetic wave having a frequency equal to the resonance frequency of the AMC unit cell impinges on its surface, the AMC unit cell reflects the wave with a characteristic phase attributed to its functionality. This characteristic phase of the reflected wave is called reflection phase. At its resonance, AMC surface always reflects the electromagnetic wave with 0°, unlike a typical metal sheet which inverts the reflected wave phase by 180°. The resonance frequency of the AMC unit cell is determined by simulating the reflection phase with respect to a range of frequency as shown in Fig.2. The frequency where the reflection phase of the AMC unit cell drops at 0° is called its resonance frequency (f_0) as shown in Fig.2. The reflection

phase plot in Fig.2 also helps to determine the bandwidth ($f_1 - f_2$) of AMC unit cell ranging from +90° to -90°. Within the bandwidth, it behaves as an artificial magnetic conductor and for all other frequencies, it behaves like a typical metal conductor.

B. Interfacing of Electromagnetic simulation and Machine Learning

The capacitive coupling between the metal patch and the outer ring is controlled by the gap width, G . Additionally, the outer ring length, L has an effect on the frequency bandwidth of AMC surface. Our main focus is to predict the resonance frequency of AMC by taking the design parameters L and G as inputs. AMC unit cell with different values of design parameters was first simulated using commercial EM simulator ANSYS HFSS software [8]. The results of the EM simulation with design parameters were then recorded in a .csv file. Initially, the .csv file contains hundreds of entries of EM simulations which were then filtered out to get the main dataset. Since our main interest was in resonance frequency, we retained the dataset relevant to resonance frequency and discarded all other unnecessary frequency bands from EM simulation records. Our main dataset contains total of 129 data points of resonance frequencies for different values of design parameters, L and G . Afterwards, ML algorithms were trained on this dataset to predict the desired resonance frequency of AMC unit cell. We used python programming language on Jupyter notebook to apply the ML algorithms. 80% of data points were used for training purpose and the remaining 20% of data points were used in testing. The performance of these ML models were evaluated on the test set based on root mean squared error (RMSE) values. The following section contains the main ideas of five ML algorithms that are used in this work.

III. MACHINE LEARNING ALGORITHMS

A. ANN

Artificial neural network (ANN) is a part of machine learning that works on the principle of biological neurons and is perhaps the most used technique in electromagnetic optimization problems. ANN model consists of one or more layers with a group of artificial neurons in each and can be trained using various algorithms like gradient descent, Levenberg-Marquardt algorithm etc. An output of a neuron i in a hidden layer is,

$$\sum_{i=1}^n (w_i \cdot x_i + b) \tag{1}$$

where w_i is the weight associated with the neuron, x_i is the input to the neuron and b is the bias of the neuron [9]. The final output is produced after applying an activation function. In the case of hidden layers, the most suitable activation function is ReLU. For the output layer, the linear activation function is used in regression problems. Our ANN model has an input layer, two hidden layers with 44 neurons in each, and an output layer with a single neuron. The numbers of layers

and neurons are chosen via *Kerastuner* which is a framework of tuning parameters of ANN in python. It is important to choose optimal parameters of the ANN model based on the dataset. *Adam optimizer* is used with a learning rate = 0.001, which is also chosen based on the results of the *kerastuner*. Our model is trained using 50 epochs and later the model is verified on the test dataset.

B. KNN

K-nearest neighbor (KNN) is one of the simplest supervised ML algorithms that have been applied successfully in the applications of electromagnetic fields such as antenna design and optimization. In KNN algorithm, we consider the nearest points to predict a new data point and the nearest points are chosen using a distance measure like Euclidean distance, and Manhattan distance. For a new data point, based on the value of K or nearest neighbors, the mean or weighted average of the outputs of all nearest points is computed in regression problem which is [10],

$$\hat{y} = \frac{1}{k} \sum_{i=1}^k y_i \tag{2}$$

It is an instance-based algorithm with a simple model structure. It is necessary to choose the optimal value of *k* based on the dataset. By choosing a proper *k* value, the problem of higher variance or bias can be avoided. An effective method of choosing the proper value of *k* is cross-validation and in our analysis, we chose the value of *k* based on the results of 5 fold cross-validation. The *k* value with minimum error rate is chosen. From Fig.3, it can be seen that *k* = 3 has the smallest error rate. In order to fit the KNN model in data, the function *KNeighborsRegressor()* from *sklearn* library of python is used.

Fig. 3. k value vs. error rate

C. SVM

The support vector machine (SVM) is also an instance based algorithm that has gained popularity in designing and optimizing EM problems because of its great generalization property and high prediction accuracy. The data is transformed into higher dimensional feature space by using a non-linear Gaussian kernel function as following [11],

$$G(m, n) = e^{-\|m-n\|^2/2\sigma^2} \tag{3}$$

In real-world problems, it is often quite difficult to find an optimal hyperplane in a higher dimension data. The support vector regression algorithm applies the kernel function to choose an optimal hyperplane which contains maximum number of points in higher dimension. This hyperplane is used to predict the numerical output in the regression problem. Based on this hyperplane, a boundary line is chosen keeping a margin of tolerance as shown in Fig.4. The loss that is used by the algorithm is basically a uniform loss function which equally penalizes high and low misestimates [12]. In our analysis, we used the *GridSearchCV* method in python to choose the best hyper-parameters for the SVR model. We need to choose a proper kernel function, and the value of *C* which is a regularization parameter upon which the generalization power of the model depends and, the value of γ which is a parameter of Gaussian kernel function. Based on the result of *GridSearchCV* method the values of *C* and γ are decided to be 1 and 0.1, respectively.

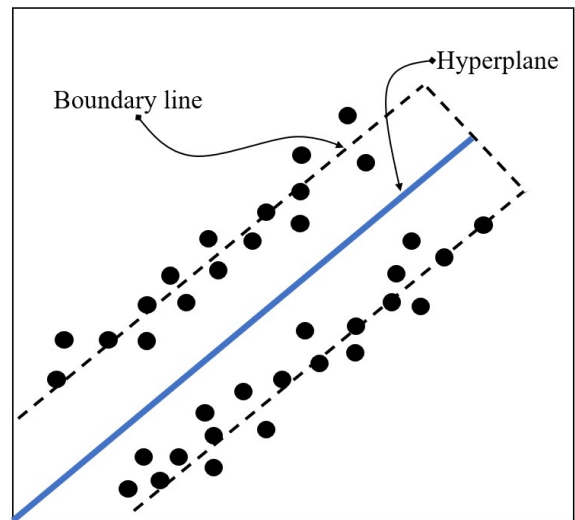

Fig. 4. Support vector machine architecture

D. XGBoost

Extreme gradient boosting (XGBoost) is a decision tree-based boosting ensemble technique well known for its execution speed and performance. It is a powerful method for prediction tasks because it gradually makes a weak learner into strong learner by correcting the prediction error using a differentiable loss function and gradient descent optimization

algorithm. Electromagnetic researchers always try to find algorithms in optimization problem that can be trained using a small dataset in less training time with better accuracy. XGBoost can be more effective than other techniques in that respect because it uses less computational expense and the training time is significantly less than that of the ANN and SVR model. Additionally, XGBoost algorithm helps to determine the most important features in a dataset and prevents over-fitting which is one of the most common problems in machine learning based models. In the case of larger datasets, XGBoost still can be a better choice because it can use all the cores of CPU by parallel processing [13] which makes it a more efficient and fast algorithm. For regression, primarily in XGboost, an average prediction is given by a base model and the residuals are calculated to form the decision trees. After calculating all the residuals, a similarity score is computed which is [14],

$$S_{m_{score}} = \frac{S_{residual}^2}{num_{residual} + \lambda} \quad (4)$$

where $S_{m_{score}}$ means similarity score, $S_{residual}$ is the sum of residuals, $num_{residual}$ is the number of residuals and λ is the regularization parameter. Based on the similarity score and the residuals, a decision tree is formed keeping a splitting criteria. Then, again the similarity scores are calculated for the leaves of both left and right hand side of the tree. After that, the gain of the tree is calculated which is [14],

$$G = (L_{score} + R_{score} - S_{m_{score}}) \quad (5)$$

where G is the gain, L_{score} is the left similarity score, R_{score} is the right similarity score, and $S_{m_{score}}$ is the previously calculated similarity score. The gain score is required for auto-pruning the decision tree which is essential to maintain the growth of the tree. The gain score is compared with a value called γ which is set at earlier. If the γ value is greater than the gain, the auto-pruning will take place. An output value is computed for the leaves of the tree which is, [14],

$$output = \frac{S_{residual}}{num_{residual} + \lambda} \quad (6)$$

The prediction of the tree for a new value will be [14],

$$N_{pred} = I_{pred} + output * l_r \quad (7)$$

where, N_{pred} is the new prediction, I_{pred} is the initial prediction and l_r is the learning rate. To implement XGBoost technique in our work, learning rate, $l_r = 0.2$, number of decision trees = 300 and maximum depth of the trees = 1 are chosen as optimal values. These parameters are also chosen via *GridSearchCV* method.

E. LASSO

Another regression analysis method that has been used in this work is least absolute shrinkage and selection (LASSO). LASSO algorithm is mainly well known for its regularization

and variable selection capability. A new term is added with the standard residuals sum squares in LASSO regression which is shrinkage penalty,

$$\frac{1}{n} \left(\sum_{i=1}^n (y_i - \sum_{j=1}^m w_j x_j + w_0)^2 \right) + \alpha \sum_{j=1}^m |w_j| \quad (8)$$

where α is the parameter in which the shrinkage depends [15]. The model sensitivity to data can be reduced by shrinkage, resulting in a robust model and the lasso algorithm tries to shrink the co-efficient (feature weight) to exactly zero which helps to remove features sequentially that are not important in predicting the value of target variables or which are unnecessary for the prediction task. In this method, only the important features whose co-efficients are not zero are chosen and the error can be significantly reduced. As tuning hyper-parameters for a ML model requires significant amount of time, in our analysis, we choose to implement *LassoCV* which has the capability to tune parameters and perform cross-validation for a lasso model without external *GridSearch* process. In our analysis, we found no coefficient becomes zero which means the two input variables have significant importance in predicting the output variable.

IV. RESULTS AND DISCUSSION

Using the combinations of optimal hyper-parameters, each ML model is trained to predict the resonance frequency of AMC unit cell for different design parameters, G and L . Table I contains some data points of test data predicted by different ML algorithms and also the simulation results from ANSYS HFSS. The first column of the table contains some random values of design parameters, G and L in mm. The combination of design parameters are taken in the range of $G = 1.0, 1.5, 2.0, 2.5, 3.0, 3.5, 4.0$ and $L = 21, 21.5, 22, 22.5, 23, 23.5, 24$. The next column of the table contains the values of resonance frequency obtained from various ML algorithms and original ANSYS HFSS simulation.

TABLE I
COMPARISON OF PREDICTED VALUES OF ML ALGORITHMS AND HFSS

Parameter G, L(mm)	Resonance Frequency of AMC unit cell (GHz)					
	ANN	KNN	SVM	XGboost	LASSO	HFSS
1.0, 21.0	4.56	5.11	5.20	5.22	5.15	5.28
1.5, 21.5	4.73	5.12	5.23	5.24	5.19	5.13
2.0, 22.0	4.90	5.29	5.27	5.24	5.23	5.38
2.5, 22.5	5.06	5.33	5.30	5.36	5.28	5.41
3.0, 23.0	5.23	5.38	5.32	5.37	5.32	5.43
3.5, 23.5	5.40	5.41	5.33	5.41	5.36	5.38
4.0, 24.0	5.56	5.34	5.32	5.38	5.40	5.38

As observed from table I, for $G = 1.0$ mm and $L = 21.0$ mm, the resonance frequency of original HFSS simulation is 5.28 GHz. The values predicted by ANN, KNN, SVM, XGBoost and LASSO model are 4.56, 5.11, 5.20, 5.22, 5.15 GHz, respectively. The value that is closest to the 5.28 GHz is 5.22 GHz which is predicted by XGBoost model.

For, $G = 1.5$ mm and $L = 21.5$ mm, the ML predicted resonance frequencies are 4.73, 5.12, 5.23, 5.24, 5.19 GHz

for ANN, KNN, SVM, XGBoost and LASSO model, respectively. The targeted frequency is 5.13 GHz obtained from HFSS EM simulation. The point nearest to the targeted frequency is 5.12 GHz, which is achieved by KNN model.

For 5.38 GHz, the design parameter values are $G=2$ mm and $L=22$ mm. For this specified set of input parameter values and frequency, the KNN model predicted the closest value which is 5.29 GHz. Other predicted frequencies are 4.90, 5.27, 5.24, 5.23 GHz, given by ANN, SVM, XGBoost and LASSO model, respectively.

The next combination of design parameter values is $G= 2.5$ mm and $L= 22.5$ mm. For this set of values, the resonance frequency from HFSS simulation is 5.41 GHz. The closest value to this frequency is 5.36 GHz predicted by XGBoost model. The values obtained from ANN, KNN, SVM and LASSO model are 5.06, 5.33, 5.30, 5.28 GHz which are also not very far from the targeted value.

For $G = 3$ mm and $L=23$ mm, the original value of resonance frequency from HFSS simulation is 5.43 GHz. The KNN predicted value is 5.38 GHz which is again quite near to the frequency obtained from HFSS simulation. The values obtained from ANN, SVM, XGBoost and LASSO model are relatively close, which are 5.23, 5.32, 5.37, 5.32 GHz respectively.

For the next targeted frequency 5.38 GHz, the set of design parameter is $G = 3.5$ mm and $L=23.5$ mm. For this particular set of design parameters, the prediction of the LASSO model is quite accurate which is 5.36 GHz. The corresponding predicted frequencies obtained from ANN, KNN, SVM and XGBoost model are 5.40, 5.41, 5.33, 5.41 GHz, respectively.

The last combination of design parameter values is $G = 4$ mm and $L=24$ mm. The resonance frequency from HFSS simulation for these design points is again 5.38 GHz. In this case, the value predicted by XGBoost is the most precise which is exactly 5.38 GHz. The frequencies estimated by ANN, KNN, SVM and LASSO model are 5.56, 5.34, 5.32, 5.40 GHz, respectively.

In order to better compare the performance of these ML models with HFSS simulation, the predictions of the ML algorithms on the entire test data which contains 30 data points including those on table I were visualized as individual plots from Fig. 5a-e. The horizontal and vertical axis represents the total number of data points and resonance frequency (GHz), respectively. The values from the HFSS simulation have been indicated with the blue curve. The curves of the predicted values by ANN, KNN, SVM, XGBoost and LASSO models are represented by black, magenta, cyan, red and green color, respectively.

From Fig.5, the overall performance of each ML technique can be distinguished. Fig.5a, it is seen that the predictions of ANN model are diverged from the actual simulated values. As our dataset has only 129 data points, this may be a possible reason of poor performance of ANN model compared to other ML techniques because often more data is required for training a neural network.

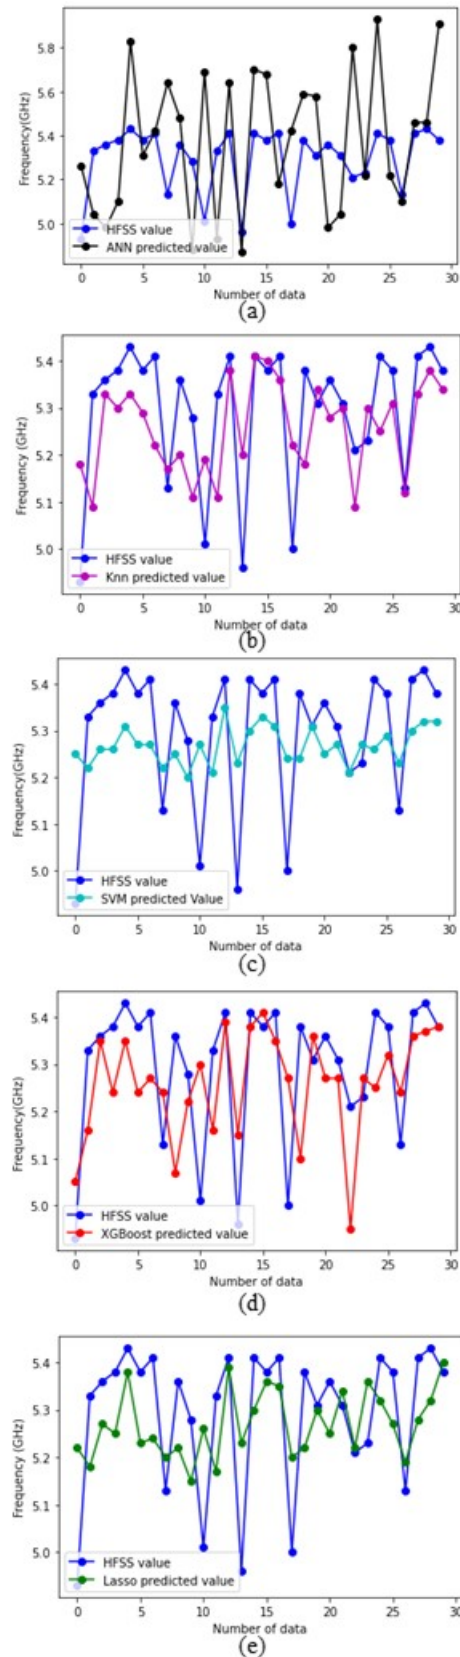

Fig. 5. Simulated and predicted resonance frequency (a) ANN vs. HFSS (b) KNN vs. HFSS (c) SVM vs. HFSS (d) XGBoost vs. HFSS (e) LASSO vs. HFSS

The results obtained from the KNN model in Fig.5b is quite satisfactory as the blue curve of HFSS is closely followed by the magenta curve of KNN model. As mentioned earlier, $k = 3$ is chosen as the optimal value due to the minimum error. The results of KNN is more precise than ANN in our analysis because KNN does not require large datasets compared to ANN model. Despite having a simple model structure, KNN showed better performance in predicting the resonance frequency of AMC unit cell.

As stated before, we tuned the parameters of SVM model with the help of *GridSearch* method and the optimal values of C and γ are chosen as 1 and 0.1, respectively. It is observed from the Fig.5c that, the overall predictions of SVM is not that much specific compared to other ML techniques such as KNN or XGBoost as the cyan curve of SVM does not follow the curve of HFSS simulated values exactly. As our dataset only contains two design parameters, namely G and L , we can say it has low dimension with a greater value of observations. SVM usually provides better result than KNN when the dimension of data is higher than the number of observations.

The XGBoost model also shows satisfactory results like KNN as shown in Fig.5d. Additionally, the performance of XGBoost is better than ANN and SVM model. XGBoost can work well on small datasets, unlike ANN. As XGBoost is an ensemble method, it is more robust and hence it has shown better prediction capability in our analysis.

From Fig.5e it can be seen that the LASSO model also provides acceptable results comparing to ANN and SVM model. For our small simulation dataset, LASSO outperforms ANN model because to get a generalized ANN model larger dataset is needed but lasso can work well even on small non-linear dataset for its regularization capability.

It can be seen from the above discussion that machine learning techniques can be successfully applied in optimization of EM problem that requires computationally expensive resources. However, performance of different machine learning techniques mainly depends on the dataset and in our experiment, all of the techniques that we applied is able to predict the resonance frequency of an AMC unit cell though there are slight differences in performance among these techniques. Also, the time taken by each ML technique to predict the resonance frequencies is significantly less than the conventional CAD-based EM simulation method e.g. in HFSS. For each sweep in HFSS simulation, the time took to find the resonance frequency was approximately 15 minutes. The HFSS simulation process was run in an Intel core-i7 processor with 32 GB RAM. On the other hand, the prediction time of each machine learning technique on the whole test data is just a few seconds on the same computing system. Table II compares the prediction time for each ML technique for the test data with HFSS which confirms that conventional CAD-based EM simulation is much slower than the proposed ML methods. It can also be seen from Table II that KNN and XGBoost model took less time in prediction than other three ML methods. Thus, the ensemble techniques like XGBoost

can be more efficient in solving complex electromagnetic problems. More generalized model can be obtained in future by collecting larger datasets for training.

TABLE II
COMPARISON OF PREDICTION TIME AMONG VARIOUS METHODS

Method Name	Time
ANN	84.36 seconds
KNN	62.36 seconds
SVM	118.23 seconds
XGboost	77.68 seconds
LASSO	86.76 seconds
EM simulation (HFSS)	15 minutes

V. CONCLUSION

In this work, we have applied machine learning algorithms to automatically predict resonance frequency of artificial magnetic conductor while taking its design parameters as input. We have used five ML algorithms which are ANN, KNN, SVM, XGBoost and Lasso and the performance of these ML models is superior compared to conventional commercially available EM simulator such as HFSS. All these ML techniques take considerably less time and computational power than traditional electromagnetic simulation methods. This shows the efficiency of ML techniques in complex electromagnetic problem.
